as of infarction as assessed by follow-up imaging and from adjacent areas of ischemia defined by MTT-prolongation. Each parameter was tested for efficiency to predict tissue outcome.

Results: Compared with areas of infarction those defined as ischemic showed significantly higher absolute values for CBP (19.4 ± 8.3 vs. 9.7 ± 5.1 ; $p < 0.01$) and CBV (2.7 ± 1.0 vs. 1.6 ± 0.7 ; $p < 0.01$), as well as significantly lower values for MTT (9.9 ± 3.2 vs. 13.1 ± 2.7 ; $p < 0.01$). Similar results were yielded by testing ratios normalized to mirrored contralateral areas. Normalized threshold values for infarction as derived by ROC analysis were found to be 0.31 for rCBP, 0.85 for rCBV and 2.9 for rMTT respectively. Efficiency to predict tissue outcome was more than 75%.

Conclusion: CT Perfusion might be a feasible method to predict tissue outcome in stroke patients. Our findings suggest that, based on quantitative analysis, efficient threshold levels to discriminate between tissue at risk for infarction and tissue with disturbed perfusion might be possible. However, further studies including successfully recanalized patients are needed.

C-0799

Exploring the continuum: 1H-MR spectroscopy in prodromal and first-episode patients with schizophrenia

G. Bohner, F. Forstreuter, J. Gallinat, H. Witthaus, H. Stiepani, Y. Gudlowski, A. Heinz, R. Klingebiel, G. Juckel; Berlin/DE

Purpose: Patients with schizophrenia are characterized by reduced levels of N-acetylaspartate (NAA) as assessed by 1H-MR spectroscopy (MRS) in schizophrenia-relevant areas. Our purpose was to explore a possible continuum of NAA changes, as a first sign of impaired neuronal integrity, from the prodromal phase to the first episode of schizophrenic psychosis.

Materials and Methods: We studied 13 patients in the early and late prodromal state of psychosis (in part patients of the European Prediction of Psychosis Study, EPOS), 10 first-episode patients with schizophrenia and 21 healthy controls matched by age and gender. Single voxel 1H-MRS (1.5 T, TR = 1500 ms, TE = 140 ms, VOI = 8 ml) was performed in the left hippocampus, the anterior cingulate cortex (ACC) and the medial prefrontal cortex. NAA/creatinine (Cr), choline (Cho)/Cr and NAA/Cho ratios were calculated.

Results: Analysis of the data revealed significantly elevated NAA/Cr and Cho/Cr ratios in the ACC of prodromal and first-episode patients compared to healthy controls. NAA/Cr ratios in the hippocampus of prodromal patients showed no significant difference compared to healthy controls. Reduced NAA/Cr ratios in the left hippocampus of first-episode patients were found; however the difference compared to healthy controls did not reach a level of significance.

Conclusion: In patients with first-episode schizophrenia expected reduction of NAA/Cr was found in the left hippocampus indicating impaired neuronal integrity. The joint elevations of NAA/Cr and Cho/Cr ratios in prefrontal areas of prodromal and first-episode patients could result from a decline in creatine indicating hypometabolism in these areas. Further studies using absolute quantification should be initiated to assess these metabolite alterations.

C-0800

Normal ageing of the brain: Assessment with quantitative MR diffusion tensor imaging

N. Papanikolaou, S. Karampekios, E. Papadaki, T. Maris, N. Gourtsoyiannis; Iraklion/GR

Purpose: To assess the distribution of microscopic brain tissue alterations related to normal ageing using magnetic resonance diffusion tensor imaging (DTI).

Methods and Materials: Axial FLAIR and DTI sequences were applied in 30 normal subjects (mean age: 33.7 years, min: 8, max: 72). Spatial normalization to the Talairach space of the non-diffusion weighted scans was performed using a standard EPI template. Transformation parameters were applied to the six diffusion weighted image sets and mean diffusivity (MD) and fractional anisotropy (FA) maps were reconstructed. A voxel based statistical analysis was performed to identify anatomical regions of the brain that correlated with age.

Results: Areas of statistically significant ($p < 0.001$) MD increase with age were located in the left and right inferior frontal gyrus gray matter, left and right insula gray matter, left middle frontal gyrus, left superior temporal gyrus white and gray matter, left and right inferior parietal lobule white matter, right inferior frontal gyrus white matter, right superior temporal gyrus, left superior frontal gyrus white matter and right superior frontal gyrus gray matter. Areas with statistically significant ($p < 0.001$) FA decrease with age were found in the right medial frontal lobe white matter, left middle frontal lobe white matter, right brainstem, right frontal lobe sub-gyral white matter, right middle temporal gyrus white matter and left frontal lobe sub-gyral white matter.

Conclusions: Diffusion tensor derived metrics are sensitive to the microscopic brain tissue alterations related to normal aging. MD changes are mainly located in the gray matter while FA changes in the white matter.

C-0801

Appearance of the meninges on contrast-enhanced MR imaging: Spectrum of normal and abnormal appearance in the brain and spinal cord

N. Sheehy, C. Farrelly, J. McCann, G. Boyle, J.F.M. Meaney; Dublin/IE

Learning Objectives: 1. To describe the normal appearance of the meninges on contrast-enhanced MR imaging within the crano-spinal axis. 2. To describe the findings in patients with cranio-spinal malignant meningeal infiltration. 3. To illustrate non-malignant causes such as sarcoidosis, infection, and post lumbar puncture and subdural-haematoma. 4. To demonstrate the potential benefits of using isotropic fat suppressed volumetric sequences.

Background: Detection of meningeal abnormality with CT and standard (non-contrast) MR is very limited. Contrast-enhanced MR Imaging affords the best opportunity to detect both dural and leptomeningeal involvement. However, dural enhancement is a normal finding and differentiation of normal from abnormal can be challenging.

Imaging Findings: A comprehensive review of the findings on contrast-enhanced MR imaging in normal subjects, and in patients with benign and malignant meningeal infiltration is presented. Correlation with other modalities is given where appropriate. The potential benefits of a T1 fat suppressed high-resolution volumetric sequence in the assessment of meningeal pathology are discussed.

Conclusion: Meningeal abnormality, most commonly due to malignant infiltration, is readily demonstrated by MR imaging but not easily identified on non-contrast MR imaging or CT.

C-0802

MR-spectroscopy in multiple sclerosis (MS) patients: Correlation between *in vivo* and *in vitro* analysis of CSF fluid

A. Sias, A. Balestrieri, L. Barberini, M. Puligheddu, M. Fraschini, F. Cesare Marincola, A. Lai, F. Marrosu, G. Mallarini, M.G. Marrosu, E. Cocco, E. Locci; Cagliari/IT

Purpose: Our study aims to find a role for MR spectroscopy, performed both *in vivo* and *in vitro* in the diagnosis of multiple sclerosis (MS), which may be helpful in those patients whose conventional MR findings might overlap those of other demyelinating diseases.

Methods and Materials: We have performed *in vivo* MR spectroscopy on 30 individuals (15 patients with known MS, and 15 healthy volunteers), and *in vitro* MR spectroscopy in the CSF of these two subgroups, on a spectrometer VARIAN 400 MHz with both solid and liquid state probes. Having performed ^1H (proton)-spectroscopy we were able to measure the concentrations of NAA, Cho, Cr, Gix, GABA, ml, and LA. Data obtained has been analyzed with software from the European Union project "Advanced Signal Processing for Medical Magnetic Resonance Imaging and Spectroscopy".

Results: The altered concentrations of the metabolites confirm the importance of MR spectroscopy and correlate with lesion development in MS patients. Our results show that MS is a diffuse white matter disease, not confined to the demyelinating plaques seen in conventional MR examinations, and the role of MR spectroscopy might be also to investigate the metabolic changes of neural pathways.

Conclusion: MR spectroscopy, both *in vivo* and *in vitro*, appears to be a highly sensitive technique in the evaluation of MS.

C-0803

Slow expressive language development in children: Typical MR imaging pattern? Critical review of 1880 cases

V. Pupillo, G. Gismondi, R. De Amicis, A. Splendiani, C. Masciocchi, M. Gallucci; L'Aquila/IT

Purpose: To assess the potential of MR imaging to study children with language impairment, through critical review of 1880 cases produced in our institute, in the hope of identifying typical MR imaging patterns. We analyzed possible alterations of morphology or signal intensity in late talking patients versus patients with different pathologies. We studied eventual relationships between language impairment and myelin development.

Methods and Materials: 1880 MR imaging examinations (age range from 1 to 8 years) have been reviewed. 60% of these examinations have been performed in children with clinically proven language impairment. All MR imaging examinations were performed with a 1.5 T GE magnet, using a head coil; T1 and T2-

Scientific and Educational Exhibits

weighted sequences were acquired on axial and sagittal planes and FLAIR on coronal plane. All pts had also been studied by means of 3D T-w FFE, with the aim of evaluating cerebral cortical architectural disorders.

Results: In 63% of cases MR imaging showed symmetrical and bilateral high signal intensity areas at a periventricular level; at 1 year MR imaging follow-up this signal alteration was not still visible in any case. In 78% cases we observed punctiform or line shape areas interpreted like dilated perivascular spaces; after 1 year, independent of clinical conditions, the MR imaging findings were not different.

Conclusion: Our experience, like other studies present in literature, suggests a possible correlation between late myelin development and language impairment.

C-0804

Advanced MR imaging in the surgical planning of intracranial tumors

G. Luccichenti¹, M. Salvati¹, A. Frati¹, C. Brogna¹, R. Delfini¹, S. Bastianello²; ¹Rome/IT, ²Pavia/IT

Learning Objectives: 1)To illustrate the rationale of the MR imaging of intracranial tumors by correlating the pathology and the neurosurgical approach with imaging principles of the MR examination. 2)To describe the advanced MR techniques (relaxometry, DWI, DTI, MT, MR spectroscopy and functional MRI) and the advantages of an integrated imaging approach.

Background: The treatment of intracranial tumors is difficult due to the combined necessities of performing radical excision of the lesion and preserving vital structures. Generally, conventional imaging does not allow the discrimination of neoplastic tissue from edema and normal surrounding structures, the accurate characterization of the lesion, and the precise location of the functional areas, which can be displaced by the lesion. This information is crucial in preoperative planning, and can be obtained through advanced imaging techniques.

Procedure Details: A method for imaging intracranial tumors with conventional and advanced techniques is provided. Simple criteria for differential diagnosis between primary and secondary, extra- and intra-cerebral lesions, and for lesion characterization with advanced techniques are provided. The features that are crucial for surgical planning are described. The integration of morphological and functional imaging into neuronavigation systems for image-guided neurosurgery is shown using clinical examples.

Conclusion: Integrating conventional morphological imaging with advanced functional and metabolic techniques is crucial for adequate preoperative planning of intracranial tumors and to enhance the performances of image-guided neurosurgery.

C-0805

T1 and T2 characterization in the brain during hyperoxia at 9.4 T

H. Uematsu; Fukui/JP

Purpose: The aims of this study were to characterize T1 and T2 changes in mice brain during hyperoxia at 9.4 T.

Methods and Materials: After T1 and T2 values of wild-type mice brain were measured on a 9.4 T MR system, the room air was changed to either 100% oxygen (N = 8) or carbogen (N = 8). Five minutes later, the same scan protocol was repeated. Statistical analysis of the data was performed using paired Students' t-test.

Results: During hyperoxia, the T1 value of the cerebral cortex significantly decreased (100% oxygen: 11% decrease, P < 0.05 and carbogen: 9% decrease, P < 0.05). No significant difference in% T1 changes were observed between the 100% oxygen and carbogen conditions. The T2 value of the cortex significantly increased during exposure to either 100% oxygen (cortex: 3.7% increase, P < 0.05) or carbogen (cortex: 5.4% increase, P < 0.05). No significant difference in% T2 changes was observed between 100% oxygen and carbogen conditions.

Conclusion: The increased dissolved oxygen may reduce the T1 during hyperoxia. The changes in T1 were not significantly different between the two types of gas. The reduced cerebral perfusion due to 100% oxygen may have little effect on T1. In the case of T2, the mechanism may be related to the BOLD effect. Carbogen is known to increase the cerebral perfusion, which may increase the T2. However, no significant difference in T2 was observed between the 100% oxygen and carbogen conditions. Therefore, the prolonged T2 during hyperoxia may be mainly caused by increased BOLD effect rather than by increased cerebral perfusion at 9.4 T.

C-0806

Brain activation in the differences game: A functional magnetic resonance imaging study

E. Fukuba, A. Wada, K. Uchida, T. Kajitani, A. Nagami, H. Kitagaki; Izumo/JP

Purpose: The differences game in which we find differences between two similar pictures is a popular game with children. Superior space recognition and concentration are needed to win this game. The radiologist also requires these skills in diagnostic imaging. We examined brain activation areas during the differences game using functional MR imaging.

Methods and Materials: Five right-handed volunteers were recruited with a mean age of 26. When the subjects looked for differences between two pictures which were side by side, we examined brain activation areas of the subjects. We applied the block design paradigm which repeated quiz presentation of 30 seconds and 30 seconds rest. In addition, we examined the second activation using the same quiz.

Results: Activation was recognized in the bilateral posterior prefrontal area, the primary visual area, and the intraparietal sulcus. In the second measurement when subjects knew the picture beforehand, activation of the right prefrontal area and the bilateral intraparietal sulcus increased.

Conclusion: In the differences game, the frontal, parietal and occipital lobe are activated. Activation of the frontal lobe reflects visual recognition, and activation of the parietal lobe reflects the three dimensional conversion of visual information and analysis. Repetition of a challenge to the game gives subjects adaptation. Re-challenge to the game that we experienced promotes the activation.

C-0807

Usefulness of proton magnetic resonance spectroscopy (¹H MRS) in the diagnosis of subclinical hepatic encephalopathy (SHE)

R. Banyś, A. Slowik, M. Pasowicz, I. Ciecko-Michalska, M. Irzyk, M. Motyl, A. Szczudlik, J. Bogdal; Krakow/PL

Purpose: SHE is a disorder of cognitive function in patients with liver cirrhosis, detectable only during neuropsychological examination, adversely affecting daily activity, and without any deficits during standard neurological examination. The disorder affects up to 70% of patients with liver cirrhosis. ¹H MRS is a fast developing, noninvasive method allowing the *in vivo* evaluation of biochemical changes in the human brain. The aim of the study was to assess the usefulness of *in vivo* ¹H MRS detection of metabolic abnormalities in brains of patients with SHE.

Methods and Materials: In this study we included 30 patients with the diagnosis of SHE and 32 healthy volunteers. ¹H MRS examination was performed on 1.5 T Magnetom Sonata (Siemens) scanner with single voxel PRESS technique (TR = 1500 ms, TE = 30 ms, 256 acquisition with the H O signal suppression). Three voxels of 8 cm³ were positioned in: 1) predominantly white matter in the posteromedial parietal cortex, 2) predominantly gray matter in the posterior occipital cortex 3) globus pallidus. Metabolite concentrations were calculated manually using integral Siemens software. Peaks from myo-inositol (ml), choline (Cho) and N-acetyl-asparatate (NAA) were normalized with respect to the creatine (Cr) peak (ml/Cr, Cho/Cr and NAA/Cr).

Results: Patients with SHE presented with significant reduction of the ml/Cr ratio as compared to controls (0.041 ± 0.011 vs 0.20 ± 0.071) and no significant changes between the two groups in Cho/Cr ratio (0.84 ± 0.15 vs. 0.85 ± 0.17) and NAA/Cr ratio (1.56 ± 0.26 vs. 1.67 ± 0.31).

Conclusion: (¹H MRS) detects *in vivo* neurometabolic changes in patients with SHE. The significant reduction of ml/Cr ratio suggests an alteration of glial function.

C-0808

The fMRI imaging study of hypnotic suggestion during pain stimulation

A. Urbanik, J. Aleksandrowicz, M. Binder, R. Chrzan, B. Sobiecka, J. Kozub; Krakow/PL

Purpose: The aim of the study was assessment of the influence of hypnotic suggestion on the patterns of neural activation during pain stimulation.

Materials and Methods: Twelve volunteers (5 men, 7 women; mean age 25) were examined on a 1.5 T MR scanner. Each subject underwent four subsequent experimental sessions with different conditions applied: 1) pain stimulation (PS), 2) PS and verbal analgesic suggestion (VAS), 3) PS and hypnotic induction (HI), 4) PS, HI and VAS. Nociceptive stimulation was performed by pricking the palmar side of the hand with a sharp piece of wood (avoiding skin puncture). To avoid pain adaptation stimulation was carried out in various points within the palmar region. Statistical analysis of the data was done using SPM2 and MarsBaR software. We assessed global patterns of neural activity and differences in the mean signal intensity within the selected ROI's (postcentral and cingulate gyri and insulae), participating in pain perception.

Scientific and Educational Exhibits

Results: In all sessions nociceptive stimulation evoked enhanced BOLD responses in postcentral gyri bilaterally (with stronger activation within contralateral gyrus), insular regions and cingulate gyri. We did not find any significant regional differences in patterns of activation in all four experimental sessions. However, ROI analysis yielded significant decrease of the signal correlated with conditions: 3)PS+HI and 4)PS+HI+VAS. These effects were strongest in the postcentral gyri and insular cortex.

Conclusion: We have observed that induction of hypnotic state and hypnotic suggestion can markedly reduce neural activity within regions responsible for pain perception.

C-0809

Fusion of MR imaging and SPECT images in the diagnosis of glioma recurrence

P. Grzelak, M. Gorska-Chrzastek, B. Goraj, J. Kusmirek, L. Stefanczyk; Lodz/PL

Introduction: In clinical practice patients with cerebral glioma are usually treated with the combination of surgery and radiotherapy. However, in the majority of patients recurrence of the disease occurs. The most essential requirement for further treatment is to diagnose the relapse as early as possible. In practice this means to differentiate active neoplastic growth from radiation induced changes and scars in the brain; the latter may mask the recurrent tumor.

Materials and Method: This study was performed on 33 patients who had had surgery and radiotherapy to a glioma of the brain. Follow-up MR imaging post gadolinium images of the brain were obtained using a 1.5 T scanner. SPECT was performed 15 min after iv administration of the 131 I-alfa-metyl-tyroline (131I-IMT). The 131I-IMT is a marker of brain tumors. Fusion of the images was performed by means of a three-dimensional technique using a PC work-station; the technique was based on statistical analysis of three-dimensional distribution of the voxels, using maximization of the statistical resemblance (mutual information).

Results: It is not technically possible to combine acquisition of the data from MR imaging and scintigraphy in one installation. In 27 patients MR imaging images demonstrated presence of a polymorphic focus, indicating recurrence of the tumor, in 4 individuals the result was equivocal due to post-operative and post-radiation changes.

Conclusions: MR imaging and SPECT fusion images enables confirmation of malignant growth at a site of morphological change in the brain, potentially corresponding to the recurrence of tumor. It helped to exclude the recurrence in a case with equivocal MR imaging images.

C-0810

Comparison of CT and diffusion-weighted MR imaging after reperfusion in a cat model of focal acute cerebral ischemia

J. Lee, D. Na, J. Park, S.-C. Hong, J. Yoon; Seoul/KR

Purpose: To determine if the early ischemic changes on CT are reversible after early reperfusion of MCA occlusion in a cat model, and to compare changes of CT attenuation with ADC change in ischemic tissue after early reperfusion.

Materials and Methods: We evaluated DWI, ADC, T2WI and CT obtained after 1 hour of right MCA occlusion and at 1 hr, 3 hr, 5 hr, and 24 hr after reperfusion, in 7 cats. Qualitative image review and quantitative ROI assessments were made.

Results: Two types of evolution of signal intensities were observed on DWI: Type 1, which showed persistent high SI, and Type 2, which showed reversal of high SI after reperfusion. Type 1 lesions were seen in all 7 cats, but type 2 lesions were seen in only 3 cats. In type 1, ADC values were relatively constantly low over time, but CT density showed a linear decline. In type 2, ADC values were reversed at either 3 hrs or 5 hrs after reperfusion, CT scans showed partly persistent low density and partly reversal of low density. Both type 1 and type 2 lesions revealed high SI on T2WI and low density on CT at 24 hrs, and pathologically proved as infarcts.

Conclusion: Subtle hypodensity of an early ischemic lesion on CT can be either reversible and not reversible after early reperfusion. The time course of ADC changes had a different pattern from that of CT density in both type 1 and 2 lesions.

C-0811

1H MRS and 18F FDG PET in patients with single epileptic seizure

A.V. Pozdniakov, L.A. Tiutin, D.E. Dyskin, A.A. Stanzhevsky, G.D. Rokhlin; St. Petersburg/RU

Purpose: To study the features of metabolic disorders in patients with repeated unprovoked epileptic seizures according to triennial follow-up.

Materials and Methods: 1H MRS and 18F FDG PET were carried out in 27 patients with single generalized tonic clonic seizure. The follow-up was performed during 3 years after 1H MRS and 18F FDG PET examinations.

Results: 1H MRS and 18F FDG PET revealed metabolic disorders in 9 of 27 patients and 7 of 27 patients respectively. Combined use of these methods showed metabolic disorders in 10 of 27 patients. The incidence of metabolic disorders was more in patients with repeated epileptic seizures (22 cases) than in patients with a single epileptic seizure (2 cases) according to triennial follow-up ($p < 0.05$). Decrease of N-acetylaspartate, creatine and choline increase, decrease of 18F FDG uptake were shown in patients with single epileptic seizure. The true positive results of combined PET and 1H MRS use were observed in 6 of 9 patients. As a rule metabolic disorders were revealed in the mediobasal part of temporal lobes. Combined 18F FDG PET and 1H MRS use showed metabolic disorders in 8 of 10 cases. According to PET data unilateral focal disorders predominated in comparison with focal bilateral disorders, whereas 1H MRS showed uni- and bilateral changes equally. The isolated focal neocortical changes in frontal lobes were found by 1H MRS only in 2 cases.

Conclusion: 1H MRS and 18F FDG PET are shown to be a feasible methods for follow-up of patients with single provoked and unprovoked seizures and prediction of epilepsy course.

C-0812

Enlarged temporal horns and transient amnesia after perimesencephalic haemorrhage

D.A. Stojanov, P. Bosnjakovic, M. Zivkovic, N. Stojanovic, S. Ristic; Nis/YU

Purpose: Many patients with perimesencephalic hemorrhage, a benign subset of subarachnoid hemorrhage, have an episode of amnesia. We studied the relation between the occurrence of amnesia and size of the ventricles, including the temporal horns.

Materials and Method: Thirty-seven consecutive patients (20 female, 17 male; mean age 51.81, SD 12.19) with perimesencephalic hemorrhage admitted to the Clinical Center Nis between January 1995 and December 2001 were asked about the occurrence of amnesia. The temporal horns were measured in three different directions: medio-lateral, antero-posterior, and oblique. Measurements were taken from the CT slice on which the temporal horns were best visible.

Results: Amnesia was reported in 13 (35.13%) of the 37 patients. The episode of amnesia started a few hours after the onset of the bleed and lasted for several hours or days. In these patients the mean size of the temporal horns was significantly larger than in patients without amnesia. Linear measurements of the temporal horns in patients with amnesia were larger in all three direction: antero-posterior (10.4 ± 5.9 mm vs. 4.1 ± 5.9 mm; $p < 0.01$), medio-lateral (11.9 ± 6.5 mm vs. 6.8 ± 5.8 mm; $p < 0.05$), and oblique (5.3 ± 3.0 mm vs. 2.7 ± 1.9 mm; $p < 0.05$).

Conclusion: Amnesia is present in about one third of patients with perimesencephalic hemorrhage shortly after the bleed. The occurrence is associated with enlargement of the temporal horns.

C-0813

MR and alterations of cortical development

J. Alvarez Linera-Prado, J. Escribano Vera, I. Garcia Morales, A. Perez Garcia, R. Martinez Alvarez, A. Gil-Nagel Rein; Madrid/ES

Learning Objectives: To review the classification of the malformations of cortical development and to demonstrate the different types, with greater emphasis on focal cortical dysplasias. The more advisable study protocols are recommended and we comment on new techniques, explaining their possible use.

Background: In the knowledge of alterations of cortical development, imaging techniques have contributed in a decisive way to their better handling and understanding. Morphological criteria are used for their classification; hence MR, especially the morphological techniques of high resolution, plays a fundamental role. We include imaging of the new techniques (Diffusion, DTI, Perfusion, BOLD and the Spectroscopy), which we assess to see if they add new information.

Procedure Details: Studies with a 3 T magnet have been made in most of the cases to obtain images with maximum spatial resolution. In each case the more advisable protocols of study are explained and their clinical correlation, with special attention to Diffusion, DTI, Perfusion, BOLD and Spectroscopy.

Conclusion: Diagnosis of the alterations of cortical development is based on the knowledge of its multiple manifestations. The use of a suitable protocol is important, since it increases the sensitivity, mainly in the case of cortical focal dysplasia. The new techniques can contribute with excellent information, although most of them are still in the early phase of development.

Scientific and Educational Exhibits

C-0814

Radiological atlas of central nervous system tuberculosis

F. Matute Teresa, A. Saiz Ayala, N. Santamaría; Madrid/ES

Purpose: To illustrate the broad spectrum of imaging findings (MR and CT) in patients with proven central nervous system tuberculosis (CNS).

Methods and Materials: We reviewed between January of 1998 and July of 2004, the imaging findings of 35 patients with proven tuberculosis.

Results: Tuberculosis can lead to localized or diffuse CNS involvement. 25 patients had meningitis, 13 patients had focal intra-axial tuberculomas: 13 brain masses and 1 intramedullary spinal lesion; 3 patients had focal extra-axial lesions: 2 lesions in pontine cistern, and one in the spine. MR showed diffuse thick, meningeal enhancement, on CT the lesions appeared hyperdense, with a characteristic pattern of basal cistern involvement. On MR tuberculomas showed low signal intensity on T1 weighted images. On T2 weighted images the signal intensity varied according to the stage of evolution of the lesion, incipient tuberculomas appeared as scattered areas of hypointensity surrounded by edema, mature tuberculomas had a necrotic center, surrounded by an isointense capsule, surrounded by edema. On CT tuberculomas are hypo or isodense lesions and they had ring or nodular enhancement.

Conclusion: A thorough knowledge of CNS tuberculosis is important because early diagnosis may prevent a permanent loss of function. MR and CT were equally sensitive in visualizing tuberculomas, but MR was slightly superior in demonstrating the extent of the lesion, and infarcts. CT is better than MR in evaluating meningeal sequelae with calcification.

C-0815

MR imaging based prospective longitudinal study on neurotoxicity of ecstasy in novice ecstasy users

M.M.L. de Win, L. Reneman, E.J.P. Vlieger, C. Lavini, W. van den Brink, G. den Heeten; Amsterdam/NL

Purpose: Ecstasy (3,4-methylenedioxymethamphetamine, MDMA) has been shown to be neurotoxic in heavy users. We studied potential neurotoxicity of a low dose of ecstasy in new users.

Methods and Materials: At baseline 200 ecstasy-naïve adults (18-35 y) with high risk for first-time ecstasy use were included. During follow-up the new ecstasy users ($N = 26$, 12M/14F, 21.5 ± 3.1 yr, 2.8 ± 5.7 tablets) were reexamined. We compared parameters of neurotoxicity measured with MR imaging techniques between baseline and follow-up sessions. MR imaging (1.5 T, Signa, GE) protocol included PD- and T2-weighted images, single voxel ^1H -MRS, DTI (DW-EPI, TE/TR = 90/8000, b = 1000, 12 directions), perfusion MR imaging (GE EPI), and a T13D scan. ADC, FA and rCBV maps were registered to the spatially normalized T13D scans. Regions of interests were drawn onto the normalized brain (both hemispheres) and resized to the original maps. rCBV-values were obtained by dividing mean CBV_(ROI) by mean CBV_(white matter). Spectra were analyzed using LC-Model. NAA, Cho and ml concentrations were calculated using Cr as reference. Wilcoxon signed ranks test was used with $P < 0.05$ as threshold for statistical significance.

Results: ml/Cr in frontal gray matter was significantly increased after ecstasy use. No significant differences in ADC, FA and rCBV values were found.

Conclusion: Increased ml probably indicates gliosis after ecstasy use, although absence of other parameters of neurotoxicity suggests that incidental use, in contrast to heavy use, does not lead to major brain damage. However, there are different factors that may play a role in individual vulnerability for acute and long-term effects of ecstasy.

C-0816

MR spectroscopic imaging for targeting in stereotactic brain biopsy

K. Karaman, L. Onat, M. Sirvancı, O. Barlas; Istanbul/TR

Purpose: To evaluate the role of MR spectroscopy in stereotactic brain biopsy.

Materials and Methods: 7 patients with intracranial tumors underwent MR imaging, proton MR spectroscopy, and stereotactic biopsy. Biopsy samples were taken from regions of maximally elevated levels of choline used by color-coded metabolite map.

Results: All patients showed elevated Cho/Cr and Cho/NAA levels. In all cases diagnosis was made by single biopsy. Low-grade astrocytoma in two cases, anaplastic astrocytoma in 3 cases, and glioblastoma multiforme in 2 cases were detected. Biopsy specimens from regions with maximally elevated Cho showed dense tumor infiltration.

Conclusion: Brain biopsy is still a necessary procedure in the diagnosis of brain lesions. MR spectroscopy supports conventional MR imaging in detecting and selecting the target area for stereotactic brain biopsy.

C-0817

Three-dimensional CISS sequence: Use in the evaluation of intra- and extra-axial brain masses

A. Tosun, A. Kartel, B. Cakir; Edirne/TR

Purpose: To assess and illustrate the value of a three-dimensional Constructive Interference in Steady State (3D-CISS) technique in different pathologies related to CSF spaces.

Materials and Method: 57 consecutive patients underwent both routine MR imaging as well as 3D-CISS examination. Parameters for the 3D-CISS images were 16.7/8.08/1 (TR/TE/excitations), flip angle 70°, matrix of 192 x 256; field of view 150-210 x 200-210, in-plain resolution, 0.82 x 0.82 mm. An axial 64-mm-thick slab with 32-64 partitions covered the target lesions based on conventional MR images. The phase-encoding direction was from right to left for every patient.

Results: There were cisternal and intraventricular lesions including arachnoid cysts ($n = 18$), choroidal fissure cysts ($n = 2$), choroid plexus cysts ($n = 4$), pineal cysts ($n = 2$), lipomas ($n = 2$), epidermoid cysts ($n = 1$), schwannomas ($n = 3$), meningiomas ($n = 7$), aneurysms ($n = 2$). Parenchymal lesions were porencephalic cysts ($n = 2$), encephalomalacia ($n = 4$), cortical dysplasia ($n = 2$), subependymal hamartoma ($n = 1$) and brain tumors ($n = 7$). 3D-CISS sequences produce high contrast between the CSF and solid structures. Cyst walls, extent and margins of tumors and small cystic components in the tumors were clearly shown on 3D-CISS images.

Conclusion: The 3D-CISS MR imaging provides superb spatial resolution and signal-to-noise ratio in the diagnosis of pathologies especially related to the CSF areas. 3D-CISS sequence is a complementary technique to conventional MR and makes accurate diagnosis easier.

Brain tumors associated with chronic epileptic seizures: A pictorial review

S. Cakirer¹, B. Yagmurlu², B. Koklu¹, Y. Karagoz¹, N. Kahraman¹; ¹Istanbul/TR, ²Ankara/TR

Learning Objectives: To describe various tumoral processes which are associated with chronic epileptic disorders. To evaluate the role of conventional and advanced MR imaging studies in the chronic epileptic seizures developing secondary to tumors.

Background: Most histological types of brain tumors that are associated with chronic epileptic seizures are rare in neuro-oncological series. Between January 2000 and May 2004, cranial MR imaging findings of 233 patients with chronic epileptic seizures with an age range of 2-67 year-old were retrospectively studied, and 37 of them were found to have tumoral lesions as the underlying lesions.

Imaging Findings: The most frequent tumors that have been found as the underlying reasons of chronic epileptic seizures are dysembryoblastic neuroepithelial tumors (DNET), pleomorphic xanthoastrocytoma (PXA), ganglioglioma, oligodendroglioma, low-grade astrocytomas and other rare tumors. The above-mentioned tumors are presented with their distinct features on conventional and advanced MR imaging studies.

Conclusion: The underlying reasons for conventional and advanced MR imaging features, the role of additional sequences for their diagnosis, and the differential diagnoses between the lesions with similar appearances have been evaluated in the chronic epileptic cases associated with tumoral lesions.

C-0820

DWI and DTI in Creutzfeldt-Jakob disease

C. Romero, F.J. Meli, H. Lambre, G. Sevlever, S. Carpiniero, R.E. Salvatico, A.L. Taratuto; Buenos Aires/AR

Learning Objectives: To report four cases of sporadic Creutzfeldt-Jakob disease (sCJD) proved with brain biopsy. To illustrate the findings of diffusion-weighted imaging (DWI) and diffusion-tensor imaging (DTI) on two patients.

Background: sCJD has an incidence of about one per million annually. In 1996, a new and clinicopathologically distinct form of CJD was described and named variant CJD. Routine MR imaging sequences may show abnormalities in the basal ganglia and cerebral cortex. However, 21% of patients with sCJD have normal MR imaging. DWI is more sensitive to the pathological changes of CJD than T2. Regions of abnormally restricted DWI have been shown both in cortex and in deep gray matter structures. We report four cases of histologically proved sCJD. All cases had DWI and two patients had DTI. We also report apparent diffusion coefficient measurement (ADC) and fractional anisotropy (FA) values in patients with DTI.

Scientific and Educational Exhibits

Procedure Details: Conventional sequences of MR imaging and DWI were done in all patients. In two cases we also did DTI. We used a 1.5 T clinical MR scanner with echo planar imaging. ADC values were measured in head caudate and lentiform nuclei in all patients. The regions were compared with data from corresponding areas in four normal age and gender-matched subjects. We also obtained FA values for the same regions. For the processing, we used a commercial software provided by the manufacturer.

Conclusion: DWI and DTI could be useful sequences within the clinical setting of presumptive CJD, and together with conventional MR imaging, they add additional information before biopsy diagnosis.

C-0821

Anatomical atlas of pig's brain by MR imaging and CT in stereotactic conditions

M.A. Pietrani, J. Zaloff Dakoff, A. Rabadan, J. San Roman, F. Eleta, R. Rosler, P. Argibay; *Buenos Aires/AR*

Learning Objectives: Present a pictorial comparing pig's brain anatomical specimens with CT and MR imaging brain slices in stereotactic conditions and emphasize potential applications for brain research.

Background: Brain research requires high resolution imaging studies with CT and MR imaging in animal models to guide biopsy and implants. Pigs are particularly useful in neuroscience research because of the similarity with human brain anatomy and physiology. Although there are several pig's brain atlases, to our knowledge no one has actually correlated with CT and MR imaging brain images.

Procedure Details: Using inhalatory anesthesia five pigs 3 month old and 20 kg weight were scanned with CT and MR imaging and then sacrificed. Three mm slice thickness axial images with helical CT and 4 mm slice thickness axial, coronal and sagittal slices with 1.5 T MR imaging were obtained using T1, T2 and MRA sequences. Anatomical specimen slices and imaging were carefully compared to identify anatomic landmarks and precisely locate specific targets with non ferromagnetic stereotactic device. This device was designed to be adjustable to animals of different age and size and also to be useful with CT or MR imaging.

Conclusion: The anatomical structures of a pig's brain can be identified by CT and MR imaging. Stereotactic procedure including biopsy and implants may be guided with CT and MR imaging for research purposes.

C-0822

Wernicke's encephalopathy: Typical and atypical MR imaging findings

A. Buzzi, C. Garcia Pellegrino, M. Hjelt, E. Paez de la Torre, P. Balcarce, A. Mancini; *Buenos Aires/AR*

Learning Objective: To recognize the typical and atypical MR imaging findings of Wernicke's encephalopathy.

Background: Wernicke's encephalopathy is a neurological disorder due to nutritional deficiency of vitamin B₁ (thiamine), characterized by a classic triad (ophthalmoplegia, ataxia and an apathetic confusional state). It occurs most often in alcoholics, however is observed in non-alcoholic patients with infectious-febrile conditions, carcinoma, hyperemesis gravidarum, small-bowel obstruction, anorexia nervosa, etc.

Imaging Findings: Typical findings of Wernicke's encephalopathy are symmetrical hyperintense lesions on T2-WI and FLAIR images in the paraventricular regions of the thalamus and hypothalamus, periaqueductal regions of the midbrain, floor of the fourth ventricle, midline structures of the cerebellum and mammillary body atrophy. Unusual finding include symmetrical hyperintense lesions in the cerebral cortex, especially along the central and paracentral sulci.

Conclusions: Wernicke's encephalopathy is caused by a large variety of clinical conditions and its characterized by typical and atypical imaging findings. The knowledge of these findings allows the correct diagnosis with MR imaging in patients without the classical clinical triad or in patients in coma. This early diagnosis allow the early indication of the proper treatment, modifying the prognosis of this disease.

Preliminary study on the mechanism of reading recovery in a pure alexia by using functional MR imaging

L. Ma, X. Weng, W. Sun; *Beijing/CN*

Purpose: To observe the changes of brain function during reading recovery by using functional MR imaging (fMRI), and to provide the experimental data in elucidating the mechanism on the recovery of reading and language function.

Methods and Materials: fMRI was performed in a native Chinese patient with pure alexia on the 45th and 130th day after the onset, respectively. Three kinds of

Chinese characters were presented during the scan and the patient was asked to judge whether he could recognize the characters or not. The brain activation maps were acquired after postprocessing, and the activated location and volume were compared between the first and second experiments.

Results: In both experiments, Broca area, Wernicke area, and the right extrastriate were significantly activated, while the left extrastriate around the lesion was markedly activated only in the second experiment, and the volume of activation in the right extrastriate in the second experiment was about 3 times as large as that in the first experiment.

Conclusion The left extrastriate cortex is one of the key areas responsible for reading function in the brain. The recovery of reading function can be compensated for in a contralateral corresponding cortical area, or it can be the result of reorganization in ipsilateral peri-lesion cortex. Both mechanisms may simultaneously play important roles in reading recovery.

C-0824

How many diffusion gradient directions will be adequate for the clinical applications of diffusion tensor imaging and tractography in cerebral tumors at 3 T MR imaging

H.H. Fu, F. Feng, Z.Y. Jin, W. Tao, R.Z. Wang, Y. Yang, H. You, X.Z. Li, F. Sun; *Beijing/CN*

Purpose: To investigate how many directions acquired in diffusion gradient imaging will be adequate for diffusion tensor imaging (DTI) and tractography (DTT) of cerebral tumors. To demonstrate abnormalities distally and detect occult white matter (WM) tract invasion by tumors on DTI and DTT images.

Materials and Method: MR imaging was performed in 8 patients with histologically confirmed tumors or metastases using a GE Signa VH/3.0 T scanner and T1WI, T2WI and DTI sequences. The diffusion gradient directions of DTI were logically selected at 55, 33, 25, 15, and 6; and b value = 1200, 128x128 matrix. Regions of interest (ROI) were drawn within the tumor, the Ratio Anisotropy (RA), Fractional Anisotropy (FA), Average DC (ADC), and other parameters were calculated for these ROI on all DTI sequences. DTT images in direction sequence were reconstructed by post processing.

Results: The relationship of tumor to WM tracts was uniquely depicted by DTT images compared to that seen on T1WI and T2WI. Four major patterns (deviated, infiltrated, edematous and destroyed) in affected WM tracts were identified and are discussed. In the high-grade tumors, the average values of RA and FA in areas of WM disruption with normal appearance was reduced significantly; by comparison, ADC was increased remarkably.

Conclusion: WM disruption can be identified clearly using the values of RA/FA/ADC and DTT images which were not affected in different acquired diffusion gradient directions (more than 6) in patients with a high-grade tumor. Detecting the other potential patterns of WM fiber tract alteration by cerebral tumors may have to increase the diffusion gradient directions.

C-0825

Radiological manifestations of suicide attempt. A multisystem and multimodality approach

E. Testempski, V. Vantali, N. Kartakis, D. Chondros; *Athens/GR*

Purpose: The purpose of this exhibit is to illustrate various types of injuries in patients after having committed a suicide attempt and to be aware of usual and unusual imaging findings related with suicide attempt.

Methods and Materials: Self-injured patients are not rarely seen in the Emergency Department and may have a variety of head and neck injuries, body and abdominal viscera injuries and also injuries of the extremities. Plain radiographs, US, CT and MR imaging are used in various combinations to evaluate the extent of these injuries. After reviewing the data of our Department, we present a pictorial multisystem and multimodality approach of common and some uncommon self-inflicted injuries.

Results: Esophageal stenosis and rupture after ingestion of caustic agents and esophageal foreign bodies in prisoners and psychiatric patients are depicted. Brain CT and MR images in patients after hanging and after receiving sedatives, anesthetics poisons and other kinds of medications are also shown. A variety of injuries of the head, of the spine, of viscera and extremities in patients having jumped intentionally from a great height are also presented. Head and body injuries in suicides with guns are also demonstrated.

Conclusion: A complete radiological assessment is necessary in these patients in poor clinical condition in order to avoid significant morbidity. The role of imaging modalities in the investigation of self-inflicted injuries is helpful in the diagnosis and management of these critically ill patients and in the differentiation from criminal injuries.

Scientific and Educational Exhibits

C-0826

Primary brain lymphomas: Distinctive imaging features

E. Xinou, G. Boulogianni, D. Chourmouzi, I. Dedes, A. Drevelegas;
Thessaloniki/GR

Purpose: To describe and compare CT and MR features of primary cerebral lymphoma (PCL) and to define its imaging characteristics.

Materials and Method: CT and MR studies of 16 patients with histologically proven PCL were reviewed (6 men, 10 women, 19-76 years, median age 50 years). Ten patients underwent CT-guided stereotactic biopsy and in five patients an open surgical intervention was performed. CT was performed in 6 cases, whereas all patients underwent MR (axial SE PD/T2, axial T1 and triplanar T1+gadolinium). The radiological evaluation included location, number of lesions, measurement of the edema, T1-T2 signal intensity and enhancement characteristics.

Results: A total of 43 lesions (0.5-5.5 cm diameter) were present in 16 patients; 11 patients (69%) had multiple lesions. Most lesions (50%) were in the periventricular areas, appearing as multiple well-defined masses with minimal surrounding edema. The most frequent locations were in descending order: Cerebral hemispheres (50%), cerebellum (25%), basal ganglia (12.5%), pons (12.5%), third ventricle (12.5%) and leptomeninges (12.5%). The hypothalamus ($n = 1$) and the corpus callosum ($n = 1$) were rare locations. On CT scan, most lesions (85%) were isointense or hyperintense. On MR, all lesions were isointense or hypointense compared to the gray matter on T1-weighted images and 62.5% were isointense on T2-weighted images. Dense homogeneous enhancement was observed on both CT and MR studies in 87.5% of the lesions; rim enhancement was depicted in one AIDS patient with multiple lesions. Diffuse leptomeningeal enhancement was demonstrated in two and subependymal enhancement in one case.

Conclusion: Periventricular location, iso- or hyperdense appearance on CT, T1 and T2 isointensity on MR and dense homogeneous enhancement are imaging characteristics that can suggest the diagnosis of PCL.

C-0827

Granulomatous angiitis of the central nervous system. A pictorial review

N. Sheehy, M. Farrell, P. Brennan, J. Thornton; Dublin/IE

Learning Objectives: 1. To describe imaging findings in granulomatous angiitis of the central nervous system (GANS). The findings on CT, MR imaging, MRA and DSA are included. 2. To demonstrate how GANS can mimic a number of pathologies including vascular, inflammatory, infectious and neoplastic aetiologies. 3. To demonstrate the use of imaging modalities in guiding biopsy.

Background: GANS is an idiopathic, isolated cranial vasculitis that may occur in association with infectious agents such as varicella or neoplastic diseases such as Hodgkin's disease. It may present with a variety of clinical events such as encephalopathy, coma, seizures and stroke. Diagnosis is hampered by the absence of a specific clinical, laboratory or radiological investigation. Frequently a brain biopsy is necessary to confirm the diagnosis. Because of its protean clinical and radiological manifestations, GANS is frequently included in the differential diagnosis of patients with neurological disorders.

Imaging Findings: A comprehensive review of the imaging findings in 6 cases of biopsy-confirmed GANS is illustrated.

Conclusion: In this e-poster, we demonstrate the multiple imaging findings of GANS.

C-0828

Detection of brain hyperintensities on fluid-attenuated inversion-recovery (FLAIR) images in multiple sclerosis (MS): In-plane high resolution (HR) versus standard low resolution (LR) matrix

F. Sardanelli, A. Fausto, B. Cotticelli; Milan/IT

Purpose: To compare the detection of brain hyperintensities on fast FLAIR images using a HR or a standard LR matrix in MS patients.

Methods and Materials: Ten consecutive MS patients (9 females, aged 22-64) underwent (1.5 T) a fast FLAIR paraaxial sequence (TR/TE/TI = 8300/135/2500 ms; ETL = 21; one excitation; FoV 230 mm; 20 no-gap slices, 5-mm thickness; 256x256 (LR) matrix; pixel = .90x.90 mm; time 3' 36"). The sequence was repeated using a 512x512 (HR) matrix with a 0.45x0.45-mm pixel and 7' 46" time. Patient-by-patient, for each slice, brain hyperintensities were counted, grading them as certain (C) or probable (P). Signal-to-noise ratio (SNR) was calculated for both sequences in each patient. Wilcoxon test.

Results: A total of 1179 hyperintensities (C/P = 1069/110) using LR matrix and of 983 (891/92) using HR matrix were counted, C/P ratio remaining unchanged (9.7) for both matrices. C hyperintensities ranged 32-to-351 (median = 117) and

23-to-282 (93), respectively; P hyperintensities 5-to-27 (10) and 2-to-26 (8), respectively. The number of total and C hyperintensities was significantly larger with LR matrix and mean SNR was 49.2 (LR matrix) and 18.5 (HR matrix), with a significant drop of about 60% ($P < .01$); no significant difference was found for P hyperintensities.

Conclusion: The lower SNR of FLAIR with HR matrix reduces significantly the number of total and certain hyperintensities in brain imaging of MS patients, probably due to the heavy reduction of voxel (only a fourth of LR voxel). The level of certainty in detecting brain hyperintensities remain unchanged, confirming the high sensitivity of FLAIR sequence.

C-0829

3 T 1H-MRSI assessment of spatial distribution of metabolites in cerebral gliomas

S. Pollici¹, A. Di Costanzo², G. Giannatempo³, T. Popolizio³, A. Carrieri¹, T. Scarabino³; ¹Novara/IT, ²Naples/IT, ³San Giovanni Rotondo/IT

Purpose: This research aims to characterize the spectrum of metabolites in tumour and surrounding tumour tissue by using 1H-MRSI.

Methods and Materials: We studied twenty-eight patients with histologically verified cerebral glioma. Region of interest (ROI) were positioned on necrotic areas, non-necrotic areas, lesion edges and on apparently normal or edematous surrounding tissues. The Cho, NAA, Cr, and LL signal in the ROI were compared with the signal of the same metabolite in the corresponding region of the opposite non-pathological hemisphere.

Results: The metabolite distribution in high and low grade gliomas was correctly characterized in the examined areas. Cho, NAA and LL, in our experience, have a different distribution in high and low grade tumor tissue, and in surrounding edematous regions with and without tumour infiltration.

Conclusions: 3 T 1H-MRSI is a non-invasive technique that allows recognition of the grade of the tumour, differentiation of the proliferating neoplasm from normal tissue, necrotic areas and edematous tissue; both secondary to neoplastic infiltration and from radiation. This research shows that the different spatial distribution of metabolites in a glioma allows distinction of high grade gliomas from low grade gliomas and highlights the heterogeneity and characteristics of these lesions. 3 T 1H-MRSI supplies useful information for the stereotactic biopsy, surgical resection and for radiotherapy planning.

C-0830

Tips and tricks in cerebral perfusion CT: Classification and literature review

A. Littera, A. Ferrari, A. Stecco, A. Boccardi, C. Civardi, A. Carrieri; Novara/IT

Learning Objectives: The exhibit allows the technician and radiologist to know the artifacts and pitfalls which can be found in each step of perfusion CT of the brain. Solutions for improvement in the quality of examination are shown.

Background: Dynamic Perfusion Computed Tomography is a well assessed technique to evaluate brain perfusional parameters in patients with ischemic stroke, in order to perform thrombolytic therapy.

Procedure Details: There are several technical aspects that can affect the perfusional data evaluation and the final report of the examination. We analyze and classify all these aspects, to allow the technician and the radiologist to know exactly what to avoid and what to choose, and we indicate when possible the way to improve the quality of the examination. The pitfalls can be divided into two major groups, related to technique and to elaboration. Among technical pitfalls we include: type of scanning (spiral/continuous mode, non-spiral/discontinuous mode), slice thickness choice, anatomic coverage, gantry tilting, Kv choice, infusion rate, prep delay. Data elaboration pitfalls include: movement software correction, artery/vein choice to begin the analysis, evaluation of the artery time/intensity curve morphology.

Conclusion: Knowing the type of artifacts or technical errors and the way to avoid them is mandatory to obtain satisfactory perfusional color maps, and correct CBV, CBF and MTT values.

C-0831

Multislice computed tomography (MSCT) and magnetic resonance imaging (MRI) in the evaluation of cerebrospinal fluid (CSF) fistulae with rhinorrhea

A. Bellussi, M. Cristofaro, L. Rovighi, A. De Santis, C. Bibbolino; Rome/IT

Learning Objectives: To illustrate the high sensitivity and accuracy of msct in association with MR, in identifying dural osseous defects with CSF leak, complicated by bacterial meningitis.

Background: From September 2002 to May 2004 we observed 7 cases of CSF fistulae in patients affected by bacterial meningitis. 4 cases were secondary to

Scientific and Educational Exhibits

trauma, 1 due to a congenital malformation and 1 due to a bone defect in the clivus (a very rare location as far as we know). The last was subsequent to ethmoidal surgery.

Procedure Details: CT examinations were performed with a 4 row scanner (GE Lightspeed QX I) at 4x1.25 mm detector collimation, 120 kv, 200 mA, 0.8 sec, table speed 3.8 mm (pitch 0.75). Data reconstruction interval was 0.62 mm. Images were reformatted on coronal and sagittal planes. MR images were obtained using a Philips Gyroscan 05 NT device. T1 SE and T2 TSE multiplanar sequences were performed and when necessary suitable decubitus imaging was obtained. In selected cases T2 TSE 3D images were acquired.

Results: We found that msCT examination was able to demonstrate the precise location and size of CSF fistulae in all cases, even when MR was not reliable in imaging the definite site of the bone breach. Four patients were successfully operated on and recovered.

Conclusions: In the evaluation of patients affected by CSF leak, msCT should be considered an indispensable integration to MR findings.

C-0832

Acute demielinating tumor-like disease: Multiple sclerosis Marbourg's variant

G. Iannucci¹, A. Stecco¹, D. Danieli², F. Causin², M.D. Marchi², V. Pinna², A. Carrieri¹; ¹Novara/IT, ²Vicenza/IT

Purpose: There are a few cases of Marbourg's disease reported in the medical literature. Marbourg's disease is described as a fulminant, monophasic, malignant multiple sclerosis that can result in death from severe disseminated demyelination within a few weeks. The MR imaging shows tumor-like lesions with large and confluent demyelination, without specific characteristics.

Methods and Materials: Case 1: 41 year old man, who was healthy until admission when he developed a headache, hemiparesis and a stupor. Two weeks after admission he became unconscious and underwent emergency neurosurgery with frontal left lobectomy. Case 2: 39 year old woman, who was healthy until admission when she developed headache and aphasia. Two days after admission she developed hemiparesis and stupor and a week later died. MR imaging scans, laboratory and clinical examinations were obtained from each of the two patients.

Results: MR imaging scans from each patient showed a frontal lobe tumor-like lesion. Conventional MR imaging sequences didn't allow us to better characterize the lesions. The histological findings were identical in each patient, corresponding to myelin loss with numerous macrophages, myelin breakdown products and a subtle perivascular infiltration of lymphocytes. Histological specimens were obtained from the frontal lobe in case 1 and from the whole brain in case 2.

Conclusion: Our study describes two cases of Marbourg's disease MS with large focal cerebral demyelinating lesions. They showed the same lesions in the frontal lobe with clinical and radiological characteristics typical of brain tumor but different in clinical evolution. The relevance of this study is about the rare recognition of Marbourg's disease in the medical literature.

C-0833

The body representation in the first somatic sensory area of human brain: An fMR imaging study

G. Polonara, M. Fabri, C. Mabiglia, T. Manzoni, U. Salvolini; Ancona/IT

Purpose: The present research aims at studying with fMR imaging the body representation in the first somatic sensory area of human brain.

Materials and Methods: Nine healthy volunteers were examined using a 1.5 T MR system. Tactile stimulation was applied by rubbing various cutaneous regions with a rough sponge (palm and back of the hand, foot, forearm, arm, shoulder, leg, thigh) or with a soft cotton pad (face, medial or lateral trunk) at a frequency of 1 Hz. Two 5-min protocols were used: one consisted of ten 30-sec alternating periods of rest and stimulation, the other of sixteen 18-sec alternating periods of rest and stimulation, followed by a 12-sec rest period. With the first protocol, a single body region was rubbed in all 5 stimulation periods, with the second, two body regions were alternately rubbed during the 8 stimulation periods.

Results: Cortical activation was found in the post-central gyrus (PCG) of the contralateral hemisphere. Stimulation of different body regions activated topographically different cortical regions: foci evoked by foot, leg, trunk, arm, hand and face stimulation were arranged medial to lateral throughout PCG, indicating a somatotopic map whose general features are in agreement with previous human functional (PET and MEG) and monkey recording studies. Proximal body and hand activation foci were also present in the posterior part of ipsilateral PCG.

Conclusion: Definition of the cortical cutaneous map with fMR imaging with an MR magnet commonly used for diagnostic purposes may be useful in pre-operative functional studies.

C-0834

Highly active antiretroviral therapy (HAART) and MR imaging of progressive multifocal leukoencephalopathy

E. Busi Rizzi, V. Schininá, M.L. Giancola, L. Rovighi, D. Larussa, A. Antinori, C. Bibbolino; Rome/IT

Purpose: To evaluate whether highly active antiretroviral therapy (HAART) modifies MR imaging appearances of progressive multifocal leukoencephalopathy (PML) among patients with HIV infection and whether MR imaging pattern and survival correlate.

Methods and Materials: We retrospectively reviewed MR imaging of 31 HIV+ patients with histological or clinicovirological diagnosis of PML, 18 with positive JCV-DNA in cerebral spinal fluid (CSF). 12 patients were naive for antiretrovirals and 8 were taking HAART at diagnosis. Median CD4: 69 x cells/ml, median plasma HIV-RNA: 4.89 x log₁₀ copies/ml. MR examinations were performed on a 0.5 T system, axial T1 spin-echo images before and after administration of contrast material, T2 fast spin-echo and T2 FLAIR images were obtained in all patients. Number, size, location, distribution, scalloping, signal intensity and contrast enhancement of the lesions were evaluated.

Results: Patients with positive or negative JCV-DNA in CSF displayed a similar pattern, except for a higher risk of pons involvement in JCV-DNA positive PML (OR 1.50 (1.08-2.08), P = 0.028). Analysing differences according with antiretroviral exposure no significant differences were observed in naive compared to experienced patients or between HAART-treated or not treated patients at diagnosis. Bulb involvement (p = 0.030) and mass effect were associated with higher risk of death (p = 0.009). MR findings were unrelated to immunological status.

Conclusions: MR PML pattern was not influenced by antiretroviral exposure. JCV positive and JCV negative PML presented similar MR imaging findings and these features are very relevant to distinguish PML with negative JCV-DNA in CSF from other leukoencephalopathy.

C-0835

Atypical multiple sclerosis: MR imaging findings and differential diagnosis

G. Lucchienti¹, M. Spadaro¹, P. Bramanti², C. Colonese¹, U. Sabatini¹, C. Uggetti³, S. Bastianello³; ¹Rome/IT, ²Messina/IT, ³Pavia/IT

Learning Objectives: 1)To illustrate the diagnostic criteria of MS and the findings of atypical MS phenotypes with conventional MR imaging. 2)To describe the differential diagnosis of atypical MS with other diseases of the CNS. 3)To propose a diagnostic algorithm, including advanced MR techniques, laboratory and clinical evaluations, for diseases that appear similar to MS.

Background: Atypical forms of Multiple Sclerosis and other diseases of the central nervous system may show similar patterns in MR. The differential diagnosis includes: vascular diseases (CADASIL), vasculitis (polyarteritis nodosa, systemic lupus erythematosus, Sjogren's syndrome, Behcet disease, giant cell arteritis and small single brain infarcts), secondary demyelinating diseases (Progressive Multifocal Leukoencephalopathy, Acute Disseminated Encephalomyelitis (ADEM)), multiple metastases or malignant brain tumor, inflammatory diseases (sarcoidosis), infectious diseases and metabolic diseases (Metachromatic Leucodystrophy).

Procedure Details: For each of the differential diagnoses a clinical case is demonstrated. A diagnostic algorithm that is useful for differential diagnosis in the clinical setting is presented. For correct diagnosis, the MR findings are correlated with the clinical and laboratory findings.

Conclusion: An accurate differential diagnosis is crucial to enable the appropriate therapy to be initiated without delay.

C-0836

Assessment of tissue characterization of gliomas: Comparison of tumor blood volume by perfusion-weighted MR imaging and TI-201 SPECT

H. Uematsu, T. Tsuchida, H. Kimura, M. Toyooka, H. Itoh; Fukui/JP

Purpose: TI-201 uptake is useful for evaluating the degree of glioma malignancy. Increased vascular leakage is considered to be a contributor to TI-201 uptake in early scans; however, studies on the contribution of tumor blood volume in the TI-201 accumulation are sparse. Perfusion-weighted magnetic resonance (MR) imaging can provide quantitative tumor blood volume values. The aim of this study was to clarify the contribution of tumor blood volume in TI-201 uptake in gliomas.

Methods and Materials: We evaluated 10 patients with glioblastoma multiforme. After the injection of TI-201 (74 MBq), early (15 min later) and delayed (3 hrs later) SPECT scans were acquired. TI-201 uptake ratios of tumors to contralateral normal white matter (T/N ratio) were calculated for both the early and delayed scans. Perfusion-weighted MR imaging with a gadolinium contrast agent can provide the tumor blood volume values. For the quantitative analysis, TI-201

Scientific and Educational Exhibits

uptake (T/N ratios) in the early and delayed scans were compared with tumor blood volume.

Results: In visual assessment, the tumor blood volume on the parametric map was concordant with the TI-201 early and delayed SPECT images. In the quantitative analysis, T/N ratios in the early scan were well correlated with tumor blood volume ($r^2 = 0.61$, $p < 0.01$). In the delayed scan, there was also significant correlation between T/N ratios and tumor blood volume ($r^2 = 0.53$, $p < 0.05$).

Conclusion: Tumor blood volume may contribute to greater TI-201 uptake seen on both the early and delayed scans.

C-0837

Head/neck CT angiography and CT perfusion in the assessment of patients with carotid occlusion

R. Takagi, H. Sato, H. Hayashi, N. Hidaka, H. Yoshihara, T. Kumazaki; Tokyo/JP

Purpose: To demonstrate the value of the combination technique of Head/neck CTA and CTP in a clinical study of patients with carotid occlusion.

Methods and Materials: 13 patients who were shown to have carotid occlusion by MRA underwent both head/neck CTA and CTP using 16-slice MD-CT. Initially, a dynamic perfusion series was acquired, head/neck CTA was performed from the origin of the aortic arch to the circle of Willis. The regional cerebral blood flow (CBF), cerebral blood volume (CBV) and mean transit time (MTT) maps were calculated. The head/neck CTA images were reconstructed. The MRA, neck CTA, head CTA and CTP images were reviewed. The interpretation of each of the 4 modalities was compared with the other results.

Results: MRA showed total ICA occlusion in 10 and distal occlusion in 3 patients, and did not depict ipsilateral MCA in 3 patients. Neck CTA revealed total ICA in 2 patients. Head CTA showed ipsilateral MCA in all patients. Head CTA showed ICA occlusion at supraclinoid segment in 4, narrowed ICA in 8, and normal in one patient. CTP showed increased CBV, decreased CBF and prolonged MTT at ICA territory in 2 patients. The other 11 patients were shown normal CBV and prolonged MTT at MCA territory. CBF map showed decreased CBF at MCA territory in 5, basal ganglia in 3 and normal in 3 patients.

Conclusion: In the assessment of patients with carotid occlusion, CTP represents various ischemic changes according to auto-regulation and collateral circulation. The combination diagnosis of head/neck CTA and CTP provides valuable information.

C-0838

Paracavernous sinus venous structures: Anatomical variations and pathological conditions evaluated on fat suppressed 3D fast-gradient-echo MR imaging

S. Tanoue, H. Kiyosue, Y. Hori, M. Okahara, Y. Sagara, J. Kashiwagi, H. Mori; Oita/JP

Learning Objectives: To know the anatomical variations of paracavernous sinus venous structures. To describe the usefulness of fat-suppressed 3D fast-gradient-echo MR imaging in evaluating venous structures of the skull base.

Background: The cavernous sinus (CS) communicates with several paraCS venous structures; receiving blood flow from superficial middle cerebral vein, sphenoparietal sinus, superior ophthalmic vein, and draining into superior and inferior petrosal sinuses, pterygoid and basilar plexuses. Anatomical variations of these veins have been previously reported, however some details such as the relationship between the sphenoparietal sinus and the superficial middle cerebral vein, are still controversial. The anatomical variations of paraCS veins, especially drainage patterns of superficial middle cerebral vein, were evaluated on MR imaging.

Procedure Details: Thirty cases, including patients without any lesions affecting CS or paracavernous veins and patients with carotid cavernous fistulas, were examined by using fat-suppressed, contrast-enhanced, 3D fast-gradient-echo MR imaging. Two neuroradiologists evaluated the images on a viewer, with regard to normal anatomy and any pathological findings of the paraCS veins.

Conclusion: Fat-suppressed 3D fast-gradient-echo MR imaging clearly depicts the paraCS venous structures in normal and pathological conditions. There were several variations in the drainage pattern of the superficial middle cerebral veins, e.g. draining into the sphenoparietal sinus, the CS, and other paracavernous veins. Knowledge of the variations is important for diagnosis and endovascular treatment of the CS lesions.

C-0839

Early diagnosis of postoperative empyema in brain and spine: Use and pitfalls of MR imaging

A. Wada¹, T. Hayashi², T. Katsume¹, E. Fukuba¹, M. Matsuo², H. Kitagaki¹; ¹Izumo, Shimane/JP, ²Tenri City, Nara/JP

Learning Objectives: Diffusion weighted MR imaging is a useful method to diagnose pyogenic empyema. In the post operative state, there are several conditions which reveal similar findings to pyogenic pus on diffusion-weighted images. We exhibit the use and pitfalls of MR diagnosis of postoperative empyema.

Background: Epidural and subdural empyemas are one of the most serious complications after brain and spine surgery. Postoperative empyema is not frequent, but has a high fatality rate, especially in compromised patients. Early diagnosis and treatment affects the patient's prognosis. We experienced five cases of post-operative epidural or subdural empyema and two cases of post operative reaction which showed similar MR findings to empyema. We noticed that there were some pitfalls in the MR diagnosis of postoperative empyema.

Procedure Details: Diffusion weighted MR imaging was performed in all seven cases. Content of the empyema (pus) showed remarkably high signal intensity and this finding contributed to the early diagnosis and treatment of the empyema. The high signal intensity of pus decreased after treatment (surgical resection or antibiotic therapy). There are other factors which show high signal intensity on DW images such as an inserted metal device, bleeding and an air collection.

Conclusion: Diffusion weighted MR imaging is useful in the early diagnosis of postoperative empyema with awareness of some pitfalls.

C-0840

Metallic artifact reduction techniques for MR imaging of the brain: Evaluation of fast-inversion-recovery T1-weighted images (fast-IR-T1WI)

M. Kawanishi; Chiba/JP

Purpose: In magnetic resonance (MR) imaging of the brain, magnetic fields can be locally distorted by ferromagnetic implants, such as fillings in teeth or aneurysmal surgical clips. In this study fast-IR-T1W imaging was performed and the ability of metallic artifact reduction was evaluated.

Methods and Materials: 10 patients with ferromagnetic implants were the subjects of this study. Fast-IR-T1WI were obtained with the following parameters: TR/TE/TI 2789/22/410 msec; echo train length 9; FOV 24 cm; matrix 256x192 and scan time 33.5 sec. Standard Spin-Echo-T1-weighted images (SE-T1WI) were also performed and were compared with fast-IR-T1WI. Reduction ability of metallic artifacts was evaluated.

Results: In all cases fast-IR-T1WI was superior to reduce metallic artifacts to standard SE-T1WI.

Conclusion: Fast-IR-T1WI is useful for patients with ferromagnetic implants. Fast-IR-T1WI is considered a good technique to reduce metallic artifacts in brain MR imaging.

C-0841

Normalization of CNS metabolite disturbances in clinically asymptomatic HIV patients after HAART treatment. MRS study

E. Tarasow, A. Wiercinska-Drapalo, J. Jaroszewicz, J. Walecki, A. Alathiaki; Bialystok/PL

Purpose: MR proton spectroscopy (1H MRS) enables early detection of metabolic changes, which occur in the course of AIDS Dementia Complex Syndrome (ADC). The goal of the study was the evaluation of highly active antiretroviral therapy (HAART) and its influence on the character and intensity of metabolic changes in brain 1H MRS spectra in clinically asymptomatic HIV-infected patients as well as search for correlation between the treatment and 1H MR spectroscopy results and immune deficit degree.

Methods and Materials: In the group of 20 HIV+ patients, the examination of the central nervous system (CNS), MR and 1H MRS were conducted twice: Before HAART treatment and during the therapy; on average after 6 months (4-9 months of treatment).

Results: The levels of NAA/Cr in the control MRS examination were close to the values observed before treatment. However, a statistically significant increase in the NAA/Cho ratio ($p < 0.05$) was noticed. The control examination showed a decrease of Cho/Cr and ml/Cr ratios, though statistically insignificant ($p > 0.05$). NAA and Cr contents in reference to the signal of non-suppressed water increased insignificantly in the follow-up examination. However, a statistically significant decrease in Cho/H₂O and ml/H₂O levels ($p < 0.05$) was observed.

Conclusion: The therapy with HAART affects normalization of metabolite levels in the central nervous system in clinically asymptomatic HIV+ patients and di-

Scientific and Educational Exhibits

minishes the risk of ADC occurrence. Myoinositol and choline levels estimated in 1H MRS may act as indices for antiretroviral treatment efficacy.

C-0842

MR imaging manifestation of central nervous system lesions in von Hippel-Lindau disease

L. Cyrylowski, G. Zaborowski, M. Sawicki, K. Krzystolik, C. Cybulski, L. Sagan, A. Walecka, J. Lubinski; Szczecin/PL

Purpose: The aim of the study was to evaluate localization, type, and MR appearance of the central nervous system (CNS) lesions in von Hippel-Lindau disease (vHL).

Methods and Materials: The study group comprised 42 patients from 34 Polish families (26 women, 16 men; mean age 34.5 years) with diagnosed vHL. MR imaging of the head and the spine was performed with 1.5 T unit, using dedicated coils. T2w, precontrast T1w, and postcontrast T1w sequences were obtained.

Results: One hundred and eleven lesions in 30 (71%) patients were detected, including 53 (47%) subsellar lesions [47 (42%) in the cerebellum, 6 (5%) in brain-stem], 2 (3%) suprasellar, and 56 (50%) in the spinal cord. Eighty seven solid (78%), 17 cystic-solid (15%), and 7 (7%) cystic lesions were found. Multiple lesions were diagnosed in 8 (26%) patients in the spinal cord, 12 (40%) in the cerebellum, and 1 (3%) in the brainstem. Multifocal lesions have been observed in 16 (53%) cases. Almost all solid lesions were isointense both in T1w and T2w. They were detected only with postcontrast imaging. Nineteen lesions were resected in 11 patients; pathological examination revealed hemangioblastomas in all cases.

Conclusion: Postcontrast T1w images are of the most value in the detection of CNS lesions in vHL patients. Proper prophylactic and diagnostic management can possibly identify asymptomatic carriers of germline vHL mutations. Early detection and treatment of small lesions can probably prolong survival of the patients and limit complications of the disease.

C-0843

MR CSF-flow examination in children with a ventriculo peritoneal shunt: The differentiation of shunt dependent and shunt independent hydrocephalus

M. Szafirska, A. Urbanik, A. Swierczyna, S. Kwiatkowski, S. Sztuk, I. Herman-Sucharska; Krakow/PL

Purpose: The aim of the study is the presentation of the value of MR examination of CSF flow through the cranial part of the ventriculo peritoneal shunt in the evaluation of shunt dependent hydrocephalus.

Methods and Materials: Thirteen patients 8-18 years of age in the course of longterm treatment using ventriculo-peritoneal shunts were examined. The examinations were performed with the use of Signa Horizon 1.5 T (GEMS) unit with 2D CINE/GR/PC sequence in the plane perpendicular to the direction of CSF-flow in the shunt. Flow parameters were calculated using the Flow Analysis program (the presence or absence of CSF-flow through the shunt as well as the flow velocity in ml/min were evaluated). No clinical manifestations of shunt obstruction had been observed in any of the patients prior to MR examination.

Results: In 5 children no CSF-flow was noted indicating shunt independent hydrocephalus. In 7 children CSF-flow was present (the flow velocity of 0.1-1.3 ml/min) indicating shunt dependent hydrocephalus.

Conclusion: MR examination allows the determination of the absence or presence of CSF-flow as well as its direction and velocity. This examination enables the differentiation between shunt dependent and shunt independent types of hydrocephalus, which is of great significance in the clinical management of patients after shunt implantation.

C-0844

Differences in regional BOLD responses in the primary and secondary auditory cortex by mixed noise and speech like stimuli

M. Golebiowski, P. Bogorodzki, E. Janko-Piatkowska, T. Wolak, M. Orzechowski, R. Kurjata, W. Szeszkowski; Warsaw/PL

Purpose: The aim of the study was to investigate the hierarchical organization within the auditory cortex of humans with mixed noise and speech like auditory excitation using functional magnetic resonance imaging (fMRI) technique.

Materials and Method: For each of 20 healthy subjects (16 males and 4 females, 19 right-handed and 1 left-handed) at age 23.6 ± 0.7 four functional sessions with block type speech like stimuli (15 repetitions of the BA-LU) and variable amount of noise were acquired. Statistical parametric maps were generated under SPM99 software and additionally, the raw Blood Oxygenation Level Dependent (BOLD) signal intensities from left and right primary (A1) and secondary (A2)

auditory cortex regions were averaged to form a time series spanning the entire length of the experiment. The variation of resulting curves was described with percent signal change (PSC) measure.

Results: The random effect analysis shows strong activations in both A1 ($T = 10.59$ in left hemisphere and $T = 9.94$ in right hemisphere) and A2 ($T = 11.73$ in left hemisphere and $T = 8.75$ in right hemisphere) regions. Additionally, we noted substantial correlation of PSC measure with noise level in A1 ($R = 0.95$, $T = 13.4$) and practically no correlation in A2 ($R = 0.05$, $T = 0.2306$).

Conclusion: The experiment revealed auditory hierarchical architecture with the special emphasis on primary and secondary cortex function fields. An attenuation of noise at secondary cortex with good response for BA-LU stimuli was noted.

C-0845

Single voxel ^1H MR spectroscopy of cerebral gliomas at 3.0 T: Comparison of short and long TE sequences in tumor grading

J.-h. Kim, K.-H. Chang, M. Han, D. Na, B. Kwon, I. Song; Seoul/KR

Purpose: To investigate the usefulness of short and long TE sequences at 3.0 T single voxel proton MR spectroscopy (^1H -MRS) in the grading of cerebral gliomas.

Methods and Materials: Single voxel ^1H -MRS was performed at 3.0 T in 27 patients with cerebral glioma. Pathological diagnosis included 5 WHO grade II tumors, 11 grade III tumors and 11 grade IV tumors. ^1H -MRS spectra were obtained with TR of 2000 msec and with both short TE (35 msec) and long TE (144 msec) PRESS sequences at the possible homogenous solid area in the brain tumors. Choline (Cho)/creatinine(Cr), Cho/N-acetylaspartate(NAA), and (lipid(Lip) + lactate(Lac))/Cr ratios were measured at the both spectra and compared among those three grades of the gliomas.

Results: (Lip + Lac)/Cr ratios of grade II, III and IV tumors at short TE were 0.82 ± 0.41 , 4.2 ± 7.5 and 11.1 ± 11.4 , respectively ($p < 0.001$ between grade II and IV). The Cho/Cr ratios of grade II, III and IV tumors at long TE were 1.90 ± 1.01 , 2.37 ± 1.27 , and 4.68 ± 4.49 , respectively ($p < 0.05$ between grade II and IV). (Lip + Lac)/Cr ratio at long TE, Cho/Cr ratio at short TE, and Cho/NAA ratio at both TEs also tended to be greater with higher grades but there were no significant differences among the grades.

Conclusion: Both short and long TE sequences of 3.0 T single voxel ^1H -MRS are complementary in the grading of the cerebral gliomas because of their own advantages.

C-0846

Assessment of small vessel stents for intracranial angiography by 16-slice CT angiography

H.-J. Choo, K.S. Choo, T. Lee, S. Kim, H. Jeong, T. Moon; Pusan/KR

Purpose: To determine whether 16-slice CT angiography is suitable for the evaluation of luminal patency and visibility of intracranial stents.

Methods and Materials: Twelve stents (7 middle cerebral arteries, 4 intracranial vertebral arteries, 1 pterocavernous internal carotid artery) of two different types were evaluated in 12 patients. CT was performed on a 16-slice scanner (detector collimation 12×0.75 mm; table feed 2.8 mm/rotation; 300 mAs; 120 kVp; reconstruction with standard and optimized sharp kernel). Longitudinal multiplanar reformations were evaluated for stent patency and visible lumen diameter by two experienced radiologists who were blinded to the reports from the conventional angiography.

Results: Evaluation of stent patency using CT angiography was correctly correlated with those using conventional angiography. On average, 65% of the stent lumen diameter was visible using optimized sharp kernel. Significant improvement of lumen visualization (20%, $P < 0.01$) was observed using the optimized sharp kernel compared with the standard sharp kernel.

Conclusion: 16-slice CT using the dedicated sharp kernel might provide useful information for evaluation of patency of stent and lumen diameter of intracranial stents.

C-0847

SPECT with HMPAO-Tc99m application to measure the cerebellar blood flow in patients with Chiari malformations

A.N. Yalfimov, L.A. Tyutin, A.V. Pozdniakov; St. Petersburg/RU

Purpose: The purpose of this study was to investigate the cerebellar blood flow in patients with Chiari malformations (CM).

Methods and Materials: 45 patients with CM were included in the study. To assess the cerebellar blood flow SPECT with HMPAO-Tc99m (Ceretec) was performed in all patients.

Scientific and Educational Exhibits

Results: Significant flow heterogeneity in the cerebellum and reduction of cerebellar blood flow in 15-20% of 25 patients was observed. 3 of them had symptoms of hydrocephaly. All 25 patients underwent surgical treatment. SPECT with Ceretec revealed significant cerebellar blood flow improvement a month after surgical treatment.

Conclusion: SPECT with Ceretec is a feasible method for measuring cerebellar blood flow and monitoring of surgical treatment in patients with Chiari malformations.

C-0848

Possibilities of PET with ^{11}C -Sodium Butyrate (^{11}C -SB) for morpho-functional estimation of brain malignant tumors (BMT)

N.A. Kostenikov, L.A. Tyutin, N.P. Fadeev, V.E. Savello, R.M. Zhabina; St. Petersburg/RU

Purpose: To define the role and significance of PET with ^{11}C -SB in the diagnosis of BMT.

Methods and Materials: 2D-PET scans (Ecat Exact HR+) were performed in 85 patients with BMT (glioblastomas, meningosarcomas, medulloblastomas, anaplastic astrocytomas and cancer metastases). 30 min dynamic scans were carried out immediately after intravenous administration of 450-750 MBq ^{11}C -SB by bolus. The diagnoses had been verified histologically & morphologically. The T/NT ratio and fatty acid (FA) metabolism were obtained in both tumors and unchanged cerebral cortex parts by the time/activity curve. The following parameters were determined: A T/NT ratio, the tumor vascularization degree (VD), the FA uptake rate (UR), the FA metabolization (washout) rate (MR), the oxygenation index (OI).

Results: The obtained results showed that ^{11}C -SB allows not only the visualization of BMT, but also enables definition of their VD (angiogenesis). It is noted that increased VD, high UR & MR are characteristic for BMT, such as glioblastomas and meningosarcomas. IO, calculated on the quantitative analysis of the time/activity curves, allows evaluation of the degree of tumor hypoxia that has an important role in prognosis. Moreover, this method allows the possibility of evaluating the influence of peritumoral edema on tumor vascularization and metabolism.

Conclusion: The performed studies showed that dynamic PET investigation with ^{11}C -SB allows precise visualisation of BMT of various histological subtypes and the estimation of their morphological state. This new data using ^{11}C -SB on FA metabolism in BMT supplements our knowledge about tumour biology.

C-0849

Technetium-99m-MIBI SPECT and image fusion with CT or MR imaging for the assessment of primary brain tumors and brain metastases

V.S. Dekan, G.E. Trufanov, S.D. Rud, V.A. Fokin, I.V. Boikov; St. Petersburg/RU

Purpose: To assess the value of ^{99}Tc -MIBI SPECT images and fused images with CT or MR in the diagnosis of brain tumors or metastases.

Materials and Method: 18 patients with CT or MR findings of brain neoplastic lesions underwent SPECT (E.Cam Variable, Siemens) with ^{99}Tc -MIBI after CT (Somatom Volume Zoom, Siemens) or MR (Magnetom Symphony, Siemens). 13 patients underwent CT or MR and SPECT after operation or chemotherapy. The digital workstation of the SPECT gamma-camera was used to make fused images. Quantitative analysis of native SPECT images was performed by comparing uptake indices in tumors and intact brain tissue.

Results: All 18 patients were histologically proven by biopsy or at operation and by SPECT as malignant lesions. One of them was shown to be the metastasis from a lung cancer, six were glioblastomas, 11 patients had differing grades of astrocytoma. The fused images helped to increase sensitivity of SPECT from 78% to 97% and specificity of CT and MR imaging from 68% to 83%.

Conclusion: ^{99}Tc -MIBI brain SPECT is an effective diagnostic tool for evaluation of brain malignant lesions and estimation of their malignant grade. Fused images with CT or MR imaging can increase the specificity of tumor detection.

C-0850

Long-term brain MR follow-up in patients with neurological form of Wilson's disease

D. Kozic¹, I. Petrovic², M. Svetel², M. Lucic¹, J. Ostojic¹, V. Kostic²;

¹Sremska Kamenica/YU, ²Belgrade/YU

Purpose: To evaluate the degree of pathological substrate regression within the brain parenchyma during a chronic course of chelating therapy in patients with Wilson's disease (WD).

Materials and Method: Brain MR reexamination was performed in 13 patients with the neurological form of WD after 3.5-7 years of treatment. MR was also performed in 1 patient who discontinued therapy for several months.

Results: Complete reversal of putaminal T2W signal alteration was noted in 38% of patients, partial regression in 15%, while more prominent signal alteration was present in 1 patient. Complete or near complete regression of T2W signal alteration was evident in the caudate nuclei, midbrain, pontine base and pontine tegmentum in 60%, 71%, 85% and 83% of patients, respectively. Paramagnetic deposition in the globus pallidus and substantia nigra was significantly less prominent in 80% of patients. Complete regression of lesions was seen in both patients with thalamic involvement. New lesions in the thalamus, putamina and pontine base and worsening of the T2W hyperintense signal in midbrain tegmentum were found in a patient who temporarily discontinued treatment.

Conclusion: Compared to previous reports in which MR reexamination was performed after 6-12 months, our long-term follow-up study showed gradual resolution of T2W signal alteration within the brain parenchyma in the majority of patients with neurological presentation of WD. Our results suggest that T2W signal elevation, particularly in the brain stem, is most likely consistent with chronic, but reversible inflammatory changes due to the toxic effect of copper, rather than with gliosis, necrosis and cavitation. Rapid deterioration is evident after chelating therapy discontinuation.

C-0851

Perfusion CT: Patterns of presentation in acute stroke

J. Munuera, A. Rodríguez, X. Perich, A. Solano, M. Gomis, N. Calvo, A. Ois, J. Roquer; Barcelona/ES

Purpose: To describe the perfusion CT (PCT) findings in acute stroke patients and to establish a classification based on the different observed patterns.

Methods and Materials: 19 patients with symptoms lasting less than 6 hours were prospectively evaluated: 11 territorial infarcts, 2 lacunar infarcts and 6 transient ischemic attacks (TIA). The protocol was: Brain CT scan plus angio-CT and a PCT. We evaluated the acute ischemic signs; findings of cerebral flow, volume and time to peak (TTP); and angiographical findings. The whole study lasted 10 minutes. A transcranial doppler was performed during the acute phase in all patients. The results were correlated to the clinical data and in 8 cases with a brain MR imaging performed 48 to 72 hours later.

Results: In 9/11 patients with territorial infarcts the PCT showed an infarct pattern; associated in four of them with a penumbra area. In one patient a hyperflow pattern was observed; and the only patient with a normal PCT was affected by a vertebrobasilar stroke. The PCT was also normal in the two patients suffering a lacunar stroke. Among the patients suffering a TIA the PCT was normal in five, showing in one case a hypoperfusion area.

Conclusions: 1. PCT is an alternative to diffusion-perfusion MR imaging in acute stroke patient evaluation, with easy application in the daily practice. 2. Using the combination of TTP with cerebral volume and flow findings it is possible to delineate the different acute ischemic patterns. 3. More studies are necessary to associate these patterns with different types of stroke.

C-0852

Malignant vs benign cystic brain masses: Role of perfusion MR imaging in the differential diagnosis

B. Yagmurlu, H. Tuna, I. Erden; Ankara/TR

Purpose: To determine the role of MR perfusion imaging in the differential diagnosis of cystic brain masses with similar appearances on conventional series and therefore challenging the radiologist.

Materials and Method: Thirty-one patients with single or multiple cystic brain masses (total of 40 lesions) were enrolled in the study. Of these, 12 were high grade gliomas, 18 were metastases and 10 were pyogenic abscesses. All patients had conventional MR scans with additional perfusion studies performed by using contrast enhanced T2* dynamic susceptibility imaging technique preoperatively. rCBV (cerebral blood volume) maps were used for multiple sampling from the mural component of the masses. A ratio analysis was made by comparing the data obtained from the lesion wall (L) with the normal appearing white matter (WM) and the difference between the two groups (malignant vs benign) as well as three subgroups (glioma, metastasis and abscess) were evaluated. Pathological confirmation was made for each patient postoperatively.

Results: Ratio of L/WM was 5.89 ± 2.8 in malignant lesions where benign lesions indicated a value of 1.76 ± 0.8 ($p < 0.01$). A significant difference was found between metastatic lesions and abscesses as well ($p < 0.05$). Assessment among the malignant lesions themselves showed an overlap between glial tumors and metastatic lesions with values of 6.8 ± 2.0 and 5.45 ± 3.1 respectively ($p = 0.08$).

Conclusion: MR perfusion imaging seems very effective in determining whether a cystic brain mass is benign or malignant but a slight overlap between the tumors of glial origin and metastasis was found.

Scientific and Educational Exhibits

C-0853

Diffusion-weighted MR imaging in intracranial infections

A. Tosun, I. Serifoglu, A. Kartel, B. Cakir; Edirne/TR

Purpose: To describe the MR findings of intracranial infections and assess the value of diffusion-weighted imaging in the diagnosis.

Methods and Materials: A total of 20 patients, twelve having meningoencephalitis, five with brain abscesses, two with cerebral tuberculomas and a single case of PML, were evaluated at a 1.0-T unit. We analysed conventional images and compared them with diffusion-weighted images. In all patients, diffusion-weighted echo-planar sequence with parameters 6600/160/1 (TR/TE/AC), a high b value ($b = 1000 \text{ s/mm}^2$) were obtained and fifteen patients pre and post contrast turbo FLAIR images were examined. The final diagnosis was made on the basis of clinical features, laboratory findings including CSF studies, and histopathological examination.

Results: In all cases except the meningitis abnormally hyperintense lesions of varying extent and location were noted on T2-weighted and precontrast FLAIR images. Encephalitis lesions and tuberculomas are characterized by variable hyperintensity on diffusion-weighted images. Cerebral abscesses, subdural empyemas and cholesteatomas complicated with meningitis or cerebral abscess ($n = 4$) were markedly hyperintense on diffusion-weighted sequences. Patients with meningitis without parenchymal involvement did not exhibit any abnormality of diffusion. Diffusion-weighted imaging demonstrated the parenchymal lesions as areas of restricted proton diffusion more clearly than conventional imaging.

Conclusion: Diffusion-weighted imaging is assuming an increasingly important role in the evaluation of intracranial infections and has assumed an essential role in the detection of parenchymal lesions such as encephalitis, abscess and empyema with respect to restriction of movement of water molecules.

C-0854

MR imaging findings of the craniocervical junction in Morquio's disease

N. Danchaivijitr, D. Thompson, A. Vellodi, D.E. Saunders; London/UK

Purpose: To establish the clinical and radiological criteria for timing of surgical intervention in children with Morquio's disease.

Materials and Methods: A retrospective review of patient's notes and serial neuroimaging studies of the craniocervical junction of all children with Morquio's disease currently under the care of Great Ormond Street Hospital was carried out. Plain films (flexion and extension views), CT and MR imaging of the cervical spine were studied for atlanto-axial (AA) subluxation and instability, cord compression, odontoid peg abnormalities and compressive soft tissue mass.

Results: Fourteen children were identified (8 boys, mean age 3.4 years, range 1 to 6 years). All patients had an abnormal odontoid peg, narrow cervical spinal canal and foramen magnum. Eight patients had AA subluxation with associated cord compression in seven cases; six had a posterior fixation and two are awaiting surgery. Three patients had no evidence of AA subluxation but had neurological deficit; one from cord compression from retro-odontoid soft tissue mass. The other three had no AA subluxation or cord compression and were clinically stable. Eleven children were referred for surgery. Mean age at surgery was 6.2 years, range 4 to 9 years. Indications for surgery include cord compression with or without AA subluxation and progressive neurological deficit.

Conclusion: In Morquio's disease, cord compression at the cranio-cervical junction can occur in the absence of AA subluxation. A combination of multimodality serial imaging and clinical monitoring are crucial in order to optimize the timing for surgery.

C-0855

Cerebral proliferative angiopathy: A distinct subgroup of brain AVMs?

A single centre experience

P. Zabakis, S. Lamin, S. Jenkins, V. Papanastassiou, J. Bhattacharya; Glasgow/UK

Purpose: Brain arteriovenous malformations (BAVM) show wide phenotypic variation. Diffuse AVMs represent a distinct and uncommon subtype for which Lasjaunias has proposed the term cerebral proliferative angiopathy (PA). We present our experience of this rare form of AVM.

Methods and Materials: From our departmental database and AVM clinic, 8 patients with PA were identified. We reviewed case records and imaging studies. All patients had angiography and MR imaging. Age and mode of presentation are described as well as clinical course and angioarchitecture of the malformations.

Results: There were 4 males and 4 females with mean age of presentation of 25 years. None of the patients initially presented with haemorrhage. The radiological features included large size lesions, diffuse-pattern nidus with presence of brain

parenchyma within the abnormality, absence of large AV shunts, relatively slow flow, arterial occlusive disease pattern and sprouting angiogenesis. In contrast, typical BAVMs present later (mean 45 years), most commonly with haemorrhage, have no intervening brain parenchyma and show no evidence of sprouting angiogenesis. Most of the lesions were deemed incurable although some underwent partial treatment.

Conclusion: Proliferative angiopathy, having specific angioarchitectural characteristics and probably a different aetiology, represents a distinct subgroup of cerebral arteriovenous malformations and follows a different clinical course.

C-0856

Brodmann's cortical areas revealed by fMRI imaging

C.-V. Salvan, J.L. Ulmer, E.A. DeYoe, D.L. Daniels, R.W. Prost, L.P. Mark; Milwaukee, WI/US

Learning Objectives: Our objective is to reveal Brodmann's areas using fMRI imaging and to create a functional brain map, and consequently to obtain a new perspective in understanding the human brain and its pathological processes.

Background: Brodmann's cortical areas were established based on local differences in the arrangement of nerve cells (cytoarchitecture). From anatomical, physiological and pathological data it is known that they are related to different brain functions.

Imaging Findings: BOLD functional MR imaging data of sensori-motor, language, auditory and/or visual systems were acquired in normal subjects and eloquent cortices were mapped using a 1.5 T scanner (GE-EPI, TR/TE-2000/40 or 3000/50, flip angle 90, FOV 240, 64/64 matrix, 18 or 28 slices with 4 or 5 mm thickness depending from task) and a cross-correlation analysis with a $p < 0.01$. Using a variety of tasks (sensori-motor, language, visual, auditory) we mapped eloquent cortical areas and determined the relationship to Brodmann's areas, as well as the "talk" of these areas for specific brain functions. Implications for pathology are also discussed.

Conclusion: Functional MR imaging can reveal Brodmann's areas and help us understand cortical organization, as well as physiological and pathophysiological mechanisms of the brain.

C-0857

Toxoplasmosis encephalitis after bone marrow transplantation: CT and MR features

C. Mueller, T.G. Mang, P. Kalhs, M.M. Thurnher; Vienna/AT

Purpose: Toxoplasmosis encephalitis is a rare but severe complication in patients following bone marrow transplantation (BMT), requiring immediate therapy. The aim of this work is to describe the CT and MR features of toxoplasmosis encephalitis after BMT.

Material and Methods: We present two cases of pathologically confirmed cerebral toxoplasmosis after allogeneic BMT and compare them to cases from the literature. The imaging studies of our patients included unenhanced CT ($n = 4$), post contrast CT ($n = 2$) and unenhanced and post contrast MR imaging ($n = 3$) and were evaluated for lesion location and size, presence of edema and hemorrhage, enhancement and findings on diffusion-weighted imaging (DWI).

Results: In both patients CT and MR imaging revealed more than 20 lesions in the cerebellum and both hemispheres. In one patient all lesions were hyperdense on unenhanced CT and hyperintense on unenhanced T1-weighted MR images. On DWI the lesions showed low signal with a hyperintense rim, representing acute hemorrhage. In the second patient the lesions were hypodense on unenhanced CT and hyperintense on T2-weighted MR images. Most of the lesions showed high signal on DWI with reduced apparent diffusion coefficient (ADC), consistent with restricted diffusion. In both patients the lesions were non-enhancing and showed no significant edema.

Conclusion: Toxoplasmosis encephalitis in patients after BMT has unique features on CT and MR images, appearing as multiple intracerebral lesions with lack of enhancement. MR imaging findings differ from those described in AIDS patients.

C-0858

Detection of intracranial aneurysms with multislice CT: Comparison with digital subtraction angiography

F. Saccardy, J. Drouineau, C. Hardit, J.-C. Ferrié, J.-M. Charonnet, P. vandermark, J.-P. Tasu; Poitiers/FR

Purpose: To assess the diagnostic performance of multislice CT (MSCT) in the detection of intracranial aneurysms, by comparing the results to digital subtraction angiography (DSA) which is the standard method.

Scientific and Educational Exhibits

Methods and Materials: 28 patients with non traumatic acute subarachnoid hemorrhage or unruptured intracranial aneurysms were included and underwent both MSCT and DSA within 12 hours. CT angiography was performed on a sixteen slice CT using collimation of 16x0.75 mm, with a minimal longitudinal spatial resolution of 0.6 mm. A neuroradiologist blinded to DSA results reviewed CT data at a computer workstation, by using multiplanar volumetric reformats (MPVR), maximum intensity projections (MIP), and volume rendering technique (VRT).

Results: DSA detected 20 intracranial aneurysms in 18 patients. Sensitivity, specificity, positive predictive value and negative predictive value for CT angiography were respectively 100%, 83%, 90.9% and 100%. The smallest aneurysm detected with MSCT was 3 mm (3-18 mm, mean 9 mm). All the aneurysms were located on the anterior circulation, except one on cerebral posterior artery.

Conclusion: MSCT with sixteen detector-rows is equivalent to DSA for detection of intracranial aneurysms. MSCT seems be useful in the early diagnosis of the cause of a subarachnoid hemorrhage, replacing DSA.

C-0859

Radiation dosage in pituitary surgery: Comparison between conventional and computer assisted methods

E. Schulz, U.H. Melchert, A.F. Haude, U.R. Krause, B.M. Stoeckelhuber, S. Ulmer; Lübeck/DE

Purpose: Comparison of the radiation dosage to the patient's lens in pituitary surgery using intraoperative computer assisted navigation system (CAS) based on computed tomography (CT) and intraoperative conventional fluoroscopy.

Methods and Materials: In pituitary surgery, the patient's head is positioned between the C-arm array for intraoperative fluoroscopy to enable mapping of the location of the dissectors. This technique is very effective in terms of speed, costs, and availability; however it has the disadvantage of a 2-dimensional projection. Newer technologies such as CAS based on CT offer 3-dimensional information. Using the Alderson-Rando head phantom, thermoluminescence dosimeters (TLD) were placed on the temporal bone and on the phantom's lens on either side. Continuous fluoroscopy focused on the sella was performed. For CAS, the range of the CT image stack included the maxilla bone up to the frontal bone to cover the entire surgical approach and the floor of the sella.

Results: In CAS, each TLD was displayed on the two CT slices. Radiation dosage in CAS was approximately 6800 nC on each side. In conventional fluoroscopy, radiation dosage at the radiation entrance side was 400 nC and at the opposite side 50 nC measured for a 1-minute fluoroscopy time.

Conclusion: Radiation dosage was significantly increased in CAS; however, CAS supplies more detailed and multiplanar information. The decision which modality to use remains case specific (age and sex of the patient, cumulative dosage for the surgeon).

C-0860

Correlation of repeated brain CT-scan findings with intracranial pressure catheter (IPC) values in intensive care unit (ICU) patients: Preliminary report

M. Michalakou, E. Astrinaki, M. Kokkinaki, N. Mourkogiannis, E. Psarakis, M. Gargoulaki, R. Kourgeraki, G. Vrouhos, L. Triantafillou; Iraklion/GR

Purpose: To examine the extent that intracranial pressure (ICP) can be determined by head CT and whether there is a good correlation between ICP changes and evolution of findings in CT follow-up.

Materials and Method: We retrospectively reviewed 227 head CTs and the charts of 45 ICU head-trauma patients 18-57 years old, recording the GCS on admission, APACHE II scale and ICP values. Initial head CT was performed on admission, the second 24-48 h after, or 24 h postoperatively and the third 48-72 h thereafter. CT was also performed whenever there was a sudden change in ICP. CTs were evaluated by two radiologists, unaware of clinical data at the time of the examination, based on Marshall CT classification of head trauma.

Results: The reason for ICP monitoring included GCS less than 8, and/or abnormal CT findings. Initial CT classified 17 patients as DI II, 13 as DI III, 4 as DI IV, 9 as NEML and 2 as EML. In patients with stable ICP, 13% had CT changes. Change in CT follow-up associated in 83% with ICP alterations. In four patients uncorrelated ICP monitoring values to CT findings raised the suspicion of functional impairment thus a second ICP catheter was required; revealing monitor malfunction, showing higher pressure than actually applied.

Conclusion: ICP monitoring is a safe procedure for monitoring brain damage in ICU patients. Frequent head CTs without alteration of ICP do not add more information required for patient management. Limiting their use as a monitoring method for these patients is cost-effective, time preserving and carries a smaller transportation risk for ICU patients

C-0861

Aicardi syndrome: MR imaging and clinical findings

C. Hadjigeorgi, J. Nikas, G. Pitsoulakis, M. Theofanopoulou; Athens/GR

Purpose: Aicardi syndrome is an X-linked congenital disorder associated with early-onset infantile spasms, EEG abnormalities and severe developmental delay. It consists of multiple anomalies of the brain, eye and axial skeleton. We report the clinical and neuroradiological findings in three cases.

Materials and Method: 3 girls (3, 11 and 4 months old) with no family history of neurological disease, presented with psychomotor retardation and the first 2 with infantile spasms. The electroencephalogram was abnormal in all cases (burst-suppression patterns) while ophthalmological examination revealed chorioretinopathy in all children and microphthalmia in 1. The patients underwent MR imaging.

Results: MR imaging demonstrated corpus callosum agenesis in all three cases. In 2 this was associated with interhemispheric cysts and cortical dysplasia; polymicrogyria and subependymal heterotopia.

Conclusion: The diagnosis of Aicardi syndrome is based on characteristic clinical, electroencephalographic and imaging findings. MR is the imaging modality of choice, as it reveals agenesis of the corpus callosum, but can also demonstrate associated anomalies in the spectrum of cortical dysplasias.

C-0862

The role of perfusion CT in acute stroke

G. Katona; Budapest/HU

Purpose: To evaluate perfusion CT (PCT) capability in predicting reversibly damaged brain tissue and outline its advantages and limits.

Methods: The patients were examined using multirow CT (8 row multidetector LightSpeed Ultra, GE) for suspected acute cerebral ischaemia. Initially non-enhanced CT (NCCT) images were acquired. Then a dynamic perfusion series was acquired over a 50 s period using 50 ccm contrast bolus (300 mg/ml). For evaluation dedicated perfusion software was applied. On the color-coded parameter maps hypoperfused brain tissue was identified then its regional cerebral blood volume (rCBV), flow (rCBF) and mean transit time (MTT) values were calculated in part compared with abnormalities identified on diffusion weighted MR images performed additionally.

Results: All areas of ischaemia visible on NCCT were also identified by perfusion mapping. The areas revealed reduced CBF and prolonged MTT. Furthermore areas of hypoperfused brain tissue discovered by PCT analysis were identified which remained indiscernible on review of the NCCT series.

Conclusion: NCCT has a clearly defined role in the current management of acute stroke. The additional information supplied by PCT can be rapidly obtained without removing the patient from the scanner table. In spite of some limitations and the disadvantages compared to MR (PWI, DWI) and other perfusion techniques PCT may be useful in identifying reversibly ischaemic tissues because it can be performed quickly and safely on critically ill patients. Integration of PCT into the diagnostic workup of stroke is a promising approach which may reinforce the role of CT in the management of acute stroke.

C-0863

Brain MR spectroscopy in the evaluation of Wilson's disease: Correlation with clinical status and response to therapy

A. Sias, A. Balestrieri, L. Barberini, M. Puligheddu, M. Fraschini, A. Murru, L. Demelia, F. Marrosu, G. Mallarini; Cagliari/IT

Purpose: The aim of our study is to correlate the presence of signal intensity alterations in the brain of patients affected by Wilson's disease, through MR-spectroscopy.

Methods and Materials: We have examined 20 adult individuals (10 patients with a known diagnosis of Wilson's disease and 10 healthy volunteers) with single-voxel spectroscopy performed on a 1.5 T magnet. We have placed a total of four VOIs (each VOI measuring 20 mm³) bilaterally in the basal ganglia and white matter, with TR/TE 2000/136 ms. We have also performed the same study with a decrease of TE, to establish if there is any alteration in the amount of metabolites other than NAA.

Results: Our results show a correlation between the therapy and the results obtained, in patients undergoing treatment, while untreated patients show classical Wilson's disease brain alterations, but the limited preliminary data available does appear to overlap the same findings of other encephalopathies.

Conclusion: MR spectroscopy appears to be a highly sensitive diagnostic tool in a distinct neurological condition such as Wilson's disease. Further work will be needed, in a larger patient sample, to narrow the interpersonal variables that might be obtained through this approach, and to better characterize the MR spectroscopy signals obtained.

C-0864

Evaluation strategies of multiple sclerosis with conventional and advanced techniques

G. Luccichenti¹, E. Giugni¹, A. Paolillo¹, F. Cademartiri², A. Pichieccchio³, S. Bastianello³; ¹Rome/IT, ²Rotterdam/NL, ³Pavia/IT

Learning Objectives: 1)To illustrate the standard and the advanced (MT, relaxometry, DWI, DTI, MRS) imaging techniques for the assessment of multiple sclerosis 2)To describe the MR imaging patterns of multiple sclerosis and the diagnostic criteria. 3)To learn the strategies for the quantification of the disease progression of different MS phenotypes that can be carried out in clinical routine.

Background: Multiple Sclerosis (MS) is a demyelinating disease of the CNS of unknown origin, with a relapsing and remitting, primary or secondary progressive course. The diagnosis is made by combining the clinical examination, the laboratory tests of the CSF and the MR imaging findings. The quantification of disease progression and the assessment of therapy response can be performed through visual or automated segmentation with estimation of lesion volume or of advanced indicators (MTR, FA, metabolite)

Procedure Details: conventional and advanced MR imaging techniques are described. MR findings are shown and the differential diagnosis is illustrated using clinical cases. Diagnostic criteria are discussed. Quantitation techniques for follow-up are described using examples.

Conclusion: The knowledge of imaging findings, differential diagnosis, and the quantitation techniques of conventional and advanced MR imaging is useful to optimize the examination and to integrate the quantitation techniques into clinical routine.

C-0865

Central nervous system involvement in limited forms of Wegener's granulomatosis: CT and MR imaging findings

G. Zuccoli, B. Tumiati, F. Nicoli; Reggio Emilia/IT

Learning Objectives: To illustrate the CT and MR findings of CNS involvement in patients with limited forms of Wegener's granulomatosis (WG).

Background: WG is a systemic necrotising granulomatous vasculitis of unknown cause that typically involves the upper and lower respiratory tracts and the kidneys. Limited forms have been described in which some features of the disease may be absent. Nervous system involvement (peripheral neuropathy) is frequent, but it has been found that CNS involvement is rare occurring in less than 10% of patients. CNS lesions with or without contrast enhancement, thickening of the dura, infarcts, pituitary gland and infundibulum involvement may be found in patients affected by WG. The three patients subject of this educational exhibit belong to a larger group of 37 patients with WG. They are affected by limited forms of the disease. MR or CT examinations were performed to investigate suspected CNS involvement.

Imaging Findings: In one patient CT showed thickening of the right tentorial edge associated with right venous sinus thrombosis. In the second patient MR showed abnormal contrast enhancement of the nasal fossa extending upwards to the surface of the anterior cranial fossa with nodular thickening and mass effect of the dura mater. In the third patient both dura mater thickening and enhancement and pituitary axis involvement were found. In the second and third patient regression of the CNS involvement was demonstrated after therapy.

Conclusions: We demonstrated various patterns of CNS involvement in limited form of WG by using MR or CT imaging.

C-0866

Role of MR spectroscopy in patients with temporal lobe epilepsy (TLE)

A. Sias, A. Balestrieri, L. Barberini, M. Puligheddu, M. Fraschini, F. Marrosu, G. Mallarini; Cagliari/IT

Purpose: To characterize with MR spectroscopy the brain anomalies in patients suffering with temporal lobe epilepsy (TLE).

Materials and Methods: We examined 10 patients with a known diagnosis of TLE. The patients underwent MR spectroscopy and high density EEG. MR examinations were performed on a Philips 1.5 T magnet, using PRESS sequences with TR/TE = 2000/136 and 2000/31, 1024 samples, 128/256 averages. Epileptic foci were preliminarily localized through automatic analysis with a specific software (Curry).

Results: MR spectroscopy confirmed the lateralization data obtained through EEG in all patients. Concentrations of NAA, Cho, Cr, ml, obtained using short TR/TE sequences allowed evaluation of altered hippocampal function even in patients with a normal conventional MR examination.

Conclusion: MR spectroscopy, combined with high density EEG, is a promising

diagnostic tool which will be helpful to monitor disease development and response to therapy.

C-0867

Cerebral perfusion measurements using continuous arterial spin labeling (CASL): Transit time measurements of normal subjects

H. Kimura¹, H. Kabasawa², H. Uematsu¹, Y. Koshimoto¹, Y. Yonekura¹, H. Itoh¹; ¹Fukui/JP, ²Hino/JP

Purpose: Arterial perfusion imaging (ASL) provides a quantitative measurement of cerebral blood flow (CBF). The most concerning parameter for ASL technique for quantification is the transit time problem. The nature of low signal to noise ratio (SNR) of the method makes transit time measurements difficult and time consuming. The continuous ASL (CASL) on 3.0 T can produce the better SNR of perfusion signal due to both higher Lamor frequency and prolonged T1 times. We present the theoretical framework of two compartment model including transit time as well as CBF.

Method and Materials: CASL Perfusion imaging was implemented on 3.0 T MR system (GE, Signa 3 T, LX) using multi slice single shot echo planar imaging. For the calculation of arterial transit time, we also changed the post label wait time from 300 ms to 1800 ms. We applied the model with transit time and CBF to CASL perfusion data obtained from six normal subjects.

Results: CBF and arterial arrival time maps were successfully created using two-parameter fitting procedure. The averaged values of transit time ranged from 474 to 712 ms from lower to upper slice in gray matter, whereas those ranged from 732 to 1179 ms in white matter. The overall gray and white matter CBF value was 44.6 ± 10.6 and 13.0 ± 3.9 ml/min/100 g, respectively. The CBF values calculated using the model showed the trend of low values relative to those in previously reported in 1.5 T data.

Conclusion: CASL imaging using two-compartment model provides a means of assessment both of arterial transit time and CBF.

C-0868

Cerebral vascular malformations and developmental anomalies in patients with extracranial carotid stenosis in CTA

K. Gruszcynska¹, J. Baron¹, Z. Zieliński²; ¹Katowice/PL, ²Tychy/PL

Learning Objectives: Presentation of cerebral vascular malformations, Circle of Willis normal variants and developmental anomalies visible in CTA, which can alter cerebral blood flow in patients with extracranial arterial stenosis.

Background: Although Circle of Willis anatomical variants usually have no clinical significance, they can become the cerebral ischemic infarction risk factor in patients undergoing carotid endarterectomy or stent placement. Cerebral vascular malformations or aneurysms visible on CTA in these patients may require earlier treatment than stenosis itself.

Procedure Details: Cerebral artery variants, developmental anomalies and vascular malformations which were diagnosed on CTA, (Twin, Marconi CT unit), in 70 patients with extracranial carotid stenosis will be presented. MIP, MPR and 3D reconstructions will depict detailed Circle of Willis anatomy highlighting those anomalies which can alter cerebral blood flow during the surgical or interventional procedure. CTA results were compared with a control group; 34 patients without extracranial stenosis. Posterior or anterior cerebral artery hypoplasia or aplasia were seen in 37% examined and 35% of control patients. In 12 cases they coexisted with intracranial stenosis. In 4% of examined patients cerebral aneurysms were found, multiple in two cases. Arterial dolichoectasy was seen in 4 patients and DVA in 1.

Conclusion: Cerebral artery developmental anomalies can be found in equal frequency in patients with and without extracranial carotid stenosis. The knowledge of Circle of Willis possible vascular variants and anomalies can help to select patients with increased risk of cerebral blood flow alteration during endarterectomy or stent placement.

C-0869

Fusion of MR imaging and SPECT images as a method of planning spectroscopy of recurrent brain tumors

P. Grzelak, M. Gorska-Chrzastek, K. Tybor, W. Gajewicz, J. Kusmirek, B. Goraj, L. Stefanczyk; Lodz/PL

Purpose: The essential modalities for morphological imaging of the brain are magnetic resonance imaging (MRI) and (for metabolic imaging) single photon emission tomography (SPECT). By using image fusion of different modalities, the location of areas exhibiting functional changes can be more easily identified. This study compares the results of iodine-131-alpha-methyl-tyrosine SPECT (IMT-

Scientific and Educational Exhibits

SPECT) with MRI in recurrent brain tumor detection. We used fusion images as the method of planning 1H-MRS and verifying the metabolic content of the regions.

Materials and Method: We investigated 27 patients post neurosurgical treatment, 25 of them were also following radiation therapy. IMT-SPECT and MRI were performed during the same week. Iodine-131-alfa-methyl-tyrozin (131-IMT) is a marker of brain tumors. Fusion of the images was done in a three-dimensional technique using a PC work-station; the technique was based on a statistical analysis of three-dimensional distribution of the voxels, using maximization of the statistical resemblance (mutual information). Regions of the highest accumulation of the 131-IMT were found by using subtraction method. In the result these areas were then subject to 1H-MRS (SVS or CSI).

Results: In all tumors the area of accumulation of 131-IMT was smaller when compared with the Gd-enhanced MR images. The concentration of IMT within brain tumors was heterogenous and the delineation of the highest metabolic area was possible. This allowed planning of H1-MRS. In 25 patients a good quality of 1H-MRS spectra were obtained.

Conclusion: The fusion images optimize selection of a site for spectroscopy investigation in recurrent tumors.

C-0870

Can unsaturated fatty acid emulsion technique be used as a model for research on BBB disruption?

H.J. Kim, Y.W. Kim; Pusan/KR

Purpose: The authors investigated whether fatty acid emulsion affects the BBB, whether disrupted BBB is reversible and whether this technique may be a model for BBB research.

Materials and Methods: The fat emulsion was made with 0.1 ml of oleic acid or linoleic acid and 20 ml of saline. The carotid artery was infused with oleic acid emulsion in 14 cats (Group 1) and with linoleic acid emulsion in 12 cats (Group 2). Gd-enhanced T1-weighted (Gd-T1WI), diffusion-weighted (DWI) and apparent diffusion coefficient (ADC) map MR imaging was obtained at one hour and one day after infusion. Qualitative analysis was performed. Quantitative analysis of the signal intensity ratio (SIRs) of the lesion to the contralateral hemisphere was performed on Gd-T1WIs. SIRs were analyzed statistically with t-test. The brain tissue was removed for light and electron microscopic examination.

Results: The lesions appeared as contrast enhancement on Gd-T1WIs, as isointensity or mild hyperintensity on DWIs and as isointensity on the ADC maps at 1 hour in both groups. On day 1, contrast enhancement was much decreased or absent in both groups and ADC maps showed isointensity. SIRs on Gd-T1WIs were significantly higher in Group 1 than in Group 2 at 1 hour ($p < .05$). SIRs were nearly 1.0 on day 1 in both groups. Histological findings showed minimal changes.

Conclusion: Infusion of unsaturated fatty acid emulsion revealed vasogenic edema of the brain and reversible changes. This unsaturated fatty acid emulsion model may be used as a model for research on BBB disruption.

C-0871

The assessment of early neurorehabilitation effectiveness with MR imaging

R.M. Umarova, M.V. Krotenkova, M.M. Tanashyan, L.A. Chernikova, R. Konovalov; Moscow/RU

Purpose: To evaluate the influence of early repetitive neuromuscular stimulation (NS) with MR imaging on brain infarct evolution in stroke patients.

Methods: Twenty two patients were studied with serial magnetic resonance imaging (T2WI, T1WI, DWI and PWI study) within the first 48 hours of ischemic stroke onset and again at periods of 5, 21 days and 3 months. The lesion expansion between acute and outcome studies was assessed. 15 patients (basic group) were started with NS of the paretic upper limb immediately after MR imaging examination, NS was continued during 3 weeks.

Results: Subjects from the basic group had better recovery of motor function versus the control group ($p < 0.05$). Two MR imaging patterns among all patients were obtained. Acute PWI>DWI lesion volume mismatch predicted brain lesion expansion, and was seen in ten patients, six of them were from the basic group. At the same time the expansion volume in the basic group didn't exceed the same volume of the control group and the acute PWI lesion. In DWI>PWI group there were not diffusion lesion expansion in basic group. So in spite of early beginning of NS in basic group the infarct evolution didn't worse.

Conclusion: We didn't find any deterioration of the diffusion and perfusion lesions in basic group with NS. Our study indicates that MR imaging data may be useful in evaluating the effectiveness and safety of early rehabilitation therapy.

C-0872

Quantitative assessment of brain perfusion by MR imaging in patients with arterial hypertension

D. Ustuzhanin, M. Kozhuhova, V. Sinitsyn, T. Pustovitova, O. Stukalova, I. Chazova, S. Ternovoy; Moscow/RU

Purpose: To evaluate quantitative values of brain perfusion in patients with arterial hypertension.

Materials and Method: Thirty patients (mean age 55 years) with arterial hypertension and one or more cerebrovascular events in anamnesis were included in the study. The control group consisted of fifteen healthy volunteers (mean age 42 years). For each person time-intensity curves were calculated. Relative cerebral blood flow (CBF), relative cerebral blood volume (CBV), time to peak (TTP), mean transit time (MTT) parametric maps were calculated for 4 slice levels in the brain (convex, central part of lateral ventricles, basal ganglia, cerebellum). CBF, CBV, MTT, TTP values were determined in two regions of interest (left and right hemispheres) for each slice level.

Results: CBV and CBF values did not differ significantly between the two groups. MTT was significantly shorter in healthy controls than in patients with arterial hypertension (5.2 ± 1.2 s vs. 6.6 ± 1.6 s, $p < 0.05$) only in one slice level (convex). TTP was significantly shorter in healthy controls in three slice levels: 6.2 ± 1.7 s vs. 9.8 ± 2.9 s, $p < 0.01$ (convex), 6.7 ± 1.7 s vs. 9.0 ± 2.6 s, $p < 0.04$ (basal ganglia), 7.3 ± 1.5 s vs. 9.6 ± 2.4 s, $p < 0.03$ (cerebellum).

Conclusions: Our study suggests that whereas CBF and CBV values did not differ significantly one can find some differences in TTP and MTT between normals and hypertensives. So MTT and TTP parameters can be useful for determining a group of patients at high risk.

C-0873

Comparison of detectability of endocranial lesions in multiple sclerosis at 1.0 and 3.0 Tesla.

T. Stosic-Oncincal, V. Peric, S. Lavrnici, M. Gavrilov; Belgrade/YU

Purpose: To estimate the relative sensitivity of MR examination for brain lesions in multiple sclerosis at 1.0 Tesla (T) and 3.0 T using identical acquisition conditions.

Methods and Materials: 19 patients with multiple sclerosis were examined both at 1.0 T (Siemens Impact Expert) and 3.0 T (Philips Intera) using T1-weighted spin echo (T1W-SE) with and without gadolinium contrast injections, T2W SE and fluid attenuated inversion recovery (FLAIR) imaging. Images were examined independently by three experienced neuroradiologists using focal lesion counting.

Results: 3.0 T scans compared with 1.0 T scans demonstrate a 26.5% increase in the number of detected contrast enhanced lesions and an 11.3% increase in the number of detected lesions on FLAIR MR tomograms.

Conclusion: High-field 3.0 T MR imaging demonstrates better sensitivity in the detection of focal brain lesions in multiple sclerosis. This improvement is more apparent in contrast enhanced lesion detection and less noticeable in FLAIR detected lesions.

C-0874

Benefits of early endovascular treatment of ruptured intracranial aneurysms: Clinical outcome and vasospasm incidence

R. Diaz Aguilera, J.M. Martos Becerra, J.J. Espejo Herrero, D. Bautista Rodriguez, F. Bravo Rodriguez, F. Delgado Acosta, A. Cano Sanchez, G. Perez Ortega; Cordoba/ES

Purpose: Endovascular embolization of ruptured intracranial aneurysms is a treatment option which is increasingly being used. The aim of this prospective study was to compare the incidence of vasospasm and the clinical outcome of patients who were treated with coils early after the hemorrhage (SAH) (< 48 hours) with those treated later.

Methods and Materials: We reviewed 49 patients (36 women and 13 men) who underwent endovascular treatment for aneurysmal SAH between June 2001 and June 2004 in our institution. 19 patients were treated within 48 hours of ictus. We collected epidemiological data, angiographic findings, CT findings (Fisher scale) and clinical outcome (Hunt and Hess and Rankin scales)

Results: Mean age was 57.2 years (range 26-81). 22 patients had a Hunt and Hess grade I-II subarachnoid hemorrhage. According to the Fisher classification, 14 patients were grade I-II and 20 were grade III-IV. 44 patients had aneurysms of the anterior circulation and 5 were on the posterior circulation. One (5.26%) of the nineteen patients treated within 48 hours after SAH showed vasospasm and in those treated later, twelve (40%) suffered from vasospasm.

Conclusion: Early endovascular treatment is a feasible and safe procedure in

Scientific and Educational Exhibits

the management of SAH after ruptured intracranial aneurysm. There was less incidence of vasospasm within the first 48 hours.

C-0875

New brain lesions at diffusion-weighted MR after carotid angioplasty and stent placement

J. Gil, J. Guijarro, J. Palmero, A. Vera, D. Dualde, R. Dosdá; Valencia/ES

Purpose: To evaluate with magnetic resonance imaging (MR) the incidence and clinical significance of cerebral ischemic lesions after carotid angioplasty and stent placement (CAS).

Materials and Method: Eighteen consecutive CAS procedures were performed in seventeen patients (for high-grade carotid stenosis). The patients underwent neurological examination before and 1 day and 3 months after CAS. Diffusion-weighted MR imaging (DW1) of the brain was performed before and after stent implantation. Any hyperintense signal was interpreted as a postprocedure ischemic lesion.

Results: Thirteen patients (72.2%) had unchanged postprocedure brain DW1. New ipsilateral lesions were found in five cases (27.7%) and in one, lesions were also found in the contralateral side (5.5%). In four patients, the lesions were clinically silent and one patient had a minor stroke.

Conclusion: CAS is associated with new areas of cerebral ischemia. The majority of new lesions are clinically silent.

C-0876

Value of the apparent diffusion coefficient in the differential diagnosis of brain glial tumors

A. Martínez de Aragón, C. Pérez López, J. Echeveste, A. Bravo, B. Rodríguez-Vigil, B. Marín; Madrid/ES

Learning Objectives: To show the role of diffusion weighted magnetic resonance imaging added to conventional MR imaging sequences in the diagnosis of the type and grade of malignancy of brain glial tumours.

Background: High sensitivity and specificity of diffusion weighted magnetic resonance imaging in the diagnosis of acute cerebral infarction and abscesses has been reported. This sequence also provides information about certain tumours like epidermoid cysts; however its usefulness in other brain tumours has still to be determined.

Imaging Findings: MR imaging and diffusion studies performed in 38 patients with brain gliomas, confirmed at surgery, were retrospectively reviewed. ADC value and diffusion signal intensity from different areas of the lesion were measured and compared. Presence of necrosis, macroscopic peritumoral areas, and areas that enhanced with paramagnetic contrast were specifically evaluated. Every value was compared to the diffusion weighted signal intensity value of the contralateral normal specific tissue.

Conclusion: Areas with high cellularity, necrotic areas, and bleeding areas have signal diffusion intensity and ADC values different from that of the normal brain. Together with conventional MR imaging, these values can guide in the diagnosis of the type and grade of glial brain tumours. Diffusion magnetic resonance imaging, due to its short duration, should be performed, together with more conventional sequences, on patients with brain tumours because it provides more thorough information regarding histology and grade of malignancy of the primary tumours. This sequence is especially useful when perfusion and spectroscopy is not available and in non-cooperative patients.

C-0877

MRS and DTI of two siblings with Hallervorden-Spatz syndrome

C. Lee, W.-H. Lee, C.-M. Ling, P.-S. Yen, P.-N. Chong, S.-K. Lee; Hualien/TW

Learning Objectives: To demonstrate brain lesions and show how state of art MR imaging techniques help clinical assessment in PANK2 disease.

Background: Hallervorden-Spatz syndrome is an autosomal recessive disorder characterized by dystonia, parkinsonism, and iron accumulation in the brain. Many patients with this disease have mutations in the gene encoding pantothenate kinase 2 (*PANK2*); they are said to have pantothenate kinase-associated neurodegeneration. Typically, T₂-weighted magnetic resonance imaging (MRI) of the brain shows a specific pattern of hyperintensity within the hypointense medial globus pallidus (tiger-eye sign). Two Chinese siblings (female aged 5 and her brother aged 9) were found with typical symptoms and signs of PANK2 syndrome. We present their detailed MRI studies including T₂-weighted MRI, FLAIR, multi-voxel MRS and diffusion tensor imaging (DTI).

Imaging Findings: T₂WI showed decreased signals in bilateral basal ganglia predominantly in the hypointense medial globus pallidus. The Tiger-eye sign was found in the sister only. Multiple voxel MRS demonstrated neuron loss not only in

the basal ganglia but also in the thalamus, especially in NAA/Choline ratio map. In particular, NAA/Choline ratio demonstrated more neuron loss in the sister that was compatible with clinical presentation. Widespread decrease of white matter fractional anisotropy (FA) were shown in the DTI images; compatible with generalized axon swelling in pathology reported in the literature.

Conclusion: MRS and DTI images may be useful in the evaluation of PANK2 disease neuron degeneration.

C-0878

The diagnostic utility of perfusion-weighted MR imaging, diffusion-weighted MR imaging and MR spectroscopy in mesial temporal sclerosis

S. Cakirer¹, B. Yagmurlu², B. Koklu¹, Y. Karagoz¹, N. Kahraman¹; ¹Istanbul/TR, ²Ankara/TR

Purpose: To determine the lateralizing value of perfusion-weighted MR (PWI), diffusion-weighted MR (DWI) and MR spectroscopy (MRS) in cases of mesial temporal sclerosis (MTS), and to detect correlation between conventional MR imaging and PWI, DWI, and MRS.

Methods and Materials: We evaluated ten patients with MTS in the interictal period, and ten normal control participants on a 1.5 T MR scanner. The protocol included coronal FLAIR, SS EPI T₂*-weighted PWI with mesial temporal rCBV measurements, DWI with coronal trace ADC map generation, and single voxel MRS for hippocampal gyri in both patients and controls. Regions of interests (ROI) were drawn on each hippocampal gyrus for calculation of rCBV, mean ADC values, and MRS. Absolute ADC asymmetry indices, perfusion asymmetry indices, average NAA/(Cr+Cho) ratio asymmetry indices were calculated.

Results: rCBV values, mean ADC values, and average NAA/(Cr+Cho) ratio of hippocampal gyri were more asymmetric in patients compared to normal controls ($p < 0.001$ according to Wilcoxon). rCBV values for MTS sides in patients were significantly lower than normal sides ($p < 0.001$). Mean ADC values for MTS sides in patients were significantly greater than normal sides ($p < 0.001$). Average NAA/(Cr+Cho) ratio for MTS sides in patients were significantly lower than normal sides ($p < 0.001$). rCBV values, mean ADC values, and NAA/(Cr+Cho) ratio for both sides of normal controls were not significantly different. Lateralization using absolute ADC asymmetry indices significantly correlated with lateralization based on rCBV asymmetry indices, and NAA/(Cr+Cho) ratio asymmetry indices (according to Spearman).

Conclusion: PWI, DWI, and single voxel MRS may detect interictal asymmetries, and concordant lateralization of the abnormal hippocampal gyri in patients with MTS.

C-0879

A pictorial review of the radiological imaging findings in III, IV and VI cranial nerve palsies using CT and MR imaging techniques

M. Khanna, R.L. Preston, K. Tonge; London/UK

Learning Objectives: 1. Learn the anatomy of the intracranial course of the III, IV and VI cranial nerves. 2. Learn to interpret the radiological appearances and findings of pathology along the course of the III, IV and VI cranial nerves. 3. Understand the use of different CT and MR imaging techniques to highlight abnormal pathology

Background and Imaging Findings: The III, IV and VI cranial nerves arise in the dorsal midbrain and pons, traversing anteriorly through the posterior and middle cranial fossae to exit at the superior orbital fissure. Their long intracranial course renders them susceptible to a wide range of focal and diffuse pathologies. They can be subtle and to maximise imaging potential requires correlation with neurological findings to localise the lesion. CT and MR imaging techniques can be tailored to the precise anatomical location with additional contrast enhancement or specialised sequences as required.

Conclusion: This exhibit will illustrate, using the most suitable CT and MR imaging techniques, the radiological appearances of pathology affecting the III, IV and VI cranial nerves in adult and paediatric images. They will be divided into mid-brain, subarachnoid space, cavernous sinus and superior orbital fissure locations. Examples will include vascular lesions, primary brain tumours, infection and multisystem disorders.

C-0880

Brain diffusivity in patients with neuropsychiatric systemic lupus erythematosus and acute neurological symptoms

M. Hughes, B. Foerster, R.C. Welsh, H. Rahbar, P.C. Sundgren; Ann Arbor, MI/US

Purpose: To investigate whether diffusion-weighted imaging (DWI) using apparent diffusion coefficient (ADC) histograms can depict statistically significant cer-

Scientific and Educational Exhibits

bral abnormalities in patients with acute symptoms of neuropsychiatric systemic lupus erythematosus (NPSLE) versus normal controls.

Methods and Materials: Conventional MR imaging of the brain and diffusion-weighted echo-planar imaging (DWI) was performed on a 1.5 T scanner (GE Medical Systems) in 9 female NPSLE patients, aged 35-59 years, mean 44.4 years, and in age matched healthy controls. Whole brain ADC histograms were constructed on each patient. The histogram results of each group were compared. P-value < 0.05 was set for statistical significance using the Students t-test.

Results: Eight of the nine patients (89%) had abnormal findings on MR imaging. The most common findings were focal areas of increased signal on T2-weighted and FLAIR images in the white matter without associated pathological contrast enhancement. Other abnormal findings included infarcts, brain atrophy and meningeal enhancement. The NPSLE patients had a mean ADC value of 1041×10^{-6} mm²/sec and the control had a mean ADC value of 946×10^{-6} mm²/sec. The mean ADC values were significantly higher ($p < 0.0002$) in the NPSLE patients compared to the controls.

Conclusion: ADC histogram analysis demonstrated increased general diffusivity in the brain in NPSLE patients with acute symptoms compared to healthy normal controls. These results suggest a loss of tissue integrity in the brain parenchyma of NPSLE patients occurs which facilitates motility of free-water protons. Larger studies are in progress to further evaluate this method and determine potential use in monitoring disease progression and treatment efficacy.

Diffusion tensor fraction anisotropy in the cervical spinal cord:

Reproducibility in 10 normal subjects

N. Abdala, R.D. Nascimento, H. Carrete Jr., R.G. Nogueira, S.M. Goldman, J. Szeinfeld; São Paulo/BR

Purpose: To quantify anisotropic water diffusion through variables like Apparent Diffusion Coefficient (ADC) and Fraction Anisotropy (FA) using Diffusion Tensor Imaging (DTI), in the cervical spinal cord of normal subjects.

Methods and Materials: Ten healthy volunteers were recruited (6M, 4F), mean age 29.5 years. DTI images of the cervical cord were acquired in a 1.5 T magnet. The imaging protocol consisted of axial Multi-Shot Echo Planar sequences, gradients sensitized to diffusion in 6 directions, TR 3500 ms, TE 70 ms, $b = 0$ and 800 s/mm², 20 excitations. Slabs of twenty-six 3 mm interpolated slices were obtained. Three ROI measurements were performed in three cord segments, with calculation of ADC/FA mean values.

Results: Overall means and SD for ADC and FA values of cervical cord were 1.549×10^{-3} mm²/s $\pm 0.596 \times 10^{-3}$ mm²/s, and 0.517 ± 0.207 , respectively.

Conclusion: The FA values of the cervical spinal cord obtained in this initial experience are within the standard deviations of a previous report. Conversely, ADC values are in discordance with other authors' experience, possibly due to the method employed. Factors to explain the variability of ADC/FA values observed throughout the cervical cord remain to be established. The validation of normal ADC/FA value limits becomes mandatory as the experience employing ADC and DTI in the spinal cord is mounting up. Standardization of imaging protocols, post-processing software and ROI measurement, could potentially lead to statistically significant thresholds which may correlate with the maintenance or loss of normal anisotropic water diffusion.

C-0882

The craniocervical junction (CVJ): Anatomy, bony variants and acquired pathology

A. Bermejo, L. Herraiz, M. Martin, J. Benito, M. Miralles, A. Ramos; Madrid/ES

Learning Objectives: To summarize the normal embryological development and anatomy of the CVJ and the craniometric measurements used in the radiological assessment of the region. To illustrate the spectrum of bony anomalies of the occipital bone, atlas and axis. To describe traumatic lesions of the CVJ, with emphasis on the mechanisms of injury and appropriate imaging techniques that lead to proper management.

Background: Congenital, developmental and acquired anomalies of the CVJ may result in atlantoaxial instability or may affect the vertebral vascular system. Evaluation of CVJ disorders can be challenging, and management depends on the correct radiological diagnosis. We retrospectively reviewed CT studies of 651 patients with upper cervical injury admitted to our Hospital between 2001 and 2003.

Imaging Findings: Imaging procedures included lateral radiographs, flexion and extension films, CT with multiplanar reformatting and MR. Anomalies were divided into congenital and acquired, including trauma. Occiput anomalies include basilar invagination, condylar tertius, basiocciput hypoplasia and atlanto-occipital assimilation. Atlas anomalies include aplasia, hypoplasia, and clefts. The axis may present fusion abnormalities or dysplasias of the odontoid process. Many acquired processes may also affect the CVJ. Fractures were classified attending to each affected segment.

Conclusion: The CVJ is a common site for anatomic variants and acquired pathology. Knowledge of the normal anatomy as well as the spectrum of bony variants, acquired anomalies and fractures of this region is vital for the emergency radiologist for correct image interpretation and ultimate management.

C-0883

CE-MRA in the diagnosis of spinal DAVF

P. Zabakis, I. McDonald, D. Hadley, C. Santosh; Glasgow/UK

Purpose: Accurate pre-treatment localization of the level of a spinal dural arteriovenous fistula (SDAVF) is very important. Pre-operative selective DSA is considered to be the gold standard in pre-treatment mapping of these lesions. However it is invasive, time consuming and sometimes non-diagnostic. The purpose of this retrospective analysis was to evaluate the use of CE-MRA in DAVFs with spinal drainage.

Scientific and Educational Exhibits

Methods and Materials: 9 patients (7M, 2F) (age range 44-77 years old, mean 67) with suspected spinal vascular lesions were evaluated with MR Angiography. In 7 patients a SDAVF was present and 2 had an intracranial dural AV fistula with spinal drainage. 3D CE-MRA studies were performed with a 1.5 T Signa NV/I system (GE medical systems) using a phased array spine coil. Seven patients were imaged using a first pass elliptic centric ordered technique. In two cases an ECTRICKS (Elliptic Centric Time Resolved Imaging of Contrast Kinetics) technique was used. Selective spinal angiography was also performed in all patients. **Results:** MRA showed abnormal draining vessels in all cases and accurately identified the level of the fistula in 5/9 cases. In another case it proved to be a valuable tool in detecting the fistula level. MRA failed to identify both the feeding arteries and the fistulous connection of the intracranial fistulae with spinal drainage. **Conclusion:** CE MRA proved to be an effective, quick, non-invasive and ionizing radiation-free technique for the diagnosis of spinal dural AVFs. The recent CE-MRA technique (EC-TRICKS) which provide dynamic information was successful in both cases in which it was used

C-0884

MR imaging and US value in myelomeningocele experimental surgical sheep model

D. Elias, G. Izbizky, S. Medina Portillo, M. Pietrani, P. Farias, J. San Roman, F. Eleta; Buenos Aires/AR

Purpose: To evaluate the role of US and MR imaging in the assessment of an experimental animal model of myelomeningocele (MM).

Materials and Method: A surgical MM-like lesion was created in 32 fetal lambs. In 21, the defect was repaired before delivery (cases); 11 fetuses were used as controls. All procedures were monitored during surgery with US. The lambs were clinically evaluated after delivery. MR imaging studies were performed in 8 cases. Complete Central Nervous System (CNS) scans were performed in order to find associated anomalies. Fourteen (14) lambs had histological evaluation.

Results: Intrauterine MR imaging was performed in 5 cases. MM like defects and kyphosis were clearly characterized by this method. Associated CNS malformations were ruled out (including Arnold Chiari). We also performed MR imaging in three new born lambs in which intrauterine surgery to correct defects had been done. In this group one tethered cord was delineated. All 11 fetal sheep with unrepairs MM developed motor sequelae. Eight (8) lambs with defects corrected before birth walked independently without any difficulty. During corrective surgery, the lesions resemble MM on visual macroscopical inspection. In those animals without correction, histological sections of spinal cord showed severe damage.

Conclusions: The use of US and MR imaging is adequate for monitoring this experimental model. Although ultrasound is the method of choice for prenatal diagnosis and follow-up of myelomeningocele, MR imaging is an useful technique for accurate diagnosis of associated anomalies (brain migration disorders, tethered cord)

C-0885

Evaluation of the effects of sildenafil citrate (Viagra) on vertebral artery blood flow of patients with vertebro-basilar insufficiency

Z. Bozgeyik, E. Kocakoc, S. Berilgen, H. Ozdemir, A. Tekatas, E. Ogur; Elazig/TR

Purpose: Sildenafil is used widely for the treatment of erectile dysfunction. This substance induces relaxation of smooth muscle in the corpus cavernosum. Although it is widely used, there are limited number of studies about the effects of sildenafil on major vascular structures. The effects of sildenafil citrate on vertebral artery blood flow are also unknown. The aim of this study was to investigate effects of sildenafil citrate on vertebral artery blood flow of patients with vertebro-basilar insufficiency (VBI) using color duplex sonography (CDS)

Materials and Methods: Twenty-one patients with VBI (aged 31-76; mean 61.0 ± 10.5) were included into this study. Peak systolic velocity, end diastolic velocity, resistance index (RI), pulsatility index (PI), diameter, area, and flow volume of vertebral arteries were measured before the administration of sildenafil citrate; 45, and 75 minutes after the administration of sildenafil using CDS.

Results: The significantly changed parameters were as follows; significant increase in post drug values of bilateral vertebral artery diameters, areas, and flow volumes compared to before drug administration values. There were no statistically significant changes of other measured parameters.

Conclusion: Sildenafil citrate causes an increase in vertebral artery diameter and flow volume. This effect may reduce symptoms of VBI in patients and sildenafil may be used for the treatment of these patients in the future. This theory needs to be investigated further with detailed, multi-center studies on the long-term effects of chronic sildenafil administration on different VBI patient groups.

Pediatric

C-0886

Imaging of pediatric liver transplantation

M. Parrón, T. Berrocal, C. Prieto, P. Cortés, I. Pastor, R.R. Lemos; Madrid/ES

Learning Objectives: To illustrate the different modalities of liver transplantation performed in children. To provide an imaging overview of early and late complications following pediatric liver transplantation. To evaluate the efficacy of conventional and Doppler US, CT, MR imaging and interventional procedures in the diagnosis and management of these complications.

Background: 349 liver transplants have been performed in 277 children in our institution (204 cadaveric whole-liver transplants, 112 cadaveric reduced-size grafts, 26 reduced-size grafts from living-related donors, 3 hepato-renal and 4 hepato-intestinal transplants). The imaging studies of those with any complications were reviewed. B-mode and Doppler ultrasound were performed in all the cases, while CT, MR imaging, or vascular studies were performed depending on the complication and whenever US and Doppler images were not conclusive.

Imaging Findings: Specific topics addressed include vascular complications (stenosis and thrombosis of the hepatic artery, portal vein, inferior vena cava and hepatic veins), biliary complications (strictures, stenoses, perforation and stones), abdominal fluid collections (hematomas, bilomas, ascites), infections, rejection, and lymphoproliferative disorders. The different modalities of liver transplantation performed in children will be shown. The key findings at each imaging modality will be discussed and compared with the surgical findings or underlying pathological features when available. Pitfalls, diagnostic difficulties and differential diagnosis will be emphasized.

Conclusion: Evaluation of patients with liver transplant frequently requires multiple imaging modalities for diagnosis and planning treatment. Because many of these disorders have characteristic imaging appearances, this exhibit will help the practising radiologist to better understand and recognise complications involving the transplanted liver.

C-0887

Evaluation of [^{18}F]FDG-PET and CT/MR imaging for monitoring therapy response in children with Hodgkin's disease

I. Sorge, A. Krausse, R. Kluge, C. Mauz-Körholz, D. Körholtz, W. Hirsch; Leipzig/DE

Purpose: To compare CT/MR imaging with PET with respect to its potential in monitoring the effect of chemotherapy in children with Hodgkin's disease (HD). Adults with HD who undergo adequate therapy have a low risk of relapse even if they still have residual masses on cross sectional imaging, i.e. the positive predictive value (PPV) is only 20%. For [^{18}F] FDG-PET the PPV is known to be substantially higher (about 80%).

Methods and Materials: Within the scope of the international GPOH-HD Pilot 2002 study in 43 HD-children CT/MR imaging was paralleled by PET imaging. In consensus conferences CT/MR imaging as well as PET findings were documented in 21 regions for each patient. Complete remission (CR) was defined as residual masses < 2 ml and > 90% regression of all initially involved lesions in follow-up CT/MR imaging and as normal FDG uptake in all regions in follow-up PET.

Results: In initial imaging 222 and 247 positive lesions were detected by CT/MR imaging and PET respectively. In follow-up imaging 81 regions were found to be still positive in CT/MR imaging but only 30 in PET. Out of 19 children with low stages ($\leq \text{IIa}$) only 2 were classified as CR in CT/MR imaging but 10 by PET.

Conclusion: Cross sectional imaging does not seem to be sufficient in recognising complete remission of Hodgkin's disease. A systematic use of PET for therapy monitoring should be warranted also in childhood HD. This might contribute to reducing over-treatment and drug side effect without a loss of treatment efficacy.

C-0888

MR imaging of the brain in Wilson's disease of childhood: Findings before and after treatment

J.-E. Cheon, I.-O. Kim, W. Kim, K. Yeon; Seoul/KR

Learning Objectives: To illustrate the MR findings of the brain in Wilson's disease in children at initial stage and follow-up after treatment, and to correlate MR manifestations with clinical response to treatment.

Background: Wilson's disease is an uncommon, autosomal recessive disorder involving copper metabolism that results in abnormal accumulation of copper in various tissues, mostly in the liver and the brain. Copper chelating agents are believed to improve the neurological symptoms. In this study we will illustrate the changes of MR findings before and after treatment of Wilson's disease.

Scientific and Educational Exhibits

Procedure Details: The study included 50 children with Wilson's disease (M:F = 26:24, mean age, 10.2 years). All patients had been treated with copper chelating agents since the diagnosis of Wilson's disease had been established. T1WI and T2WI MR images were obtained. Fifteen patients underwent a total of 20 follow-up MR scans during follow-up period (12-63 months). MR findings were divided into three groups; group I revealed normal MR findings, group II had increased signal in the basal ganglia and the midbrain on T1WI, and group III had increased signal in the globus pallidus, basal ganglia, thalamus, midbrain and pons on T2WI. High signal intensity areas on T2WI reflected cerebral involvement of Wilson's disease, and showed good correlation with neurological symptoms and clinical response after treatment.

Conclusion: MR imaging findings of Wilson's disease could be categorized into distinct groups. MR imaging could be helpful in assessing the clinical response to treatment in patients with Wilson's disease.

C-0890

Imaging of hip disorders in pediatric patients: A pictorial review

M. Parrón, T. Berrocal, A. Álvarez, D. Bernabeu, R.R. Lemos, N. Gómez-León; Madrid/ES

Learning Objectives: To understand the embryology, pathology, and imaging features of a wide spectrum of congenital and acquired alterations involving the hip in children. To know the utility of each imaging modality that can be applied to the management of these conditions. To emphasize pitfalls and differential diagnoses of these entities.

Background: We retrospectively reviewed the imaging findings of patients with disorders involving the hip from our database of musculoskeletal pathology. Plain radiographs were performed in all patients. Ultrasound, CT or MR were performed whenever plain radiographs were not conclusive. The embryology and pathological basis of the radiographic findings are discussed. The key findings at each imaging modality are shown and compared with the underlying pathological features when available.

Imaging Findings: Specific topics addressed include congenital and developmental abnormalities (hip dislocation, coxa vara, femoral capital dysplasias), femoral head necrosis of unknown (Legg-Perthes disease) and known etiology (Gaucher disease, hemoglobinopathies, corticosteroid therapy, and post-traumatic), infectious and inflammatory diseases (synovitis, arthritis, osteomyelitis, osteochondritis), synovial chondromatosis, slipped capital femoral epiphysis, benign and malignant neoplasms (osteoid osteoma, osteosarcoma, Ewings tumor, lymphoma) and trauma. Pitfalls, diagnostic difficulties and differential diagnoses are emphasized.

Conclusion: Evaluation of patients with hip disorders frequently requires multiple imaging modalities for diagnosis and planning treatment. Because many of these disorders have characteristic imaging appearances, this exhibit will help the practising radiologist to better understand and recognise pathology affecting the paediatric hip.

C-0891

High-resolution susceptibility weighted imaging (SWI) as a new diagnostic tool in children

H.-J. Mentzel, A. Rauscher, J. Böttcher, C. Fitzek, U. Brandl, J.R. Reichenbach, W.A. Kaiser; Jena/DE

Purpose: To evaluate the diagnostic potential of high resolution susceptibility weighted imaging (SWI) in children with vascular malformations. This blood oxygen level dependent (BOLD) method is based on susceptibility-induced phase contrast and is sensitive not only to the oxygen content of intravascular blood but also to breakdown products such as hemosiderin, due to increased signal dephasing.

Methods and Materials: We studied children with suspected vascular malformations on a 1.5 T MR unit (Siemens, Vision plus) using a standard head coil. Conventional MR imaging consisted of T1- and T2-weighted SE sequences, FLAIR and susceptibility sensitive EPI sequences (slice thickness 6 mm). 2D TOF-MR angiography was performed. A high-resolution 3D highly T2*-weighted gradient echo sequence with first-order flow compensation, and radiofrequency spoiling was used for SWI (TR 67 ms, TE 40 ms, flip angle 25°, FOV 256 mm, 512 matrix). Magnitude and phase images were reconstructed.

Results: With SWI highly detailed information about the veins was obtained in all patients. In a patient with Sturge-Weber syndrome early detection of vascular anomaly was possible; in patients with cavernoma more lesions could be detect-

ed compared to the conventional scans. In other patients developmental venous anomalies could be diagnosed clearly.

Conclusion: In children high-resolution SWI may be of special importance in the early detection and assessment of vascular malformations which are difficult to diagnose with other MR methods.

C-0892

Ultrasound in the diagnosis of acute abdominal pain in children during oncological treatment

U. Zaleska-Dorobisz, B. Jankowski, J. Kurcz, K. Moron; Wrocław/PL

Purpose: To assess the use of 2D and Doppler ultrasonography in children with acute abdominal symptoms during oncological therapy.

Methods and Materials: We analyzed 249 abdominal ultrasound examinations of 133 children with neoplasms and acute abdominal symptoms. Examinations were performed during chemotherapy, radiotherapy and after hematopoietic stem cell transplantation. All the patients were under routine hematological control. Based on the clinical symptoms and the laboratory tests we analysed two groups of children; a) 111 with neutropenia and b) 22 without neutropenia. In patients who underwent surgery the final diagnosis was established on histopathology. In the other cases diagnosis was based on clinical, laboratory and ultrasound findings.

Results: In the group of 133 children with acute abdominal symptoms most (69%) had acute lymphoblastic leukaemia (ALL), 12% had acute myeloblastic leukaemia (AML), Ewing sarcoma 2.2%, osteosarcoma 2.2%, NHL 6.0%, HL 3%, nephroblastoma 3%, neuroblastoma 2.2%. Clinical symptoms were very severe. Nonspecific gastrointestinal inflammation and typhilitis were the main cause of the acute abdominal pain in 71 children; perforation of the gastrointestinal tract (11), intestinal occlusion (10), acute pancreatitis (7), appendicitis (12), abscess (14), acute cholecystitis (6), peritoneal fluid was found in 45. The accuracy of ultrasound findings verified intraoperatively and by histopathological examination was 84%. In all cases the morphological changes were directly related to the duration of signs and symptoms.

Conclusion: High-resolution US is the first imaging method in the diagnosis of abdominal symptoms in children with neoplasms and neutropenia. US could be used for monitoring of treatment. Proper diagnosis can be established only with clinical information.

C-0893

Ultrasonographic findings of the fecally impacted appendix: Differentiating from acute appendicitis

N. Park, C. Park, E. Lee, M. Kim, S. Song; Koyang/KR

Purpose: To identify the ultrasonographic findings of the fecally impacted normal appendix in order to prevent unnecessary surgery due to its misdiagnosis as acute appendicitis.

Methods and Materials: 126 patients underwent ultrasonography between January 2004 to June 2004 for right lower quadrant pain. 8 cases including 3 pathologically confirmed cases and 5 clinically and follow-up ultrasonographically confirmed cases were diagnosed as a fecally impacted normal appendix. The criteria that we used to distinguish the fecally impacted appendix from acute appendicitis included preservation of normal wall layering of the appendix, absence of periappendiceal fat infiltration and lack of increase in blood flow of the appendiceal wall on color Doppler study.

Results: Fecal material within the appendix was seen as heterogeneous hyper-echoic intraluminal content without posterior shadowing. Fecal impaction was confined to the distal segment of the appendix in all cases. The AP diameter of the distended appendix was measured as 5.5-10.3 mm, while the mean diameter was 6.5 mm. The normal wall layers of the appendix were preserved and there was no evidence of periappendiceal fat infiltration in any of the cases. No demonstrable increase in blood flow in the appendiceal wall was seen.

Conclusion: Fecal impaction increases the outer transverse diameter of the normal appendix, thereby frequently leading to misdiagnosis of the fecally impacted appendix as acute appendicitis. Recognition of preservation of normal layering of the appendiceal wall, no periappendiceal mesenteric infiltration and no demonstrable increased blood flow in the appendiceal wall is expected to help prevent unnecessary surgery.

Scientific and Educational Exhibits

C-0894

Prenatal assessment of lung hypoplasia in congenital diaphragmatic hernia (CDH): Correlation between volumetric MR imaging and biometric ultrasound measurements

M. Fit  , G. Enriquez, A. Castellote, E. Gratac  s, J. Delgado, J. Piqueras, E. Carreras, J. Lucaya; *Barcelona/ES*

Purpose: To investigate the correlation between the relative fetal lung volume (RFLV) values measured with MR imaging planimetry and lung-to-head ratio (LHR) determined by ultrasound in fetuses with CDH.

Methods and Materials: Nineteen fetuses with an ultrasound diagnosis of CDH (16 left and 3 right) underwent MR imaging using single-shot rapid acquisition with relaxation enhancement and T1-weighted sequences. A total of 22 MR imaging exams were performed; fetal lung volume and liver volume were measured using planimetry. The RFLV was calculated according to a standard formula using the liver volume as a reference and expressed in percentage. The LHR was measured by ultrasound. Spearman correlation analyses were performed in the total group and in the cases of left hernias with ipsilateral apical cap.

Results: Among the 16 left-sided hernias, an ipsilateral pulmonary apical cap was identified by MR imaging in nine cases, seven in the first study and two after intrauterine tracheal plugging. The correlation coefficients (*r*) between the values obtained with the two methods were 0.60 (*p* < 0.005) for the total group of 19 and 0.13 (*p* > 0.5) for left hernias with ipsilateral apical cap.

Conclusion: There was a good overall correlation between the two methods. However, the correlation was poor in the subgroup of patients with apical cap. Presence of an apical cap may explain the prognostic variability reported for cases with borderline LHR values. Addition of volumetric MR imaging may improve the accuracy of current algorithms for determining pulmonary hypoplasia, indicating intrauterine treatment in borderline cases and predicting postnatal survival in patients with CDH.

C-0895

Significance of recurrent lung opacities in premature infants treated for respiratory distress syndrome: The SLOP study

S.P. Prabhu, S. Winterbottom, S. King; *Bristol/UK*

Purpose: To determine the significance of recurrent opacities on chest radiographs of neonates treated with surfactant for RDS after an initial period of improvement.

Methods and Materials: In this prospective study, serial chest radiographs on 61 premature infants (gestational age < 32 weeks) with RDS were analyzed pre- and post-surfactant at 3 days, 10 days, 36 weeks post conceptional age and at 3 months. The pattern of chest radiographic response was classified as (a)progressively clear, (b)recurrent opacification and (c)no response. Clinical characteristics including type of surfactant, mode of ventilation, presence of patent ductus and intraventricular haemorrhage were also recorded.

Results: In 23 infants (37%), RDS changes cleared within 3 days. 16 infants (26%) developed recurrent opacities within 10 days after an initial period of improvement. 22 infants (36%) failed to respond to surfactant. The corresponding mean birth weights for the three groups were 1.5, 1.12, and 0.82 kg and mean gestational ages 32, 27, and 25 weeks. The incidence of chronic lung disease was highest amongst infants with recurrent lung opacities.(63% vs. 51% in non responders, *p* < 0.001). The pattern of chest radiographic response in premature infants was primarily affected by gestational age and birth weight.

Conclusion: Recurrent lung opacities after initial improvement in neonates with RDS is an adverse factor in development of bronchopulmonary dysplasia. Recurrent lung opacities after surfactant may be a predictor of chronic lung disease in the preterm infant and necessitate reporting of neonatal films as a series in the first 2 weeks to avoid missing this important pattern.

Congenital deformities of the hand: Preoperative evaluation with multiple-detector row CT angiography

M. Rieger, A. Mallouhi, H. Piza, B. Czermak, M. Freund, W. Jaschke; *Innsbruck/AT*

Learning Objectives: To demonstrate the usefulness of multislice CT examination in the preoperative evaluation of congenital deformities of the hand in children.

Background: Congenital hand deformities are relatively rare and vary greatly in appearance. Preoperative diagnostic work-up usually depends on conventional radiography. However, osseous deformities may be accompanied by abnormal vessels, muscles, tendons, and joints. For corrective surgery of congenital hand deformities, all its components and morphological characteristics should be precisely recognized. Multiple-detector row CT allows not only the visualization of osseous structures in three-dimensional perspective but also provides important information about tendons and arteries. The morphological changes found in cutaneous and osseous syndactyly, hypoplasia, symbrachdactyly, macrodactyly, cleft and club hand, mirror hand, and various numerical and metrical variations of the fingers will be discussed and analyzed as well as their impact on treatment planning. Syndromes like Apert, Schnueiring, Poland and Larsson that are associated with hand deformities will also be demonstrated.

Procedure Details: High-resolution multislice CT angiography (GE, LightSpeed QX/i; LightSpeed 16) of the forearm was preoperatively performed in 32 children under general anaesthesia. Contrast medium was applied by a power injector through a cubital or foot vein. The vascular, osseous and ligamentous conditions were reconstructed by means of an advantage windows workstation (GE, AW 4.0; AW 4.2).

Conclusion: Multislice CT angiography as the only preoperative work-up in children with congenital hand deformities is sufficient to demonstrate all abnormalities, which were important for corrective operation

C-0899

Uncomplicated versus torqued testicular appendages in childhood:

Sonographic appearances with embryologic correlation

M. Vakaki, G. Pitsoulakis, V. Dermentzoglou, V. Begli, C. Koumanidou; *Athens/GR*

Learning Objectives: To familiarize Radiologists and especially Pediatric Radiologists to the presence of more than the one well-known (appendix testis) testicular appendages and to highlight the significance of the correct sonographic diagnosis in the boy with an acute scrotum.

Background: Five testicular appendages, representing remnants of the degenerating mesonephric and paramesonephric ducts, have been identified microscopically. The appendix testis (hydatid of Morgagni) and appendix epididymis are the most common and have various sonographic appearances. Everyone of the above 5 appendages is liable to torsion, an important differential diagnosis versus testicular torsion, in the boy who presents with an acutely painful scrotum. Previous sonographic studies have mainly focused on Morgagni's torsion. Nowadays, high-resolution sonography with high-frequency transducers has made it possible to visualize the other normal or torqued testicular appendages, also.

Imaging Findings: In this exhibit, the embryology and anatomy, as well as the varying sonographic appearances of the testicular appendages are described and illustrated. Sonographic features of appendiceal torsion are also demonstrated. The differential diagnosis, including testicular torsion and acute epididymo-orchitis, is discussed.

Conclusion: The correct sonographic diagnosis is of utmost importance, as the clinical symptoms are often misleading, considering that appendiceal torsion is a self-limiting condition and can be managed conservatively, acute epididymo-orchitis also needs medical treatment, whereas testicular torsion requires urgent surgical intervention to save the testis.

C-0900

Range of sonographic appearances of the normal breast in children and young adolescents

M. Vakaki, G. Pitsoulakis, V. Dermentzoglou, V. Manoli, C. Koumanidou; *Athens/GR*

Learning Objectives: To present the changing sonographic appearance of the normal breast parenchyma in young children from birth to adolescence. To familiarize pediatric radiologists with normal variations of growing breast, to avoid misdiagnosis of normal as abnormal, and to emphasize the role of sonography in the imaging investigation of breast masses.

Scientific and Educational Exhibits

Background: Although the sonographic features of normal breast parenchyma in adults are well-known, similar data are lacking in children. On the other hand, sonography is the imaging method of choice in the evaluation and characterization of breast masses in childhood. The spectrum of breast diseases in children is different from that in adults and most of them are benign.

Imaging Findings: The sonographic characteristics of normal breast development and normal variations from birth to adolescence are described. Their differential diagnosis from pathological conditions is discussed and their correlation with Tanner grading system of breast development is presented.

Conclusion: Knowledge of the variable sonographic appearances of normal developing breast is quite important for successful use of breast sonography in imaging of the pediatric and adolescent breast.

C-0901

Contrast enhanced ultrasound in evaluation of pediatric blunt abdominal trauma

V. Miele, V. Buffa, A. Cortese, M. Galluzzo, G. Regine, L. Adami; Rome/IT

Purpose: To evaluate contrast enhanced US (CEUS) in the diagnosis of pediatric traumatic hepatic and splenic lesions when compared to conventional US.

Methods and Materials: In years 2002-2003 73 pediatric patients (age 5-16 ys) with blunt abdominal trauma (isolated or in polytrauma) were studied with conventional US and US with second generation contrast agent (Sonovue, Bracco, Italy). 18 patients were studied with angio-CT. We evaluated the presence of hepatic or splenic lesions and the size, echopattern and capsular involvement of the traumatic lesion.

Results: Conventional US revealed traumatic splenic and hepatic lesions in 7 and 8 patients respectively. CEUS revealed other hepatic and splenic lesions in 4 and 3 patients. Traumatic lesions with CEUS were hypoechoic with respect to enhanced hyperechoic parenchyma and size and margins were better defined. Capsular envelopment of the liver (3 cases) and spleen (2 cases), not identified with conventional US was demonstrated with CEUS. CEUS correlated well with CT. All hepatic lesions were treated conservatively; in 2 patients splenectomy was performed.

Conclusion: CEUS is more accurate when compared to conventional US in the detection and classification of hepatic and splenic traumatic lesions. In the pediatric age-group CEUS can substitute for CT and is preferable for follow-up. CT should be reserved for polytrauma.

C-0902

High-resolution ultrasound of angled buckle fractures in children

M. Valle¹, L. Bacigalupo¹, F. Pugliese¹, P. Toma¹, S. Bianchi², C. Martinoli¹; ¹Genoa/IT, ²Geneva/CH

Learning Objectives: To provide an overview of the most common angled buckle fractures in children. To familiarize radiologists with the appearance of these fractures. To emphasize the role of US for the identification of radiographically occult fractures in children.

Background: Angled buckle (torus) fractures are very common in children and derive from the application of axial loading to the involved bone, causing an impaction fracture, in combination with lateral forces leading to the angulation of the cortex. Although pediatric radiologists are familiar with the appearance of these subtle fractures on plain films and with the typical sites where they occur, angulated buckle fractures are frequently missed radiographically.

Imaging Findings: This exhibit will provide an overview of the US appearance of a series of radiographically occult fractures involving the metaphysis of the long bones of the hand (phalanges) and foot (bunk bed fracture), the wrist (distal radius) and the elbow (radial head, supracondylar). In most cases, angled buckle fractures present sonographically with a curved or fragmented appearance of the metaphysis compared with the contralateral side. The appropriate US scanning technique for detecting these subtle fractures and potential pitfalls in the interpretation of pathology will be discussed.

Conclusion: US is helpful to detect radiographically occult angled buckle fractures in children, especially in the case of multiple bone involvement. This technique may avoid the need for oblique or contralateral views, limiting the X-ray exposure to the patient.

C-0903

Changes of sonographic features of peripheral lymph nodes in Hodgkin's disease during specific therapy

V.P. Khartchenko, P.M. Kotlyarov, E.V. Abbasova, R.A. Parkhomenko; Moscow/RU

Purpose: To investigate changes of sonographic features of lymph nodes (LN) during therapy for Hodgkin's disease (HD).

Methods and Materials: 160 children with HD were examined (apparatus Logiq-7 GE). The following parameters of the LN were evaluated: diameters, shape, index of roundness, echogenicity, differentiation of the cortex and medulla, matting, vascular pattern, RI, spectrum of blood flow velocity. More than 400 LN were evaluated with B-mode, of which 100 were additionally examined using Color flow (CF) and Power Doppler (PDI), and Pulse-wave modes.

Results: The LNs affected by HD were enlarged, with a tendency of matting, the index of roundness approached 1, the outline was uneven, the general echogenicity was low, corticomedullary differentiation was not clearly seen. CF and PDI showed predominantly mixed chaotic vascular pattern (central + peripheral). RI was 0.55-0.71. During specific therapy the size and number of the LN decreased, their echogenicity increased, symmetrical corticomedullary differentiation appeared, vascular pattern became hilar with its gradual reduction. In some LN signs of micro- and macrocalcifications were seen. RI decreased (0.51-0.55), with no change in peak velocity.

Conclusion: Modern sonographic techniques objectively reflect changes of the peripheral LN affected by HD during therapy. One of the most informative parameters is change of RI and should be considered together with the reduction of the size, number of LN and normalization of the echo-structure. RI is increased in the specifically affected LN and decreases after effective treatment. The absolute values of peak blood flow velocity are not informative to assess the effect of treatment.

C-0904

Association of isolated preauricular skin tags and renal anomalies in the local UK population

T.A. Szyszko, Z. Stetina, C. Ward, D. Lindo; London/UK

Purpose: To look at the association of isolated preauricular skin tags and renal anomalies in the local population. Ear and renal anomalies are seen in multiple congenital anomaly syndromes; however, the principle evidence for the specific association of isolated preauricular skin tags and renal anomalies is a paper from Israel showing an 8.6% incidence in 70 infants. There is no European data for any such association.

Methods and Materials: We looked at the indications and outcomes of 151 renal ultrasounds requested on infants born in Kingston Hospital in 2003. The indications were categorised as: two vessel cord; preauricular skin tags; antenatal abnormality and "other" (including UTI). The outcomes were categorised as "normal"; "abnormal" or "did not attend".

Results: 141 (93%) of the 151 infants attended renal ultrasound examination. 100% of the infants with isolated preauricular skin tags had a normal renal ultrasound examination. 100% of the infants with two vessel umbilical cords had a normal renal ultrasound. 60% of infants with abnormal antenatal renal scans and 87% of the "other" indications also had normal scans. A telephone survey revealed that 30% of all units with delivery suites in the UK routinely referred infants with isolated preauricular skin tags for postnatal renal ultrasound assessment.

Conclusion: In the local population there were no renal anomalies found in infants with isolated preauricular skin tags and no renal anomalies found in infants with two vessel umbilical cords suggesting that there is no association and no need for routinely referring these infants for postnatal renal ultrasound examination.

C-0905

A pictorial review of pineal region masses and pathologies in children

J.L. Babar, L.K.R. MacPherson; Birmingham/UK

Learning Objectives: To illustrate the spectrum of pathologies that may affect the pineal gland and parapineal structures in children. To outline certain imaging characteristics that are associated with specific tumours and non-neoplastic lesions.

Background: Pineal tumours constitute approximately 3-8% of paediatric brain tumours. Pineal region lesions fall broadly into two categories; tumours arising from the pineal gland, and masses extending into the pineal region from adjacent structures. Clinically, children may present with abnormal eye movements (Parinaud's syndrome), symptoms related to hydrocephalus and neuroendocrine dysfunction, or as an incidental finding on cross-sectional imaging. The role of imaging

Scientific and Educational Exhibits

is to attempt to differentiate these lesions by identifying their origin, recognising different imaging characteristics, and noting any associated complications, concurrent tumours or disseminated disease.

Imaging Findings: The radiological appearance, particularly with reference to CT and MR imaging, of pineal gland tumours, including pineal cell and germ cell neoplasms are reviewed. Other parapineal tumours and non-neoplastic masses encountered, including cysts and vascular malformations are described. A pattern-based approach depending on the anatomical site affected and radiological appearance, in conjunction with clinical details is used to provide an aid to the diagnosis.

Conclusion: Neuroimaging has achieved a marked improvement in the preoperative delineation of benign and malignant pineal masses, and in distinguishing true pineal tumours from other parapineal pathologies in children.

C-0906

True FISP versus HASTE MR imaging in the diagnosis of non-cerebral foetal anomalies

B.J. Op de Beeck¹, P. Ramaekers¹, R. Salgado¹, F. De Ridder², L. De Catte², F. Vanhoenacker¹, P. Parizel¹; ¹Edegem/BE, ²Brussels/BE

Learning Objectives: To illustrate the most common non-cerebral foetal anomalies. To compare the image quality of two ultra-fast sequences (True FISP and HASTE) in prenatal MR imaging. To outline the advantages and limits of the technique compared with foetal ultrasonography.

Background: Foetal MR imaging provides the potential advantage of superior soft tissue characterization with better differentiation of tumour from normal tissue compared with US. The HASTE technique has been widespread in foetal MR imaging. True FISP offer some advantages: a better signal-to-noise ratio at a short TR, a high T1/T2 contrast, and a lower specific radiofrequency absorption rate. In this exhibit we will describe the use of both ultra-fast sequences in the diagnosis of non-cerebral foetal anomalies, the advantages and the limits compared with foetal ultrasonography.

Procedure Details: We included 15 patients with a suspicion of non-cerebral foetal abnormalities on ultrasound. Imaging was performed on Magnetom Vision and Sonata 1.5 T scanners (Siemens, Erlangen, Germany). HASTE and True FISP sequences were used in the 3 anatomical planes. Diagnostic confirmation was obtained with foetal ultrasound and post-partum imaging. The indications were: meningocele, sacrococcygeal teratoma, diaphragmatic hernia, cystic adenomatoid malformation, pulmonary hypoplasia, gastroschisis, meconium peritonitis, Potter syndrome and campomelic dysplasia.

Conclusion: True FISP images demonstrated superior contrast resolution and less blurring of the lesions despite the higher susceptibility to band-like artefacts. Ultra-fast MR imaging may further aid our understanding of developmental anatomy, help characterize congenital lesions, delineate associated findings, and ultimately assist in the management of both foetus and mother.

C-0907

Pediatric MRA with Gd-BOPTA

G.K. Schneider, P. Fries, M. Gruber, B. Kramann, R. Seidel; Homburg a.d. Saar/DE

Purpose: Vascular malformations in pediatric patients often present complex anatomy and implicate the need for an adequate imaging modality to correctly diagnose and subsequently plan therapy. This study reviews different congenital vascular malformations visualized by contrast enhanced MRA with the use of Gd-BOPTA, a high relaxivity contrast agent.

Methods and Material: MRA was performed on a 1.5 T magnet in a total of 38 patients (2 days to 8 years). MRA was performed either with sedation or after intubation and controlled ventilation corresponding to the age of the patient and the vascular territory imaged. For MR angiography Gd-BOPTA was applied intravenously at a dose of 0.1-0.2 mmol/kg body weight with injection by hand during ongoing sequence acquisition without the use of a test bolus.

Results: At the injected dose Gd-BOPTA produces excellent and homogeneous delineation of the aorta and the supra-aortic branches even in newborn babies in which vessel diameters of < 3 mm have to be considered. Long breath-hold intervals due to controlled ventilation allow for dynamic whole body imaging of the arterial and venous system in one imaging session and thus may give a complete overview of the vasculature.

Conclusion: Gd-BOPTA in contrast enhanced MRA of pediatric patients produces excellent delineation of even very small vessels and thus allows a diagnostic workup of even newborn or premature babies. Increased relaxivity as compared to other gadolinium chelates may result in better vessel demarcation making Gd-BOPTA favorable in contrast enhanced MRA of pediatric patients.

C-0908

Intraarticular osteoid osteoma in children

M. Hasiotou, E. Manoli, G. Pitsoulakis, N. Petras, I. Anastopoulos, E. Evangelidakis; Athens/GR

Purpose: To demonstrate and discuss the imaging findings of intraarticular osteoid osteoma (OO) in childhood.

Methods and Materials: The medical files of 35 patients (22 males and 13 females) with intra-articular osteoid osteoma were retrospectively studied. Patients' age ranged from 4 to 15 years and in all cases the final diagnosis was established histologically. We studied the imaging findings on plain films, computed tomography, magnetic resonance imaging and bone scintigraphic studies. The disease was located in the hip, spine, knee, ankle, heel, metatarsal bone and in the elbow.

Results: In 9 cases the plain films were unremarkable due to the absence of sclerosis and the projection of articular structures. Computed tomography, bone scintiscan and magnetic resonance imaging study were indicative for the disease in all cases, contributing to the localization of the lesion. The typical findings of the radiolucent nidus and of surrounding sclerosis were not present in all cases. Atypical imaging findings were also observed; joint effusion, cortical disruption, soft tissue swelling, marrow oedema, osteophyte formation, distal periosteal sclerosis, soft tissue mass, regional osteopenia and muscle wasting and fat obliteration.

Conclusion: In cases of intra-articular localization of OO, diagnosis may be challenging. Clinical presentation is often misleading. Bone scintigraphy and CT are important diagnostic tools for accurate and prompt diagnosis. MR imaging, especially after intravenous introduction of gadolinium helps in cases with vague symptoms or nonspecific findings on CT.

C-0909

Sonographic analysis with second-generation ultrasound contrast agents in pediatric liver transplantation

R. Nani, S. Placidi, G. Pezzotta, M. Gaffuri, A. Tomasoni, G. Bonini, R. Agazzi; Bergamo/IT

Purpose: To investigate the use of second generation sonographic contrast in sonographic follow-up of pediatric liver transplantation.

Methods and Materials: The pediatric liver transplantation center of OORR of Bergamo, from October 2002 to November 2003, performed in 40 patients, 44 liver transplantations (34 split-liver, 10 whole liver). All patients were studied with US-color-Doppler. 30 patients were studied with harmonic imaging US (ATL 5000) and sonographic contrast agent (SonoVue) before the use of invasive techniques (angiography, CT, PCT) in suspected vascular and biliary complications.

Results: 11 vascular complications were demonstrated (9 thromboses and 2 stenoses); 5 in the hepatic artery, 4 in the portal vein and 2 in the sovrahepatic v. 8 biliary complications were demonstrated: 3 stenoses, 3 fistulae, 2 bilomas. 15 fluid collections in split livers close to the surgical resection were found (cut surface of the liver). The enhancement pattern of hepatic vessels in the subsequent vascular phases (portal and late) confirmed the suspicion of vascular steno-trombosis, while the parenchymal phase was better for biliary duct detail.

Conclusion: Sonographic analysis with SonoVue contrast agent is a useful, non-invasive technique that improves the accuracy of traditional US in pediatric liver transplantation. The use of ultrasound agents has significantly improved the diagnosis and characterization of intrahepatic and extrahepatic lesions (necrosis, abscess, bilomas).

C-0910

Imaging of back pain in children and adolescents

N.J. Khoury, M.M.S. Arabi, F. Abi-Fakher, M.H. Hourani, M.C. Haddad; Beirut/LB

Learning Objectives: To present the imaging findings of the wide spectrum of musculoskeletal diseases causing back pain in children and adolescents.

Background: Back pain in children is a rare condition but may denote a serious health problem, hence full clinical history, physical examination and appropriate laboratory studies should be obtained.

Imaging Findings: In this scientific exhibit, we present the imaging findings of the variable musculoskeletal diseases that are associated with back pain in children and adolescents. These disease processes include: scoliosis of various causes, spondylolisthesis, spondylolisthesis, traumatic injuries, disc degeneration and herniation, Scheuermann's disease, spondylodiscitis, tumors (primary, secondary, hematogenous), and miscellaneous conditions (e.g. metabolic disorders, sickle cell disease, osteoporosis). The imaging modalities used include plain radiographs, CT scan, MR imaging and nuclear studies.

Scientific and Educational Exhibits

Conclusion: A wide spectrum of diseases causing back pain in children is presented. Radiologists should be aware of the imaging findings of this rather uncommon entity.

C-0911

Contrast enhanced versus baseline ultrasonography in characterization of enlarged peripheral lymph nodes in children

U. Zaleska-Dorobisz, B. Kazanowska, K. Moron; Wroclaw/PL

Purpose: To compare contrast enhanced ultrasonography to conventional US in the characterization of benign and malignant enlarged peripheral lymph nodes in children.

Methods and Materials: Ninety seven enlarged superficial lymph nodes in 40 children (18 girls and 22 boys; age range, 1- 16 years) were evaluated using color Doppler (CD), power Doppler before and after contrast (Levovist) agent administration(CEUS). The patterns of intranodal flow were identified. Hilar vessels with branches running in the long axis of the lymph node with branches to the cortex indicated lymphadenitis (sensitivity 94%, specificity 100%). Of the neoplastic lymph nodes, 90% showed predominantly peripheral vessels. Histologically, lymphadenitis was found in 62 nodes, metastases in 24 nodes, HL in 6 and NHL in 5 cases. Geometric dimension, architecture, and margin of the node and detection and localisation of vessels were evaluated. The ultrasound diagnoses were compared to the final diagnoses based on clinical tests, surgical and histological examination.

Results: The transverse- to longitudinal diameter ratio in combination with architecture and margin analysis resulted in a correct diagnosis in only approximately 80% of the nodes. With contrast enhanced CD and PD, 90% of nodes showed vessels, and 30% of nodes demonstrated vessels with this technique exclusively.

Conclusion: Enlarged peripheral lymph nodes in children can be categorized as inflammatory or neoplastic with high diagnostic accuracy on the basis of their vascular patterns as seen on contrast enhancend color Doppler US.

C-0912

Evaluation of the abnormal anatomy in infants with double outlet right ventricle with MR imaging

L. Bokeriya, A. Ivanitsky, V. Makarenko, L. Urpolskaya, I. Rychina; Moscow/RU

Purpose: To define the possibilities of cardiac MR imaging in the diagnosis of double outlet right ventricle (DORV) in infants.

Methods and Materials: 16 infants (13m 3f, weight 6.9 ± 2.9 kg, growth 67.9 ± 8.58 sm) with DORV were investigated by MR. MR images were acquired on a Signa GE system, field strength was 1.0 T. To reduce flow and motion artefacts ECG triggering and respiratory compensation and sedation were used in all patients. We used multislice spin-echo and gradient-echo technique. The selected slice thickness was 3-4 mm. Images were analyzed off-line on an Advantage Windows workstation. For the analysis of abnormal anatomy we used a segmental approach.

Results: For the evaluation of morphology, ECG-gated spin-echo images are optimal. In all patients we could define situs, atrioventricular connections, type of ventricular loop, the orientation of the great arteries to each other and ventricular arterial connections. Twelve patients had situs solitus, two patients right isomerism, one patient left isomerism and one infant had situs inversus. In all cases both vessels were located in the right ventricular out flow tract. The best images were oblique coronal and sagittal. The position of ventricular septal defect (VSD) and orientation and size of the outlet septum and the relation between the VSD and the arterial valves were defined by transverse and oblique MR images. MR imaging findings were confirmed by echocardiographic, angiographic and surgical findings.

Conclusion: MR imaging is excellent in depicting the details of DORV and it may obviate cardiac catheterization and angiography; it may be used in infants with DORV.

C-0913

The abdominal plain film in the newborn: How much can we obtain?

A. Bermejo, F. Ballenilla, L. Herraiz, M. Perez, M. Miralles, A. Martinez; Madrid/ES

Learning Objectives: To encourage a systematic reading of the newborn thoracoabdominal plain film in order to distinguish the normal radiological abdominal appearance from congenital or acquired abnormalities. To obtain the optimal information for accurate diagnosis and management, focused on gastrointestinal pathology.

Background: We reviewed 5,200 radiographs performed in 4,000 patients admitted to the Neonatology Department from 1998 to 2003.

Imaging Findings: Abdominal pain, distension, vomiting, mass and delayed/absent meconium passage were the usual requirements for radiological assessment. Reading of the film should include the analysis of intestinal gas pattern, solid organs, lung and diaphragms, catheter location, skeleton and soft tissues. We focused on intestinal gaseous pattern (location, distribution, bowel loop morphology, distension and wall thickening) and correlated it with symptomatology, physical exam and final clinical, surgical or pathological diagnosis. Only in 20% of the cases gas pattern distortion was secondary to organic gastrointestinal problems that required surgery. The other causes were non-surgical, systemic or extraabdominal pathology.

Conclusion: A systematic plain film analysis may lead to an accurate diagnosis in intestinal neonatal pathology and/or proper orientation for further management.

C-0914

Bronchopulmonary foregut malformations presenting as mass lesions in children

M. Kocaoglu¹, D.P. Frush², M.S. Ugurel¹, I. Somuncu¹; ¹Ankara/TR, ²Durham, NC/US

Learning Objectives: The objects of this presentation are to review the embryology, discuss the clinical presentation and to illustrate the imaging findings of bronchopulmonary foregut malformations (BFMs) presenting as mass lesions in the pediatric population. The role of the radiology in the evaluation and the management of this condition will be emphasized.

Background: The BFMs have embryologic similarities eventually involving lung parenchyma, conducting airways, vessels, or the esophagus. These malformations also may present with heterogeneous imaging features, including mass or mass-like lesions. This grouping of BFMs includes congenital cystic adenomatoid malformation, pulmonary sequestration, congenital lobar emphysema, foregut cysts, arteriovenous malformation and benign lung cysts. BFMs mostly demonstrate a single histopathology, however hybrid malformations, combination of different bronchopulmonary structures, have been reported. These disorders may manifest in various ways from incidental findings on radiography, to life threatening respiratory compromise.

Procedure Details: Imaging features of congenital cystic adenomatoid malformation, pulmonary sequestration, congenital lobar emphysema, foregut cysts, arteriovenous malformation and benign lung cyst with the hybrid malformations are discussed and appropriate imaging strategies consisting of radiography, CT, MR imaging and sonography are provided.

Conclusion: Familiarity with the presentation and imaging features of bronchopulmonary foregut malformations presenting as a congenital mass or mass-like lesion comprising is important. Moreover, imaging plays a central role in the evaluation of these lesions. Selection of the appropriate modality and technique is fundamental in this evaluation. With this, the presence and type of lesion can be defined and appropriate management determined.

C-0915

MR imaging assessment of fetal lung volume

J. Po, R.A. Barth, H. Ringertz, R. Bammer; Stanford, CA/US

Purpose: 1)To measure fetal lung volumes on MR images and quantify normal volume range. 2)To determine whether T2 signal intensity of fetal lungs correlates with development.

Methods and Materials: T2 weighted SSFSE images of 33 fetuses from 2001 to 2004 were analyzed. Regions-of-interest (ROIs) were traced around the lung parenchyma. Fetal lungs were characterized as normal ($n = 25$) and abnormal ($n = 7$) based on the radiology report. Volumes were calculated by summing the approximate volume of each slice [ROI surface area * (slice thickness + gap)]. Average total lung volume for each fetus was plotted against gestational age. A linear regression line was plotted through the normals, and 95% prediction intervals were calculated. ROIs were drawn over liver, amniotic fluid, CSF, stomach, bladder, and maternal psoas muscle to calculate lung signal intensity ratios. Signal intensity ratios were plotted against gestational age.

Results: Lung volumes were strongly correlated with gestational age. Lung volumes of 4 fetuses with thoracic abnormalities (27.7-36.3 weeks) fell outside the 95% prediction intervals defined by the normals. Lung volumes of 3 abnormal fetuses (19.4-24 weeks) fell within the intervals. Signal intensity ratios did not correlate significantly with gestational age.

Conclusion: At gestational ages greater than 25 weeks, MR imaging may distinguish abnormally developing fetuses based on lung volume. A graph of 95% prediction intervals would be a clinically useful tool to guage appropriate fetal lung

Scientific and Educational Exhibits

development. To address contradicting reports in the literature, we did not find significant evidence of lung T2 signal intensity increase with maturity.

C-0916

Incidence, clinical presentation, MR imaging and histological findings of intracranial neoplasms in children under the age of two and added utility of gadolinium in their initial diagnosis

M. Petrou, B.R. Foerster, P. Eldevik, P. Maly, P.C. Sundgren; *Ann Arbor, MI/US*

Purpose: To evaluate the incidence, clinical presentation, MR imaging findings and histology of intracranial neoplasms in children under the age of two, and to assess the added utility of gadolinium in their initial MR imaging work-up.

Materials and Methods: After completing a retrospective review of all the brain MR imaging examinations performed at our institution between 1995-2002 we concluded that the added utility of gadolinium in this set of exams is very limited. It does, however, provide valuable information in cases of newly diagnosed or known neoplastic disease. We then investigated how many exams were conducted for the initial work-up of intracranial neoplasms, and reviewed their clinical presentation and histological diagnoses.

Results: Out of a total of 1466 brain MR imaging examinations performed, only 17 were performed for initial work-up for intracranial tumors. All of these patients had significant neurological deficits and/or definite evidence of increased intracranial pressure on clinical exam. None of the patients presented with nonspecific symptoms. 11 of the 17 patients underwent a CT exam prior to MR imaging, and in all 11 cases the tumors were detected on CT. In all 17 patients, the tumors were easily identified on the MR noncontrast images, and contrast was only helpful to characterize the tumor further and assess for meningeal involvement.

Conclusions: We conclude that not using contrast for brain MR imaging in this age group would not result in a missed diagnosis of new intracranial malignancy. In the absence of significant neurological deficits, the clinical concern for an intracranial tumor can almost be excluded.

C-0917

Three-dimensional ultrasound (3DUS) of the neonatal brain: Clinical application in patients of the neonatal intensive care unit (NICU)

G.A. Fritz, M. Riccabona, H. Deutschmann, C. Weitzer, B. Resch; *Graz/AT*

Purpose: To prospectively evaluate the clinical value of 3DUS of the neonatal brain.

Methods and Materials: 60 patients from the NICU (gestational age: 25-42 weeks, mean: 31.6 weeks, age: 0 to 90 days, median: 10 days) underwent 2d- and 3d-neurosonography. Both studies were evaluated independently by two observers for comparison. Inter- and intraobserver variability was calculated.

Results: All 3DUS were of diagnostic quality and could be performed without sedation. 3DUS missed no essential diagnosis as established by 2DUS. Diagnoses included normal or physiologically immature neonatal brain sonograms ($n = 21$), plexus cysts ($n = 4$), plexus bleedings ($n = 10$), intraventricular haemorrhages grade I-III ($n = 8$), periventricular pathology such as periventricular echodensities ($n = 4$) and periventricular haemorrhages or cerebral infarctions ($n = 6$), hydrocephalus ($n = 4$), widened subdural spaces ($n = 2$) and one cerebral tumour. 3DUS imaging time (4.8 ± 2.6 min) was significantly shorter than for 2DUS (9.1 ± 6.1 min). The additional axial plane improved the sonographic potential for differential diagnosis. 3DUS allowed an improved standardisation and documentation especially valuable for follow-up. No statistically significant differences in intra- and interobserver variabilities were noted compared to 2DUS. Restrictions of 3DUS that have to be considered are the lack of duplex sonography and the lower resolution compared to conventional ultrasound.

Conclusion: 3DUS of the neonatal brain at the intensive care unit is feasible with diagnostic quality without sedation. 3DUS improves comparison during follow-up, as well as standardisation and documentation, and can be considered a useful adjunct in neonatal 2D-neurosonography.

C-0919

Spontaneous air leaks in the neonate: Imaging appearances and clinical significance

M. Raissaki, E. Drakonaki, E. Hatzidaki, C. Giannakopoulou, N. Gourtsoyiannis; *Iraklion/GR*

Learning Objectives: To underscore the occurrence and significance of spontaneous air leaks in neonates. To present and discuss the imaging features and

differences in types of air leaks in the neonatal chest radiograph. To demonstrate the complementary role of CT.

Background: Air leaks in neonates comprise pneumothorax, pneumomediastinum, pneumopericardium, pulmonary interstitial emphysema (PIE) and usually occur during assisted ventilation. Spontaneous air leaks are considered rare. During a 6-year-period, 21 neonates, (7 preterm, 14 full term), presented with respiratory distress and a pre-intubation abnormal chest radiograph, indicating an air-leak. 62 radiographs and 4 CTs were reviewed. Two neonates had undergone IPPV for 3-6 hours and were successfully extubated 12 and 24 hours prior to symptoms.

Results: Spontaneous air leaks detected were pneumomediastinum (7 patients, anterior in 6, infra-azygous in 1, coexisting with pneumothorax in 2), pneumothorax (17 neonates, in 2 bilaterally, coexisting with PIE in 3) and no case of spontaneous pneumopericardium. Perithymic lucency with/without elevation and peripheral radiolucency were the most sensitive signs for pneumomediastinum (85.7%) and pneumothorax (94.1%), respectively. Three neonates were successfully treated with oxygen therapy. A pleural tube was placed in 14 neonates and an endotracheal tube in 5. CT delineated the exact location of air, associated pressure effect and resolution.

Conclusion: Air leaks in preterm and full term neonates may occur spontaneously and are treated conservatively, or with endotracheal and/or chest tube placement. Chest radiography usually suffices for the diagnosis, especially when the thymus is outlined and/or elevated. Confusing appearances are confidently delineated with CT.

C-0920

Radiation dose and image quality in neonatal radiography

E. Dougeni¹, H. Delis¹, A. Karatza¹, C. Kalogeropoulou¹, S. Skiadopoulos¹, G. Malatara¹, E. Efstatopoulos², G. Panayiotakis¹; ¹Patras/GR, ²Athens/GR

Purpose: Neonates, especially the premature, frequently undergo a large number of chest and abdominal radiographs during the first days of their life. Their increased radiosensitivity, due to the highly mitotic state of their cells, plus their longer life expectancy, highlight the importance of minimizing dose while maintaining diagnostically acceptable imaging. A study of radiation dosimetry and image quality carried out in the Special Baby Care Unit of the University Hospital of Patras is presented.

Methods and Materials: Neonates were categorized depending on their birth-weight into 4 groups. Exposure parameters (kVp, mAs, field size) of 190 radiographs, performed with the same mobile unit, were recorded. Entrance Surface Dose (ESD) was estimated and Dose-Area Product (DAP) was measured directly. Interpretation of the images was performed by two independent observers in random order, based on the visibility of certain anatomical features and catheters, assessed in a 5-grade scale.

Results: ESD values increased with weight and ranged from 15.2 to 60.3 μ Gy. DAP measurements also demonstrated a wide variation among groups, from 0.23 to 0.92 μ Gym². The evaluation of image quality revealed the feasibility of achieving a high total image quality score, using both low and high kVp techniques.

Conclusion: The majority of the ESD values were below the dose reference levels proposed by the National Radiological Protection Board. However the results show that use of high kVp techniques could result in further reduction in neonatal dose, without degrading image quality. Wide dose variations highlight the need for developing examination protocols for neonatal radiography.

C-0921

Incomplete obliteration of canal of Nuck and processus vaginalis:

Sonographic diagnosis with embryological correlation

M. Vakaki, G. Pitsoulakis, C. Kosmas, P. Christopoulos, C. Koumanidou; *Athens/GR*

Purpose: Failure of complete closure of processus vaginalis (PV) (males) or canal of Nuck (females) during fetal life results in a spectrum of abnormalities. The purpose of this study was to evaluate the role of sonography in the diagnosis and differentiation of the various abnormalities, to highlight the clinical significance of the prompt and proper sonographic diagnosis and to correlate the sonographic findings with embryology.

Methods and Materials: The medical data of 161 boys (1 day to 14 years) and 6 girls (20 days to 14 years) with abnormal closure of the PV or canal of Nuck, respectively, were reviewed. The children were examined due to painful/painless, inguinal/inguinoscrotal swelling, without known underlying disease. Sonographic examination of the inguinal and scrotal areas was performed with high-frequency transducers, supplemented by color Doppler and abdominal sonogram, when necessary.

Scientific and Educational Exhibits

Results: The sonographic examination of the boys revealed: 30 communicating hydroceles, 14 incarcerated and 28 non-incarcerated inguinal/inguinoscrotal hernias, 43 testicular hydroceles, 13 funicular spermatic cord hydroceles and 33 encysted spermatic cord hydroceles. The sonographic examination of the girls showed: 3 noncarcerated inguinal hernias, involving bowel loops and the ipsilateral ovary, one case of ovarian inguinal herniation and 2 Nuck cysts. The embryology, sonographic patterns and sonographic differential diagnoses are presented. **Conclusion:** Sonography is the imaging method of choice in the diagnosis of all types of PV or Nuck canal abnormal closure. To the best of our knowledge, they represent rare and little-known developmental disorders. The pediatric radiologist's awareness is essential for an accurate sonographic diagnosis and determination of timely appropriate management.

C-0922

CT multislice in pediatric tracheopulmonary malformations

V. Buffa, M. Galluzzo, G. Regine, M. Atzori, V. Miele, L. Adami; Rome/IT

Purpose: To evaluate the usefulness and potential of multislice CT (MSCT) in the diagnosis and preoperative evaluation of pediatric tracheobronchopulmonary malformations.

Methods and Materials: 12 children (8:4 m/f, 2-15 months) with tracheomalacia (7 cases), pulmonary sequestration (3), adenomatoid cystic malformation (2) were studied with an 8-channel multislice CT (LightSpeed Ultra, GE, USA) using i.v. contrast media (slice thickness 1.25 mm, reconstruction interval 0.6 mm, 100 kV, 80 mA). Image processing was performed with an Advantage 4.1 workstation (GE, USA). Multiplanar and 3D images were related to bronchoscopy and surgery. **Results:** All cases of focal areas of tracheal stenosis/compression were diagnosed with accurate demonstration of vascular malformations. In pulmonary sequestration MSCT depicted abnormal vessels allowing differential diagnosis with adenomatoid cystic malformations. The procedure was fast, non-invasive and without complications.

Conclusion: MSCT is highly accurate for the detection and characterization of pediatric tracheopulmonary malformations, depicting the anatomical details relevant for surgery.

C-0923

The application of high frequency sonography in the diagnosis and monitoring of inflammatory bowel disease in children

U. Zaleska-Dorobisz, A. Stawarski, T. Pytrus, F. Iwanczak, K. Moron; Wroclaw/PL

Purpose: To present the usefulness of high frequency standard and color Doppler sonography in the diagnosis and therapy monitoring of nonspecific inflammatory bowel diseases (IBD) in children.

Methods and Materials: We studied 48 boys and 40 girls with nonspecific IBD: 35 with Crohns disease (CD), 37 with ulcerative colitis (UC), 16 with other non-specific IBD. We performed high resolution 2D sonography to evaluate the bowel wall thickness. Vascularity was assessed with color Doppler. The superior and inferior mesenteric artery flow; mean velocity, RI and PI were measured. We correlated with the clinical activity of the disease, colonoscopy and histology.

Results: CD predominantly involved the small intestine. The bowel wall was greatly thickened more than 8-10 mm. Mucosal ulcerations penetrated into the wall in 22 children, in 11 we found fistulas and peritoneal abscesses. The mesentery and fat around the bowel was thickened in all children. UC was limited to the left colon. The colon wall was thickened more than 5-9 mm. Mural inflammation was located on the mucosal surface with superficial ulceration and pseudopolyps (45%). Color Doppler revealed hyperemia with increased vascularity of the involved bowel wall. The RI and PI were significantly lower in active disease. After treatment RI and PI values increased significantly ($p < 0.005$).

Conclusions: High resolution and Doppler sonography is able to detect bowel wall abnormalities of most IBD in children. Doppler flow parameters in mesenteric arteries correlated strongly with disease activity. Doppler US could be used for monitoring treatment efficacy.

C-0924

Imaging evaluation of paediatric thoracic cystic lesions

V.M.V.T. Mascarenhas, L. Lobo, J. Fonseca-Santos; Lisbon/PT

Learning Objectives: To describe the imaging features of paediatric cystic thoracic lesions (CTL) and outline their main differential diagnostic pitfalls. To emphasise the role of imaging evaluation in treatment and guiding follow-up.

Background: CTL (defined as either fluid- or air-filled spaces separated from normal lung by an identifiable boundary) are common incidental or pathological

findings in the pediatric age group. A more precise diagnosis is essential to an adequate orientation in treatment and follow-up. In this regard, imaging evaluation particularly with chest radiography, sonography (especially in younger patients) and CT as the main techniques, undertake a pivotal role. We describe diagnostic imaging features, differential diagnosis problems and a systematic age-dependent framework approach to CTL among selected cases studied in our department.

Imaging Findings: Referred cases were reviewed based on age as the main factor, location (including single/multiple and uni/bilateral lesions) and morphological features. The main diagnostic entities considered were congenital lesions presenting in the newborn (congenital diaphragmatic hernia; cystic adenomatoid malformation; sequestration; congenital lobar overinflation and lymphangioma) or after the newborn period (parenchymal, bronchogenic and thymic cysts) and acquired lesions presenting in the perinatal period (pulmonary interstitial emphysema; bronchopulmonary dysplasia) or in children/young adults (pneumatoceles; abscess; systemic diseases).

Conclusion: Although there is a wide range of entities presenting as CTL in infants and children, a framework based on an age-dependent algorithm allows a more precise diagnosis or at least a considerable narrowing of diagnostic possibilities in the majority of cases, which is essential for therapeutic orientation.

C-0925

Parenchymal cyst-like lesions in tuberous sclerosis

C. Eun, Y.-W. Kim, S. Choi, S. Lee; Busan/KR

Purpose: To investigate the presence of small cyst-like lesions in the cerebral white matter on MR imaging of patients with tuberous sclerosis.

Methods and Materials: MR images were reviewed retrospectively in 15 patients in whom a clinical diagnosis of tuberous sclerosis had been made during the past 5 years. The incidence, MR findings, and possible pathogenesis of cyst-like lesions of the white matter were evaluated.

Results: Cyst-like lesions in the cerebral white matter were found in three of the 15 patients. The signal intensity of these lesions was isointense with CSF on T1-, T2-, and FLAIR sequences. The cystic lesions ranged in number from 1 to 6 per patient and were usually 1 to 2 cm.

Conclusion: Cyst-like lesions in the cerebral white matter were seen on the MR images of 20% of 15 patients with tuberous sclerosis. Cystic lesions are a rare but typical cerebral manifestation of tuberous sclerosis and tuberous sclerosis should be taken into consideration in patients with such lesions.

C-0926

Proton MR spectroscopy and MR imaging in childhood hypomyelinating disorders

K.M. Koprivsek, M. Spirovski, D. Kozic, R. Semnic, M. Lucic, N. Prvulovic, J. Ostojic; Sremska Kamenica/YU

Purpose: Hypomyelinating disorders (HD) are rare childhood leucoencephalopathies, characterized by a permanent deficit in myelin deposition in the brain. The purpose of our study was to define possible MR imaging and spectroscopy patterns, which could help distinguish subtypes of HD and HD from other leucoencephalopathic forms.

Methods and Materials: We have examined 42 children, at a 1.5 T unit, with suspected leucoencephalopathies, as well as 30 age-matched controls. HD was suspected in 12/42 children. After conventional brain MR imaging and single-voxel proton-MRS (SE135/STEAM20), patients were divided into subgroups according to biochemical profiles and predominant features of white matter abnormalities. Corresponding laboratory/clinical data were matched and reviewed. The correlation between MR and clinical diagnosis was tested by Spearman-rank test.

Results: Pathological MR imaging/MRS findings were detected in 34/42 patients. Six children had normal brain MR imaging with abnormal biochemical profiles. In 2/42 MRS were normal, despite diffuse pathology detected on MR imaging. In HD-group MR imaging demonstrates: cerebral/cerebellar atrophy (9 and 6 pts), white matter lesion (diffuse 4, supra- and infratentorial 12 and 4 pts, respectively), capsula interna abnormalities (2 pts) and basal ganglia lesion (3 pts). Corresponding MRS revealed: normal findings (2/12), decrease in all metabolites (2/12), mild elevation of myoinositol and creatine levels (6/12). Using detected MR imaging/MRS patterns we made final MR diagnoses for the HD-group: Pelizaeus-Merzbacher disease (2 pts), Salla disease (2 pts), H-ABC-syndrome (4 pts), Cockayne-syndrome (1 pts) and unknown origin (3 pts). Spearman-rank value confirmed correlation between MR and clinical diagnoses ($P < 0.05$).

Conclusion: MR imaging combined with MR spectroscopy can facilitate the diagnosis of HD. Detectable pattern could be specific for some subtypes.

Imaging of disorders involving the stomach in pediatric patients: A pictorial review

A. Álvarez Luque, T. Berrocal, L. de Pablo, J. Gutiérrez, L. Martín, N. Gómez León; Madrid/ES

Learning Objectives: To understand the embryology, pathology, and imaging features of a wide spectrum of congenital and acquired alterations involving the stomach in children. To understand the utility of each imaging modality that can be applied to the management of these conditions. To emphasise pitfalls and differential diagnoses of these entities.

Background: Congenital and acquired disorders affecting the stomach are a significant cause of morbidity in infants and children, frequently requiring multiple imaging modalities to diagnose and plan treatment. This teaching exhibit analyses and illustrates practical aspects of a wide spectrum of usual, unusual, and exceptional disorders affecting the stomach, with particular emphasis on radiological manifestations. The efficacy of the different imaging modalities in the diagnosis and management of these conditions will be evaluated.

Imaging Findings: Specific topics addressed include congenital and developmental abnormalities (pyloric atresia, microgastria, antral web, situs inversus, diverticula, duplication cysts, ectopic pancreas in the gastric antrum), volvulus, hypertrophic pyloric stenosis, inflammatory diseases (gastric ulcer, eosinophilic gastroenteritis, Menetrier disease, gastric tuberculosis, gastric involvement in chronic granulomatous disease, emphysematous gastritis, corrosive gastritis), Zollinger-Ellison syndrome, foreign bodies, bezoars, varices, hernias, benign tumors (hamartoma, adenoma, teratoma, hemangioma and lipoma); malignant tumors (leiomyosarcoma, leiomyoblastoma, stromal tumor, lymphoma), and postsurgical complications.

Conclusion: This exhibit provides an overview of the pathological processes affecting the stomach in pediatric patients as well as the utility of the various imaging techniques available. Because many of these disorders have a characteristic appearance, this exhibit will help the practising radiologist to better understand and recognise these entities.

C-0928

Pediatric urolithiasis: High-resolution sonography and clinical review

V. Garriga, N. Roson, S. Medrano, M. Zarcero, X. Pruna, M. Cuadrado, A. Marin, S. Carbó, S. Vizcaya, M. Català; Granollers-Barcelona/ES

Learning Objectives: To describe high-resolution sonography (HRUS) of pediatric renal stone disease including nephrolithiasis and nephrocalcinosis. To emphasize the usefulness of high-resolution sonography in the evaluation of underlying cortical or urinary tract abnormalities, complications and follow-up of renal stone disease. To review the anatomical, clinical and epidemiological factors in pediatric urolithiasis.

Background: Urolithiasis is usually considered a disease of adults, but it certainly occurs in the pediatric age group. The clinical presentation in children differs from the acute renal colic in adult, being less specific and difficult to identify. In addition, the increase in our immigrant population has lead to a high prevalence of the disease. On the other hand, unenhanced computed tomography has been widely used to demonstrate renal stone disease, but the high radiation dose, higher cost and sedation are still disadvantages when studying children.

Procedure Details: We performed a retrospective review of all pediatric sonographic studies with urolithiasis. Description of size, location, number of lithiasis, urinary tract abnormalities or signs of infection were recorded. Clinical, analytical and epidemiological data were reviewed in each patient. Later complications and follow-up studies were also analyzed.

Conclusion: The HRUS is able to well characterize lithiasis, to detect its association with anomalies of urinary tract, and to follow-up calculus disease. This non-invasive technique may avoid the use of CT, especially in young children and those with greater risk of recurrence. The HRUS of a child with urolithiasis gives not only diagnostic information but also defines the medical or surgical management of the patient.

C-0929

Ultrasonographic measurements of the adrenal and thyroid dimensions and their correlation with length, gestational age and birth weight of healthy neonates

F. Golpinar, C. Ozer, M. Nass Duce, A.H. Turhan, T. Akbas, G. Sert, E. Kara, A. Atici; Mersin/TR

Purpose: The aim of this study is to create normal standards by measuring the dimensions of the thyroid and adrenal glands in healthy newborns and to correlate these measurements with their gestational age, birth weight and height.

Methods and Materials: The dimensions of thyroid and adrenal glands of 218 healthy newborns were measured. The transverse dimension of the isthmus and transverse, sagittal and anteroposterior dimensions of the two lobes were noted. Then, the volume of each lobe was calculated. Two dimensions for each adrenal gland were measured. The newborns were classified into thirteen groups according to their gestational ages, four groups according to their height and six groups according to their weight. The thyroid volumes, dimensions of thyroid glands and dimensions of adrenal glands were correlated with each of these parameters.

Results: The mean value of the right thyroid lobe was 238 mm³, that of the left lobe was 222 mm³. The length and thickness of the right and left adrenal glands were 12.2 mm and 2.6 mm; 11.3 mm and 2.33 mm, respectively. There was a positive correlation between thyroid volume and length, gestational age and birth weight, but we could not find any correlation between adrenal measurements and these parameters.

Conclusion: Evaluation of dimensions is as important as hormone levels in diagnosing disorders of the thyroid and adrenal glands. It is thus crucial to correlate the average volumes and dimensions with length, gestational age and birth weight of newborns.

C-0930

Prenatal fetal lung volume measurement using magnetic resonance imaging (MRI) in pairs of twins with congenital diaphragmatic hernia (CDH)

A.K. Kilian, M. Schröder, T. Schaible, C. Düber, K.W. Neff; Mannheim/DE

Purpose: To compare fetal lung volume (FLV) based on magnetic resonance imaging (MRI) in healthy and affected twins with congenital diaphragmatic hernia (CDH).

Methods and Materials: Three pairs of twins with CDH in one fetus of each pair and 11 age-matched normal control fetuses were evaluated using prenatal fetal MR imaging at 34 weeks gestation. MRI was performed on a 1.5 T Magnetom Sonata (Siemens, Erlangen, Germany). Diagnosis of CDH and FLV evaluation was based on T2-weighted HASTE imaging in coronal, transverse and sagittal direction. FLV of the affected and the healthy fetuses was calculated by semiautomatic segmentation of the fetal lungs followed by 3D volumetry.

Results: MRI confirmed the diagnosis of CDH in one fetus of each pair, all left-sided. All three affected twins showed significant reduction of FLV compared to the healthy twin. FLV was found to be 12.5 ml for the affected twin and 56.2 ml for the healthy twin for the first pair of twins, 15.4 ml (twin with CDH) vs. 55.3 ml (healthy twin) for the second pair of twins and 13.2 ml (CDH) vs. 49.1 ml (healthy) for the third pair of twins. Age-matched normal control fetuses demonstrated a mean FLV of 65.6 ± 16.9 ml at 34 weeks gestation.

Conclusion: MRI fetal lung volume measurement of twins with CDH offers the most effective correlation between lung volumes of healthy children and children with CDH because of the very similar conditions. The FLV of healthy twins is also reduced compared to normal controls.

C-0931

CT findings of non-odontogenic tumors of the jaw in childhood

M. Hasiotou, E. Manoli, M. Ioannidou, M. Zarifi, E. Evangelidakis; Athens/GR

Purpose: Tumors of the bones of the jaw are classified as odontogenic and non-odontogenic. The latter are additionally characterized as benign or malignant depending on their mitotic and pathological behavior. This study intends to demonstrate the CT imaging characteristics of non-odontogenic tumors of the mandible and the maxilla in children.

Methods and Materials: We retrospectively studied the CT examinations of 31 children (20 females and 11 males) aged 3 to 15 years that were examined in our department. The underlying disease was histologically confirmed in all cases; Langerhan's cell Histiocytosis (7), non-Hodgkin's lymphoma (6), acute lymphoblastic leukemia (1), fibrous dysplasia (5), metastatic neuroblastoma (3), osteosarcoma (2), aneurismal bone cyst (2), hemangioma (2), Ewing sarcoma (1), primitive neuroectodermal tumor (1), osteoma (1).

Results: The radiological CT findings were described according to the site (mandible, maxilla), the type of the bone lesion (lytic, osteoblastic, periosteal reaction, cortical disruption, internal diaphragms) and the participation of the adjacent soft tissues (soft tissue mass, "floating" teeth) and finally correlated to the histological reports.

Conclusion: Today's modern imaging modalities provide important information about not only the type of a mass lesion in the jaw, but also useful details concerning the extent of the disease and the potential invasion in surrounding soft tissues. This becomes a major advantage when referring to children given the exceptional difficulty in the performance of diagnostic biopsy sampling.

Scientific and Educational Exhibits

C-0932

Abdominal sonographic examination in the pediatric emergency room and incidental findings

M. Vakaki, G. Pitsoulakis, V. Dermentzoglou, C. Kosmas, C. Koumanidou; Athens/GR

Purpose: Sonography is the initial imaging method of choice in almost every acute abdominal problem in childhood. It usually provides valuable diagnostic information. Rarely, however, the sonographic findings are unexpected and significant for the child's health or even life. The purpose of this retrospective study was to determine the prevalence and significance of incidental findings detected on the abdominal sonogram for trauma and acute abdominal pain.

Methods and Materials: During a 6-year period, 6124 sonograms were performed in our radiology department in children with blunt abdominal trauma or acute abdominal pain of unknown aetiology. Those in which incidental findings had been recorded were assessed.

Results: Incidental findings were detected in 257 (4%) cases. Some were benign requiring further investigation and others more serious or even malignant: 8 hepatomegalias, 68 splenomegalias, 20 hyperechogenic livers, 16 cholelithiasis, 3 situs inversus, 4 renal ageneses, 5 renal ectopies, 6 significantly small kidneys, 6 horseshoe kidneys, 8 nephrolithiasis, 4 dilatations of the renal collecting systems, 4 renal cysts, 5 multicystic dysplastic kidneys, 4 autosomal recessive kidney disease, 40 simple or hemorrhagic ovarian cysts, 4 ovarian teratomas, 3 uteri didelphys associated with unilateral renal agenesis, 8 enteric duplication cysts, 3 mesenteric cysts, 1 cystic teratoma, 1 splenic dermoid cyst, 18 nephroblastomas (one associated with contralateral nephroblastomatosis), 14 neuroblastomas and 2 with hepatic metastases and 1 hepatoblastoma.

Conclusion: In the emergency setting the pediatric radiologist has to be particularly careful in order to avoid missing a significant diagnosis which may have important implications for the young patient.

C-0933

Soft tissue swelling of the hand or foot in childhood: The role of sonography

M. Vakaki, G. Pitsoulakis, V. Dermentzoglou, M. Tsianta, E. Emmanouil, C. Koumanidou; Athens/GR

Purpose: Soft-tissue swelling of the wrist, hand, ankle or foot, except in the case of trauma, represents an uncommon pediatric clinical problem. Until recently the imaging approach was not easy as the plain radiograph is not usually diagnostic. MR imaging is unsuitable as the routine imaging method due to the need for sedation and the high cost. The aim of our study is to present the role of sonography in the imaging investigation of this clinical problem.

Methods and Materials: 35 children (44 days to 14 years old) were sonographically examined due to wrist/hand/ankle/foot soft-tissue swelling. The clinical history and presentation varied. Children with a recent history of fall or trauma were excluded. The sonographic examination (gray-scale/color Doppler) was performed with high-frequency transducers.

Results: The sonographic findings included: periarticular ganglions (n = 8), tendon sheath ganglions (n = 4), tendinitis (n = 1), tenosynovitis (n = 4), bursitis (n = 2), coexistence of periarticular ganglion and neurofibroma (n = 1), cystic lymphangioma (n = 2), hemangioma (n = 4), neurofibroma (n = 3), foreign bodies (n = 4). Sonographic appearances were more or less characteristic. In 2 children a solid soft-tissue mass with non-specific features was sonographically depicted. CT and MR imaging followed. Histological examination established the diagnosis of benign xanthoma and malignant sarcoma, respectively. All remaining cases were confirmed surgically or by clinical follow-up.

Conclusion: The well-known advantages of sonography are of utmost importance during childhood. Nowadays, with high-definition modern equipment, the sonogram can provide an accurate diagnosis in the majority of hand/foot soft-tissue swellings, indicating the proper management. Further imaging investigation (plain radiograph, CT or/and MRI) should be performed only in selected cases with negative or indeterminate sonographic findings.

C-0934

Imaging evaluation of pediatric patients with peritoneal malignancies

G. Pitsoulakis, M. Vakaki, M. Zarifi, C. Hadjigeorgi, M. Xasiotou, I. Nikas, N. Evlogias; Athens/GR

Purpose: Peritoneal involvement by malignancy is rare in childhood and its spectrum is different from that in adulthood. The aim of this study is to present the imaging findings (US, CT, MR) in a variety of different cases of peritoneal malignancy.

Methods and Materials: The radiological studies (US, CT, MR) of 21 patients,

aged 1 month to 13 years, with peritoneal malignancies were retrospectively evaluated.

Results: The US, CT and MR appearances of 7 cases of leukemia, 5 cases of lymphoma (4 of them Burkitt's lymphoma), 3 cases of histiocytosis, 2 cases of intraabdominal desmoplastic small cell tumor, 2 cases of neuroblastoma gr IV, one case of congenital rhabdomyosarcoma and, finally one case of intraperitoneal metastases of a malignant rhabdoid tumor. All the above cases were histologically confirmed. The differential diagnosis and the characteristic findings are discussed.

Conclusion: Although rare and, in the majority without specific imaging features, most cases of peritoneal malignancy allow a narrow differential diagnosis, as long as the pediatric radiologist is aware of their existence and their imaging findings.

C-0935

Atypical presentations of pediatric osteomyelitis

N. Ruscalleda, R. Huguet, J. Ribo, J. Blanch, A. Capdevila; Esplugues de Ll./ES

Purpose: This pictorial essay shows some cases of pediatric osteomyelitis observed in our radiology department in which diagnosis proved to be difficult. We also describe some changing aspects related to the diagnostic approach.

Methods and Materials: Over the past ten years, we have diagnosed 152 cases of osteomyelitis; these have been subject to different imaging and microbiological techniques.

Results: Although pediatric osteomyelitis is usually located in long bones, we have observed an increase in the number of cases of osteomyelitis located in axial skeletal and small bones. Of the 152 cases 41 of were located in axial skeletal or small bones and 15 were multicentric. Although in the majority of cases the presentation is acute, we also observed an increase in the number of subacute forms in which clinical diagnosis is more difficult. This could be associated with an increase in atypical pathogens such as *Kingella kingae*.

Conclusion: Osteomyelitis is a serious disease that requires swift diagnosis in order to prevent or minimize consequences. The typical appearances of pediatric osteomyelitis in different imaging techniques is well established and diagnosis is therefore usually simple. However, there are some cases that are extremely difficult to differentiate from other entities.

C-0936

Utility of the posterior fontanelle approach in cranial sonography

R.M. Lorente-Ramos, Y. del Valle-Sanz, M.J. Alcaraz-Mexía; Madrid/ES

Purpose: To assess the utility of adding posterior fontanelle imaging to the anterior fontanelle approach in routine neonatal cranial sonography.

Methods and Materials: From 20th February to 30th June 2004, 136 consecutive transcranial sonograms were performed in 90 newborn patients. All patients underwent a US study within 72 hours from birth and follow-up sonograms were performed when needed. The sonographic sections were obtained, first through the anterior fontanelle in coronal, sagittal and oblique planes, and then through the posterior fontanelle when it was possible or otherwise through the posterior region of the sagittal suture, in sagittal, axial and oblique planes.

Results: We performed 1 sonogram in 69 patients, 2 sonograms in 12 patients, 3 in 5 patients, 6 in 2 and 12 in 1 patient. Low-birth-weight was the most frequent indication for sonography with 10 patients weighing less than 1500 g. Thirty-four sonograms were abnormal in 21 patients. In 19 patients findings were similar both with anterior and posterior fontanelle imaging (one primary choroid plexus hemorrhage, one posterior fossa cyst, one extensive intraparenchymal hemorrhage, and periventricular hyperechogenicity in 16 patients). In two patients hemorrhages within choroid plexus were suspected at anterior fontanelle views and lobular choroid plexus were diagnosed with posterior fontanelle imaging. In normal sonograms posterior fossa structures were better depicted through the posterior fontanelle.

Conclusion: Although our preliminary results do not support routine examination through the posterior fontanelle it is useful in selected cases as a complementary tool and helps in depicting posterior fossa structures.

Superficial melanoma and its metastases in the eyes of skin electrophysiological imaging (SEI)

Y.F. Babich, M.A. Nuzhdina; Kiev/UA

Purpose: A new functional imaging modality SEI enables non-invasive dynamic imaging of skin and underlying tissues in a complex of electrophysiological parameters. Our current work consists in lab-clinical investigation of the Skin Electrical Landscape' (SEL) dynamics in normals and pathology with the purpose of finding out early distinguishing features between malignant and benign lesions at the background of normal SEL.

Methods and Materials: SEI enables to monitor the SEL simultaneously in 6 electrical parameters. Proliferating nevus (7) and nodal melanoma (6) were chosen as model objects of investigation. In order to bring to light functional heterogeneities of the imaging region, non-thermal millimeter EMF (1 min, 0.5 mcW/sq.sm) and static MF (1+1 min of reversed orientation, ~20 mT) were used as stimulant factors. Through -SEL-frame-sequence-analysis resulted in detailed dispersion maps (DM). Subsequent phase plane analysis was applied to the distinctive DM points.

Results: New phenomena of the SEL dynamics have been discovered, specifically: Its spontaneous cluster character, which appeared to be noticeably correlated with the skin lesions' topology; hyperactive zones at the visible melanoma boundary; multilevel quasi-stationary character of the SEL abnormal points; high-speed MF-induced processes (presumably of enzyme origin). The SEL analysis revealed detailed, visually indistinguishable, pattern of primary melanoma, which was confirmed histologically. Remote (invisible) areas with similar SEL characteristics were determined.

Conclusion: SEI seemingly enables detailed metabolic mapping and monitoring of superficial tumours and their invisible metastases but further joint research with the additional use of appropriate functional imaging modalities is needed.

C-0940

Synchrotron radiation microangiographic imaging of tumor-derived blood vessels in rabbit model of cancer for observation of angiogenic activity

K. Umetani¹, M. Kobatake², A. Yamamoto², T. Yamashita², S. Imai², Y. Kajihara²,
¹Sayo-gun, Hyogo/JP, ²Kurashiki-shi, Okayama/JP

Purpose: To investigate the microangioarchitecture of tumor-derived angiogenic vessels, in vivo imaging experiments were carried out for depicting small blood vessels in a VX2 carcinoma transplanted into a rabbit auricle.

Methods and Materials: A microangiography system with spatial resolution in the micrometer range was developed using a high-resolution detector and a third generation synchrotron radiation source at SPring-8. Monochromatic synchrotron radiation X-rays transmitted through an object were detected by the X-ray direct-conversion type detector incorporating the X-ray SATICON pickup tube. In two real-time imaging modes, input fields of view were 9.5 mmx9.5 mm and 4.5 mmx4.5 mm, and pixel sizes were 9.5 and 4.5 microns in the case of the 1024x1024-pixel format, respectively.

Results: After contrast agent injection to the auricular artery, the microangiography system could provide images of immature vascular networks in the malignant tumor transplanted into the rabbit auricle. Small blood vessels of around 10 microns in diameter and the distribution of abnormal staining were observed and analyzed for the prediction of the level of angiogenic activity.

Conclusion: The microangiography system using the nearly parallel synchrotron radiation beam presents advantages over light microscopes for clarifying internal angioarchitecture of centimeter-sized objects with spatial resolution in the micrometer range. Using the imaging system, anti-angiogenic responses in preclinical drug testing can be assessed by observing changes in the angioarchitecture and perfusion characteristics of the tumor in animal studies.

C-0941

Age and gender related differences of adipose tissue compartments:

A whole body MR imaging study

J. Machann, C. Thamer, B. Schnödt, H.-U. Häring, C.D. Claussen, A. Fritzsche, F. Schick; Tübingen/DE

Purpose: Quantification of all major adipose tissue compartments by MR imaging in a large cohort of healthy volunteers at an increased risk for type 2 diabetes. Analysis of body fat distribution with respect to gender and age and metabolic data.

Methods and Materials: One hundred and thirty healthy volunteers (80 females, 19-69 years, 50 males, 21-65 years) underwent whole body MR imaging on a 1.5 T whole body unit (Magnetom Sonata, Siemens). A T1-weighted fast spin-echo technique was applied for fat-water discrimination. Parameters: TE/TR 12 ms/490 ms, slice thickness 10 mm, interslice gap 10 mm, acquisition time 12 s. Post-processing: segmentation of adipose tissue (AT) and quantification of total (TAT), subcutaneous (SCAT) and visceral adipose tissue (VAT). Determination of insulin sensitivity (ISI) by glucose clamp.

Results: Females are characterized by significant higher%TAT compared to males (f:33.5 ± 7.4%, m:22.8 ± 5.7%, p < 0.0001). On the other hand,%VAT is significantly higher in males (f:2.3 ± 1.0%, m:3.8 ± 1.3%). Furthermore,%VAT significantly increases with age in both gender groups (p < 0.001) whereas the other AT compartments are nearly unchanged (n.s.). ISI shows strong correlations with%VAT in both gender groups, but is independent on age (n.s.) in our study population.

Conclusion: Reliable quantification of different adipose tissue compartments in the human body is possible by common MR techniques. Especially the amount of visceral adipose tissue which is thought to be directly involved in the pathogenesis of insulin resistance markedly depends on gender and age. Those dependencies must be considered in cross-sectional metabolic studies. Supported by a grant of the Deutsche Forschungsgemeinschaft (DFG, KFO 114/1).

C-0942

An elastic registration scheme for the alignment of thoracic CT data of patients with stage III non-small cell lung cancer during radiotherapy treatment

G. Matsopoulos¹, V.E. Kouloulias², N. Mouravliansky¹, P. Asvestas¹, K. Delibasis¹, N. Uzunoglu¹, A. Kelekis², N. Kelekis², ¹Athens/GR, ²Xaidari/GR

Purpose: The establishment of an automatic three-dimensional (3D) non-rigid registration scheme for the alignment of thoracic computed tomography (CT) data of patients with stage III non-small cell lung cancer (NSCLC) during radiotherapy.

Methods and Materials: Initially anatomical set of points are automatically segmented slice by slice from the two CT scans of the same patient in order to serve as interpolant points. A rigid-body transformation is then applied to provide a pre-registration of the data. The novel application of the Self Organizing Maps (SOMs) is adopted. Then, Radial Basis Functions (RBFs) using the shifted log function is subsequently employed for elastic warping of the image volumes. Fifteen patients have been selected in this study having lung tumors and undergoing radiotherapy treatment.

Results: All CT data has been successfully registered by the proposed methodology as it has been revealed by detailed observation of the results by experienced radiologists. The proposed elastic registration scheme resulted in an average accuracy of around 6 mm against a surface-based registration method resulting an average accuracy of around 11 mm.

Conclusions: An automatic elastic registration scheme is proposed applied on thoracic CT data of patients diagnosed with NSCLC. The scheme can recover deformations occurred due to inspiration and/or any physiological movements during acquisition. This scheme could provide objective measurements of target volumes during radiotherapy treatment planning.

C-0943

Monte Carlo study on radiation absorption properties of Gd2O2S, CsI, LSO, CaWO4 phosphor screens for mammographic X-ray imaging

P. Liaparinos¹, I. Kandarakis², D. Cavouras², D. Nikolopoulos², G. Panayiotakis¹,
¹Patras/GR, ²Athens/GR

Purpose: The quantum detection efficiency (QDE) of the most commonly used CaWO4, Gd2O2S, CsI phosphor screens was compared with the recently introduced high efficiency Lu2SiO5 (LSO) powder scintillating phosphor under mammographic conditions using Monte Carlo methods.

Methods and Materials: A Monte Carlo program was developed for the simulation of X-ray interactions within the aforementioned phosphor materials in order to investigate their efficiency to detect radiation. Radiation absorption properties of phosphor screens were examined assuming molybdenum spectrum X-ray beam in the tube voltage range 20-30 kV. Phosphor coating thickness was chosen to vary from 25 up to 35 mg/cm². X-ray spectra and mass attenuation coefficients were taken from published tabulated data. A large number of photons (107 histories) were applied giving a statistical error less than 0.5%.

Results: Results obtained from Monte Carlo simulation showed that CsI exhibits highest radiation absorption properties in the whole voltage and thickness range. The detection efficiency of 30 mg/cm² CsI screen was found to vary from 93% down to 78% in the range of tube voltages from 20 kVp up to 30 kVp. For a corre-

Scientific and Educational Exhibits

sponding LSO screen the detection efficiency was found to vary from 78% down to 62%.

Conclusion: Considering the intrinsic columnar structure of CsI crystals which reduces light spreading and improves image resolution, CsI is significantly better to mammographic imaging systems although it has lower effective atomic number and density than LSO as well as than Gd₂O₂S, CaWO₄. Acknowledgments: This work was financially supported by EPEAEK program 'Archimidis'.

C-0944

Influence of rib structure on detection of subtle lung nodules

M. Ikeda, T. Ishigaki, S. Itoh; Nagoya/JP

Purpose: To access the influence of anatomic noise on the detectability of subtle lung nodules depicted on chest radiographs, focusing on the relationship between rib structures and nodule positions.

Methods and Materials: From the normal chest radiography images, 132 square regions were extracted, and the centers of these square images were on the upper margin of a rib, the inside of a rib, the lower margin of a rib and the central region between two adjoining ribs. Simulated nodules were digitally superimposed on the centers of these extracted square images. 12 radiologists viewed 50 soft-copy images including these 792 processed images, including the noise-added images. The observer's confidence level for the nodule-added square image was used as an index of observer performance.

Results: Results indicated a statistically significant effect of the relationship between rib structures and nodule positions on the detection performance ($P < 0.001$). The nodule detectability on the images with a center located between two adjoining ribs was significantly the best, whereas it was significantly the worst on the noise-added images with a center located between two adjoining ribs. Further, the detectability of the nodules located on ribs showed a tendency to decrease in the order of the upper margin, the inside and the lower margin of a rib. However, these differences were small.

Conclusion: The rib structure overlying a subtle lung nodule on chest X-ray images will have a detrimental effect on nodule detection performance as anatomic noise, regardless of the nodule location on ribs.

C-0945

Tutorial on physical principles of MR imaging: Spin behavior study

L. Chaustre-Mendoza, D. Moratal-Pérez, L. Martí-Bonmatí, Y. Flórez-Ordóñez, J. Millet-Roig; Valencia/ES

Learning Objectives: This tutorial shows to radiologists the spin behavior in the presence of a magnetic field and under the excitation of a RF pulse. It graphically animates and displays the precession movement of the spins and their behavior in a slice under the application of phase and frequency encoding gradients.

Background: The spin precession of the nucleus around its own axis acts as a small magnetic moment that behaves as a magnet. After applying an external main magnetic field, the small magnetic moment tends to align with it describing a precession movement. The encoding gradients generate a variation of the main field based on the position.

Procedure Details: The graphical user interface was developed under MATLAB 6.5. First, the user chooses some input parameters (main magnetic field strength, type of nucleus, applied RF excitation pulse flip angle). Then, the user will observe the precession movement of the selected nucleus and the amplitudes of the longitudinal and transverse magnetizations during the relaxation step, being able to analyze T1 and T2 relaxation times. The user will graphically evaluate the spins behavior of a slice under the application of a frequency and a phase encoding gradients.

Conclusion: The graphical study of the spin behavior under a RF pulse excitation in a magnetic field is, in general, a very useful way to explain the origin of the MR signal. This is a very important step in order to clarify how the MR image is obtained. It will be very well appreciated by radiologists.

C-0946

Performance evaluation of a clinical 64-slice spiral CT scanner

Y. Kyriakou, M. Kachelriess, J.U. Krause, W.A. Kalender; Erlangen/DE

Purpose: To evaluate a 64-slice cone-beam CT system with respect to image quality and susceptibility to cone-beam artifacts.

Methods and Materials: Our 64-slice CT scanner (Sensation 64, Siemens Medical Solutions, Forchheim, Germany) acquires 64 overlapping slices of 0.6 mm thickness. A z-flying focal spot (zFFS) switches between two z-positions and thereby allows one to acquire two slices per detector row. We used a thin wire phantom and a delta phantom (50µm gold disc) to quantify the spatial resolution. We

evaluated the 0.5 s standard spiral scan mode for pitch values ranging from 0.5 to 1.5 in steps of 0.1. Further, a high contrast spatial resolution phantom consisting of rows of small holes oriented along x/y and along x/z was measured. Additionally we used a water phantom to assess image noise and an artifact phantom to search for spiral windmill artifacts.

Results: Neither image noise nor spatial resolution (0.7 mm FWHM in-plane and 0.65 mm FWHM in the z-direction) were dependent on the pitch value. The 0.4 mm holes holes were separated both along x/y and x/z, documenting an isotropic resolution. Image noise was constant in the rotation center but showed a sinusoidal dependency off-center. Spiral windmill artifacts, which predominantly appear for higher pitch values, remained low due to the zFFS even for the largest pitch value.

Conclusions: The zFFS technology provides an isotropic resolution of 0.4 mm and achieves considerable windmill artifact suppression.

C-0947

Optimising scan protocols and assessing image quality in clinical MR imaging

G. Lucchicenti¹, F. Cademartiri², U. Sabatini¹, E. Giugni¹, M.G. Egito³, S. Bastianello³; ¹Rome/IT, ²Rotterdam/NL, ³Pavia/IT

Learning Objectives: 1) To illustrate the fundamentals of MR imaging through basic concepts which can be universally applied to imaging sequences, examination protocols and image interpretation. 2) To provide the basic criteria to assess image quality. 3) To provide simple criteria to optimise MR scan protocols for clinical radiology.

Background: The development of MR scanners and advanced techniques makes the scan protocol increasingly difficult to be optimised for clinical use. For this reason, the deep knowledge of the MR basis is crucial to perform a diagnostic examination within reasonable times and costs, considering the MR workflow. The clinical MR imaging can be summarised in these three aspects: 1) the generation of the signal (the magnetization), 2) the signal encoding and 3) the image contrast. The knowledge of the relationships between these aspects is crucial for optimising the scan protocol.

Procedure Details: The fundamentals of the MR imaging acquisition technique are described through a simple visual based approach using graphs, phantoms and clinical cases. The algorithm for the optimisation of the scan protocol is provided. The major artifacts of MR imaging are shown using phantoms and clinical examples.

Conclusion: The basic concepts of MR imaging are crucial for the optimisation of the imaging sequence, the examination protocol and for image interpretation.

C-0948

Reliability of contrast-detail (C-D) diagrams deduced from a Markov chain and reduction in the number of observation times

T. Niimi¹, K. Imai¹, M. Ikeda¹, H. Maeda¹, A. Mano¹, Y. Enchi²; ¹Nagoya/JP, ²Osaka/JP

Purpose: Contrast-detail (C-D) diagrams are being used to evaluate image quality in medical diagnostics. To improve the accuracy of C-D analysis, observers must interpret many phantom images. This process in image quality evaluation requires a lot of time and labor. In this study, we devise a C-D analysis method which can reduce the number of observation times effectively using information theory called Markov chain.

Methods and Materials: A commercially available Burger phantom was employed as a test object and 20 phantom radiographs with 0.8 background densities were prepared. Examinees were 29 radiological technicians and 6 radiologists. The observers interpreted all phantom radiographs independently of each other with the room lights off. Assuming that the observer's interpretation of the phantom radiographs involve a simple Markov process, the contrast detectability for each signal diameter was calculated using data obtained from interpretations of two phantom radiographs and a C-D curve was constructed based on this result. Reproductions of the C-D curve were also investigated using some arbitrary set of two phantom radiographs. In addition, a normal C-D curve was constructed using arithmetical averages of contrast detectability obtained from interpretations of all phantom radiographs.

Results: All C-D curves deduced from the Markov chain agreed well with each other. Furthermore, these C-D curves were in excellent accord with the normal C-D curve obtained from interpretations of all phantom radiographs.

Conclusions: C-D curves deduced from the Markov chain are reliable and introduction of the Markov chain makes it possible to reduce the number of observation times.

Scientific and Educational Exhibits

C-0949

The strict meaning of the area under a contrast-detail (C-D) curve

K. Imai¹, T. Niimi¹, M. Ikeda¹, H. Maeda¹, A. Mano¹, Y. Enchi²; ¹Nagoya/JP, ²Osaka/JP

Purpose: A receiver operating characteristic (ROC) analysis and a contrast-detail (C-D) analysis are being used for image quality evaluation in medical diagnostics. A quantitative index describing a ROC curve is the area under it and is useful in image quality evaluation. In contrast, a C-D analysis does not have a proper index. Intuitively, the area under a C-D curve may be a useful index in image quality evaluation. The purpose of this study is to clarify the meaning of the area under a C-D curve using information theory.

Methods and Materials: A commercially available Burger phantom was employed as a test object and 20 phantom radiographs with 0.8 background densities were prepared. 17 radiological technicians interpreted all phantom images independently of each other. A C-D curve was constructed based on this interpretation. Furthermore, image information $I(y)$ received by observers was calculated from detective probability $P(y)$ corresponding to the contrast detectability for each signal diameter ($I(y) = -\log_2 P(y)$). Image information $I(x)$ of the test object was calculated in a similar way ($I(x) = -\log_2 P(x)$, $P(x)$: generating probability of image signals).

Results and Conclusion: A small area dS under the C-D curve decreased with a signal diameter: the contrast detectability increased with it. The increase in the contrast detectability means the reduction in the image information loss. The information losses are given by $I(x)-I(y)$. The information loss calculated from this equation reduced with the signal diameter. Therefore, the area under a C-D curve given by integrating dS is equivalent to the total information loss.

C-0950

Preliminary studies on a quantum noise reduction filter in 16-slice multislice CT (MSCT)

T. Ishihara, T.S.S.R. Ishihara; Kashiwa, Chiba/JP

Learning Objectives: 1) To perform filter processing to reduce image SD and improve CNR while maintaining acceptable resolution. 2) To describe a new quantum noise reduction filter and confirm its clinical usefulness. 3) To compare images acquired at full dose and filter-processed images acquired at half dose.

Background: MSCT has higher resolution but also higher image noise. Noise varies with the target, and density resolution and target size cannot be ignored. We developed a 3-axis nonlinear quantum noise reduction filter and compared the spatial and density resolution of source and filtered images.

Imaging Findings: At a filter setting of 144, high contrast resolution fell. All 9 teeth (0.6 mm) of a comb were seen. The filter was set to improve granularity and low contrast resolution while maintaining high contrast resolution to improve image quality at full dose and for exposure compensation in low-dose areas. The teeth were not seen when resolution was reduced by > 60%. Image quality was similar at half and full dose for the same resolution. The higher SD and lower resolution due to patient size were compensated.

Conclusion: Filter processing reduces resolution slightly but is clinically useful. In the future, filter settings at each target size and for low-dose compensation may be set automatically.

C-0951

Development of a new three-dimensional image reconstruction algorithm to reduce cone-beam artifacts

T. Gomi¹, K. Koshida², T. Miyati²; ¹Nagano/JP, ²Kanazawa/JP

Purpose: An image reconstruction algorithm to reduce cone-beam artifacts in cone-beam CT was investigated.

Methods and Materials: Beeze sphere numerical phantom were arranged at different positions on the longitudinal direction and a computer simulation was performed. Due to differences in projection angle, data projected onto the detector surface were projected along trajectories exhibited as different periodic functions depending on the distance and position from the center of rotation. Therefore, projection in several detector channels by several projection data resulting from periodic functions is considered responsible for the increase in cone-beam artifacts with reconstruction planes at positions further from the center of rotation. We present here a new algorithm: 1) Weighting with respect to projection data at individual projection angles is changed. 2) The correction coefficient is distributed so as to be larger in the vicinity of the center of the detector with respect to individual channel data for a detector and smaller in the vicinity of the edges. 3) Corrected projection data were 3D back-projected. Evaluation and analysis of a new algorithm and the thorax numerical phantom were used.

Results: The effect of decreasing cone-beam artifacts of an object located at the edges was markedly increased in reconstruction planes at positions further from the center of rotation. Computer simulations showed that the spatial resolution (modulation transfer function) is improved by 14-20%, image noise (standard deviation) is improved by 10-18%.

Conclusions: We confirmed that this algorithm decreases cone-beam artifacts and generates high-quality reconstruction images.

C-0952

Fat suppression in MR imaging: Techniques and clinical applications

S.M. Dias, C. Pina Vaz, M. Gouvêa; Porto/PT

Learning Objectives: To review the most widely used fat signal suppression techniques in Magnetic Resonance Imaging and illustrate the main clinical applications. To describe the basic physical principles, advantages and limitations of each method.

Background: Fat signal suppression is a routinely used tool in Magnetic Resonance Imaging. It improves sensitivity for lesion detection and provides invaluable information in tissue characterization. Minimizing signal from fat in Magnetic Resonance can be achieved with different techniques: Selective fat saturation, selective water excitation, inversion-recovery imaging and opposed-phase imaging, among others.

Procedure Details: The authors present a review of the most common techniques of fat signal suppression and their physical principles based on the experience of our tertiary care hospital. The clinical applications, indications and disadvantages of the different methods are discussed and illustrated thoroughly.

Conclusion: There are several fat suppression techniques in Magnetic Resonance Imaging, which work by exploiting particular characteristics of the radio-frequency signals from fat and water. Understanding the mechanisms of each method provides insight into appropriate applications and anticipation of potential pitfalls.

C-0953

Measurement of carotid artery specimens comparing two CT imaging modalities using a 64-slice clinical CT scanner and a flat-panel detector

C-arm system

T. Riedel, Y. Kyriakou, D. Schäfer, M. Lell, W. Lang, W.A. Kalender; Erlangen/DE

Purpose: To assess CT image quality of carotid artery specimen measurements on a C-arm system equipped with a flat-panel detector in comparison to a 64-slice clinical CT scanner.

Methods and Materials: Carotid specimens were measured on a commercial C-arm system (Axiom Artis dFC, Siemens, Forchheim, Germany) and a clinical CT scanner (Sensation 64, Siemens, Forchheim, Germany). The C-arm is equipped with a flat-panel detector consisting of a photodiode array of amorphous silicon (a-Si) providing 960x960 pixels with a pixel size of 184µm coupled to a 600µm thick phosphor (CsI:TI) for X-ray absorption. The system offers a scan range of 240° of rotation with angular steps of 0.6°. The clinical 64-slice CT scanner acquires 64x0.6 mm overlapping slices.

Results: The structure of small calcifications and of the carotid artery wall was detected in both CT imaging systems. The C-arm provided a higher spatial resolution (better than 200µm) compared to the clinical CT scanner (400µm). Multiplanar reformations of the reconstructions confirmed the resolution isotropy in axial, coronal and sagittal. Especially the higher spatial resolution of the C-arm system allowed for a precise determination of the sizes of the artery lumen and of the single calcifications.

Conclusions: CT imaging of carotid artery specimens in air using C-arm systems equipped with flat-panel detectors demonstrated the possibility of accurate delineation of the artery wall and calcifications. Since it provides real 3D data it may be a fast alternative to histology in morphological analysis.

C-0954

Dose and low contrast detectability of new anode materials in mammography: Monte Carlo simulation studies

H. Delis¹, G. Spyrou², L. Costaridou¹, G. Tzanakos², G. Panayiotakis¹; ¹Patras/GR, ²Athens/GR

Purpose: Mammography is currently the technique with the highest sensitivity for early detection of breast cancer. As screening mammography refers to asymptomatic women, the task of optimization between image quality and radiation dose is critical. A way towards optimization is the introduction of new anode materials. Two new materials were evaluated, in terms of dose and low contrast detectability, using Monte Carlo simulation.

Scientific and Educational Exhibits

Methods and Materials: Several materials with characteristic energies inside the useful range of mammography were evaluated for their mechanical and thermal suitability as anode materials. The materials fulfilling the requirements were ruthenium (Ru) and silver (Ag). Using an analytical model, theoretical spectra were derived for these anode materials, for a number of tube voltages and filters. A recently developed and validated Monte Carlo simulation model was used to derive the dose and the low contrast detectability of these spectra.

Results: Ru/Ru (ruthenium anode / ruthenium filter) spectra demonstrate similar performance compared to Mo/Mo spectra, increasing slightly (2.1%) the Entrance Surface Dose, while providing increased low contrast detectability. In the case of harder spectra, Ag/Al-W spectra demonstrate analogous performance with W/Al spectra, for both dose and low contrast detectability.

Conclusion: New anode materials, such as Ru or Ag, could alternatively be used in mammography. Although further study is required, Monte Carlo simulation results demonstrate that dose and low contrast detectability of new theoretical systems are comparable, and in some cases improved, with respect to commonly used systems.

C-0955

The importance of detector type, detector material, reconstruction filter and reconstruction algorithm in simulated computed tomography breast imaging

A. Gaitanis¹, I. Kandarakis¹, D. Cavouras¹, N. Kalivas¹, N. Dimitropoulos¹, D. Nikolopoulos¹, G. Panayiotakis²; ¹Athens/GR, ²Patras/GR

Purpose: The aim of this work was to investigate the quality of an image produced by a Computed Tomography Breast Imaging (CTBI) system, taking into consideration the effect of detector type, material, reconstruction algorithm and reconstruction filter.

Methods and Materials: Software simulating a CTBI system was created. The simulated CTBI system consisted of: a) an X-ray source, b) the subject (software phantom including simulated glandular, carcinomas and calcifications structures), c) the detector array and d) the reconstruction software. Molybdenum target X-ray tube with voltages ranging from 20 to 40 kV was considered. The detector array was considered to be a linear one. The Quantum Detection Efficiency (QDE) of various scintillator materials such as CsI:Tl, Gd2O2S:Pr(UFC), Y1.34, Gd0.60O3(Eu,Pr)0.06 (Hilight) etc in several thicknesses were calculated. Also, the conversion of detected photons into the light was taken into consideration. To reduce noise energy weighted detector function was introduced. The reconstruction process was performed using Filtered Back-Projection (FBP) algorithm and several reconstruction filters such as Shepp-Logan, Hanning, etc for 360 projections. Calculated image characteristics were Signal to Noise Ratio (SNR) and Relative Contrast (RC).

Results: For carcinomas and calcifications highest SNR was obtained by a combination of Hilight scintillator, 160 mg/cm² thickness, 360 projections and Hanning reconstruction filter, while the highest RC was obtained by the same combination but for Ram-Lak reconstruction filter.

Conclusion: Detector type, detector material and reconstruction filter affect the detectability of carcinomas and calcifications in a computed tomography breast image. Acknowledgments: This work was financially supported by EPEAEK program 'Archimidis'.

C-0956

Influence of liquid crystal display (LCD) monitors on observer performance for detection of nodular lesions on chest radiographs

H. Usami, M. Ikeda, T. Ishigaki, H. Fukushima, K. Shimamoto; Nagoya/JP

Purpose: To access the influence of liquid crystal display (LCD) monitors on the detectability of nodular lesions depicted on chest radiographs, by comparing with a high-resolution cathode ray tube (CRT) monitor.

Methods and Materials: Ten radiologists observed 247 soft-copy images on LCD monitors with a pixel array of 1280×1024, 1600×1200, 2048×1536, 2560×2048 and a CRT monitor with a pixel array of 2560×2048, and were asked to indicate his or her confidence level regarding the presence of a nodule by using a continuous rating scale. These images were the chest radiographs with and without a lung nodule from "Standard Digital Image Database" created by the Japanese Society of Radiological Technology. The luminance distributions of all monitors were adjusted to the same and the ambient illumination was 200 lux in all image reading sessions. Observer performance was analyzed in terms of the receiver operating characteristics (ROC), and the statistical analysis of the differences among the five monitors comprised the analysis of variance of pseudovalue of the area under the binormal ROC curve computed by the jackknife analysis method.

Results: No statistical significant differences of nodule detection performance were found among the four LCD monitors and the CRT monitor, and there was no significant difference of the observer's confidence level for the image with a nodule among them.

Conclusion: The nodule detection performance on the LCD monitor with a higher spatial resolution than a matrix size of 1280×1024 is equivalent to the one on the high resolution CRT monitor.

C-0957

Proton MR imaging spectroscopy and fMR imaging changes associated to simple and complex movement in clinically isolated syndromes suggestive of multiple sclerosis

F. Preoteasa, I. Lupescu, R. Capsa, N. Cimpeanu, S. Georgescu, A. Cimpeanu; Bucharest/RO

Purpose: We conducted a pilot study to characterize plaques of multiple sclerosis (MS) using MR Spectroscopy and to put in evidence by fMR imaging that brain plasticity in MS can limit the clinical consequences of the structural brain damage associated with MS.

Methods and Materials: The study was performed on a 1.5 T GE Signa LX system. The fMR imaging and MR Spectroscopy data were acquired from 12 right-handed patients with established multiple sclerosis (MS) and 12 right-handed healthy subjects (the control group). The fMR imaging data were acquired during the performance of simple and complex motor tasks and the data were analyzed using statistical parametric software (SPM2).

Results: We found the N-Acetylaspartate (NAA)/Creatinine (Cr) ratio is correlated with the level of physical disabilities and, compared with control group, the patients showed, especially, more significant activations of the contralateral primary sensory cortex.

Conclusions: The pilot study that we conducted showed that Magnetic Resonance Spectroscopy (MRS) can add valuable information about the metabolic changes that occurs in multiple sclerosis (MS) and fMR imaging might quantify the efficiency of brain plasticity in response to MS injury.

C-0958

How do CT doses depend on patient size and radiographic techniques?

W. Huda, A. Vance; Syracuse, NY/US

Purpose: To investigate how patient size and radiographic techniques affect organ (local) doses and effective doses in MDCT imaging.

Method and Materials: Patients ranging from the newborn to oversized adults were modeled as equivalent cylinders of water. Monte Carlo techniques were used to estimate energy imparted to these water cylinders by MDCT systems. Energy imparted was converted to the average dose in the directly irradiated region, as well as to the corresponding effective dose. Patient doses were determined per 100 mAs for representative scan lengths, assuming an X-ray tube voltage of 120 kV and a helical pitch ratio of 1.

Results: The water cylinder diameter of patient heads ranged from 112 mm (newborn) to 182 mm (adult), whereas patient bodies ranged from 98 mm (newborn chest) to 352 mm (oversized adult abdomen). Head doses were 14 to 19 mGy/100 mAs, whereas body doses were 7 to 25 mGy/100 mAs, with the smallest patients receiving the highest doses. Head effective doses were 0.3 to 2.3 mSv/100 mAs, whereas body effective doses were 1.4 to 6.6 mGy/100 mAs. Increasing the tube voltage from 120 to 140 kV increased patient doses by 50%, whereas reducing the tube voltage to 80 kV reduced average doses threefold.

Conclusion: Patient doses undergoing any type of CT examination MDCT systems have been quantified for patients ranging from the newborn to oversized adults. At the same techniques (kV/mAs), newborns have effective doses approximately five times higher than those of oversized adults.

C-0959

An assessment of the performance of PACS workstation monitors in Ireland

C.K. Wade, M.F. McEntee, P.C. Brennan; Dublin/IE

Purpose: As workstation monitors are used increasingly in medical imaging, quality control programmes become vital to track variations in their performance. This study examined the performance of workstation monitors used for soft-copy reporting in Ireland, comparisons were made to standards where available and guidelines were drawn up for a quality assurance programme.

Methods and Materials: Initially, the calibration of each monitor was assessed using the IHE test plan or other equivalent software programme. Using the SMPTE test pattern the maximum luminance, spatial uniformity of luminance, temporal luminance stability, geometry and sharpness were assessed. Veiling glare and

Scientific and Educational Exhibits

spatial resolution was assessed using a selection of the AAPM TG18 test patterns.

Results: 97% of monitors were calibrated correctly to the DICOM GSDF standard. All monitors attained the guideline level for maximum luminance as set by the ACR (1999), 94% of monitors had acceptable levels of non-uniformity of luminance, whilst only 52.9% of monitors had acceptable levels of geometrical distortions. The results from the TG18 test patterns evaluation demonstrated that all monitors were affected by veiling glare and none of the monitors examined reached the standard for spatial resolution.

Conclusions: The results of this work demonstrate that regular assessment of workstation monitor performance is necessary as part of the radiology department's quality control programme. Using the results a quality control programme has been drawn up outlining the necessary image quality parameters to assess, intervals for testing, equipment required and personnel necessary. The TG18-QC test pattern can facilitate the testing of all relevant parameters.

C-0960

Retrospective patient dose analysis of digital radiography systems in routine clinical use

A. Schuncke, U. Neitzel; Hamburg/DE

Purpose: According to the European Medical Exposure Directive 97/43 patient dose values observed in clinical practice shall be compared to the Diagnostic Reference Levels (DRL). We investigated the use of examination logfiles, containing the exposure parameters of all images produced in an examination room, for determining average patient doses and their distribution.

Methods and Materials: The log files generated in flat-panel detector based digital radiography systems (Philips Digital Diagnost) at 11 different hospitals were used to acquire data regarding the dose-area product and the entrance air kerma as well as the detector exposure for all X-ray examinations performed in clinical routine. A retrospective statistical analysis of the data with respect to the average dose levels (kerma-area-product, entrance air kerma) was performed for several examination types and compared to the DRL.

Results: While dose values for individual patients vary widely due to different patient size, median values for ten or more examinations of the same type are rather stable and can be used for comparison to the DRL. We found rather large differences in median dose level for the same type of examination at different hospitals. However, almost all values were far below the DRL. Correlation of median patient dose for chest examinations with the level of detector exposure was only moderate ($R^2 = 0.70$ for pa and $R^2 = 0.56$ for lat)

Conclusion: Examination log files can be used for retrospective dose analysis in clinical routine. Median dose values determined in this analysis can be used for correlation with diagnostic reference levels.

C-0961

The exposure index: Definition of "speed" in digital radiography

U. Neitzel; Hamburg/DE

Learning Objectives: To compare the concept of film speed in conventional radiography with the definition and properties of the exposure index in digital radiography.

Background: In contrast to conventional screen-film systems, digital detectors do not have a fixed sensitivity or speed. Due to their large latitude they can be used at widely varying dose levels, while the displayed image exhibits a constant density or brightness because of signal normalization. The exposure index is used as a means to give feedback to the user about the actual dose level applied for imaging.

Procedure Details: Different definitions for the exposure index exist in digital radiography systems today. The exposure index is commonly determined from the pixel values of the actual image, which means that, unlike film speed, it is a property of the image and not of the detector. Besides the dose level, the value of the exposure index can be influenced by the type of the image, the radiation quality, and in some digital detectors also by the image processing.

Conclusion: The exposure index can be used as a feedback tool for radiation protection purposes. When comparing it to film speed care has to be taken because of different influencing factors. A standardization of exposure index definitions and scales seems appropriate to facilitate comparison between different digital imaging systems.

C-0962

The effect of patient weight on image noise in thoracic and abdominal CT:

Dosimetric analysis and clinical applications

V. Tsapaki, C. Triantopoulou, P. Maniatis, I. Siafas, D. Chrysostomou, P. Koukkou, E. Koulentianos, J. Papailiou; Athens/GR

Purpose: The purpose of the study was to investigate the influence of patient weight on image noise and radiation dose in routine CT examinations, during the International Atomic Energy Agency Research Co-ordination Project on *Dose Reduction in CT while maintaining Diagnostic Confidence*.

Methods and Materials: 50 patients were scanned using the routine abdomen protocol and 50 using the thorax protocol. Patients were divided into 5 categories according to weight. Noise (N) measurements were performed on 3 image levels, the median value of which was set as N. Dose measurements were performed in terms of the Computerized Tomography Dose Index (CTDI) using a special pencil-shaped ionization chamber. Total patient doses were assessed by estimating the Dose Length Product (DLP).

Results: Thoracic CT: No correlation was found between N and weight. Therefore, patient dimensions do not seem to affect image noise. Abdominal CT: N correlated well with weight ($R^2 = 0.62$), thus the amount of noise in the image was largely affected by patient size. Mean CTDI and DLP were 19.5 ± 3.5 mGy and 540.4 ± 201.2 mGycm for thoracic CT and 19.5 ± 2.3 mGy and 739.7 ± 182.2 mGycm for abdominal CT. These values were lower than the European reference dose levels.

Conclusions: Radiation doses using current technical parameters are satisfactory. For thoracic CT the parameters could be changed so as to lower even more radiation dose to the patient. On the contrary for abdominal CT, alterations of parameters in heavy patients in an effort to lower radiation dose should be performed cautiously, as the effect on image noise is more prominent.

C-0963

Image processing techniques for the manipulation, processing and storage of mammography radiological data

V.E. Kououlia¹, G. Matsopoulos², N. Mouravliansky², P. Asvestas², K. Delibasis², N. Uzunoglu², A.D. Kelekis¹, E. Efstatopoulos¹, N. Kelekis¹; ¹Xaidari/GR, ²Athens/GR

Purpose: The development of advanced image processing techniques for the manipulation, processing and storage of mammography radiological data.

Methods and Materials: The image processor includes the following tools: Image enhancement based on filters for the histogram equalization, the unsharp masking and the contrast limited adaptive histogram equalization, image segmentation to provide regions of interest (ROIs), classification tool and image registration and fusion. In particular, the segmentation tool consists of an automatic method based on mathematical morphology operations and a manual method, the classification tool consists of two sub-modules: The feature extraction module and the classifier, classifying normal from pathological cases, and the registration tool based on an automatic and a manual methods.

Results: The results of segmenting ROIs showed that the proposed automatic method outperforms the top hat filtering method and the watershed transformation, both qualitatively and quantitatively. The classification based on the Second Order Statistics, as feature extraction technique and a multilayer feedforward Artificial Neural Network produce a classification rate of 97% for the normal cases, 86% for the pathological and an overall performance of 93%. Finally, the registration methods of mammographic images acquired at different times by the automatic method based on the extraction of the external breast boundaries and the manual method have shown no statistical difference in terms of performance.

Conclusions: The developed image processing tools have been incorporated within a www-based system for managing patient data from mammography in a very user-friendly manner, requiring only basic knowledge of the Windows-type environment from the user-medical experts.

C-0964

Evaluation of the dose efficiency index compared to receiver operating characteristics for assessing CT low contrast performance

T. Ishida¹, S. Tsukagoshi², M. Okumura², K. Kainuma², K. Kondo²; ¹Fukui/JP, ²Tochigi/JP

Purpose: The dose efficiency index (DEI) is a dose invariant measure that quantifies the low contrast performance of CT scanners. The purpose of this study is to compare the DEI method with ROC analysis.

Method and Materials: A diluted contrast medium phantom comprised of low contrast targets of variable size and concentration was scanned at 80 to 135 kV

Scientific and Educational Exhibits

on a MSCT scanner. Eight radiologists reviewed the images and identified discernable targets. The likelihood of detection was measured as a function of target size and scan condition. Both DEI and ROC analysis were then performed, and the correlation between the two methods was calculated.

Results: When a difference in low-contrast resolution was seen under a certain condition using the ROC method, the difference under the same condition was also seen using the DEI method. The work efficiency of the DEI method is 6 times that of the ROC method. Both the ROC method and the DEI method showed significant differences between 120 kV and 80 kV when the phantom was scanned using the abdominal conditions. A possible cause is the energy-dependence of the contrast medium. The coefficient of correlation between DEI and ROC analysis was 0.985.

Conclusion: We investigated the relationship between the ROC method and the DEI method. The DEI method is an effective alternative to ROC analysis for characterizing the low contrast performance of CT scanners. It is much simpler to calculate than ROC and is useful in comparing scanners from different manufacturers or as part of ongoing quality assurance.

C-0965

Image degradation and pseudo-lesions from inappropriate use of post-processing techniques

T. Yamaoka, N. Inamoto, K. Ike, H. Nakagawa; Kyoto/JP

Learning Objectives: To review various post-processing techniques and recognize factors affecting post-processing images.

Background: Multi-detector CT (MDCT), which provides images with more information than those of single helical CT, is now seen as a standard clinical CT scanner. Appropriate post-processing of MDCT images can give much more information than evaluations of thin source images. However, incorrect use of these processing techniques can hide important information. Additionally, several factors affecting source images may influence post-processing images. Post-processing of inappropriate source images might even simulate pathological conditions. Such factors can be divided into three categories. First is related to source image quality: Slice thickness, slice interval, reconstruction algorithm, tube current and helical pitch are included in this category. Second relates to post-processing parameters and includes slab thickness, window setting (opacity curve) and softening filter. Third relates to artifacts of source images and includes beam hardening, motion and ring artifacts.

Procedure Details: MDCT scanners with a 4 detector row system were used to obtain source images, which were calculated with changing thickness, interval and algorithm. Post-processing images were made on a commercially available workstation. Maximum and minimum intensity projections, variable thickness viewing, volume rendering and virtual endoscopic images were made. We will demonstrate inappropriate post-processing images in comparison with acceptable images.

Conclusions: Radiologists and technologists should pay attention to several factors affecting post-processing images to enable the best images to be available.

C-0966

Clinical experience of a multifunctional image-guided therapy room

Y. Iwasaki, Y. Hama, T. Kaji, S. Kosuda; Tokorozawa/JP

Learning Objectives: To know the concepts of multifunctional image-guided therapy room. To know the implementation strategies of multifunctional image-guided therapy room. To review a comprehensive approach combining emergency care and elective computer-assisted therapy.

Background: Since minimally invasive therapy is essentially image-guided therapy, a new physical place for these activities has to be devised: The multifunctional therapy room integrates sophisticated imaging and image guidance modalities together with life support equipment.

Procedure Details: We developed, and started to clinically use, a multifunctional image-guided therapy room with a unified multidetector CT/fluoroscopy DSA system and US. A significant impact on the care of vitally threatened patients is given by using this room not only for elective image-guided therapy but also for emergent one-stop diagnosis and treatment.

Conclusion: The use in one-stop emergent diagnosis and treatment can possibly have a profound impact on corresponding patient pathways and outcomes. It may also further enhance the cost-benefit ratio. Motivation, technology, implementation strategies and funding of this image-guided, integrated and interdisciplinary therapy room, as well as a comprehensive approach combining emergency care and elective computer-assisted therapy, are discussed in this paper.

C-0967

Radial tomography: From acquisition lines to image grid

N.E. Myridis; Thessaloniki/GR

Purpose: We promote herein the approximation of irrational lines by broken lines (line segments), in radial techniques applied in MR imaging or other tomographic fields. The advantages are time and complexity reduction in reconstruction.

Methods and Materials: *Problem.* Given an irrational line (α, β) -i.e. a line with irrational slope- we wish to approximate that line by a sequence of pairs of rational numbers, i.e. by discrete line segments. The substitution sequences are Sturmian sequences (Jacobi-Perron (J-P) algorithm). The significance is the assignment of irrational spectral lines to line segments on the image grid, during the reconstruction procedure. *Algorithm:* 1. The algorithm is defined on unit square and uses maps defined by known equations. 2. For the line (α, β) a sequence $F(\phi^r(\alpha, \beta))$ is associated. 3. A sequence of pairs of rational numbers can be generated, thus approximating the initial line.

Results: A majority of tomographic techniques deals with radial lines, usually irrational. An interpretation of radial continuous lines in discrete grids might be considered. Focusing on a microscale, a spectral line is indeed a broken line (e.g. due to transitions of gradients etc). In radial trajectories algorithms, irrational lines (i.e. not passing from grid nodes) can be approximated by broken lines according to a Sturmian substitution algorithm. A couple of lines can be omitted. The number of required lines in reconstruction could be reduced at least by 25%.

Conclusion: The impact of J-P algorithm is critical for several known reconstruction techniques. Data burden and reconstruction time reduction of at least 25% results.

C-0968

Evaluation of the performance of two digital "flat panel" cardiac imaging systems using the NEMA cardiac benchmarking phantom

B. Tuohy, E. Keavey, L. Finlay, A. McGarrigle, K. Daly, J. Crowley, W. Van Der Putten; Galway/IE

Purpose: Until recently all cardiac angiography equipment availed of a conventional Image Intensifier-TV chain for image capture and display. However, many new cardiac catheterisation laboratories are being installed utilising an all-digital flat panel (FP) imaging design, which replaces the conventional analog image intensifier based imaging approach. This paper investigates the claim made by Manufacturers of this technology that considerable improvements in image quality, and reduced radiation exposure to staff and patients are achieved by this design.

Methods and Materials: By using the NEMA Cardiac Benchmarking phantom, entrance dose rates at varying levels of attenuation, static and dynamic spatial resolution, and contrast resolution were assessed on two modern recently installed digital "flat panel" cardiac systems from different manufacturers.

Results: Image quality findings for both FP systems are similar and are a significant improvement over conventionally designed systems. For average sized patients, entrance doses in fluoroscopic mode are approximately 25 mGy/min, however for larger patients, the equivalent dose rate reached 122.7 mGy/min. In addition, doses as large as 1.12 mGy/frame are reached during digital acquisition serial "runs" on "large" patients.

Conclusion: Image quality shows a marked improvement on modern FP cardiac imaging systems over conventionally designed systems. Entrance doses are similar between FP based systems and conventional technology in the case of average sized patients. However in the case of large patients, our findings suggest the FP approach delivers significantly higher doses, and therefore serious consideration should be given to reducing the dose for this patient population.

C-0969

An evaluation of the accuracy and precision of DEXA systems in the west of Ireland using the european spine phantom

E. Keavey, B. Tuohy, W. van der Putten; Galway/IE

Purpose: Over the past decade, Dual-Energy X-ray Absorptiometry (DEXA) has established itself as the most widely used method of measuring Bone Mineral Density (BMD). However, there is no uniformity in reporting results and in presenting reference data. This leads to difficulties in clinical practice when patients are followed up on different machines. Here the accuracy and precision of DEXA devices in the west of Ireland was assessed using the European Spine Phantom (ESP). This is composed of three semi-anthropomorphic hydroxyapatite vertebrae of varying densities surrounded by soft tissue equivalent plastic. Hence the ESP resembles human bone and soft tissue when scanned on bone densitometers. A total of 7 DEXA machines were evaluated.

Scientific and Educational Exhibits

Methods and Materials: The ESP was used to measure BMD on each machine using standardized protocols. Reproducibility and accuracy was assessed on each unit by determining projected areas, bone mineral content (BMC) and BMD for each vertebra. A further, long-term study was also carried out on some of the units to include the day-to-day variation in instrument performance.

Results: Initial findings indicate surprisingly large variations of up to 3.5% BMD between different machines of the same manufacturer. This was shown to depend on the type of vertebra scanned. Long term stability of each machine was found to be good.

Conclusion: The European Spine Phantom is an essential tool to audit typical bone densitometry systems. Differences are found between units and the implications for cross-calibration of DEXA units will be discussed.

C-0970

Objective assessment of image quality in conventional and digital mammography

P. Monnin, D. Lepori, F.R. Verdun; Lausanne/CH

Purpose: To compare in terms of NEQ and DQE a digital mammography system (GE) with the most recent Kodak, Fuji and Agfa screen-film systems.

Methods and Material: The characterization of the mammography systems were performed using a 28 kV Mo/Mo beam. Air kerma values were measured using a 6 cc ionizing chamber. The assessment of spatial resolution was performed by the determination of the modulation transfer function (MTF) of the detector. Noise power spectra were measured with homogeneous images acquired at three exposure levels that cover an air kerma range at the entrance of the detector of 10. The NEQ and DQE of these mammography detectors were obtained from these data.

Results: The constant contrast due to the linear response and the lower intrinsic noise of the digital system translates into a better image quality over a larger dynamical range than screen-film systems, especially when dealing with the detector of low contrast lesions.

Conclusion: Digital mammography systems have a high potential of image quality over a large dynamical range and a low intrinsic noise. They appear to be superior than conventional screen-film systems when dealing with the detection of low contrast lesion especially in the most glandular part of the breast.

C-0971

Computer analysis for the respiratory changes in X-ray translucency on chest radiographs using a dynamic flat-panel detector (FPD) system

R. Tanaka¹, S. Sanada¹, N. Okazaki², T. Kobayashi¹, M. Suzuki¹, T. Matsui¹, N. Hayashi¹, O. Matsui¹; ¹Kanazawa/JP, ²Arizona, AZ/US

Purpose: Recently developed dynamic flat-panel detector (FPD) with a large field of view, make it possible to obtain breathing chest radiographs, which provide respiratory kinetics information. The purpose of this study was to analyze the change of X-ray translucency in each local lung area on breathing chest radiographs and then investigate their relationship with the respiratory physiology.

Methods and Materials: Breathing chest radiographs in normal subjects were obtained using a dynamic FPD system in posteroanterior (PA) standing position and the right and left decubitus position. Images were sequentially obtained 30 frames within 10 seconds in the maximum voluntary respiration. We measured the change of X-ray translucency in each local lung area.

Results: Our method could detect the changes of X-ray translucency in each local lung area resulting from breathing phase. In the PA standing position, the changes of X-ray translucency in the lower lung fields was larger than those in the upper lung fields, and those in the right and left lung field were almost same. In the decubitus position, the changes of X-ray translucency in the upper area were smaller than those in the lower area. The results were consistent with well-known properties in respiratory physiology.

Conclusion: Chest radiography using a dynamic FPD combined with our computerized methods could detect the respiratory changes in each local lung area in the normal subjects, which resulted from the ventilation. We think that breathing chest radiography could be effective for diagnosing pulmonary diseases, such as chronic obstructive pulmonary disease and restrictive pulmonary disease.

C-0972

Precision of densitometric assessment of bone mass in mens' age-related bone loss: A comparison between DXA, pQCT and QUS

S. Petcu, G.D. Pop, C.E. Georgescu; Cluj-Napoca/RO

Purpose: Due to gender and disease-specific differences, a different approach to assessing BMD in men could be taken into account. We compared some diag-

nostic methods of osteoporosis in men who have the advanced age as a major risk factor.

Methods and Materials: The purpose of the study was to calculate and compare the short-term precision (CV%) of different osteodensitometric techniques and at different sites, assessing men aged 50 to 70, and to evaluate sensitivity (Se) and specificity (Sp) of radial pQCT and calcaneal QUS in detecting spinal bone loss defined by DXA AP spinal measurement. We selected a population of 75 men without secondary causes of osteoporosis, divided into three groups of 25 according to their BMD as measured by DXA: Osteoporotic, osteopenic and normal. The patients had their bone mineral density measured by three means: QUS using Achilles Express, DXA using DPX-PRO and pQCT using Stratec XCT 900.

Results: CV% of each technique and for each site was calculated, showing the best reproducibility for pQCT, followed by DXA. QUS had a very good Sp at T-score -2.5 (91.3%), but poor Se (28%), while pQCT showed a quite opposite feature, with low Sp but high Se. We obtained good correlations between measurements at different sites.

Conclusions: In conclusion, there are no significant differences between the values assessed by us when comparing to literature data about women. This study recommends again pQCT as the most suitable follow-up technique in detecting early changes in trabecular bone, changes preponderantly observed in this age group.

C-0973

Diagnostic efficacy of the twinkling-artifact in detection of calcifications

A.I. Gromov, A.Y. Vasilyev, B.I. Zykin, S.Y. Kubova, V.V. Kapustin; Moscow/RU

Purpose: To improve the sonographic detection of calculi.

Methods and Materials: We analyzed 417 cases of the twinkling-artifact in hyperechoic structures of inner organs and studied its appearance in 52 calcifications revealed CT.

Results: The Doppler twinkling-artifact was visualized in all organs, except liver and splenic calcifications: 61% of gallstones, 83% urinary stones, thyroid calcifications 65%, breast 71%, uterus 39%, ovary 72%, prostate 81%, scrotum 75%. The experiment determined that the artifact appeared in 86% gallstones with particles of calcium, detected by CT, and only 36% cholesterol gallstones (density < -30 HU). Use of color Doppler improved the efficacy of the detection of urinary stones in 15%, in the middle part of ureter in 38%. In 11 cases, we revealed renal stones 1-3 mm without any visualization in gray-scale imaging due to the artifact (CT confirmed). The artifact permitted determination of the nature of hyperechoic structures with reverberation within the renal parenchyma: "Milk of calcium" in calyceal diverticulum (was showed in 91% with maximum intensity). Using the artifact we detected breast calcifications of 1-2 mm (17 from 24 cases), which hadn't been visualized in gray-scale imaging. In B-flow imaging we determined this artifact, appeared as a twinkling white vertical line behind calcifications.

Conclusions: The twinkling-artifact is an additional diagnostic sign, improving the efficacy of the detection of urinary stones and breast calcifications. It visualizes in all organs, except liver and spleen. Frequency of the artifact's visualization depends on X-ray density of stones. The effect determines in B-flow imaging.

C-0974

Improvement of spatial and temporal resolution in 64-slice CT coronary angiography

F. Cademartiri, N.R. Mollet, G. Runza, M. Belgrano, M. Midiri, R. Pozzi Mucelli, G.P. Krestin; Rotterdam/NL

Learning Objectives: 1. Describe the technical features of a new generation of multislice CT scanner. 2. Describe the issues and the solutions adopted to improve spatial and temporal resolution. 3. Provide cases that show the clinical impact of the technical improvements.

Background: Coronary arteries can be studied reliably in a selected population of patients with relatively low and regular heart rate using 16-row multislice CT angiography. The clinical role of this technique is yet not well defined and several limitations to its widespread implementation remain. In particular, the effective temporal and spatial resolutions are still insufficient when the scan is applied to higher and irregular heart rates and to high-density structures such as large calcified plaque and stents. For this reason the technical developments are focused towards hardware improvements that can widen and strengthen the fields of application of multislice CT.

Imaging Findings: We describe a multislice CT scanner able to scan 64 slices per rotation with a voxel size of 0.3x0.3x0.4, and a rotation time of 0.33 s (effective temporal resolution up to 165 ms). Schemes of the main technical achievements will be displayed as well as clinical examples with conventional coronary angiography correlation.

Scientific and Educational Exhibits

Conclusion: The new 64-slice CT allows improved non-invasive coronary artery imaging.

C-0975

Metallic stents in MR imaging: Signal reduction in the lumen caused by RF effects

H. Graf, G. Steidle, U.A. Lauer, C.D. Claussen, F. Schick; *Tübingen/DE*

Purpose: The principles of radio frequency (RF) induced MR signal reduction in the lumen of metallic stents were examined theoretically as well as experimentally at 0.2 T and 1.5 T using tube models.

Methods and Materials: For the theoretical approach, the stent was assumed as tube, its axis along a linearly polarized RF excitation field. Calculations were performed with the transformer theory to obtain the RF amplitude in the tube lumen. The dependence on the electrical parameters of the tube, electrical resistance R and reactance $Y = wL$ (L : inductance, w : angular frequency) was determined. The obtained results were verified experimentally using carbon fibre tubes in the size of peripheral/coronary stents. Spin-echo imaging was applied at both field strengths.

Results: The calculations predicted, that > 90% of the RF-field amplitude can be reached in the tube lumen at a ratio $R/Y > 2$, with a rapid drop at lower ratios. RF shielding effects reduce at lower frequency (field strength) and for tubes with smaller diameter d . For the carbon fibre tubes with solid wall, resistance was high enough to confirm the theoretical predictions. For the $d = 8$ mm diameter tubes, lumen visualization ($R/Y > 2$) could be achieved at 0.2 T but not at 1.5 T. At 1.5 T, the lumen of the $d = 3$ mm tube could be visualized also.

Conclusion: RF shielding inside electrically conducting stents reduces, if the stent is small and displays high electrical resistance (material conductivity, strut arrangement). For enlarged field strength, shielding effects increase.

C-0976

Effect of a multislice scanner on patient effective dose: A Monte Carlo study

A. Tzedakis, J. Damilakis, K. Perisinakis, J. Stratakis, N. Gourtsoyannis; *Iraklion/GR*

Purpose: To assess the percentage differences in patient effective dose between 16-slice spiral and sequential CT scanning.

Methods and Materials: The MCNP(4C2) Monte Carlo code was used for simulation of a Siemens, Somatom Sensation 16 scanner. A mathematical anthropomorphic phantom was used, to calculate the effective dose. Patient effective doses were normalized to air kerma on the scanner axis of rotation. Four regions of the phantom body were scanned by 16-slice spiral and sequential mode. These regions are described as trunk, abdomen and pelvis, chest and head and neck.

Results: The percentage differences in effective dose between spiral and sequential mode for corresponding studies were ranged from 1.9 to 11.9%, 3.7 to 35.8%, 5.2 to 29.1% and 2.9 to 21.5% for head and neck, chest, abdomen and pelvis, and trunk examinations, respectively. Greater dose is always delivered to patients from spiral CT in comparison to that from sequential scanning. This is due to additional exposure of tissue, on both edges of the scan field that is needed for spiral mode. Patient effective dose from multislice spiral CT depends on slice thickness and beam collimation.

Conclusion: Multislice spiral CT delivers a considerable higher radiation dose to patients in comparison with sequential CT scanning.

C-0977

Art appreciation through radiology

C.G. Cronin, A. Alhajeri, C.J. Roche; *Galway/IE*

Learning Objective/ Background: To describe the non-medical adaptations of radiology in the World of Art. In this pictorial review we will illustrate the interesting uses of radiographic techniques in: 1. Detecting Art Forgeries. 2. Creating Original Art. 3. In Advertising.

Procedure Details: Art dealers claim that greater than 15% of all art sold at auctions are fake. X-ray fluorescence can detect fake paintings that had been forged on old canvases or over some other painting. Famous forgeries over the years include a work of art alledged to have been done by Picasso titled "Absinthe Drinker." Radiographs revealed an abstract painting underneath, which was a historical impossibility. Radiographs revealed faces and hunting scenes under paintings on canvases (which could not have been removed) and extra layers of paintings on forgeries carried out by Hans Van Meegeren of Veneers work. Art has progressed from famous paintings of Picasso to the fine art of X-ray Photography. These initially were mainly Floral Radiographs. This technique uses an industrial type generator, mammography film or graphic art film for

higher contrast, high resonance digital scanner and computer systems for contrast, coping and image adjustments. Recently in Ireland, the Advertising Industry has effectively used an interesting series of radiograph pictures in a sports advertising campaign.

Conclusion: This poster outlines radiology's impact on art. It illustrates a number of interesting radiological investigations and adaptations in the field of art/art history. Undoubtedly, radiology will continue to grow and diversify in both medical and non-medical areas.

C-0978

Optimisation of patient doses in angiography and interventional radiology: Proposal for auditing structure

L. Struelens¹, F. Vanhavere¹, H. Bosmans², R. Van Loon³, K. Smans¹; ¹*Mol/BE*, ²*Leuven/BE*, ³*Brussels/BE*

Purpose: The optimization principle, keeping doses as low as possible, without jeopardizing image quality is not straightforward for interventional radiology (IR). It is obvious that quantitative data about radiation exposures are of great interest for optimization purposes. In Belgium, there is lack of data concerning patient doses for IR examinations and no auditing structure to gain these data is determined.

Methods and Materials: The study started with the measurement of patient doses in 7 different hospitals, using thermoluminescent and dose-area-product meters. These results were entered into a database for analysis, together with the procedure and technical parameters (kVp, mAs, fluoroscopy time, number of frames, etc.).

Results: The measurements delivered us average dose values for angiography of the lower limbs, angiography of the carotid arteries and cerebral embolisations. These doses were analyzed against the different procedure and technical factors and guidelines were deduced from these observations. Practically, we propose, as part of a dose audit protocol, to register total DAP, total number of frames and/or fluoroscopy time, patient data and average kVp. Such audit protocol is illustrated for the procedure angiography of the lower limbs on the measured DAP data and recorded parameters for 111 patients.

Conclusions: If doses to patients are to be reduced, radiologists should be aware of their performance and how it relates to patient's dose. Hence, the results of this study were presented to all radiologists of the contributing hospitals. Through questionnaires they gave feedback on the different proposed guidelines for optimization of patient dose in IR.

C-0979

Investigation of magnification in digital radiography and validation of an automatic magnification calibration method

G. Ahuja¹, L. White¹, X. Wang², D.H. Foos²; ¹*Toronto, ON/CA*, ²*Rochester, NY/US*

Purpose: To investigate the distribution of femoral head magnification factors in digital radiography and to validate an automatic magnification calibration method for orthopedic surgical planning.

Methods and Materials: Thirty eight images of post-operative patients with prosthetic femoral heads (PFH) of documented sizes were acquired with computed radiography (CR). A radio-opaque sphere of 1.0inch in diameter was positioned on each patient adjacent to the hip during imaging. The actual magnification factor (G_{actual}) was calculated based on the measured PFH diameter and the known true dimension. An algorithm was developed that can automatically detect the radio-opaque sphere and determine its diameter in the image, from which the magnification factor of the sphere (G_{sphere}) was calculated. The measured PFH diameter was corrected with G_{sphere} and with the default magnification factor (15%) used in the conventional screen/film technique for orthopedic surgical planning. The two results were compared against the true size of the PFH.

Results: The value G_{actual} has a median that is 2.9% greater than default and deviates significantly for very large and small patients. With the automatic method, the median of the error in measuring the PFH diameters reduces to 0.51 mm from 0.70 mm.

Conclusion: Using the default magnification error of 15% when making PFH measurements, introduces significant magnification errors for very large and small patients. This error can lead to inappropriate PFH selection in the preoperative planning of reconstructive orthopedic procedures. The automated method corrected this error and would play a significant role in preoperative planning.

Scientific and Educational Exhibits

C-0980

Optimization of an algorithm for the arterial input function evaluation in CT brain perfusion

U. Anselmi¹, F. Saiani², L. Mascaro¹, R. Gasparotti¹, D. Mardighian¹; ¹Brescia/IT, ²Milan/IT

Purpose: In brain perfusion CT, an accurate evaluation of perfusion parameters needs an optimization of the AIF function suitable for the Central Volume theory. Aim of the study is to setup a strategy to best fit, through the Gamma Variate function, the temporal signal of the bolus passage in brain vessels.

Methods and Materials: A dynamic sequence of 50 CT images (temporal resolution 1.1 s, 80 kVp, 124 mAs) monitoring the bolus passage were collected for 4 patients. The anatomical identification of cerebral veins and arteries was performed by a neuroradiologist and the signal curve analysed for the pixel with the highest CT value, generally the central pixel of the vessel. A minimization routine provided by the CERNLIB was used. The optimization algorithm consisted of many iterative steps, including filtering of tail points, in order to cancel recirculation effects, and erosion of the first points, not yet involved in bolus passage. At every step the goodness of fit was compared with the previous one by means of normalized chi-square and Global Correlation of the four parameters of the Gamma-Variate model.

Results: Best normalized chi-square value and best Global Correlation parameters to stop the iteration process resulted to be respectively 0.02 and 0.90 and 30-45% of analysed curves were rejected using this strategy.

Conclusion: A strategy was set up to best fit CT signals from a bolus passage in brain vessels. Our results can be used to write an automatic program for the AIF mapping of perfusion brain studies.

(mean \pm standard deviation) in crano-caudal direction, 4.2 ± 3.4 mm in right and left direction, and 4.8 ± 3.0 mm in antero-posterior direction. The difference of the most unmatched margin was 28 mm, probably due to the respiratory motion. The average differences of center point of the 38 lesions was 8.2 ± 3.7 mm.

Conclusion: Although our manual fusion technique caused more larger misregistration compared to PET/CT studies, it was considered clinically acceptable. This simple technique could be helpful in clinical setting when a PET/CT device is not available.

C-0981

Measurement of MTFs for liquid crystal displays by rectangular waveform analysis

A. Horii¹, A. Chihara², M. Takamura¹, K. Ichikawa¹, Y. Kodera¹, M. Ikeda¹, T. Ishigaki¹; ¹Nagoya/JP, ²Kumamoto/JP

Purpose: To investigate the characteristics of liquid crystal displays that the numbers of pixels differ.

Methods and Materials: We measured MTFs of liquid crystal displays by rectangular waveform analysis. This is the method of taking a picture of the bar pattern on the monitor surface with a digital camera and analyzing the picture with a personal computer. The monitors used are the liquid crystal displays of 1M (about 1 million of the number of pixels), 2M, 3M and 5M, and a CRT display of pixel number of 5M. The display of 2M used two kinds (IPS system and VA system) from which liquid crystal operation mode differs.

Results: In the liquid crystal displays except the display of 1M, MTFs became high as the pixels increased. For the liquid crystal displays, MTFs in horizontal direction was higher than MTFs in perpendicular direction except 2M VA system. For the liquid crystal display of 2M VA system, MTF in horizontal direction became equal to MTF in perpendicular direction. For the monitors of the same number of pixels (5M), MTF of a liquid crystal display was high compared with MTF of a CRT display.

Conclusions: MTFs of liquid crystal displays are influenced on the form of a pixel, composition of pixels and the liquid crystal operation mode.

C-0982

Accuracy of manual fusion of CT and PET images using a fixation device

E. Minota, Y. Nakamoto, K. Matsumoto, S. Sakamoto, T. Okada, M. Senda; Kobe/JP

Purpose: Clinical usefulness of a combined PET/CT scanner has been recognized in oncology, because accurate image fusion can be easily obtained, yielding higher diagnostic confidence and accuracy. Manual fusion of PET and CT may cause more misregistration when compared to PET/CT. However, this could be acceptable in clinical in terms due to cost-effectiveness. The purpose of this study was to evaluate the differences in the positions between PET and CT images obtained separately, using a fixation device for positioning.

Methods and Materials: The study population comprised 30 patients referred for evaluation of known or suspected cancer, including lung cancer ($n = 14$), malignant lymphoma ($n = 11$) and colorectal cancer ($n = 5$). The patient was positioned using a vacuum cushion, and median and bilateral lines were marked on the surface of the skin. PET and CT scans were performed using the same fixation device and markers for positioning. Difference in the position between the two images was measured on a workstation.

Results: The absolute differences in the positions of the liver were 9.1 ± 7.4 mm

Evaluation of virtual endoscopy at extremely low exposure dose

Y. Hirano¹, Y. Miyatani², H. Matsuya³, M. Iriyama³, S. Honma³, D. Ohura³, H. Sasaki³, N. Ohmi³, K. Sasaki³, Y. Takada³, ¹Otaru-city, Hokkaido/JP, ²Tokyo/JP, ³Sapporo-city/JP

Learning Objectives: To employ CT virtual endoscopy (VE) for screening examinations of the gastrointestinal tract. To minimize exposure dose in CT screening examinations. To evaluate the detectability of lesions in the gastrointestinal tract.

Abstract: In CT VE for gastrointestinal tract screening, exposure dose must be minimized. The usual exposure dose is intended for the visualization of lesions in solid organs, but the ideal exposure dose for VE of the stomach or large intestine has not been determined. The present study addressed the following three points in achieving extremely low-dose scanning.

Procedure Details: 1. Evaluation of changes in detection of elevated and depressed lesions due to noise. 2. Evaluation of image filter to achieve extremely low exposure dose. 3. Evaluation of clinical images obtained by extremely low-dose scanning.

Conclusion: By employing a scanning technique intended for VE only and by using the exposure dose reduction function provided in the CT system, the conventional scan exposure dose (CTDIw) of 16 mGy could be reduced to 1.7 mGy (i.e., 1/10th) while ensuring high detectability for elevated and depressed lesions. (Conventional method: 120 kV, 300 mA, 0.5 s/rot., Super-low-dose method: 120 kV, 30 mA, 0.5 s/rot.). Although multislice CT meets the basic requirements for 3D imaging of the gastrointestinal tract, extremely low-dose scanning must be achieved before screening examinations are performed.

C-0984

Impact of different flip angles on in-stent signal intensity in contrast-enhanced MR-angiography (CE-MRA) of current self-expanding stents

D. Blondin, B. Fritz, Y. Rado, A. Saleh, U. Mödder, M. Cohnen; Düsseldorf/DE

Purpose: Experimental study to evaluate the influence of different flip angles (FA) and stent orientations in the main magnetic field (B_0) on intraluminal signal intensity (SI) of modern self-expanding stent types in CE-MRA at a 1.0-T-scanner.

Materials/Methods: 12 stents of different diameters (8, 10, 12 mm, 2 stainless steel, 10 nitinol) were released in tubes filled with gadopentetate dimeglumine (Magnevist®, Schering) diluted in physiological saline (1:25) and immersed in a water-filled phantom parallel and transverse to B_0 . 6 stents were deployed at 10 mm diameter, 2 at 8 mm, and 4 at 12 mm, respectively. Imaging was performed with a T1-weighted three-dimensional gradient-echo sequence, using different FA (10°, 40°, 70°, 100° and 130°). After transfer to a remote PC-workstation, SI (relative units) within the stents, outside the stents (within the contrast filled tube), and background noise was determined using ROI-measurements. The perceivable stent diameter was measured using electronic calipers.

Results: Maximum SI was observed at a FA of 130° with an increase of approximately 100 relative SI-units per 30° resulting in a doubling of SI from 10° to 130°. Best signal-to-noise ratio yielded a flip angle of 100°. Apart from two stents (steel), in-stent diameter accounted for 80-95% of tube diameter without dependence on FA.

Conclusions: SI inside the stents increased significantly with increasing FA. Highest SI was reached at 130° FA, however, signal-to-noise ratio was worse than at 100° FA. In conclusion, CE-MRA at 1.0-T should be performed at higher FA to increase in-stent signal intensity.

C-0985

Registration and fusion of CT and MR 3D models in patients with brain tumours

G. Tezapsidis, A. Manolitsas, L. Tarazi, I. Tsitouridis; Thessaloniki/GR

Purpose: To describe two registration techniques, landmarks based and surface matching, of CT and MR imaging scans in patients with brain tumor and evaluate the utility of the fused 3D models.

Methods and Materials: 11 patients with various brain tumours were examined with both CT and MR images. CT and MR images were registered using two techniques, landmark based and surface matching. The images from CT were segmented and three-dimensional models of the bone structures were produced. The images from MR were segmented and three dimensional model of brain only and tumor only were produced. The three dimensional models were fused in one model which included bone structures from CT and brain and tumor from MR.

Results: In 10 patients the registration and fusion of 3D models was completed

successfully. In one patient the registration was unsuccessful due to movement artifacts in MR images. The fused 3D models were better at depicting the relationship between bone, brain and lesion than conventional display of different imaging modalities alone.

Conclusion: Registered 3D models from CT and MR images from patients with brain tumours can give information more clearly and accurately than single modality images alone. This information's can be used in daily clinical practice such as radiotherapy treatment planning or surgery or in basic clinical research.

C-0986

Optical index of the diaphragmatic motion during breath holding

T. Katsuda; Okayama-City/JP

Purpose: Lung computed tomography (CT) images for lung volume measurement have been obtained during full inspiration breath holding (B-H). It is, however, known that the lung volume changes due to diaphragmatic motion occurring both in cranial and caudal direction during B-H. To obtain appropriate CT images, it is necessary to consider the diaphragmatic motion. This study investigated the optical index of the moving direction of patient's diaphragm before imaging.

Methods and Materials: Forty patients underwent helical chest CT and immediately scanned sequential dynamic upper abdominal CT of which had been obtained for their clinical necessity, were used for this study. The relation between discrepancy of the antero-posterior dimension (Height) or lateral dimension (width) and discrepancy of right lung volume at almost the same plane position on CT images around the xiphoid process obtained in the same patient at different intervals after initiating B-H were evaluated by Spearman rank correlation test. In addition, the data distribution charts were evaluated.

Results: Discrepancy of heights at 4 cm in the caudal position from the xiphoid process showed the greatest correlation to right lung volume ($r = -0.770$; $p = 0.0021$). In 15 of 17 cases, the heights were correlated to the right lung volumes. There was no correlation between widths and lung volumes.

Conclusion: The optical index of the diaphragmatic motion could be identified by the abdominal wall motion. Abdominal thickness is increased when the patient inhales air and the diaphragm moves in a cranial direction during B-H.

C-0987

Lead coats as vectors of nosocomial infection

O. Mc Donnell, M. Hyland, J. Britten, R. Graham; Belfast/UK

Learning Objectives: This audit was undertaken to determine whether lead coats may act as vectors for nosocomial infection in the radiology department.

Background: Nosocomial infections are hospital acquired infections that occur 48 hours after admission to hospital. They are a significant cause of morbidity and mortality in the hospitalised patient. It is a significant problem particularly with the advent of MRSA. Its source may be from the patients own body or from contact with others. The hands of medical and nursing staff are most frequently responsible. However many articles of hospital workers' clothing and equipment have been identified as vectors of harmful organisms including pens, stethoscopes, neck ties, white coats, and ultrasound probes.

Procedure Details: A standard of 100% sterile cultures was established. Fifteen lead coats were identified. A dry swab was soaked in sterile saline and wiped across the surface of each coat. The swabs were cultured and details of flora examined at 48 hours. All coats grew skin commensals to include coagulase negative staphylococcus, micrococcus species and bacillus species. Three of fifteen coats cultured streptococcus viridans. One of fifteen coats cultured methicillin sensitive staphylococcus aureus.

Conclusion: The target was therefore not met. We therefore recommend cleaning each coat after each use with an alcohol based wipe. In cases where heavy contamination may occur the use of a disposable plastic apron is suggested. Re-audit is planned in 1 year after institution of the above changes.

C-0988

X-ray examinations of women of reproductive age in Finland

A.O. Kettunen¹, A. Servomaa²; ¹Oulu/FI, ²Helsinki/FI

Purpose: According to the Med.Dir (97/43/Euratom) special protection requirements are needed in childhood and during pregnancy. This study was focused on finding out the current practice of pelvic X-ray examinations of woman in fertile age.

Material and Methods: A questionnaire was sent to all radiation safety officers (290) in Finland; 173 questionnaires were returned. The questionnaire included questions about the number of pelvic X-ray examinations performed on a pregnant women, practice involved if the embryo or fetus has been exposed, practice

Scientific and Educational Exhibits

of excluding the possibility of pregnancy, practice of fetus dose estimation and guiding a pregnant woman after fetal expose.

Results: European recommendations for pregnant women X-ray examinations are not totally fulfilled in Finnish practice. The hospitals do not in general document the X-ray examinations of pregnant women. The most common way of excluding the possibility of pregnancy was to ask a woman whether she was pregnant by the physician and radiographer. Radiologists and referral physician were the main estimators (85%) of the fetal dose based mostly (61%) on the literature. Physicians and radiographers were the main explainers to the expectant mother about the radiation risk to the fetus.

Conclusions: To improve the practice, a guide to 'good practice' in the pelvic and lower abdomen X-ray examinations of a woman of reproductive age is needed. It should include guidelines on how to exclude and document the pregnancy of a woman of reproductive age coming for a pelvic X-ray examination and guidelines for fetal dose estimation and documentation.

C-0989

Virtual endoscopy: An additional imaging tool for the depiction of regions that the actual endoscopy cannot approach

A. Manolitsas, G. Tezapsidis, L. Tarazi, I. Tsitouridis; Thessaloniki/GR

Purpose: The purpose of our study is to demonstrate the applications of virtual endoscopy in regions where the actual endoscopy cannot be applied.

Methods and Materials: We studied 23 virtual endoscopies, (16 with SCT and 7 with MRI). In particular, 11 virtual angiographies, 4 virtual otoscopies, 3 virtual endoscopies of the upper urinary tract and 5 virtual endoscopies in closed cavities as the sphenoidal or frontal sinus. The examinations were performed using a Picker 5000 Spiral CT scanner, a Siemens Expert 1 T MR scanner, a Picker Voxel Q visualization workstation and Analyze version 5.0 software.

Results: The imaging findings were always in agreement with those of original CT and MR scans. We studied the results of the method and described the advantages and disadvantages.

Conclusion: Virtual endoscopy is a useful approach for assessment of volumetric CT and MR data, which can provide precise and realistic information for the inner surface of each examined structure. Moreover it is an additional, non-invasive, imaging method that can be applied in regions that the actual endoscopy cannot approach.

C-0990

Comparison of clinical evaluation of a flat-panel detector system and a computed radiography system for digital chest radiography

M. Ogawa, H. Kobayashi, K. Masuyama; Bunkyo-ku/JP

Purpose: Although a flat-panel detector digital chest radiography system (FPD system) has recently been introduced in a clinical setting and is in the limelight, a computed radiography system (CR system) is also evolving day by day. At present, a new CR system, which can detect emissions of lights from both sides of the imaging plate and has a flexible noise control (FNC) function as a new image processing, has been developed and introduced in some facilities. There are not a few facilities which use these two digital chest radiography systems under mixed conditions. We expected that the quality of images of both systems is not necessarily equal. Therefore we compared the difference of clinical utility between FPD system and CR system using postprocessed hard-copy images by conducting observer performance tests.

Methods and Materials: First, we studied the visual detectability of low contrast simulated nodules using a chest phantom. Observer performance data were analyzed by receiver operating characteristic (ROC) analysis. For statistical analysis, we used the jackknife method. In addition, we conducted observer performance tests with a contrast-detail (C-D) phantom and the method of paired comparisons using PA chest images.

Results: The result of the evaluation with ROC analysis and the method of paired comparisons indicated that a new CR system was equal or superior to FPD system. As for study of C-D phantom, both systems were almost equal.

Conclusion: As for observer tests with postprocessed hard-copy images, the quality of images of both systems is almost equal.

C-0991

Radiodiagnostics for hip and shin prosthesis after mine explosion and gunshot wounds

A.Y. Vasilyev, M.V. Vykhlyuk, I.N. Gipp; Moscow/RU

Purpose: To define the optimal extent of radiological examinations in evaluation of hip and shin stumps before prosthesis.

Methods and Materials: 60 patients with hip stumps and 18 patients with shin stumps were examined after mine explosions (81.0%) or after gunshot wounds (19.0%). All patients underwent the following examinations: routine radiography, microfocus radiography with the magnification factor of 5, high resolution ultrasoundography, helical computed tomography.

Results: The semiotics of changes in hip and shin stumps was defined with the help of radiological data. Doppler ultrasonography is recommended for determining the condition of soft tissues of the stump. Microfocus radiography has advantages when compared with the routine radiography in detecting small structural changes at their early stages and therefore is recommended for determining the condition of osseous structures. Both of those methods are sufficient for shin and hip stump evaluation during the preparation for prosthesis of the amputation stump. Computed tomography is recommended in difficult cases with grave general condition of the patient and vast wounds.

Conclusion: The application of up-to-date high resolution radiological methods allows to obtain reliable information about soft tissues and osseous structures of amputation stump. The application of radiological examinations in compliance with the suggested algorithm is necessary during the preparation of the stump for prosthesis.

C-0992

Guide, instruct and encourage. Radiographers' views on tutoring

T. Holtinkoski, A. Niemi, A. Kettunen; Oulu/FI

Purpose: The purpose of this study was to describe the tutoring of clinical practice from the viewpoint of the radiographers. Answers were sought to the following questions: 1) How the curriculum and the objectives of the students guide the tutoring given by the radiographers? 2) What is the tutoring like from the viewpoint of the radiographers? 3) How is the clinical practice evaluated? 4) On what kind of matters related to the tutoring would the radiographers want further information?

Methods: The data was collected quantitatively by means of a structured questionnaire. The target group for the study was the tutoring radiographers (N = 130). The structured questions were analyzed with SPSS/PC-software.

Results: The formulated practical objectives are carried out during the clinical practice of the students. One third of the tutors gave sufficient instruction in formulating students training objectives. Over half of the tutors knew what the student should learn during the training period. Tutors considered themselves to be able to sufficiently take into account the initial level of the student. Tutoring was generally considered demanding but not strenuous. The main opinion of the tutoring was that evaluation supports and encourages learning. It is guided by objectives, the student has an active role in it and the evaluations are usually correct.

Conclusion: This study increases knowledge of the tutoring of clinical practice. The results can be utilised in developing the tutoring both in radiological departments and polytechnics.

C-0993

Improved MR imaging of the extremities using a flexible multiple element phased array body coil

B. Schmitz, A.J. Aschoff; Ulm/DE

Learning Objectives: To learn how to improve MR image quality by using commercially available phased array body coils for imaging of the extremities.

Background: The advent of parallel MR imaging techniques gave rise to the development of multi-channel phased array coils. These coils were primarily designed for improvements in cardiac or abdominal imaging. Besides improved parallel imaging capabilities signal to noise ratio (SNR) is substantially enhanced. However, as a by-product this new coil design is very flexible which allows the extension of the application. Imaging of the extremities becomes possible by wrapping the coil around knee, shoulder, wrist or ankle. This ad hoc improves SNR and moreover transfers all parallel imaging possibilities to extremity imaging.

Procedure Details: Siemens Symphony 1.5 T scanner was extended with a commercially available package to allow 8 channel imaging with a 12 element phased array coil. Besides routine use in cardiac and abdominal examinations, the coil was used as a replacement of the regular flexible extremity coil. Images showed an immediately obvious improvement in SNR and image quality without artefacts.

Conclusion: In this exhibit we show how to replace regular flexible extremity coils with newer commercially available flexible multi-element phased array body coils for an improved imaging of the extremities.

C-0994

Lens dose reduction in paediatric CT brain scan using the supra-orbitomeatal baseline technique

K.K. Fung, K.H. Choi; Hung Hom/HK

Purpose: The increasing collective dose from CT scans has been a great concern in recent years. The aim of this study was to determine the effect of using two different scan planes in routine CT brain on lens dose reduction and resulted image quality in paediatric patients.

Methods and Materials: Fifty-two paediatric patients aged 1-12 years were selected for this study. They were randomly divided into two equal groups to receive the CT brain scans. One group underwent scanning with a modified technique using the supra-orbitomeatal (SOM) baseline and the other group with the conventional orbitomeatal (OM) baseline. Lens dose measurements were made using LiF:Mg,Ti TLD pellets. The resulted image quality and overall diagnostic value were also evaluated by 5 radiologists using the 5 point confidence scales. An adult head phantom was also scanned with the use of these two scan planes and the corresponding lens doses were measured.

Results: By using the SOM baseline instead of the OM baseline, the eye lenses were avoided from direct irradiation of the X-ray beam. Results showed that the measured lens dose can be reduced on average by 81%. The degree of lens dose reduction was nearly the same in the adult phantom (84%) experiment. Results also showed that the image quality and overall diagnostic value were similar using either scanning plane. Reliability tests showed consistent results.

Conclusion: It is recommended to use the SOM baseline in routine CT brain scan to reduce the lens dose for both adult and paediatric patients.

skills. In addition, the study indicated that students learned through an increased awareness of their own learning processes. Moreover, learning was found to improve social interaction with the Radiographers, Radiologists and Teachers. For better results, attention should be paid to support the learning process of plain X-ray examinations through increased awareness which enables students to monitor and review their progress in the key components of plain X-ray examinations.

C-0995

Reduction of skin exposure in interventional radiology

A. Kawabe, Y. Nakagiri, T. Katsuda, A. Matsushita, T. Maruyama, H. Wakasa, S. Kadohisa; Okayama-city/JP

Purpose: Radiation injury is one of most common problem in Interventional Radiology. One of reasons is scattered radiation from catheter table. To reduce the scattered radiation, polystyrene foam is placed between phantom and catheter table as an air gap. In this study, adequate thickness of polystyrene foam is decided for clinical practice.

Material and Methods: The polystyrene foams (2 cm thick, 28 kg/m³) are used instead of the air gap. Vinyl chloride foam (3 cm thick) is inserted into carbon plates (1 mm thick) for which substitute the catheter table. To measure surface dose and depth dose in each thickness of polystyrene foams from 0 cm to 20 cm. Twenty centimeter of Mix-DP plates are used as an object. X-ray tube voltages are 70-90 kVp.

Results: Surface doses were decreased 16% and 22% (80 kVp) at the thickness of 6 cm and 10 cm polystyrene foams, respectively. Depth dose at 14 cm Mix-DP was similar as compared to the dose without polystyrene foams.

Conclusion: The polystyrene foam as the air gap is able to decrease surface dose by the scattered radiation from catheter table without any deterioration of image quality. This method is easy to set and less expensive. Thickness of polystyrene foams 2 cm to 10 cm are useful for clinically to reduce surface dose.

C-0996

Student descriptions of learning how to perform plain X-ray examinations during practical studies

A. Holmström, A. Kettunen; Oulu/FI

Learning Objectives: To describe the experiences of radiography students learning how to make plain X-ray examinations during their practical studies.

Background: Plain X-ray examinations are patient's basic radiological examinations in Finland. Radiographers are responsible for making those examinations properly. During radiography studies the students study plain X-ray examinations both in academic and practical studies. There is a rather small number of research concerning students' learning of plain X-ray examinations during their practical studies.

Procedure Details: This study was qualitative in nature. The data comprised 21 learning diaries provided by radiography students during their 3rd and 7th term when they were practising plain X-ray examinations. The diaries were analysed by means of content analysis and quantifying expressions.

Conclusion: The study showed that the key components of the process of learning to conduct plain X-ray examinations were patient care, technical expertise and decision-making skills. Students in the 3rd term emphasized technical expertise, while students in the 7th term underlined the importance of patient care. Both student groups brought attention to the significance of learning decision-making

Quantitative analysis of carotid artery atherosclerosis by micro-CT

A. Mohr¹, F.W. Roemer², A. Guermazi², C. Heiss³, C. Schmidt¹, P.J. Schaefer¹, H.K. Genant²; ¹Kiel/DE, ²San Francisco, CA/US, ³Giessen/DE

Purpose: To evaluate micro computed tomography (micro-CT) for two- and three-dimensional analysis of carotid artery atherosclerosis.

Methods and Materials: Micro-CT scans (STRATEC 0.125 mA, 40 keV) were performed on 10 carotid arteries (63 - 73 years) at 60 µm isotropic resolution. Image evaluation included the analysis of multiplanar reconstructions and volume renderings based on constant threshold levels for air (-140), soft tissue (430) and calcifications (750), which were identified by histogram analysis with interactive density thresholding. The following morphological parameters were calculated: Two-dimensional: original lumen perimeter (LP), original lumen area (OA), plaque area (PA), residual lumen area (RA), calcified area (CA), gross sectional area reduction (GSAR); three-dimensional: total tissue volume (TTV), the soft tissue volume (STV), calcified tissue volume (CTV).

Results: Micro-CT depicted the typical anatomy of the arteriosclerotic carotid artery, with high contrast between calcifications, soft tissue and air. Calcifications demonstrated variable internal densities, differences within the soft plaque were less obvious and ulcerations and/or fissures could not be detected. The two- and three-dimensional analysis yielded the following

Results: LP 25.29 ± 1.3 mm, OA 45.33 ± 5.5 mm², PA 21.9 ± 7.2 mm², RA 22.9 ± 9.9 mm², CA 3.7 ± 4.7 mm², GSAR $50.3 \pm 19.3\%$, TTV 1034.7 ± 80.8 mm³, STV 1007.2 ± 55.3 mm³, CTV 31.2 ± 8.9 mm³

Conclusion: Micro-CT as a time efficient, non-destructive, high-resolution tool for the volumetric evaluation of carotid atherosclerosis. It cannot replace histology if detailed information is needed, but offers advantages when samples need to remain intact, only gross morphological features are being evaluated, calcifications are of specific interest or entire samples or specific sample volumes have to be analyzed.

C-0998

Evaluation of the Vesselness and Laplacian of Gaussian filter for vessel enhancement in CT images

S.C. Saur, S. Großkopf; Forchheim/DE

Purpose: To evaluate the Vesselness and Laplacian of Gaussian (LoG) filter for the enhancement of vessel structures in CT images.

Methods and Materials: The filters were applied on CT coronary, aortic and carotid datasets coming from Siemens Sensation 16 and Sensation 64 scanners. syno® VesselView segmentation was taken as the gold standard. Voxels smaller than -125 HU values were excluded to speed up calculation. Filter parameters were adapted to the expected vessel diameter (coronary ~3 mm, carotid ~10 mm, aorta ~30 mm). Sensitivity (sens) and positive predictive value (pdv) were chosen as evaluation criteria. The segmentation threshold for the Vesselness filter responses was determined regarding discrimination analysis, entropy analysis and percentage-based approaches. For the LoG filter, a 15x15x1 minimum filter was used. Besides this global statistical approach, the general capability of the Vesselness filter is regarded using the a priori knowledge of the segmented vessels.

Results: Best results for vesselness filter achieved with entropy analysis (sens 0.8-36.2%, pdv 3.6-9.5%) followed by discrimination analysis (sens 1.2-47.3%, pdv 3.7-8.7%) and 95%-quantile (sens 0.1-30.3%, pdv 3.5-10.1%). LoG in combination with minimum filter attained positive predictive values not exceeding 1.1%. Using a seed point region growing, the Vesselness filter outperformed the gold standard in some cases but had weaknesses on certain bifurcations and stents.

Conclusion: Both Vesselness and Laplacian of Gaussian filter provide inadequately results for the purpose of vessel enhancement in a global application with no knowledge of the vessels position. Locally, the Vesselness filter can be applied to support the segmentation process.

C-0999

MDCT of collateral venous circulation in the retroperitoneum

H. Cuéllar i Calàbria, S. Quiroga, C. Sebastià, R. Boyé, A. Miranda, A. Álvarez-Castells; Barcelona/ES

Learning Objectives: To outline the venous anatomy and embryology of the retroperitoneum. To show MDCT cases of collateral retroperitoneal veins and discuss their pathologic and physiologic causes. To describe the advantages and limitations of the MDCT technique in the study of retroperitoneal vessels.

Background: The retroperitoneal space is traversed by several venous networks characterised by their variability as well as by multiple anastomoses among them and other vascular territories. Thus, blood may be diverted through the retroperitoneum in various patterns suggestive of a number of physiologic and pathologic conditions. MDCT has improved spatial resolution with an almost isometric voxel as well as temporal resolution with faster scanning velocity allowing for precisely timed vascular studies of high quality.

Imaging Findings: MDCT studies of collateral circulation through capsular, adrenal, lumbar-azygous, ureteral, gonadal, uterine and inferior mesenteric veins, as well as direct and indirect portosystemic shunts are shown, with emphasis on MDCT technique and volume rendering. MDCT patterns are illustrated and discussed in cases of congenital variants, anterior and posterior nutcracker phenomenon, incompetent gonadal veins, inferior vena cava tumoral invasion, hepatic cirrhosis, thoracic venous thrombosis, acute ovarian arterial hemorrhage as well as arteriovenous fistulae and idiopathic varices. Computed animations illustrating flow routes are included.

Conclusion: MDCT angiography depicts retroperitoneal venous circulation in detail, yielding diagnostic information of great utility in the differential diagnosis among pathologic vascular conditions, physiologic phenomena and anatomic variants.

C-1000

Endograft placement for aortic aneurysms and dissections: Pre and post evaluation using MDCT angiography: How to do it

H. von Tengg-Kobligk, M. Ganter, D. Boeckler, C. Fink, J. Zaporozhan, F.L. Giesel, S. Delorme, H.-U. Kauczor; Heidelberg/DE

Learning Objectives: 1. Evaluation of aortic aneurysms and dissections based on typical MDCT findings. 2. Relevant scanning and post processing techniques to meet the requirements for therapeutic decision. 3. Imaging findings of typical complications after endograft placement.

Background: MDCT-Angiography can play a decisive role for the pre-procedural planning and post-procedural follow-up of endovascular repair of aneurysms and dissections. An optimal visualization of the vascular anatomy and therapeutic material is crucial for decision making and assessment of therapeutic results or even complications.

Procedure Details: The suggested protocol for patients with aortic aneurysms or dissections using a 16 row CT (e.g. Aquilion 16, Toshiba, Japan) with the following parameters: 120 kVp, 120-150 mAs, 1 mm collimation, pitch 15, ≤ 0.5 s rotation time, bolus triggering, 100-120 ml of high-concentration iodinated contrast media such as Imeron 400 (Bracco ALTANA Pharma, Germany), 4-5 ml/s flow rate and saline flush. Post processing (MPR, surface rendering, vessel tracking) is preferential on a capable workstation (e.g. Vitrea, Vital Images, USA). Typical quality criteria are: Max. contrast in the aorta: ≥ 400 HE, no/little venous enhancement, visualization of Adamkiewicz artery, entries and re-entries. Crucial post endograft findings include leakage, residual perfusion of the aneurysmal sac, endograft rupture.

Conclusion: For an optimal evaluation of complex aortic aneurysms and dissections with MDCT, thin collimation with overlap, high-concentration iodinated contrast agents, a power injector enabling high flow rates and a workstation allowing for MPR of the spinal vasculature, vessel tracking for true vessel diameter and surface rendering for surgical planning are recommended.

C-1001

Multi-detector CT angiography in the evaluation of hemodialysis access failure

N. Hongo, H. Mori, S. Matsumoto, R. Shuto; Oita/JP

Purpose: To evaluate the utility of whole arm CT angiography (CTA) obtained by multi-detector CT in stenosis or occlusion of hemodialysis access.

Materials and Methods: Seventeen patients (7 males, 10 females, mean age 62.9) underwent DSA of their hemodialysis access and multi-detector CTA within 2 weeks. 63 stenoses or occlusions were detected on DSA. For CTA, 100 ml, 300 mg/ml nonionic iodinated contrast medium was injected intravenously at the rate of 3 ml/sec in the contralateral arm, and the whole arm was scanned with 1.5 mm collimation by a 16-detector row CT scanner. Maximum intensity projection 3D images acquired from 2 mm thickness CTA images were evaluated by two radiologists and stenoses were graded as follows: 25-50% (mild), 51-70% (moderate), 71-99% (severe), 100% (occluded). These findings were compared to DSA, which served as the standard of reference.

Results: Sensitivity / specificity of multi-detector CTA for detecting > 50% stenosis were 0.94/0.98 for reader 1, and 0.91/0.94 for reader 2. Sensitivity / specificity for detecting > 70% stenoses were 0.90 / 0.88 for reader 1 and 0.90/0.79 for

Scientific and Educational Exhibits

reader 2. The rate of stenosis agreement between CTA and DSA was 87.3%. Interobserver agreement of CTA was excellent ($\kappa = 0.915$)

Conclusion: Multi-detector CT Angiography can adequately detect hemodialysis access failure. It is a less invasive tool and provides useful information about the site and degree of hemodialysis access stenosis, which can lead to successful percutaneous transcatheter angioplasty.

C-1002

Ruptured abdominal aortic aneurysm: MSCTA imaging

R. Stern-Padovan, M. Lusic, I. Sjekavica, M. Hrabak, K. Potocki, B. Oberman, J. Marinic; Zagreb/HR

Learning Objectives: 1. To describe the imaging protocol in patients with suspected leaking abdominal aortic aneurysm. 2. To present various radiological findings after rupture of abdominal aortic aneurysm.

Background: Leaking abdominal aortic aneurysm is a life-threatening condition manifested as acute flank or epigastric pain and signs of hemorrhagic shock. To avoid unnecessary delay in surgery, the correct diagnosis must be provided as quickly as possible. Due to its speed and accessibility, MSCTA is the modality of choice before emergency treatment of ruptured abdominal aortic aneurysm. An unenhanced CT scan depicts abdominal aortic aneurysm and retroperitoneal hematoma, while MSCTA accurately delineates the actual site of bleeding.

Procedure Details: MSCTA was performed using SmartPrep feature after a bolus of 80-120 ml intravenous nonionic contrast medium with 4 ml/s flow rate. Axial images were transferred to a workstation and postprocessed using maximum intensity projection (MIP), multiplanar reconstruction (MPR) and 3D volume rendering (3D VR) protocols.

Conclusion: As well as visualization of retroperitoneal hemorrhage, abdominal aortic aneurysm and pseudoaneurysm formation, MSCTA also depicts mural thrombus, aneurysm length and width, its extension into aortic branches, as well as other morphological and blood flow changes in visceral and pelvic arteries. Considering the extension of retroperitoneal hemorrhage into different anatomical compartments (periaortic, perirenal, pararenal spaces, pelvis) and retroperitoneal organs (aortoduodenal fistula), the radiologist must determine the exact location of bleeding. MSCTA is the fastest, very safe and minimally invasive radiological procedure, which gives optimal information for urgent interventional or surgical repair of a ruptured abdominal aortic aneurysm.

C-1003

Multidetector row CT angiography of the abdominal aorta and lower extremities: Post-processing and arterial wall calcification removal

J.-M. Treutenaere, T. Bernasconi, C. Renard, M.-A. Auquier, A. Remond; Amiens/FR

Purpose: To describe post-processing techniques of multidetector row CT angiography (MDCTA) of the abdominal aorta and lower extremities, in particular methods to remove arterial wall calcifications in 3D Maximum Intensity Projections (MIP).

Methods and Materials: In 2003, 534 patients with symptomatic lower extremity peripheral arterial disease underwent MDCT angiography of aortoiliac and lower extremity arteries (Lightspeed Ultra and Lightspeed 16, GEMS). Post-processing was carried out on ADW 4.1 and 4.2 workstations. Vascular mapping was obtained in 3D MIP reconstruction. We present a method to remove arterial wall calcifications by segmentation starting vascular lumen density. Quantification of vascular diameter and study of the arterial wall are analyzed in 2D projections.

Results: Complementary Digital Subtraction Angiography (DSA) was necessary in only five patients: in 2 diabetic patients distal arteries were too heavily calcified and in 3 patients with acute lower extremity ischemia, CT acquisition was made before the arrival of contrast material distally. These techniques would thus be reliable, reproducible and fast. MDCT angiography with post-processing methods presented here makes it possible to decrease the quantity of contrast material injected and to avoid complications of DSA in nearly all patients.

Conclusion: Thanks to these methods of simple post-processing realizable on any workstation, MDCT angiography facilitates pre-therapeutic assessment of lower extremity peripheral arterial disease. A prospective study of MDCT angiography versus Digital Subtraction Angiography would allow the validation of this technique.

C-1004

Role of spiral CT in detection of intramural aortic hematomas and in selection of treatment tactics

F. Todua, M. Razmadze, G. Tsivtsivadze; Tbilisi/GE

Purpose: To evaluate the clinical significance of intramural hematoma in the thoracic aorta and the role of spiral-CT in determination of treatment tactics in patients with this pathology.

Materials and Methods: 34 patients with clinical suspicion of acute aortic dissection and CT findings of a thickened aortic wall were evaluated. CT examinations were performed within 24 hours of onset of symptoms and as a regular follow-up within 3-6 months. The technique used was contrast-enhanced spiral-CT with 3-5 mm slice thickness.

Results: 15 patients had intramural hematoma in the ascending aorta. 9 underwent acute surgery and a ruptured intima was determined as the cause of the hematoma. 3 died before operation and autopsy showed intimal dissection. In 3 patients the significance of the hematoma was not appreciated in the acute phase, but was discovered later. Follow-up CT showed regression of the hematoma. 19 patients had intramural hematoma in the descending aorta and were treated conservatively. At follow-up 13 showed normalization, 4 developed aneurysm and 1 developed a small ulcer-like saccular aneurysm. In one patient the findings were unchanged.

Conclusion: Intramural hematomas in the ascending aorta are usually caused by an intimal tear and represent true dissections. Detection of intramural hematomas is of great importance in the management of patients with aortic dissection, which includes evaluation of localization and spread of the hematoma, therefore selecting the patients for surgical treatment. In cases of descending aorta intramural hematoma, conservative treatment often leads to normalization of the aortic wall.

C-1005

Evaluation of MDCT in detection of atherosclerotic plaques in WHHL animals

H. Ittrich, P. Begemann, C. Jahntz, C. Weber, A. Priest, G. Adam; Hamburg/DE

Purpose: Evaluation of native and contrast-enhanced (CE) CT in detection of atherosclerotic plaques in 16 row multidetector CT (MDCT) scanner in an animal model.

Method and Materials: Native and CE-CT was performed on 25 WHHL (12-31months) and 11 New Zealand White (NZW,control,16 months) covering the aorta. Scans were performed before and during continuous administration of iopamidol (Solutrust 300) in a MDCT scanner (Philips) using 16x0.75 mm collimation with a standard protocol (120 kV,321 mA,rotation time 0.4 sec., automated injection: 5 cm³ iopamidol diluted in 5 cm³ NaCl, flow: 1 cm³/sec, contrast optimization: automated bolus tracking option, threshold 130 HU, slice reconstruction: 2 mm thickness, 1 mm increment). The degrees of calcification, measurements of the luminal diameter in 3 regions of the aorta (ascending part, arch and descending part) and visibility of aortic wall and anatomical layering (intima, media, adventitia) were estimated by two independent investigators (IH,BP) according to a five-point-scale, ranging from 0 (not visualised) to 4 (excellent).

Results: Only 5 of 25 WHHL animals showed calcifications in the aorta (mass:4.2 ± 5.8 mg (0.4-14.4 mg), volume:30.4 ± 42.2 mm³ (3.3-104.6 mm³)). No calcifications were detected in NZW. Luminal diameter of all animals showed no significant differences or severe stenosis (7.1 ± 1.3 mm). In all animals neither wall thickness (0.7 ± 0.5) nor differentiation of layers of the wall could be estimated (0.5 ± 0.4).

Conclusion: Native MDCT is able to detect and to quantify calcified plaques of atherosclerosis in the aortic wall (WHHL). Neither native nor CE-MDCT was able to identify anatomical layers of the aorta or to detect early stages of atherosclerotic plaques (lipid plaques) in this animal model.

C-1006

Multislice CT in the determination of suitability for endovascular aortic stent grafting

D.G. Lohan, S. Walsh, C. Meehan, I. Davidson, G.J. O'Sullivan; Galway/IE

Learning Objectives: Patient selection for endovascular stent grafting of abdominal aortic aneurysms depends upon numerous measurements, obtained at the time of multislice aortic CT. We explore and explain each of these measurements in turn, and consider the potential complications of stent grafting should these criteria not be obeyed.

Background: The popularity of covered stent grafting for abdominal aortic aneurysms has greatly increased in recent years due to a combination of low intra-

Scientific and Educational Exhibits

operative morbidity and mortality, coupled with often excellent medium-term patient outcomes. However, suitability of patients for this procedure depends upon high-quality imaging, with resultant accurate quantitative measurements. No longer is maximal aneurysm diameter an exclusion criterion for this procedure, rather neck length, and diameters of proximal and distal landing zones hold greater importance.

Imaging Findings: Using images obtained from conventional angiography, where available, as well as source and Maximum-Intensity-Projection images from multislice CT, we consider the relevant exclusion criteria for endovascular stent grafting of aortic aneurysms. By way of pictorial review we present cases in whom successful stenting was performed, with pre- and post-operative imaging. In addition, we consider images of cases in whom this technique was not suitable, explaining the reason for rejection of potential candidates in each case.

Conclusion: Using images from our institute, we explain the relevant measurements and considerations on pre-operative multislice CT with regard to endovascular AAA stent grafting.

C-1007

Utility of triple channel injection of contrast material with mixture of saline, with upward acquisition for arterial trees using multislice computed tomography

N. Yanagawa, F. Morita, S. Ochi, N. Funabashi; Chiba/JP

Purpose: If contrast material is injected into the cubital vein, high computed tomographic (CT) values in the vein hamper evaluation of the aorta and major branches. We describe a new protocol employing a combination of triple channel contrast material injection and a mixture of saline (Dual Shot, Nemoto) with upward acquisition in multislice CT.

Materials and Methods: 40 subjects underwent thoracic CT (Light Speed Ultra 16, GE). 20 subjects were injected with 60 ml contrast material. Scanning was then started with upward acquisition during the injection of contrast material diluted 50/50 with saline, followed by the injection of 30 ml of saline (new protocol). The other 20 subjects were injected with 100 ml contrast material at a rate of 3 ml/sec, with scanning in the downward direction (ordinary protocol).

Results: In the new protocol, the aorta measured an average of 290 HU which was no different from the ordinary protocol, but the injection side vein and superior vena cava measured 220 and 200 HU which were lower than in the ordinary protocol. The aorta and major branches could be observed easily without artifact and we were able to construct clear three-dimensional images of arterial trees.

Conclusions: We describe a new acquisition protocol in which the aorta and major branches can be evaluated without artifact due to high CT values in veins. This modification was achieved by rapid acquisition of multislice CT. In the future, CT scans can perform faster acquisition and the protocol using contrast material diluted with saline can be modified to provide more useful.

C-1008

Multidetector spiral CT renal angiography in the diagnosis of renal artery fibromuscular dysplasia

P. Vladica, R. Sabharwal; Sydney/AU

Introduction: The aim of the study was to evaluate the role and detection rate of Multidetector Spiral CT-Renal Angiography (CTRA) as compared with Conventional Renal Angiography (CRA) in the diagnosis of renal artery fibromuscular dysplasia (FMD).

Materials and Methods: Over a three year period three hundred and sixty eight patients with suspected renovascular hypertension were screened with CTRA. Clinical indications for referral included resistant hypertension (requiring greater than three anti-hypertensive medications), labile hypertension, hypertension in combination with renal impairment, and the presence of abdominal bruits in the context of systemic hypertension. CTRA demonstrated lesions suggestive of FMD in twenty eight patients. Twenty three of those twenty eight patients underwent CRA for further evaluation. The findings of CRA in those twenty three patients were compared to CTRA. Patients with haemodynamically significant lesions on CRA underwent balloon angioplasty.

Results: Mean patient age was 62.48 ± 13.66 years. CTRA identified all 46 main renal arteries (100%) and all 10 accessory renal arteries (100%) visualized on CRA. In the diagnosis of fibromuscular dysplasia with haemodynamically significant ($> 50\%$) stenosis, the sensitivity and specificity of CTRA were 100% and 96%, respectively.

Conclusion: Our experience suggests that CTRA is a safe, reliable and accurate method for the diagnosis of FMD. Moreover, CTRA has many advantages as a diagnostic tool over CRA, including accessibility, speed, lower complication profile, versatility and cost effectiveness. CTRA shows great potential as a guiding tool for directing subsequent procedures such as CRA \pm balloon angioplasty.

C-1009

Subclavian vein thrombosis secondary to thoracic outlet syndrome: CT and CT angiography evaluation

C. Kokkinis¹, N. Makris¹, S. Stathopoulou¹, A. Peteinelli¹, M. Vlychou², K. Vassiliou², P.J. Papadaki¹, G.M. Zavras¹, J.B. Fezoulidis²; ¹Athens/GR, ²Larissa/GR

Purpose: The aim of this study was to evaluate the diagnostic usefulness of CT and CT angiography for the detection of thoracic outlet syndrome in cases of subclavian vein thrombosis.

Methods and Materials: 11 patients with subclavian vein thrombosis (non catheter-related), diagnosed by Triplex or phlebography, were examined with CT and CT angiography after contralateral contrast medium injection in neutral and abducted positions. The evaluation included axial images, 2D MPR (Multiplanar Reformation) and MIP (Maximum Intensity Projection), 3D SSD (Surface Shaded Display) and VRT (Volume Rendering Technique) images.

Results: CT and CTA depicted thrombosis of the subclavian vein in all cases. In seven of the 11 patients (64%) the examination demonstrated thoracic outlet syndrome with significant narrowing of the costoclavicular space after abduction and compression of the vein. In 3 of them a cervical rib was found. 2D MPR, MIP and 3D SSD, VRT were very useful for the detection of subclavian vein compression.

Conclusion: CT and CT angiography can be used in patients with subclavian vein thrombosis suggestive of thoracic outlet syndrome, as it can confirm or exclude it, thus aiding planning of therapy.

C-1010

CT evaluation of congenital vena cava anomalies

M. Inal, S. Leblebisatan, F. Binokay, E. Akgül, E. Aksungur, M. Oguz, S. Soyupak, K. Biçakci, M. Çeliktaş; Adana/TR

Learning Objectives: Because of having complex developmental stages, the venous system shows numerous different congenital anomalies. 13 patients with vena cava (VC) anomalies were reported here as they are rare and have different variations. It is important to detect the anomalies of either superior (SVC) or inferior (IVC) in order to prevent fatal complications during surgery or catheterization.

Background: Anomalies of IVC are seen in 0.3% of the general population and in 0.6-2% of patients with congenital heart disease (CHD). Double SVC is the most common anomaly (0.3%), reaching over 11% in patients with CHD. We report 13 cases of VC anomalies detected with CT. Two patients had double IVC, 2 with double SVC, 4 with left IVC, 1 with left IVC with hemiazygous continuation, 1 with intrahepatic segmental atresia of IVC, 1 with azygos continuation of IVC, 1 with double SVC with hemiazygous continuation and 1 with double IVC with azygos continuation. None of the patients had CHD.

Procedure Details: Between 1997-2004, 13 patients who had complaints unrelated to their venous anomalies were analyzed with CT and congenital VC anomalies were detected. Diagnoses were confirmed by venographic studies in 3 patients. CT scans were performed in helical mode with a pre-delay of 55 seconds and a pitch of 1.2.

Conclusion: VC anomalies are generally asymptomatic and detected during surgical or diagnostic procedures. Catheterization or surgical intervention may result in life-threatening complications if the physician is unaware of the anomaly.

C-1011

Failing arteriovenous hemodialysis fistulas: Assessment with multidetector CT angiography and three-dimensional (3D) techniques

E. Karadeli, N.C. Tarhan, E.M. Kayahan, N. Tutar, O. Basaran, M. Coskun; Ankara/TR

Purpose: To evaluate failing hemodialysis arteriovenous fistulas and complications with multidetector CT angiography (MDCTA) and 3D reconstruction techniques.

Methods and Materials: Between September 2003 and July 2004, 30 patients (16 M and 14 F-aged between 27-79 years old), with suspected hemodialysis access dysfunction who were referred to our radiology department for diagnostic fistulography, had 31 MDCTA (Sensation 16, Siemens, Erlangen, Germany). All fistulas were in the upper extremity. Contrast was administered from a peripheral vein of the contralateral arm as a bolus of 150-200 cc at a flow rate 5 cc/s. Transverse scans were viewed in the arterial phase with reconstruction at 1 mm intervals. Transverse and coronal MIP, and VRT images were constituted. AV fistula sites, arterial, venous system and complications were evaluated. Fistulography served as the gold standard for comparison in all patients.

Results: 14 fistulas were at wrist level, 17 fistulas were at antecubital fossa level.

Scientific and Educational Exhibits

There were 27 native and 4 graft fistulas. There were 57 venous pathologies detected with MDCTA: Cephalic venous stenoses (n = 7, 22%), subclavian venous stenoses (n = 2, 6%), cephalic occlusion (n = 3, 9%), subclavian occlusion (n = 6, 19%), axillary occlusion (n = 2, 6%), venous aneurysms (n = 21, 67%), collaterals (n = 16, 51%). 10 arterial and fistula site complications were: Stenoses in subclavian artery (n = 2, 6%), stenoses in axillary artery (n = 2, 6%), stenoses in brachial artery (n = 2, 6%), aneurysm of brachial artery (n = 1, 3%) stenoses at the anastomosis site (n = 3, 9%).

Conclusion: MDCTA is a noninvasive, effective imaging method to evaluate hemodialysis vascular access and complications. Arterial vascular pathologies that cannot be detected with conventional fistulography can also be demonstrated with MDCTA.

C-1012

Spiral CT angiography: A valuable decision-making tool for carotid endarterectomy

C. George¹, M. Titi², D. Bhattacharya², P.M. Woodhead², W.J. Stevenson², A. Pillai², D.F. Ettles¹, H. Al-Khafaf², ¹Hull/UK, ²Burnley/UK

Purpose: To compare results of duplex ultrasound scan (DUS) and spiral CT angiography (CTA) in patients with suspected carotid artery stenosis and to evaluate its impact on decision making for carotid endarterectomy.

Materials and Methods: Data were collected retrospectively in patients who had undergone both DUS and CTA for the evaluation of suspected internal carotid artery stenosis. St Mary's criteria were used for estimation of severity by DUS while direct measurement of stenosis was made from multi-planar CT reformats. Degree of agreement between these modalities was assessed, along with limitations of both.

Results: 107 patients were evaluated over a two year period (Jan 2002 - March 2004). 27 of the 214 carotid arteries scanned were excluded because of technical imaging difficulties or inadequate source data. Concordance in severity of stenosis between the imaging modalities was found in 148/187 arteries (79.14%, 95% CI 0.72 - 0.83). DUS under-estimated and over-estimated the degree of stenosis in 26/187 (13.91%, 95% CI 0.09 - 0.19) and 13/187 (6.95%, 95% CI 0.04 - 0.12) respectively, which related to difficulties encountered during DUS including high carotid bifurcation, dysrhythmias and extensive calcification. When CTA was considered in conjunction with DUS, the decision regarding operative treatment was changed in 29/187 (15.51%, 95% CI 0.11-0.21) cases.

Conclusion: While DUS remains the first line non-invasive imaging technique for carotid artery stenosis, it is subject to several limitations. CTA provides an excellent non-invasive adjunctive technique in the preoperative assessment of carotid disease and may significantly affect the decision regarding operative treatment.

C-1013

Upper extremity (UE) multidetector-row CT angiography (MDCTA):

Evaluation of arterial disease

J.C. Hellinger, A. Kamaya, A. Napoli, E. Williamson, G.D. Rubin, D. Fleischmann; Stanford, CA/US

Learning Objectives: 1. To provide MDCTA techniques for evaluating UE arterial disease. 2. To illustrate UE arterial anatomy and pathology with MDCTA.

Background: The differential diagnosis for UE arterial disease is diverse. Atherosclerosis, thromboembolism, thoracic outlet syndrome, fibromuscular dysplasia, and large and small vessel vasculitis all warrant consideration depending on the clinical history and physical examination. With optimal technique and accurate interpretation, these pathologies can be depicted with UE-MDCTA. Radiologists can therefore play a significant role in reducing the risk of cerebral and/or digital thromboembolism, which may occur during conventional UE angiography.

Imaging Procedure: Complete UE coverage includes from at least the aortic arch through to the hand, ranging between 800-1000 mm. Given the requirements for high resolution datasets, this volume may yield 1000-1500 images, potentially limiting image reconstruction time, transfer, viewing, and storage. Volume coverage, however, can be targeted to the vascular segments of interest. Patients are placed supine or prone, with the affected extremity raised above their head into the scanner. Patients can be rotated into a modified swimmers position, to ensure the extremity is as close to the gantry isocenter as possible. As will be reviewed, optimizing contrast medium delivery is essential for depicting stenoses, occlusions, dissections, and vessel wall thickening, not to mention extra-vascular structures.

Conclusion: MDCTA is a robust modality to evaluate UE arterial disease and provide alternative diagnoses. Clinical success is dependent on an understanding of the technical challenges and image findings.

C-1014

Abdominal virtual angiography

P.M. Carrascosa, C. Capuñay, M. Ulla, E. Martín López, J. Carrascosa; Buenos Aires/AR

Learning Objectives: To illustrate a new application of virtual endoscopy in the evaluation of the abdominal vessels. To be familiar with virtual endovascular images. To provide an overview of the spectrum of abdominal CTA findings.

Background: Virtual techniques have been applied to the evaluation of the gastrointestinal tract, especially the evaluation of the colon. New multidetector CT technology allows one to perform vascular CT studies of excellent quality, and the improvement of 3D and endocavitory post-processing software gives the option of introducing this technique in the evaluation of vascular structures.

Procedure Details: The CT exams were performed using a 16-row CT scanners (Brilliance 16; Philips Medical Systems) with the following parameters: 16x1.5 configuration; 2 mm slice thickness; 1 mm reconstruction interval; 120 kV; 300 mAs. The iodinated contrast material was injected using a power injector at 3 ml/sec. The vascular analysis was performed using multiplanar reconstructions, 3D images and virtual angiography.

Imaging Findings: A total of 400 abdominal CT exams were reviewed. In 93 patients, an aneurysm was diagnosed. Nine cases of aortic dissection and 2 cases of mesenteric artery dissection were found. A total of 7 partial thrombosis of the stent-graft, 5 total thrombosis of the graft limbs and 10 leaks were diagnosed. In 8 patients, portal venous thrombosis was diagnosed.

Conclusion: CTA is a non-invasive technique to evaluate the abdominal vessels. Virtual angiography allows better definition of anatomical details and clearly depicts the intraluminal vascular anomalies. Current 3D postprocessing software allows the reconstruction of good quality virtual angiography images.

C-1015

Usefulness of CT angiography in the planning and follow-up of abdominal aortic aneurysm endovascular treatment

C. Capuñay, P.M. Carrascosa, M. Ulla, E. Martín López, J. Carrascosa; Buenos Aires/AR

Purpose: To determine the usefulness of CT Angiography (CTA) in pre- and post-treatment evaluation of abdominal aortic aneurysm.

Methods: A total of 200 CTA scans were retrospectively evaluated. 122 scans were performed as a pre-treatment assessment; 78 scans were carried out as a post-treatment control. CTs were performed on 4-row and 6-row CT scanners (MX8000 and Brilliance 16; Philips Medical Systems) with slices of 2.5 mm and 2 mm thickness, every 1.3 mm and 1 mm reconstruction interval respectively, and 120 ml of contrast material were injected using a power injector. Post-processing volume rendering, MPR and MIP images were obtained.

Results: In the pre-treatment group, the measurements of the aneurysm neck, its length and diameters were determined. The iliac artery diameters and angulation were also evaluated. In the post-treatment group, 24 complications were detected: a) periprosthetic hematoma (n = 2); b) neointimal hyperplasia (n = 2); c) partial stent-graft thrombosis (n = 4); d) total stent-graft thrombosis of an iliac branch (n = 7); e) endoleak type II (n = 4); f) endoleak type III (n = 4), separation of the stents' components (n = 1).

Conclusion: CTA is an accurate, fast and minimally invasive imaging method in the pre-treatment evaluation and also in the evaluation of complications after abdominal aortic aneurysm repair.

C-1016

Evaluation of thoracic aortic pathology by MSCT (16-slice) before and after endovascular treatment

D.N. Exarhos, H. Testembasi, F. Karkantzia, D. Chondros, D. Farsaris, I. Kaskarelis; Athens/GR

Purpose: To describe the CT findings of the thoracic aorta in patients treated by endovascular stents, and assess stent deployment.

Materials and Methods: Twenty-one male patients were examined before and after stent deployment, eight with acute aortic dissection, seven with an aortic rupture and six with an aneurysm. Diagnosis and postinterventional follow-up was performed with a 16-slice multislice scan (Toshiba Aquilion), reconstructions were done on a Vitrea workstation. Scanning parameters were: SC1 mm, SW/RI4/3 mm, MPR SW/RI 3/3cor-sag. Pre- and post-contrast scans were performed in the postinterventional series. Bolus triggering was used, CM370 mg/ml, 120 ml/4 ml per sec, trigger threshold 250 HU. The biphasic protocol in the postinterventional series was optimized individually. Twenty-nine Talent stents were deployed. **Results:** Diagnosis was confirmed by aortography in all cases. Detailed preinter-

Scientific and Educational Exhibits

ventional evaluation of the extent and morphology of pathology was achieved in all patients. Stent deployment was successful. Two patients died from unrelated causes. Follow-up of nineteen patients revealed progression of a dissection in one patient, two patients had endoleaks and were treated (one surgically, one with a stent).

Conclusion: MSCT is an essential tool for the diagnosis of thoracic aortic pathology. The good access to patients, its high spatial resolution, fast data acquisition and excellent quality multiplanar 3D reconstructions allow noninvasive detailed evaluation of aortic lesions. Intraluminal stent graft interposition is an alternative to surgical graft interposition for the treatment of certain aortic lesions. MSCT is the primary diagnostic modality used for pre and postinterventional assessment of the thoracic aorta.

Vascular

MR imaging

C-1017

Pseudo-occlusion of the internal carotid artery assessed by MRA: How to avoid misinterpretation

J. Gasser, S. Celedin, K. Hausegger; Klagenfurt/AT

Learning Objectives: 1. How to deal with pseudo-occlusion of the Internal Carotid Artery (ICA) with various MR-angiographic techniques. 2. How to detect minimal residual flow in a nearly occluded ICA with MRA.

Background: Minimal residual flow in a nearly occluded ICA can be missed with contrast enhanced (CE) MRA and a false positive diagnosis of ICA-occlusion can be made. This pitfall might exclude patients from potential surgical or endovascular correction of high grade ICA-stenosis. Over the last 2 years we examined 280 patients with carotid artery disease with a combination of CE-MRA and TOF-MRA. With CE-MRA 3 false positive diagnoses of ICA-occlusion were made. We will illustrate these cases and demonstrate how MRA with different techniques can help to make the correct diagnosis.

Procedure Details: Our CE-MRA protocol was performed with random central k-space segmentation in a centric filling order (CENTRA). The 3D-TOF sequence covered a FOV from the base of the skull up to the circle of Willis. In 3 cases the CE-MRA showed a carotid "occlusion", whereas TOF-MRA showed residual flow in the ICA. We repeated the CE-MRA in these cases without CENTRA at a slower contrast infusion rate and the correct diagnosis could be made.

Conclusion: In nearly occluded carotids CE-MRA with CENTRA can be false positive for occlusion. Additional 3D-TOF-MRA is helpful to depict minimal flow in subtotally occluded ICA. CE-MRA with conventional k-space filling at a slower contrast infusion rate is more sensitive for residual flow in the carotids than CE-MRA with CENTRA.

C-1018

Accuracy of magnetic resonance for identification and characterization of carotid plaque constituents with histological correlation: A clinical experience

G. Puppini, N. Cirotta, F. Furlan, S. Quintarelli, G. Veraldi, S. Montemezzi, G. Gortenutti; Verona/IT

Purpose: To identify and characterize, using Magnetic Resonance (MR), carotid plaque constituents, such as lipid-rich necrotic core and intraplaque hemorrhage and fibrous cap integrity, among patients treated with carotid endarterectomy (CEA), matched with histological evaluation.

Methods and Materials: 15 patients (9 male and 6 female), with a total of 16 lesions, scheduled for CEA between March and August 2004, were imaged on a 1.5 T Magnetom Symphony scanner. The protocol included 4 types of sequences (T1, T2, proton density and 3D-TOF). Images were reviewed considering integrity of fibrous cap, presence of lipid-rich necrotic core and intraplaque hemorrhage. Signal intensity was compared with reference to the adjacent sternocleidomastoid muscle. 4 cross sections per lesion were compared with the corresponding histologic specimens and independently reviewed by two radiologists and one pathologist.

Results: MR identifies loss of integrity of fibrous cap, presence of lipid-rich necrotic core and intraplaque hemorrhage with a global accuracy of 90%. MR detects lipid-rich necrotic core without intraplaque hemorrhage with a sensitivity and specificity of 88.5% and 91.6% respectively, while it can define intraplaque hemorrhage alone with a sensitivity and specificity of 80% and 97.3%. Loss of integrity of fibrous cap was identified with a sensitivity and specificity of 88% and 100%.

Conclusions: MR is able to identify signs of instability of carotid plaque with high sensitivity and specificity. Therefore it may be useful to evaluate hemodynamically insignificant stenosis with a potential embolic risk, in order to choose the best treatment.

C-1019

Effect of stent orientation and flip angle on subjectively visible stent lumen in contrast-enhanced MR at 1.0 Tesla

D. Blondin, Y. Rado, B. Fritz, A. Saleh, U. Mödder, M. Cohnen; Düsseldorf/DE

Purpose: Intravascular prostheses cause susceptibility artifacts on MR images, impairing complete visualization of the stent lumen. This in-vitro study was aimed at assessment of subjective visibility of modern self-expanding stents.

Materials and Methods: 12 different stents (2 stainless steel, 10 nitinol) were released in plastic tubes completely filled with gadopentetate dimeglumine (Mag-

Scientific and Educational Exhibits

nevist®, Schering) diluted in physiological saline (1:25) and immersed in a water-filled phantom positioned parallel and transverse to the main magnetic field (B_0). 6 stents were deployed at 10 mm diameter, 2 at 8 mm, and 4 at 12 mm. Imaging was performed at 1.0 Tesla with a T1-weighted three-dimensional gradient-echo sequence, using changing Flip angles (FA: 10°, 40°, 70°, 100°, and 130°). Stent lumen visibility was subjectively assessed by three independent and blinded investigators.

Results: In 9 prostheses (all nitinol), the stent lumen was visible to a moderate extent using a FA greater than 40. In general, visibility of stent lumen increased with higher FA resulting in a good visibility at FA of 100, and 130°, respectively ($p < 0.05$). Subjective assessment of transversely orientated stents was generally graded better by all three investigators ($p < 0.05$). Six stents - 3 with a diameter of 12 mm and 3 with 10 mm - proved a good quality in the subjective rating.

Conclusion: In this in-vitro study, 9 of 12 investigated stents showed a visible lumen on contrast-enhanced-MRA at 1.0-Tesla. 6 nitinol-type stents reached a good subjective assessment of lumen visibility. Best results were observed using high flip angles and transverse orientation to B_0 .

C-1020

The pathophysiology of aortic-cardiac interaction in atherosclerotic disease and the role of magnetic resonance imaging

Z.M. Metafratzil¹, A. de Roos², A. Skopelitou¹, S.C. Efremidis¹; ¹Ioannina/GR, ²Leiden/NL

Learning Objectives: 1. To review the histochemical structure and the biophysical properties of the aortic wall. 2. To understand the role of these properties in the pathogenesis of cardiovascular disease and normal aging. 3. To describe the techniques that are used in Magnetic Resonance Imaging (MRI) to assess the changes in aortic wall distensibility.

Background: One of the main functions of the aorta is to maintain a steady blood flow throughout the capillaries by transforming the pulsatile flow generated by ventricle contraction into a continuous flow. This function minimizes the load imposed on the left ventricle during systole and keeps the flow steady in the coronaries. For this effect to be maintained, the aortic wall has to be compliant. However, elastin fibers fracture at low stresses and contribute to the decrease of the aortic compliance and thus to the increase of the pulse pressure, a risk factor for cardiovascular disease. Early detection of a decrease in the compliance can identify early cardiovascular disease in asymptomatic subjects and monitor the results of medical interventions.

Procedure Details: MRI can estimate the arterial wall compliance either by measuring the regional compliance using ECG SE and GRE sequences or by measuring the pulse wave velocity through the aorta using the phase contrast technique.

Conclusion: MRI can assess the elastic properties of the aorta noninvasively and in an accurate and reproducible way. Thus, it provides a challenging tool to identify early cardiovascular disease and monitor subtle changes of wall elasticity in response to therapeutic manipulations.

C-1021

Pulmonary vein mapping with contrast-enhanced MR venography of the pulmonary veins prior to ablative therapy

G.C. Hargaden, D. Rea, S. O'Brien, D. Keane, J.F. Meaney; Dublin/IE

Learning Objectives: 1. To describe the technique of contrast-enhanced MR venography of the pulmonary veins. 2. To highlight the issue of appropriate timing to ensure adequate demonstration of the venous anatomy. 3. To illustrate the technique of "selective" venous enhancement by subtraction of the peak arterial phase. 4. To emphasise the common anatomical arrangement of the pulmonary veins. 5. To illustrate the common variants, particularly of the lingular and middle lobe veins. 6. To emphasise that the optimal imaging plane for catheter venography can be predicted from the 3D MR data-sets.

Background: The most common arrangement of the pulmonary veins is a single superior and single inferior pulmonary vein on each side, each with a separate ostium. The lingular and middle lobe veins usually drain into the upper lobe pulmonary vein. Under- or over-incorporation of the common PV into the left dorsal atrium during embryonic development results in anatomic variations in the number, branching patterns, and length of pre-ostial pulmonary veins.

Procedural details: At least two post-contrast acquisitions, centred over the proximal pulmonary circulation and tailored to the patient's breath-hold capability, are acquired in the coronal plane. Targeted reformat images of the left atrium and pulmonary veins are constructed to optimally demonstrate the anatomy.

Conclusion: Contrast-enhanced MRA/V in the coronal plane adequately visualises the pulmonary veins and left atrium. The number and size of pulmonary veins, size of the ostium and optimum plane for imaging during catheter ablation are clearly documented.

C-1022

Gadolinium-enhanced MR venography of the venous compression syndromes

A.E. Mahfouz, H. Sherif; Doha/QA

Objectives: To describe the imaging findings of the different venous compression syndromes on gadolinium-enhanced MR venography

Background: Venous compression syndromes are caused by compression of veins at certain anatomical locations between arteries and bones or between two arteries. Examples of these syndromes include left innominate vein compression syndrome caused by compression of the left innominate vein between the sternum and aortic arch, nut-cracker syndrome caused by compression of the left renal vein between the aorta and the superior mesenteric artery, retroaortic left renal vein which may be compressed between the spine and the aorta, and May-Thurner syndrome caused by compression of the left common iliac vein between the right common iliac artery and the spine.

Procedure Details: Gadolinium-enhanced MR venography has been performed by three-dimensional T1-weighted gradient-echo images performed before and repeatedly after intravenous injection of Gd-DTPA, followed by image subtraction and maximum intensity projection. The technique has been applied to different parts of the body where venous compression syndromes have been suspected. This educational exhibit illustrates the imaging features of the different venous compression syndromes with discussion of their clinical impact.

Conclusion: Gadolinium-enhanced MR venography may be helpful for diagnosis of venous compression syndromes.

C-1023

Chronic aortic dissection: Contribution of velocity-encoded cine MR imaging and multiphasic MR angiography

V. Pineda, R. Dominguez-Oronoz, X. Merino, E. Castellà, A. Evangelista, R. Vidal; Barcelona/ES

Learning Objectives: To describe the patterns of aortic flow in the false and true lumens in chronic aortic dissection, comparing them with morphologic and functional findings in multiphasic contrast-enhanced MR angiography (MRA).

Background: Multiphasic contrast-enhanced MRA provides morphologic and functional information in the dissected aorta. Velocity-encoded cine MR imaging can determine flow velocity and flow volume noninvasively in any desired plane, using phase-contrast sequences. The evaluation of flow patterns in the false lumen may be useful for predicting enlargement of the dissected aorta, considering that aneurysm formation is an important prognostic factor in patients with chronic aortic dissection. The flow patterns are influenced by communications between the true and false lumens, and the presence of arteries originating from the false lumen.

Imaging Findings: Morphologic and functional MRA findings are correlated with hemodynamic patterns obtained by velocity-encoded cine MRI imaging measurements. Flow patterns through the false and true lumens are illustrated in different cases of aortic dissection depending on the location, size and number of communications between both lumens. Analysis of blood flow in patients with and without arteries originating from the false lumen are shown.

Conclusion: Different hemodynamic patterns are found in chronic aortic dissection. There is a relationship between the flow characteristics in velocity-encoded MR imaging measurements and multiphasic MRA morphologic findings and enhancement patterns of both lumens.

C-1024

Evaluation of Takayasu arteritis with MR imaging and contrast enhanced magnetic resonance angiography (CEMRA)

A. Beresnak, E. Gomez, S.E. Rombolá, A. Simoncini; Buenos Aires/AR

Learning Objectives: To show the usefulness of a combined study (MR imaging and CEMRA) for evaluating the arteries in patients with Takayasu arteritis.

Background: Digital subtraction angiography (DSA) is the method generally used for the evaluation of patients with Takayasu arteritis, but it only allows the evaluation of the lumen. MR imaging combined with CEMRA allows us to evaluate both the lumina and the walls of the arteries. We studied 6 patients with Takayasu arteritis, observing the vessels involved, and the involvement of the lumen and the wall.

Procedure Details: We used a 1.5 T unit, using a body coil. We applied axial T2 FSE and axial T1 SE sequences in thoracoabdominal regions and CEMRA was performed using coronal FFE 3D with a double dose of gadolinium, and the delay time was determined through MR fluoroscopy. According to the *Numano classification* we detected 1 case of type I (17%), 2 type IV (33%), 3 type V (50%). In 5

Scientific and Educational Exhibits

patients we found luminal involvement (83%) and 1 had involvement of both lumen and wall (17%).

Conclusion: MR imaging together with CEMRA allows us to evaluate patients with Takayasu arteritis in a minimally invasive manner, delineating the disease extension and detecting both luminal and wall compromise. It does not use iodine contrast agents and the contraindications are those inherent to MR imaging.

C-1025

Evaluation of Gd-DTPA in detection of atherosclerotic plaques at 3 Tesla in WHHL animals

H. Ittrich¹, A. Priest¹, C. Jahntz¹, C. Weber¹, J. Meding², G. Adam¹;
¹Hamburg/DE, ²Berlin/DE

Purpose: To estimate the ability of Gd-DTPA (Magnevist) to enhance lipid atherosclerotic plaque on a clinical 3 T MR Scanner in an animal model.

Material and Methods: High resolution MR imaging of the aortic arch was performed on 6 WHHL (14-29 months) and 3 NZW rabbits (control, 16 months) before and at 10-minute-intervals up to 1 hour after injection of 200 µmol/kg Magnevist on a 3 Tesla MR scanner (Philips Intera), using an 8-channel head array coil. IR-TurboFLASH-Sequences (TE/TR = 2.6/7.8 ms, TI 120 ms, FA 20°, shot repetition time 300 ms, 15 excitations per shot, matrix 256x179, resolution 0.55x0.55x2.5 mm) of different parts of the aorta (perpendicular to wall) and in parasagittal orientation (cover whole aorta) were used to detect uptake of Gd-DTPA. SNR-measurements were performed by placing ROIs in the aorta. For each time point the groups were compared by Student's t-test.

Results: Measurements of luminal diameters showed no significant differences or severe stenosis (6.5 ± 0.6 mm). Significant increased uptake in aortic wall and delayed wash-out could be detected in the WHHL-group (SNR pre administration 2.6 ± 1.4 , 10 min.post admin. 5.2 ± 3.2 , 20 min.p.a. 4.2 ± 2.1 , 30 min.p.a. 3.6 ± 1.9 , 40 min.p.a. 3.1 ± 1.7 , 50 min.p.a. 2.9 ± 1.6 , 60 min.p.a. 2.7 ± 1.5) in comparison to the NZW-group (SNR pre admin. 2.5 ± 1.3 , 10 min.p.a. 3.3 ± 2.0 , 20 min.p.a. 2.9 ± 1.6 , 30 min.p.a. 2.7 ± 1.5 , 40 min.p.a. 2.5 ± 1.3 , 50 min.p.a. 2.4 ± 1.3 , 60 min.p.a. 2.4 ± 1.3). At the first 3 time points after administration the groups showed significant differences in SNR at a level of 5%.

Conclusion: Contrast enhanced MR imaging techniques at 3 T using clinically applicable dosages of Gd-DTPA are able to differentiate between wall segments with and without atherosclerotic changes in animals. This approach may also be suitable for detection of early stage atherosclerosis in humans.

C-1026

The correlation between the magnetic resonance imaging of clots and thromboaspiration in vitro

J. Koizumi; Isehara-city/JP

Purpose: To obtain the correlation between the direct MR imaging of clots and thromboaspiration in vitro.

Materials and Methods: Venous blood from the same human was clotted in vitro by addition of thrombin and calcium chloride. The clots in vitro were positioned between the two legs of the same human and the MR images were obtained immediately after clotting up to one month at 37°C of incubation. Each clot was then aspirated using the same thromboaspiration catheter. T1- and T2-values were calculated based on the mixed sequence with multiecho spin echo and multiecho inversion recovery, and proton density ratio was obtained on proton density images (TR 8000, TE 9.0) using 1.5 tesla GYROSCAN (Philips). The clots were aspirated by 8Fr. OASIS (Boston Scientific) at 2.5 mL/sec of normal saline, and the aspiration time was measured.

Results: The T1-value became shorter than that of muscle (660 ms) around one week after clotting and lasted to 257 ms at day 28, while the T2- value elongated from 31 ms to 117 ms correspondingly. Both T1- and T2- values were significantly ($p < .05$) correlated with the time after the clotting, but not with the aspiration velocity from 2.790 to 1.200 mL/sec or the proton density ratio from 763 to 630 correspondingly.

Conclusion: In vitro experiment suggests that the clots from one week to one month after clotting reveal higher signal intensity than muscle on T1-weighted image and respond well to thromboaspiration.

C-1027

Zero-filling interpolation processing (ZIP) technique can effectively suppress segmental stenosis artifact in small arteries in anatomical phantoms

R. Lin¹, R.H. Wu¹, Z.W. Xiao¹, G.R. Liu¹, K.M. Kong¹, Z.J. Lang²;

¹Shantou, Guangdong/CN, ²Dalian/CN

Purpose: The purpose of this study was to evaluate the zero-filling interpolation processing (ZIP) technique for contrast-enhanced MR angiography (CE-MRA).

Methods and Materials: Phantoms of arteries were made with different lumen diameters. Gadolinium-enhanced three-dimensional MR angiography was performed on a GE 1.5 T scanner. The parameters of FSPGR pulse sequence were: flip angle 30°, TR 6 ms, TE 1.4 ms, bandwidth 31.25 kHz, slice thickness 1.2 mm, matrix 256x256. These sequence parameters were kept constant for the studies, whereas one of four additional selections was chosen: (1) with ZIP1024 and ZIPx4 techniques; (2) only with ZIP1024 technique; (3) only with ZIPx4 technique; (4) without ZIP technique. For image quality evaluation, MR maximum intensity projection (MIP) images were created. Signal-to-noise ratio (SNR) was measured on MIP images. Vessel edge was determined using full width at half maximum (FWHM) for lumen diameter calculation.

Results: The FWHM results of lumen measurements for all ZIP techniques were more accurate than conventional technique in all phantoms, no matter what size the artery was. The vessel edge with ZIP1024 technique was more distinct than conventional technique ($P < 0.01$). The segmental stenosis artifacts in small arteries in phantoms were only effectively suppressed with ZIPx4 technique.

Conclusion: ZIP technique is excellent for CE-MRA to obtain high quality MR angiography. ZIPx4 technique can effectively suppress segmental stenosis artifact in small arteries in phantoms.

C-1028

Role of CE-MRA in studying vascular complications after kidney transplantation

C. Quirico, A. Stecco, P. Oronzo, G. Marano, D. Rozzati, F. Crinò, C. Borracini, A. Carriero; Novara/IT

Purpose: To assess accuracy of CE-MRA in patients with vascular complications after kidney transplantation.

Methods and Materials: 30 patients suspected of having renal artery stenosis after kidney transplantation, underwent ce-MRA. The imaging was performed on a 0.5 T (GE), using a body-flex coil and a 3D fast gradient echo sequence with and without contrast enhancement (GD-BOPTA 2.0 ml/sec). The MRA and post-processing images (reformat MIP) were evaluated by two radiologists.

Results: In 18 out of 30 patients (60%) ce-MRA showed a RA stenosis. Diagnostic accuracy of ce-MRA in the detection of renal artery stenosis was 100% compared to DSA.

Conclusion: ce-MRA imaging allows a complete anatomic and functional evaluation of patients with impaired graft function or vascular complications after kidney transplantation, and is associated with low nephrotoxicity. Ce-MRA shows high sensitivity in detection of significant renal artery stenosis.

C-1029

Non-renal artery incidental findings in a renal artery stenosis MR protocol: A pictorial essay

P. Bermudez Bencerrrey, J. Fortuño Andrés, J. Falcó Fages, J. Perendreu Sans, A. Darnell Martin, J. Branera Pujol; Sabadell/ES

Learning Objectives: To describe the spectrum of extra-renal artery incidental findings that it is possible to find in a renal artery stenosis MR protocol. The presentation emphasizes the necessity for a systematic review of all morphologic and angiographic MR pulse sequences in a renal stenosis MR protocol in order to identify clinically relevant incidental findings.

Background: Magnetic resonance is a widely accepted technique for the evaluation of renal artery stenosis. Although 3D T1 gradient-echo is the most important sequence to evaluate renal artery stenosis, non-vascular morphologic T1 and T2 MR weighted images are useful to evaluate renal size, parenchymal anatomy and to identify incidental neoplastic renal lesions.

These extra-renal artery incidental findings are common in patients undergoing MR study for the detection of renal artery stenosis. Most of these findings are inconsequential and do not require additional interventions, but in a minority of patients it is possible to demonstrate clinically relevant findings.

Procedure Details: In this pictorial issue we review high, moderate and low significance extra-renal artery vascular and non-vascular incidental findings in our renal artery stenosis studies from 1998 to 2003.

Scientific and Educational Exhibits

Conclusion: Systematic review of all morphologic and angiographic MR pulse sequences in a renal stenosis MR protocol permits the identification of clinically relevant incidental findings.

C-1030

Three dimensional cine phase contrast MR imaging: Evaluation of ascending aortic aneurysms

J.C. Hellinger, M.T. Draney, M. Markl, M. Alley, R.J. Herkens; Stanford, CA/US

Learning Objectives: 1. To review the flow patterns of ascending aortic aneurysms. 2. To demonstrate the use of three dimensional CINE phase contrast MR imaging for depicting ascending aortic aneurysm flow dynamics.

Background: Ascending thoracic aortic aneurysms generate variable flow patterns. These include circumferential flow, right handed helices in early systole, vortical retrograde flow during end-systole / early diastole, and "corkscrew" flow during the early diastolic phase. In a single acquisition, time-resolved, three-dimensional CINE phase contrast MR imaging (3D PC-MRI) can provide characterization of these complex flow dynamics four dimensionally (4D). In this exhibit, we illustrate our early experience with 3D PC-MRI to evaluate ascending aortic aneurysms.

Procedural Details: During 3D PC-MRI acquisitions, ECG and respiratory gated data are acquired throughout the cardiac cycle. Noise filtering and eddy current correction techniques are applied. To generate the 4D displays, cut-planes are first placed at selected levels in the 3D dataset. The data is then processed with visualization tools (EnSight, CEI), including vector fields, streamlines, and / or transient particles. 4D displays can be processed reliably and efficiently, providing invaluable information for planning surgical repair of ascending aortic aneurysms.

Conclusions: 3D PC-MRI is a promising imaging technique to noninvasively evaluate flow patterns in aneurysms of the ascending thoracic aorta. Continued application will determine its role in clinical decision making.

C-1031

MR angiography of lower extremities with moving-table infusion-tracking technique

A. Beresnak, E. Gomez, S.E. Rombolá, A. Simoncini; Buenos Aires/AR

Learning Objectives: To show the usefulness of lower extremity MR angiography with a moving-table infusion-tracking technique in the evaluation of arterial disease.

Background: Arterial pathology of lower extremities is usually evaluated with invasive methods such as digital subtraction angiography and with Doppler ultrasound, which is non-invasive but operator-dependent. This poster describes the technique, image findings, limitations and advantages of contrast-enhanced MR angiography (CEMRA). 39 patients with suspected pathology in the lower limbs were studied between 2001 and 2004.

Procedure details: A 1.5 T unit with a moving table feed was used, with a coronal FFE 3D sequence and a double dose of gadolinium. Leg and pelvic regions were imaged. Unenhanced images were subtracted from gadolinium-enhanced ones, and MIP projection images were generated with different rotation angles. 13 patients had stenosis or vascular occlusion (33%); in 10 of these, vascular encasement by a tumor was diagnosed (26%); 8 were normal (20%), 5 showed vascular malformations (13%), 2 pseudo-aneurysms (5%) and 1 aneurysm (3%). **Conclusion:** CEMRA with automatic table feed allows us to obtain in one single study images from the aorta, iliac and lower limb arteries in a quick and minimally invasive manner, with excellent image definition, which allows us to evaluate the different pathologies. It does not use iodinated contrast agents and is not operator-dependent. Its limitations are the contraindications inherent to any MR imaging procedure and the low resolution at the level of the lower third of the leg and foot.

C-1032

Renal artery fibromuscular dysplasia: Findings on contrast-enhanced MRA

S. O'Brien, C. Farrelly, N. Sheehy, G. Hargadon, S. O'Keeffe, J.F.M. Meaney; Dublin/IE

Learning Objectives: 1. To highlight the features of FMD of the renal arteries. 2. To present the imaging findings in 5 patients with FMD demonstrated on CE-MRA. 3. To emphasise the spatial resolution limitations of current CE-MRA techniques in the diagnosis of FMD. 4. To highlight advances in technology that will improve the ability to detect mild grades of FMD.

Background: Fibromuscular dysplasia (FMD) of the renal arteries is a relatively uncommon disorder which may be responsible for up to 10% of cases of reno-

vascular hypertension. The disorder is more common in females between 15 and 50 years but may present for the first time after the age of 60 years. Although CE-MRA is a proven modality for detection of atherosclerotic renal artery stenosis (which typically affects the ostium and proximal renal artery), the beaded appearance of FMD is more difficult to detect due to the fact that it typically occurs more distally where the artery is smaller, where more motion artefact is present, and where resolution constraints are more marked.

Imaging Findings: The findings on CE-MRA are presented in 5 patients with FMD who underwent 3D CE-MRA at 1.5 T using bolus detection to ensure correct timing.

Conclusion: FMD of moderate severity can be detected with CE-MRA despite significant challenges. Detection of milder degrees of FMD requires higher resolution imaging than is routinely available at present.

C-1033

Virtual MR endoscopy of aortic aneurysms and dissection

E. Squillaci, M. Speradio, M. Di Roma, S. Fabiano, V. Fiaschetti, G. Simonetti; Rome/IT

Learning Objectives: To report technique and pitfalls of MR Virtual Endoscopy (VE) of the aortic lumen. To understand the role of VE in MRA of aortic aneurysms. To compare VE vs MIP and Volume Rendering (VR) images.

Background: The potential advantages of VE have not yet been considered in the MR evaluation of aortic aneurysms and dissection.

Procedure Details: 22 patients affected by aneurysm in the thoracic (n = 9) or abdominal aorta (n = 13) with 7 dissections underwent contrast-enhanced MRA (0.2 mMol/kg) at 1.5 T (Philips Gyroscan Intera, Best The Netherlands) with a phased array body coil. MR protocols, including new pulse sequences (SENSE, SS-SE-EPI), are discussed as well as more common artifacts and pitfalls. Methods to obtain VE images on an external workstation are described. Aneurysm extension and involvement of aortic branches, intimal flap evidence and aortic dissection extension was considered as well as time for post-processing. Good imaging quality was obtained in all patients. A comparison with MIP and VR images is performed and comparative case are presented. MIP images allow a more precise detection of the intimal flap compared with VR. VE provided better results compared with VR and MIP for the evaluation of aortic branches involvement.

Conclusion: In our experience VE can be a helpful diagnostic tool in the evaluation of aortic aneurysms and dissections.

C-1034

High-speed 2D MR cerebral venography using spiral spoiled gradient-echo sequence

K. Uchida¹, K. Oda², T. Kajitani¹, E. Fukuba¹, A. Wada¹, H. Kitagaki¹; ¹Enya, Izumo, Shimane/JP, ²Miwa, kurashiki, okayama/JP

Purpose: We quantitatively compared 2D MR venography with both spiral SPGR (spoiled gradient-echo) and the SPGR in a phantom study and clinical study.

Methods and Materials: All images were acquired on a 1.5 T MR machine. In the phantom study, a plastic tube with pulsatile flow was used to simulate the cerebral venous system. Using fast SPGR and spiral SPGR sequences, the contrast-to-noise ratio (CNR) and Full Width Half Maximum (FWHM) of the plastic tube phantom were evaluated while altering flow velocities inside the phantom and the angle between the phantom and acquisition plane (tilt angle). In the clinical study, fifteen healthy volunteers were examined with both fast SPGR and spiral SPGR sequences following informed consent. The CNR of veins and sinuses were measured and evaluated.

Results: In the phantom study, the CNR of both the fast SPGR and the spiral SPGR were reduced with a decrease in tilt angle. The reduction in the CNR for the spiral SPGR were smaller than those of the fast SPGR, indicating that the spiral SPGR is a more consistent technique. In the clinical study, the CNR of the spiral and the fast SPGR were almost equal for each cerebral vessel. However, the scan time of cerebral venography with the spiral SPGR was only twenty percent of that with the fast SPGR sequence.

Conclusion: The temporal resolution for 2D MR cerebral venography is better with the spiral SPGR sequence than with the fast SPGR sequence, without loss of image quality.

Scientific and Educational Exhibits

C-1035

Nonenhanced peripheral MR angiography using peripheral pulse-triggered three-dimensional half-Fourier fast spin-echo in patients with chronic kidney disease

N. Yanagimachi¹, Y. Imai¹, M. Higashi²; ¹Isehara/JP, ²Yokohama/JP

Learning Objectives: To demonstrate the clinical usefulness of nonenhanced peripheral MR angiography in patients with chronic kidney disease.

Background: MR angiography using peripheral pulse-triggered three-dimensional half-Fourier fast spin-echo provides selective visualization of arteries or veins by diastolic and systolic subtraction without contrast media. Although this technique is more effective in fast-flow vessels, appropriate flow-spoiled gradient pulses in the readout direction permit distinction of arteries from veins even in slow-flow peripheral vessels in the hand and foot. This noninvasive technique is useful in evaluating peripheral vascular disease in patients with reduced renal function and in vascular mapping before creation of hemodialysis access fistulas in patients with end-stage renal disease. The possible applications of this technique in evaluation of hemodialysis access fistula complications are discussed.

Imaging Findings: In healthy volunteers, the peripheral vessels are depicted in good quality. In patients with chronic kidney disease, various arterial and venous diseases, such as arteriosclerosis obliterans and deep vein thrombosis are depicted. On preoperative MR angiography of the forearm for a hemodialysis access fistula, radial and ulnar arteries and superficial veins are well demonstrated. Images of hemodialysis access fistulas show only flow voids on this technique.

Conclusion: Nonenhanced peripheral MR angiography is useful in evaluating various vascular diseases in patients with chronic kidney disease.

C-1036

Diagnosis of abdominal aortic aneurysms

M.A. Aliev, V.A. Jakupov, Y. Akhmetov, A.M. Tayev, B.Z. Kassymov, S.E. Serikova; Almaty/KZ

Purpose: To evaluate magnetic resonance (MR) imaging accuracy in the characterization of mural thrombi in abdominal aortic aneurysms (AAA).

Material And Methods: 25 patients (22 men, 3 women; mean age - 68 years) with an AAA with mural thrombus thicker than 1 cm at sonography underwent T1- and T2-weighted spin-echo MR imaging. The thrombi were prospectively classified as one of three signal intensity (SI) categories: category 1 corresponds to low SI on both T1- and T2-weighted images; category 2, high SI on T1-and T2-weighted images; and category 3, inhomogeneous SI with hyperintense areas on both T1- and T2-weighted images. During surgery, thrombi were classified as organized, unorganized, and partially organized. MR imaging and surgical findings were compared.

Results: SI category 1 corresponded to organized thrombi in 15 of 15 patients. Category 2 corresponded to unorganized thrombi in 6 of 6 patients. In category 3, focal hyperintense areas corresponded (both for presence and location) to unorganized portions of partially organized thrombi in 4 of 4 patients.

Conclusion: MR imaging is accurate method in AAA thrombus characterization.

Peripheral

C-1037

Suspected entrapment syndrome of the popliteal vein: How to diagnose it. Is it rare?

H. Minamiguchi, M. Sato; Wakayama/JP

Learning Objectives: To demonstrate and understand the entrapment syndrome of the popliteal vein.

Materials and Methods: From October 2003 to March 2004, we examined 42 patients (84 limbs) with chronic leg symptoms (calf numbness, calf swelling without redness) or with the history of pulmonary embolism. We evaluated venous diameter and flow rate of the popliteal vein in three positions: (neutral {N}, dorsal flexion{DF} and plantar flexion{PF}) with ultrasound sonography and/or venography.

Results: Twenty-four patients (57%) and 35 limbs (42%) were diagnosed as entrapment syndrome of the popliteal vein. Eleven patients had the syndrome in both limbs, 7 in left and 6 in the right limb. Twenty-six limbs showed entrapment syndrome in PF, 14 in DF and 2 in N. Two had an anomaly of the gastrocnemius muscle and 7 had obvious compression by gastrocnemius muscle during the movement.

Conclusion: Entrapment syndrome of the popliteal vein is not rare, and it may cause calf deep vein thrombosis and/or pulmonary embolism.

C-1038

Radiological imaging of thoracic outlet syndrome

G. Bodner, H. Gruber, M. Schocke, M. Bernathova; Innsbruck/AT

Learning Objectives: The purpose of this exhibit is to review radiological imaging appearance of TOS.

Background: Thoracic outlet syndrome (TOS) is a compression of the neurovascular structures at the thoracic outlet region. It can be caused by anatomical abnormalities or acquired changes in the soft tissues and bony structures in the region. The brachial plexus is the most frequently affected structure, followed by the subclavian vein and artery. Diagnosing and treating thoracic outlet syndrome can be challenging and time consuming, hampering patients quality of life.

Procedure Details: We present a series of 16 cases reviewing the imaging manifestations of TOS from MRT, MSCT, sonography and arteriography. Other causes mimicking a TOS are also presented.

Conclusion: The clinical suspicion of TOS can be supported by specific imaging findings without the need for interventional procedures.

C-1039

Sonographic approach for imaging calf veins: An anatomic study

M. Bernathova, H. Gruber, M. Pavelka, G. Bodner; Innsbruck/AT

Learning Objectives: To propose a valid sonographic approach to identify the posterior tibial veins, peroneal veins and the muscle veins (gastrocnemius and soleus veins) from the lateral and medial sides.

Background: Compression sonography is currently the method of choice to diagnose deep venous thrombosis of the femoral and popliteal vein. Controversially discussed, however, is the value of compression sonography in detecting a venous thrombosis in the calf. This may be due to lack of knowledge regarding the sonographic compartmental anatomy of the calf.

Procedure Details: We performed a cadaveric study comparing transverse sonographic images and corresponding cryosections from both calves of a cadaver specimen. Important sonographic landmarks to identify calf veins are the shape of the tibial and fibular bone, the gastrocnemius and soleus muscle and the different crural fascias. In addition we present selected cases of patients with calf vein thrombosis with special regard to sonographic landmarks.

Conclusion: The anatomic landmarks visible in sonography are helpful in identifying the main calf veins.

C-1040

Peripheral arterial blood flow and intima-media thickness in patients with predialysis stage chronic renal failure

Z. Serafin, B. Sobociński, P. Strzesniewski, W. Lasek, P. Strozecki, A. Kapala, J. Manitius, S. Dabrowski; Bydgoszcz/PL

Purpose: Progression of atherosclerosis in hemodialysis patients with end-stage chronic renal failure (CRF) has been demonstrated by increased carotid artery

Scientific and Educational Exhibits

intima-media thickness (IMT). The aim of this study was to evaluate the condition of the peripheral artery system in patients at the predialysis stage of renal failure. **Methods and Materials:** 35 patients at the predialysis stage of CRF and 15 healthy volunteers were included in the study. IMT was measured in the brachial artery using B-mode ultrasonography. Flow spectra were evaluated with duplex-scan mode and flow parameters were calculated for the brachial artery, and for distal parts of the radial and ulnar arteries.

Results: Brachial artery diameter and IMT were significantly higher in CRF patients than in controls (mean 4.1 vs. 3.4 mm, $P < 0.001$, and 0.46 vs. 0.37 mm, $P < 0.05$, respectively). Brachial blood flow volume was also larger in CRF patients (mean 179.5 vs. 145.5 ml/min.), but the difference was not statistically significant. In peripheral arteries, blood flow volume was significantly lower in CRF patients than in controls (22.3 vs. 34.2 ml/min., $P < 0.04$). There was a positive correlation between patients' age and IMT ($P < 0.01$), and a negative correlation between brachial flow volume and pulsatility and resistive indices ($P < 0.02$) in both groups. In CRF patients, age correlated with PI and RI ($P < 0.01$) in all arteries.

Conclusion: The results indicate that peripheral circulatory changes in early-stage CRF patients include alterations of the brachial artery wall and a decrease of blood flow volume in distal forearm arteries.

C-1041

The brachial artery reactivity in patients with metabolic syndrome

G.E. Roytberg, E.A. Artamonova, T.I. Ushakova; Moscow/RU

Purpose: Insulin resistance is one of the main risk factors for atherosclerosis, causing endothelial dysfunction, an early event in the disease process. The aim of this study was to determine whether vascular reactivity is associated with insulin resistance (IR) and metabolic syndrome.

Methods: We studied 131 non-diabetic clinically healthy men. 2-hour oral glucose-tolerance test (OGTT) was performed, anthropometrical measurements and serum lipids were analyzed. IR was estimated by HOMA-IR model. Endothelium-dependent (flow-mediated) vasodilatation was assessed in the brachial artery by ultrasound Doppler in two groups: with metabolic syndrome according to WHO criteria ($n = 70$), and controls ($n = 61$), mean age 42.5 ± 0.9 and 41.9 ± 0.8 respectively.

Results: The two groups were similar with regard to the brachial artery diameter and brachial blood-flow velocity and volume at baseline. As compared with the controls, the patients with metabolic syndrome had less flow-mediated brachial artery reactivity ($9.0 \pm 0.4\%$ vs. $11.9 \pm 0.4\%$, $p = 0.047$). A significant correlation was found between brachial artery reactivity and HOMA-IR ($r = 0.25$, $p = 0.041$), the inverse correlation was between body mass index ($r = -0.43$, $p < 0.001$), hypertension ($r = -0.29$, $p = 0.014$), triglycerides ($r = -0.28$, $p = 0.020$).

Conclusion: The results indicate that brachial artery reactivity was significantly lower in patients with metabolic syndrome and could be used as early marker of atherosclerosis.

C-1042

Duplex imaging in quantification of peripheral arterial disease: Is it reliable?

A. Krnic, N. Vucic, Z. Sucic, S. Schmidt, F. Jelavic-Kojic; Zagreb/HR

Purpose: To assess the correlation and the measure of agreement between duplex imaging and angiography in detecting arterial disease of lower limbs. Most of the performed studies assessed accuracy in detecting lesions, but correlation has not yet been established.

Materials and Methods: 84 legs in 42 patients were studied (25 men, 17 women, median age 67) with peripheral arterial disease. Each patient had duplex ultrasonography and conventional intra-arterial angiography. Each leg was divided into 7 arterial segments, and the disease in each segment was quantified as normal, mild (< 20% diameter reduction), moderate (20-< 50% reduction), severe (50-99% diameter reduction), or occlusion. For statistical purposes, these were scored as 0, 1, 2, 3 and 4, respectively. Pearson correlation and Kappa measure of agreement were applied.

Results: For each segment correlation and the Kappa value were statistically significant at the 0.01 level. However, the highest correlation coefficients were found for popliteal, distal and proximal superficial femoral arteries ($r = 0.77$, $r = 0.76$, and $r = 0.75$, respectively); the lowest for calf arteries and common femoral arteries ($r = 0.59$, $r = 0.43$). Kappa values ranged from 0.29 for anterior tibial to 0.65 for distal superficial femoral arteries. The most severely affected segment was distal superficial femoral and least severely, the common femoral arteries (mean score ranged from 3.24 ± 1.10 to 1.55 ± 1.03 , one-way ANOVA, $p < 0.01$)

Conclusion: Duplex ultrasonography is, up to a certain degree, reliable in detecting arterial lesions, particularly in segments which are most often bypassed

and most severely affected (superficial femoral, iliac). One must be aware of its shortcomings and possible pitfalls, and rely on it rationally.

C-1043

MDCT angiography in the preoperative evaluation of peripheral arterial disease: Comparison with catheter based DSA

A. Napoli, C. Catalano, P.G. Nardis, M. Francone, F.A. Calabrese, R. Passariello; Rome/IT

Purpose: The aim of this study was to evaluate the usefulness of multidetector-row spiral computed tomography angiography (MDCTA) compared with catheter-based digital subtraction angiography (DSA) as a preoperative tool in surgical decision making.

Materials and Methods: 74 patients with peripheral obstructive arterial disease were evaluated with MDCTA and catheter-based DSA. Computed tomography angiography was performed using a multidetector-row spiral scanner with 0.5 s gantry rotation time with the following parameters: slice collimation 4×2.5 mm, slice thickness 3 mm, slice interval 1.5 mm, feed/rotation 15 mm. A 28 second standard delay time was used in all patients. A volume of 140 mL of iodinated contrast agent was administered at 4 mL/s in all patients. Three blinded readers independently evaluated DSA and MDCTA. Agreement on one of 8 different treatment options was based on a consensus decision. Intra- and inter-observer agreement was obtained with Cohen k statistical analysis.

Results: Interobserver agreement among the three readers for treatment recommendation with MDCTA and DSA was almost perfect (k value = 0.931). Intraobserver agreement for treatment selection based on DSA and MDCT angiography was almost perfect for the three readers (observer 1, k value = 0.929; observer 2, k value = 0.957; observe 3, k value = 0.942).

Conclusion: MDCT angiography can replace catheter based DSA in preoperative evaluation of patients with obstructive arterial disease

C-1044

Relationship between serum C-reactive protein levels and angiographic findings in patients with peripheral arterial occlusive disease

M. Bustamante, E. Sánchez-Salmón, P. Ruiz-Hernández, P. Merino, M. Aguilar, I. Sampredo, A. González-Tutor; Santander/ES

Purpose: Inflammatory processes are recognized as playing a central role in the pathogenesis of atherosclerosis. Several inflammatory markers have been associated with cardiovascular risk. Acute-phase C-reactive protein (CRP) has been shown to be a predictor of future cardiovascular events. In this study we analyzed the relationship between serum CRP levels and angiographic findings in patients with peripheral arterial occlusive disease (PAOD).

Methods and Materials: 33 consecutive patients (28 male, 5 female) (aged 33-87, mean 69) with PAOD submitted for angiographic examination and without previous vascular surgery were included in the study. A high sensitivity test for CRP was performed. Digital subtraction angiography of the lower limbs or MR imaging angiography findings were analyzed and scored based in the presence of stenosis or obstruction of the iliac and femoral arteries (0 = normal, 1 = stenosis, 2 = obstruction).

Results: We found statistically significantly higher values of CRP ($p < 0.05$) in patients with complete obstruction of the superficial femoral artery when compared with those with a normal or stenotic artery. There where no significant differences in serum CRP levels related to the severity of angiographic findings in the iliac arteries.

Conclusion: Serum CRP levels appear to be related to severity of arterial damage in patients with peripheral arterial occlusive disease with superficial femoral artery involvement.

Non-rigid image registration for subtraction CT angiography of the abdomen is significantly more effective when the post-contrast image is deformed to match the pre-contrast image

S. Drisis, D. Seghers, S. Srivastava, E. D'Agostino, F. Maes, G. Marchal; Leuven/BE

Purpose: Subtraction CT Angiography (SCTA) of the abdomen is affected by artifacts related to motion and local deformation. This leads to misalignment of corresponding high-intensity structures in the pre- and post-contrast images such as bones and plaques. We investigated the effectiveness of pre-to-post versus post-to-pre contrast non-rigid image registration (NRR) to optimally align both images prior to subtraction.

Materials and Methods: Pre- and post-contrast CT images of 5 patients (Sensation16, Siemens, Erlangen, voxel size $0.72 \times 0.72 \times [0.5-1] \text{ mm}$) were non-rigidly aligned with an automated image-processing algorithm (maximization of mutual information using a viscous fluid model), which either deformed the pre-contrast image to match the post-contrast image (Mode1) or vice versa (Mode2). To evaluate registration quality achieved with each mode, objects of interest, bones and plaques, were manually delineated in each data set and the percentage of overlap of 223 object pairs after NRR was computed.

Results: Overall overlap values for bone were not significantly different between Mode1 (90.14%) and Mode2 (89.74%). However, for plaques the overlap values were significantly larger ($p < 10^{-10}$) for Mode2 (69.82%) than for Mode1 (54.98%). Visual inspection showed that Mode1 NRR wrongly enlarged the plaques in the pre-contrast image to match the contrast-enhanced vessel in the post-contrast image. On the contrary in Mode2 NRR the deformation forces applied on the enhanced vessel in order to match the plaques in pre-contrast data set didn't distort the shape of this structure.

Conclusion: The order in which the images are considered for NRR significantly influences the registration result.

C-1046

Evaluation of left kidney function in patients who have undergone abdominal aortic aneurysm (AAA) surgery with renal vein ligation

P. Terlecki, J. Wronski, T. Zubilewicz, W. Kobusiewicz, A. Stepien, S. Przywara, M. Feldo, S. Mocarski, W. Krupski; Lublin/PL

Purpose: The anatomical location of AAA sometimes necessitates ligation of the left renal vein in order to gain safe access to the infrarenal aorta. This access seems to be quite safe for the patient, however opinions about its impact upon kidney function are mixed. The aim of this study is to evaluate retrospectively the long-term results of this treatment.

Materials and Methods: The retrospective analysis embraced 12 patients, aged between 56-85 (average 69.4), operated on for AAA, who had had the left renal vein ligated. Kidney function was analysed by means of urine analysis, creatinine and urea concentration, Doppler ultrasonography and, in selected cases, urography. The difference in particular dimensions was considered to be significant if it exceeded 20%.

Results: The observation period was from 8 months to 6 years. In all cases the urine analysis was normal, in 3 cases the creatinine level was increased (on average 0.31 mg%). The longitudinal dimension of the left kidney was decreased in comparison with the right side in 3 patients. The difference was not statistically significant. The Doppler examination revealed normal flow in all cases. There was no evidence of venous hypertension in the left kidney. Patients who underwent urography had normal micturition and urine concentration.

Conclusions: Left renal vein ligation does not significantly influence the kidney function and may be used as a safe surgical strategy.

C-1047

Patterns of disease in the mesenteric arteries in patients with significant renal artery stenosis as an indicator of atherosclerosis

C.J. Johnston, J. McCann, S. Ford, J.F.M. Meaney; Dublin/IE

Purpose: To use CE-MRA to assess the incidence of mesenteric artery stenosis in patients with significant renal artery stenosis, as a marker for generalized atherosclerosis

Methods: Asymptomatic patients presenting for assessment of RAS over 18 months were also evaluated for the presence of significant mesenteric artery

stenosis. Studies were performed at 1.5 T. Patients received 30 ml of gadolinium chelate via automated injector at 2 cc/s. Scan parameters included: TR 5.1 ms, TE 1.7 ms, flip angle 35°, matrix 200*512, RFOV 280-320*400 mm. Source images and operator-defined 3D reformats targeted to the region-of-interest were evaluated independently by two experienced radiologists for presence or absence of mesenteric and renal artery narrowing according to a graded scale.

Results: 108 patients with significant RAS were identified (41 bilateral, 67 unilateral). Significant (> 50%) celiac artery, SMA and IMA stenoses were identified in 19.5%, 4.9% and 29.2% patients with bilateral RAS. Figures for the unilateral RAS group were 7.5%, 3.0% and 20.8% respectively. No significant relationship existed between age or sex and degree of mesenteric or renal artery stenosis. > 50% reduction in luminal diameter of at least 2 of 3 mesenteric arteries was seen in 9.8% patients with bilateral RAS, and in 1.5% patients with unilateral RAS ($p < 0.05$, Pearson coefficient). Increasing severity of mesenteric artery stenosis correlated with worsening degrees of RAS.

Conclusion: Although mesenteric vascular disease is common in patients with renal artery stenosis, symptomatic mesenteric ischaemia was absent even in patients with multivessel disease. Mesenteric artery narrowing worsened with increasing RAS.

C-1048

Coeliac trunk and its variants: Demonstration with CT

S.K. Venkatesh, G.B.H. Lau, S. Wang; Singapore/SG

Learning Objectives: To present a pictorial essay of CT appearances of normal coeliac trunk anatomy and its variants, to familiarize interventional and abdominal radiologists

Background: Recognition of a variant coeliac artery has important diagnostic and therapeutic implications. The surgical strategy needs to be changed to prevent arterial aberrations interfering with major abdominal surgical techniques such as liver transplantation and resection, gastrectomy and pancreaticoduodenectomy. Aberrant arterial branches may also interfere with interventional radiological procedures. Before chemoembolization can be performed, a full understanding of the potential variations is necessary to facilitate selective cannulation, allowing complete treatment in chemoembolization. Careful manipulation of catheters is required to prevent spasm/dissection of the target artery. Spasm may result in inadequate flow to carry chemoembolization material into the lesion, and there may be an increase in reflux of chemoembolization material into other arteries.

Imaging Findings: The anatomical variations of the coeliac trunk are of three types: a) complete coeliac trunk with a branch arising proximally and the trunk bifurcating distally; b) incomplete coeliac trunk with a branch arising directly from the aorta and c) common origin of the main branches of the coeliac trunk with the superior mesenteric artery. We present the CT appearances of coeliac trunk variations, CT angiographic appearances and wherever possible angiographic correlation. Embryological explanation of the variations will also be presented.

Conclusion: Knowledge of coeliac artery variations should result in the accurate interpretation of disease in diagnostic imaging, as well as the optimum elective procedure in surgical or interventional radiological management.

C-1049

Aneurysms of the intra- and extra-hepatic portal vein: Helical CT demonstration.

S. Quiroga, M. Sebastià, H. Cuellar, R. Boye, A. Miranda, A. Alvarez; Barcelona/ES

Learning Objectives: To review portal venous system embryology, focussing on anomalous dilatation of the intra- and extrahepatic portal vein and related complications. To illustrate the helical CT appearance leading to the diagnosis.

Background: Portal vein (PV) aneurysms are rare, representing only 3% of all venous system aneurysms. They may be congenital or secondary to portal hypertension, and often occur at branching sites, usually in the extrahepatic PV. Aneurysms of the intrahepatic PV are less frequent, and can be located in the umbilical portion or in any portal branch. PV aneurysm complications include chronic portal hypertension, occlusion due to recurrent thrombosis, portosystemic shunt with a hepatic vein, bile duct obstruction, and rupture.

Imaging Findings: We retrospective reviewed 14 cases of PV aneurysm studied with dual-slice or multidetector helical CT. Five cases were extrahepatic and nine were intrahepatic (5 in the umbilical portion and 4 in portal branches). In five patients with intrahepatic PV aneurysm, a portosystemic shunt was also present (2 without associated liver cirrhosis). These aneurysms were occasionally associated with anatomic variations of intrahepatic portions of the PV. Partial thrombosis was demonstrated in three aneurysms of the umbilical portion of the PV.

Conclusion: Although most PV aneurysms are asymptomatic, it is important to

Scientific and Educational Exhibits

recognize them, thereby avoiding misdiagnoses such as hypervascular liver tumors, and to exclude complications such as thrombosis, rupture, local pressure effects, or development of portosystemic shunts. Contrast-enhanced helical CT can easily depict PV aneurysms and differentiate them from liver tumors by tracing the portal branches.

C-1050

CO₂ wedged hepatic venography in patients with portal hypertension:

Our experience

G. Alabau, J. Irurzun, S. Gil, F. De España, P. De la Iglesia, J. Verdu; Alicante/ES

Purpose: To describe the findings and utilities we have found in patients with liver cirrhosis in whom we have performed CO₂ wedged hepatic venography (WHV) in addition to measurement of hepatic venous pressure gradient (HVPG) or during the placement of transjugular intrahepatic portosystemic shunts (TIPS).

Methods and Materials: 39 patients were included, range 35-74 years, all of them with portal hypertension secondary to liver cirrhosis. 24 were referred for measurement of hepatic venous pressure gradient and 15 to perform TIPS. In the first group, CO₂ wedged hepatic venography was compared with direct portography with iodinated contrast (gadolinium-DTPA in an allergic case) made after portal canalization. Two of the portal hypertension cases also underwent indirect arterial portography.

Results: Good correlation was shown between CO₂ wedged hepatic venography and direct portography when performing a TIPS. CO₂ demonstrated varices during measurement of hepatic venous pressure gradient and may assess permeability of the portal vein, although it depends on the presence of collateral hepatic veins.

Conclusion: CO₂ wedged hepatic venography is an easy and safe procedure, allowing assessment of portal flow and a full radiological mapping of the portal venous system, very valuable when performing a TIPS, and it is very useful in the detection of varices and shunts during hepatic venous pressure gradient measurement.

C-1051

Preoperative evaluation of hepatic arteries in living-related liver transplantation donors with MDCT angiography

O. Ozbek, E.M. Kayahan, N.C. Tarhan, B. Cakir, C. Aytekin, M. Coskun, M. Haberal; Ankara/TR

Purpose: To assess the value of multidetector computed tomography angiography (MDCTA) in depicting hepatic arterial vascular variations in living-related liver transplantation donor candidates.

Materials and Methods: MDCTA was carried out using a 16-row CT (Sensation 16 Siemens Germany) in 32 living-related liver transplantation donor candidates in a 16-month period. Arterial phase images (0.75 mm collimation, 1 mm slice thickness, table speed of 7.8 mm per gantry rotation) were obtained after 150 ml IV contrast at a rate of 4 ml/s. Maximum intensity projection (MIP) and volume rendered (VRT) images were produced from axial raw data. All findings were compared with DSA.

Results: Excellent arterial opacification was achieved by MDCTA in all patients. Among 32 donor candidates, classic vascular anatomy of the hepatic arteries was seen in 16 patients (50%) and hepatic arterial vascular variants in 16 patients (50%) by MDCTA. The most common arterial variants were accessory left hepatic artery arising from left gastric artery ($n = 5$) and trifurcation of the common hepatic artery to gastroduodenal, right and left hepatic arteries ($n = 5$). Only a branch of the hepatic artery originating from the superior mesenteric artery, supplying the posterior segment of the right lobe, could not be identified on MDCTA.

Conclusion: Preoperative evaluation of hepatic vascular anatomy is crucial for surgical planning in living-related liver transplant donors. MDCTA is useful in depicting hepatic arterial anatomy with high accuracy in these patients. In the past, DSA was used to assess vascular anatomy; however, MDCTA is now replacing DSA to demonstrate hepatic arterial variations in living-related liver transplant donors.

C-1053

Pre- and postinterventional evaluation of abdominal vascular diseases using 16/64 row MSCT angiography

S. Leschka, H. Alkadhi, B. Marincek, S. Wildermuth; Zürich/CH

Learning Objectives: To describe an optimised scanning protocol for abdominal 16 and 64 row MSCT-angiography. To familiarize the radiologist with the pre- and postinterventional imaging features of different abdominal vascular diseases and surgical procedures. To highlight the role of post-processing in their evaluation.

Background: Multislice computed tomography angiography (CTA) has proved feasible for the pre- and postinterventional assessment of vascular anatomy. While the faster scanning speed increases volume coverage during a single breath-hold and improves the exploitation of contrast-medium, the better spatial resolution results in nearly iso-tropic voxels allowing reconstruction of high-resolution three-dimensional images with different algorithms. Burgeoning new surgical techniques often result in complex anatomic structures which are difficult to visualize with axial slices alone.

Imaging Findings: We present axial CT findings and post-processed images in 10 pre- and postinterventional vascular cases including acute mesenteric ischaemia, segmental mediolytic arteriopathy and complex vascular anatomy after different surgical interventions.

Conclusion: Multislice CT angiography is an excellent tool to assess a wide variety of abdominal vascular disease and offers a non-invasive imaging method for pre- and postinterventional evaluation. VR images in particular provide excellent visualization of pathologic conditions and their anatomic relationship with adjacent structures, that often cannot be confidently assessed by axial CT images alone.

C-1054

CT findings and clinical features of portomesenteric thrombosis

T. Yamaoka, A. Kurita, H. Azechi, Y. Endo, H. Nishikawa, M. Noguchi, Y. Nakano; Kyoto/JP

Learning Objectives: To summarize the CT findings and clinical features of portomesenteric venous thrombosis and demonstrate representative cases.

Background: Portomesenteric venous thrombosis is a rare condition; however, symptoms vary from "asymptomatic" to "severe acute abdomen", and thus may be difficult to correctly diagnose in cases with mild symptoms. Between April 1994 to August 2004, 8 patients were radiologically or pathologically diagnosed with portomesenteric venous thrombosis; cases with tumor thrombosis were excluded. We evaluate these cases from CT findings (density of thrombus, bowel wall thickening, enhancement of the bowel loop in the arterial phase, ascites, development of collateral veins, edema of the mesentery, and dilatation of the distal mesenteric vessels). We also review clinical presentation and past history, as this can affect presentation.

Image Finding: Dynamic CT was performed in 7 and plain CT in 1. On plain CT, venous thrombi were slightly high density in 4/8 cases. Bowel wall thickening, poor enhancement of the involved bowel loop in the arterial phase, ascites and collateral veins were found in 5/8, 4/7, 6/8, and 7/7 cases, respectively. Edema of the mesentery and dilatation of the distal mesenteric vessels were found in all 8 cases, however, in 2, these findings had been found in a previous study without venous thrombosis.

Conclusions: When bowel wall thickening and ascites are found in patients with an acute abdomen, attention should be paid not only to the mesenteric arteries but also to the portomesenteric vein. Dynamic CT of the whole abdomen may be helpful in making a diagnosis.

B-flow and color-coded-B-flow in sonographic diagnosis of filiform stenosis of the internal carotid artery

D.-A. Clevert¹, Jung², N. Rupp², M. Reiser¹; ¹Munich/DE, ²Passau/DE

Purpose: To evaluate diagnostic results of ultrasound B-flow in filiform (> 90%) stenosis or occlusion of the internal carotid artery (ICA) and to compare with other modalities.

Method and Materials: 60 patients with suspected occlusion or filiform stenosis of the internal carotid artery (ICA) on Doppler-ultrasound, were examined using the ultrasound B-Flow, either in color-coded or brightness mode. The pre-, intra- and poststenotic flow phenomena were all compared with color-coded duplex (CCD) and power Doppler (PD). In 18 cases contrast agent (Optison) was injected additionally. Results were compared with those of selective intraarterial DSA, and in 18 cases additional MR-angiography.

Results: Diagnosis of ICA occlusion was correct in all 27 cases using CCD, PD and B-flow. A filiform ICA-stenosis was correctly seen in all 34 cases using B-flow and contrast-enhanced power Doppler, but only in 15 cases using CCD. All 11 of 34 cases of ulcerated plaques with appositional thrombi were only detected when B-flow was used, but only 5 cases when CCD was used. Pre-, intra- and poststenotic flow phenomena in the longitudinal scan were demonstrated simultaneously using color-coded B-Flow in 33 of 34 cases, but only in 20 cases using CCD and in 27 cases using PD. In B-flow there was no overwriting of vessel walls in the intra- and poststenotic area, in the 18 cases where contrast agent was given.

Conclusions: B-flow is more reliable in ultrasound diagnosis of filiform stenosis of the ICA than other ultrasound modalities, displaying no vessel overwriting and better simultaneous intra- and poststenotic flow detection.

C-1056

All that the radiologist should know about color-Doppler US in chronic venous insufficiency

A. Cina, A. Pedicelli, C. Di Stasi, V. Lo Schiavo, A. Fiorentino, G. Cina, L. Bonomo; Rome/IT

Background: At present, color-Doppler US (CDUS) is the gold standard for diagnosis and patient screening for chronic venous insufficiency (CVI). While deep venous system disorders are well-known to radiologists, the diagnosis of superficial system disorders in most institutions remains the territory of angiologists or vascular surgeons. In recent years percutaneous endovenous technique for CVI are become available and are now also performed by interventional radiologists. **Learning Objectives:** To acquire an overview of the pathophysiologic principles of CVI. To review lower limb superficial vein anatomy, its most frequent variations and differences between perforating, communicating and collateral veins. To become familiar with CDUS findings in CVI. To be able to provide the surgeon and/or the interventional radiologist with the information necessary to select the best surgical approach and perform an adequate follow-up. To illustrate the main surgical and interventional techniques for CVI and the specific question for CDUS. To provide the interventional radiologist with the anatomical and pathophysiological background necessary to perform percutaneous procedures for CVI.

C-1057

Behcet's disease: Rare cardiovascular manifestations

N. Ben Achour, S. Bouomrani, R. Braham, S. Hammami, R. Salem, S. Mahjoub, A. Gannouni; Monastir/TN

Learning Objectives: To illustrate the spectrum of rare cardiovascular involvement patterns in Behcet's disease (BD), which have been misleading in presentation, with emphasis on pathologic associations, based on a series 17 patients among a total number of 141 BD patients.

Background: Arterial lesions are a rare but serious complication in BD. Cardiac lesions are even rarer and have the peculiarity of being the first presenting symptom in more than a third of cases. In this exhibit we describe rare cardiac, pulmonary and peripheral lesions diagnosed from 1976 to 2004. Peripheral ultrasound (US) coupled to Doppler, helical CT, angiography, scintigraphy and cardiac trans-thoracic and trans-esophageal-US findings are described and illustrated.

Imaging Findings: In our series we illustrate 3 cases of intra-cardiac thrombosis (ICT), all of them right-sided. Pulmonary aneurysms (PA) (4cases) were multiple in 3 cases (2 bilateral, 1 unilateral). Pulmonary embolism (PE), more typical but

still uncommon, were noted in 11 patients who were asymptomatic in 4 cases. Extra-pulmonary aneurysms were ruptured in two patients, in tibio-peroneal trunk (1 case) and primitive iliac artery (1 case, lethal), or unruptured in the distal superior mesenteric artery (1case), the latter being the rarest found in our series. Lesions were associated in 4 patients (ICT and PE, ICT with PE and PA, PA and extra-pulmonary aneurysms, PE and PA).

Conclusion: Although rare, arterial and cardiac BD manifestations should be well known because of their poor prognosis if untreated. Lesion association should urge a wider use of "total body" angio-screen especially following the advent of multi-row-detector-CT.

C-1058

Evaluation of endothelial function of normotensive and hypertensive subjects with flow mediated dilatation

O.O. Okten¹, N. Tuncbilek¹, M.H. Karakas², Y. Ince¹, S. Sen¹; ¹Edirne/TR, ²Malatya/TR

Purpose: Endothelial dysfunction is the inability of vascular structures to respond satisfactorily to vasodilator and vasoconstrictor agents. In this study the differences between endothelial function of normotensive (NT) and hypertensive (HT) subjects were evaluated using flow mediated dilatation (FMD) method.

Materials and Methods: 15 (10 male and 5 female) NT subjects with ages between 28-56, and 30 (19 male and 11 female) HT subjects with ages between 32-58 formed the study groups. HT subjects did not have target-organ damage and were not receiving medical treatment. All subjects were investigated in 24°C temperature and after 48 h of alcohol, 10 h of tobacco, and 8 h of food abstinence. Endothelium-dependent and sublingual nitroglycerine induced endothelium-independent FMD methods were employed under brachial artery ultrasonography. Relevant measurements were statistically compared.

Results: Average basal endothelium-dependent FMD values were 0.097 l/min in NT and 0.0714 l/min in HT subjects ($p < 0.05$). Average reactive phase endothelium-dependent FMD values were 0.1447 l/min in NT and 0.1004 l/min in HT subjects. A significant difference was found between NT and HT subjects regarding basal FMD that reflects endothelium-dependent FMD ($p < 0.001$) and reactive phase hyperemic FMD ($p < 0.05$). However no difference existed between groups regarding endothelium-independent FMD.

Conclusion: Although traditionally evaluated with biochemical indices, endothelial dysfunction, an early physiological result of atherosclerosis, may also be evaluated by the FMD method. This evaluation is critical in hypertensive subjects, who are at increased risk of cardiovascular disease, for early diagnosis of such disease and evaluation of treatment.

C-1059

Carotid artery blood flow and wall properties in patients with early stage renal insufficiency

Z. Serafin, P. Strozecki, W. Lasek, J. Manitus, B. Sobocinski; Bydgoszcz/PL

Purpose: Atherosclerosis is accelerated in hemodialysis patients with end-stage chronic renal failure (CRF), as shown by increased carotid artery intima-media thickness (IMT). However, less is known about carotid artery wall properties and carotid artery blood flow in the early stages of CRF.

Methods and Materials: Ultrasound duplex-scan of carotid arteries was performed in 31 patients in the predialysis stage of CRF and 18 healthy controls. IMT and distensibility were measured in both common carotid arteries (CCA). Blood flow spectra and were obtained in right and left CCAs, and in internal carotid arteries (ICA); mean flow parameters were then calculated. In CRF patients, results were correlated with clinical data.

Results: Mean IMT did not differ between the groups, whereas CCA distensibility was lower in CRF patients than in controls (0.53 vs. 0.76 mm, $P < 0.04$). In CRF patients, IMT correlated with age, systolic blood pressure, pulse pressure and plasma glucose level ($P < 0.001-0.02$). Duration of hypertension negatively correlated with mean velocities (TAVM, MN), and end-diastolic velocity in both carotids ($P < 0.05$). Pulse pressure correlated with pulsatility index (PI) and RI in ICA ($P < 0.03$). Total cholesterol correlated negatively with PI and RI in CCA, while HDL cholesterol correlated negatively with PI and RI in both CCA and ICA.

Conclusion: In patients in the predialysis stage of renal insufficiency, subtle carotid wall alterations are expressed by loss of distensibility. Blood pressure and cholesterol level are the main factors related to IMT and flow indices in this group.

Scientific and Educational Exhibits

C-1060

Evaluation of antibiotic therapy efficacy in patients with asymptomatic abdominal aortic aneurysm (AAA) and serological markers of chronic C. pneumoniae infection: Preliminary report

P. Terlecki, E. Mazur, J. Niedzwiedek, T. Zubilewicz, S. Przywara, M. Feldo, M. Koziol-Montewka, W. Krupski, J. Wronski; Lublin/PL

Introduction: The frequent finding of *C. pneumoniae* in atheroma and not in normal artery tissue by different methods and numerous investigators suggests that the organism may play a role in clinical manifestations of atherosclerosis, including AAA.

Material and Methods: 30 patients with AAA and serological markers of chronic *C. pneumoniae* infection were included in this study. They were treated with doxycycline at a dose of 100 mg daily for 3 months. Blood samples were collected to evaluate: serum concentrations of IgG and IgA anti-*C. pneumoniae*; C-reactive protein concentration; WBC count; lipid profile; the presence of *C. pneumoniae* DNA and RNA in blood monocytes (using PCR methods). Currently we are presenting the preliminary report: the results obtained after 2 months of antibiotic therapy received by 11 patients.

Results: Serological signs of chronic *C. pneumoniae* infection ($IgG \geq 1:128$, $IgA \geq 1:32$) were present in all patients prior to beginning the study. No significant changes were observed in specific IgG and IgA concentrations after 2 months of antibiotic therapy. 9 patients (82%) had the increased concentrations of C-reactive protein (mean concentration: 13.42 mg/l) before initiating antibiotic therapy. After 2 months of treatment the concentrations of C-reactive protein decreased significantly in all patients (mean concentration 7.37 mg/l). In 2 patients a decrease of AAA diameter was observed. The other patients showed no increase of AAA diameter.

Conclusions: Our preliminary results suggest that antibiotic therapy can be useful in the treatment of selected patients with asymptomatic AAA

C-1061

Congenital anomalies of the inferior vena cava: Cross-sectional imaging findings

J. Quintero¹, C. Pozuelo¹, Y. Roca¹, L. Monés¹, M. Torné², M. Pérez²;

¹Badalona/ES, ²Santa Coloma de Gramenet/ES

Learning Objectives: To review the normal anatomy of the retroperitoneum and to describe the congenital anomalies of the inferior vena cava (IVC) with computerized tomography (CT). We present our experience in the study and description of anomalies of the IVC with helical CT.

Background: We reviewed all the reports of abdominal CTs performed in our institution over three years. We selected the cases where congenital anomalies of the IVC were present and these were retrospectively reviewed by two radiologists who were unaware of the CT findings. The usual study protocol was: oral contrast, 5-mm collimation, pitch: 1.5, 100 mL of IV contrast medium, rate: 2.5 mL/sec, delay: 70 sec. From July 2001 to July 2004 we found 6978 consecutive abdominal CTs. We encountered 78 cases (1.11% of the studies) of congenital anomalies of the IVC.

Procedure Details: The cases reviewed were classified into: - Absence of the hepatic segment of the IVC with azygos/hemiazygos continuation (14); - Circum-aortic left renal vein (7) and retro-aortic left renal vein (43); - Double inferior vena cava (12); - Circumcaval ureter (2).

Conclusion: Congenital anomalies of the IVC have become more commonly recognized in asymptomatic patients and have been known to anatomists since 1793. Knowledge of these anomalies is essential to avoid diagnostic pitfalls. Some of these anomalies have significant clinical implications. Although vascular structures can usually be readily identified on contrast-enhanced CT scans, identification of unusual venous arrangements may be difficult in some cases. MR imaging may be used to distinguish aberrant vessels from masses.

C-1062

A pictorial review of anomalies of the thoracic aorta with embryological correlation

D.R. Bakshi, Gould, S. Powell, H. Yeang, H. Fewins; Liverpool/UK

Learning Objectives: To provide a comprehensive educational exhibit demonstrating the numerous anomalies of thoracic aortic development with embryologic correlation to attempt to achieve a better understanding.

Background: The development of the thoracic aorta is a complex process which is intimately associated with the development of the endocardial tube and which lends itself to a variety of congenital variants. The formation of the thoracic aorta takes approximately 3 weeks to complete, beginning in the presomite stage, about

20 days after fertilization. A review of this process is helpful in understanding normal variations and congenital anomalies of the thoracic aorta.

Procedural Details: An attempt is made to simplify the great number of anomalies by using Edwards' hypothetical double aortic arch model. Using CT/MR imaging, echocardiography, angiography and diagrams, we will illustrate both normal and abnormal thoracic aorta development such as aberrant subclavian arteries, double aortic arch, aortic stenosis and coarctation. These will be correlated with current embryologic understanding to provide a detailed overview.

C-1063

12 year follow-up of patients with type B aortic dissection

N. Limbucci, G. Gismondi, V. Pupillo, M. Ciriello, E. Di Cesare, C. Masciocchi; L'Aquila/IT

Purpose: To study long term evolution of type B aortic dissection with MR imaging during 12 years follow-up.

Methods and Materials: From 1992 May to 2004 May we studied 24 patients with type B aortic dissection (total 188 examinations). All MR imaging was performed with a 1.5 T unit (GE), using gated SE and Cine-MR imaging sequences until March 1998 and using contrast-enhanced 3D-FSPGR with a phased array coil from March 1998 to May 2004. We retrospectively analyzed the following parameters: maximum aortic dilatation, true/false lumen ratio, false lumen thrombosis, involvement of aortic branches and dissection extension.

Results: 1 patient (4.17%) underwent surgery because of wide false lumen dilatation (72 mm). 2 cases (8.33%) presented increase of maximum diameter (average 5.5 mm). In 6 patients (25%) MR imaging showed a variation of the false/true lumen ratio (average 0.4). In 2 subjects (8.33%) we observed partial thrombosis of false lumen and in 2 patients (8.33%) total thrombosis during early follow-up. Only in 10 patients (41.7%) was there no involvement of aortic branches. No patients had extension of dissection. 6 patients (25%) died during follow-up (mean time 3.7 years after first examination); 1 patient died from aortic rupture but the remaining 5 patients died from extravascular causes.

Conclusion: This survival study showed a very good outcome for the patients, confirming the efficacy of medical treatment and the important role of follow-up in patients with type B dissection in the identification of surgically manageable complications. MR imaging appears very effective because it is repeatable, not invasive and allows comparative measurements.

C-1064

Improved diagnosis of vessel dissections by ultrasound B-flow imaging

D.-A. Clevert¹, E. Jung², N. Rupp², M. Reiser¹; ¹Munich/DE, ²Passau/DE

Purpose: A study was completed to evaluate the efficiency of different ultrasound sound techniques (color-coded duplex sonography, power mode imaging and B-flow imaging) in vessel dissection diagnosis.

Methods and Materials: The study compared flow representation by color-coded duplex sonography, power-mode imaging and the recently developed B-flow imaging method in cases of dissection of the carotid artery (13 cases), the vertebral artery (10 cases), the abdominal artery (13 cases), the iliac artery (12 cases) and the femoral artery (25 cases). Reference standards were provided by contrast-enhanced MRA in 24 cases, CTA in 10 cases and intra-arterial DSA in the remaining cases.

Results: Boosted reflector signals provided by B-flow imaging facilitated the identification of the dissection membrane. Unlike intra-arterial DSA, CTA and MRA, B-flow imaging detected all 68 dissections. The comparative detection rates for color-coded duplex sonography, power-mode imaging and B-flow imaging were 10, 12 and 13 for 13 carotid artery dissections, 7, 8 and 10 for 10 vertebral artery dissections, 11, 11 and 13 for 13 abdominal artery dissections, 8, 9 and 12 for 12 iliac artery dissections and 20, 21 and 24 for 24 femoral artery dissections. The absence of overwriting in B-flow imaging produces more exact residual flow records, particularly for the false lumen. The reduced effect of angles facilitates the representation of fissures and membranes and enhanced near-wall flow recording improves the identification of low-reflection wall deposits.

Conclusion: B-flow imaging allows the primary diagnosis of dissection membranes, shows hemodynamic effects and facilitates the representation of membranes and any windowing.

C-1065

The role of echo enhanced ultrasonography in the investigation of extracranial vertebral arteries

A.A. Kotis, G. Chatzakis, A. Marinou, S. Karatapanis, P. Brestas; Rhodes/GR

Purpose: Evaluate the usefulness of ultrasound contrast agents on extra cranial vertebral arteries

Scientific and Educational Exhibits

Material and Methods: 15 pts performed colour Doppler sonography to investigate insufficiently detected extracranial vertebral arteries without and with echo enhancing agent I-vist 4 g, bolus concentration 16 ml. (average age 58 years). All examinations performed through Aspen Acuson scanner and head transducer 5-7 MHz. Were analyzed by two readers, with intraobserver agreement and estimated B-mode quality imaging, colour flow signal, blooming blood flow artifacts.

Results: There was increase assessment of VA by 37% and 25% according the two readers. After ultrasound contrast injection hypoplasia estimation raised in 49% vs. 45%, extra cranial occlusion 56% vs. 45%, and color flow signal in 52% vs. 34%. Only 5% of vertebral arteries showed no improvement in imaging quality after application of Levovist. Analysis of side-to-side differences of peak systolic and end-diastolic systolic blood velocities of VA showed no significant differences of flow velocities in all subjects and between men and women in CBF volume after I-vist injection. Echocontrast enlarged in each vessel segment the length that could be visualized.

Conclusion: Our study demonstrates that echocontrast provides effective Doppler signal enhancement and considerably increases the diagnostic gain in the extracranial vertebral vasculature.

C-1066

Follow up of aortic percutaneous endoprostheses with contrast enhanced ultrasound (CEUS) performed at low mechanical index (MI) and with a second generation contrast agent

L. Aiani, C. Ballarati, M. Soprani, T. Frattini, G. Belloni, A. Martegani; Como/IT

Purpose: To evaluate the accuracy of CEUS at low MI combined with low MI color Doppler (CEUS/CD low MI) in detecting endoleak after endovascular repair of aortic aneurysm. To evaluate the accuracy of CEUS/CD low MI in identifying the cause of endoleak

Materials and Methods: 28 patients diagnosed with aortic aneurysm and treated with a percutaneous endovascular approach underwent a conventional ultrasound and color Doppler (US/CD) evaluation and, in the same session, CEUS/CD low MI. Each patient underwent a spiral angioCT examination within one week.

Results: US/CD evaluation was burdened with 6 false negatives, due to the extremely low flow velocity, and 3 false positives, related to the presence of movement artefacts. CEUS/CD low MI detected 8 endoleaks, confirmed by the gold standard. No false positives were identified. The direction of blood inflow in the aneurysmal sac was correctly detected in every case, leading to the diagnosis of the endoleak type.

Conclusion: In our experience, CEUS/CD low MI has proved to be a valid, non-invasive, repeatable diagnostic technique in the diagnosis of endoleak after endovascular repair of aortic aneurysm, and can play a role in the follow-up protocol of these patients.

C-1067

3D image of Adamkiewicz artery: Preoperative assessment of thoracoabdominal aortic aneurysm

H. Yokoyama¹, S. Sanada¹, T. Ohno²; ¹Kanazawa/JP, ²Sapporo/JP

Learning Objectives: To assess the ability of multi detector 4-row computed tomography for depicting a 3D image of Adamkiewicz artery.

Background: The Adamkiewicz artery supplies most of the blood to the anterior spinal artery, which perfuses the anterior two thirds of the spinal cord. During operation for thoracoabdominal aortic aneurysm, detailed anatomic knowledge of the Adamkiewicz artery and its correlation with the intercostal and/or lumbar arteries is important to prevent postoperative paraplegia.

Procedure Details: Images were obtained with the following parameters: 0.5 sec/r, 1 mm collimation, H.P 3.5, 120 kV, 300 mA, with 40 seconds breath-hold during scanning after inhalation of oxygen. 100 ml of contrast material containing 350 mg iodine/ml was injected with a power injector (dual-shot type) into an antecubital vein at a rate of 3.5 ml/sec (70 ml). The remaining 30 ml plus the same volume of saline were then infused at a rate of 1 ml/sec simultaneously. Twenty-five seconds after the injection, the scan was performed from the level of L2 to T5 vertebrae. Transverse sections were reconstructed with a 1 mm thickness at 0.7 mm intervals.

Conclusion: In 141 patients, 107 (76%) Adamkiewicz arteries were visualized from the intervertebral foramen to the hairpin-shaped union with the anterior spinal artery. Seventy-nine arteries of Adamkiewicz (73%) originated from the left side. Sixty-eight (63%) originated between T9 and T12. Imaging was usually done with multiplanar and curved planar reformations. In cases of vertebral deformity, however, 3D images were useful to depict the Adamkiewicz arteries.

C-1068

Relation between the intrarenal arterial resistance, the carotid artery wall thickness and endothelial dysfunction (ultrasound study)

L.A. Krasilnikova, L.A. Tyutin; St. Petersburg/RU

Aim: To assess the relationship between intrarenal arterial resistance (IAR), carotid artery wall thickness (CAWT) and vasoactive dysfunction of the endothelium (VDE).

Methods: 31 male patients (mean age 55.1 ± 2.3 years) with essential hypertension were examined using ultrasound (SONOLINE OMNIA; Siemens). All vasoactive drugs were stopped one day before the study. We measured the maximal thickness of the "intima-media" complex in both the common carotid arteries. The study was also concerned with the VDE (ultrasound analyses of the brachial artery diameter response to compression or nitroglycerine). As markers of renal angiopathy we assessed the indices of IAR (PI and RI) which were measured at three points of arcuate arteries from both kidneys.

Results: In the patients (8 men) who had nitroglycerine-induced VDE (endothelium independent dysfunction) the CAWT was more than 1.0 mm and in 4 of these patients PI and RI were increased (PI > 1.4; RI > 0.8). In the 11 patients with compression-induced VDE (endothelium dependent dysfunction) only 6 patients had CAWT more than 1.0 mm and only 5 of them had high range of PI and RI. 12 patients had no signs of VDE. We observed CAWT of more than 1.0 mm in 4 patients without VDE, and only 2 of them had increased range of PI and RI.

Conclusion: VDE and abnormal CAWT range are not reliable markers of renal angiopathy in patients with essential hypertension. Nitroglycerine-induced VDE is often associated with CAWT more than 1.0 mm.

C-1069

Atherosclerosis as an inflammatory disease: Implications for the interventional radiologist

K.T. Tan¹, H.W. Aw-Yeang², D. Bakshi²; ¹Bristol/UK, ²Liverpool/UK

Learning Objectives: To understand the concept of atherosclerosis as an inflammatory disease and to be aware of the potential implications for vascular intervention.

Background: Recent advances in vascular biology have shown that inflammation plays an important part in the development and progression of atherosclerosis. Indeed, it has been demonstrated that the degree of inflammatory response can be correlated with the risk of developing adverse cardiovascular events.

Procedure Details: Of more relevance to the radiologist is the fact that an increased inflammatory response can also be related to the risk of recurrent disease following angioplasty. Indeed, it has recently been shown that peripheral artery angioplasty can elicit a strong inflammatory response. In this exhibit, we review the basic science behind the vascular inflammatory response as well as the possible mechanisms by which we can attenuate this response for potential therapeutic gain.

Conclusion: Advances in elucidating the causes of the vessel wall inflammation may be translated into therapeutic gain in the near future.

C-1070

Carotid intima-media thickness is associated with inflammation and endothelial cell adhesion molecules in end stage renal disease (ESRD)

M. Kalovoulos, A. Papagianni, K. Tsinoglou, C.A. Dimitriadis, G. Terzis, S. Dovas, D. Kirmizis, G. Grollios, D. Memmos; Thessaloniki/GR

Aim: To investigate adhesion molecule ICAM-1 and VCAM-1 levels in ESRD patients and their probable association with atherosclerotic disease as assessed by measuring intima-media thickness (IMT) of the common carotid arteries using an ultrasound scanner.

Methods and Materials: Eighty-five ESRD patients on conservative treatment, 91 haemodialyzed (HD) patients and 65 normotensive controls were enrolled.

Results: Compared with controls, ESRD and HD patients had significantly increased serum CRP and adhesion molecule ICAM-1 and VCAM-1 levels (each $p < 0.0001$), as well as IMT values (each $p < 0.001$). Moreover, compared with ESRD, HD patients had increased serum CRP, ICAM-1 and VCAM-1 ($p < 0.001$, $p < 0.001$ and $p < 0.0001$ respectively) and IMT ($p < 0.05$). In univariate analyses, IMT was correlated with age, systolic blood pressure (SBP), history of cardiovascular disease (CVD), logCRP and ICAM-1 levels in ESRD ($p = 0.0001$, $p = 0.01$, $p = 0.03$, $p = 0.02$ and $p = 0.004$ respectively) and HD patients ($p = 0.0001$, $p = 0.01$, $p = 0.02$, $p = 0.02$ and $p = 0.001$ respectively). Multivariate analyses showed that ICAM-1 was a strong independent correlate of IMT in ESRD and HD patients ($p = 0.001$ and $p = 0.001$ respectively). In addition, compared with patients with normal IMT, ESRD and HD patients with increased IMT (≥ 0.82 mm) had increased ICAM-1 ($p < 0.01$ and $p < 0.001$ respectively).

Scientific and Educational Exhibits

Conclusion: Increased endothelial cell adhesion molecule levels and advanced atherosclerosis are present in ESRD patients before starting HD treatment. The latter appeared associated with further activation of the inflammatory response and acceleration of the atherogenic process. In patients with ESRD, both on conservative treatment and on haemodialysis, ICAM-1 levels are potentially a useful surrogate marker of atherosclerosis.

C-1071

Emergency extracranial Doppler in diagnosis and monitoring the progress of primary cervicocerebral artery dissection

V. Bizimi, E. Manopoulou, P. Brestas, A. Tsikkini, E.S. Antipa, K. Bilas, P. Noti, M. Tsouroulas, C. Drossos; Athens/GR

Learning Objectives: Analyze the findings and value of extracranial ultrasonography, as the first noninvasive imaging approach, to establish a probable diagnosis and follow-up of cervicocerebral artery dissection.

Background: Cervicocephalic arterial dissection has been recognized as a neurological emergency because of an increased risk of cerebral infarction. Dissections have nonspecific symptoms, such as neurological deficits. The classic presentation is that of a headache and they occur at a relatively young age. They often occur in previously healthy individuals, developing either spontaneously or following various degrees of trauma.

Procedure Details: 152 patients with acute cerebral circulatory disturbances or cervical trauma, were examined with extracranial pulsed Doppler ultrasound, over a 3-year period (2001-2003). Twenty eight patients had dissection of the internal carotid artery, and 5 had vertebral artery dissection. All of them had their diagnosis confirmed by another reference method (digital angiography or MRA angiography). The presence of an intramural hematoma, echogenic thrombus, intimal flap, imaging of both true and false lumen in the absence of an atheroma plaque, in B-mode sonography, were considered to be positive signs. Doppler findings were variable, depending on the degree of stenosis caused by intramural hematoma (absence of flow or high resistance signal, damped wave form in the ICA, or wave form asymmetry between ICAs). The findings for vertebral artery dissection included absence of arterial flow signal or low blood flow velocities.

Conclusion: Extracranial ultrasonography substantiated clinically suspected cervicocranial artery dissection and showed efficacy to monitor evolution in the majority of cases (95%).

C-1072

CT and MR imaging aspects of superior vena cava pathologies

I. Lupescu, R. Capsa, S. Georgescu; Bucharest/RO

Aim: The purpose of our study is to create a comprehensive CT and MR imaging overview of superior vena cava (SVC) pathologies.

Material and Methods: We have reviewed 35 cases explored by spiral CT and MR imaging, with clinical signs of superior vena cava syndrome, over a period of 4 years. In addition, we have reviewed 5 cases of cardiac malformations associated with anomalies of the SVC.

Results: Amongst the 35 patients with signs or suspicion of SVC syndrome, 26 had mediastinal tumors (thymoma-6 cases, goiter-4 cases, malignant lymphomas-16 cases), 8 cases had bronchopulmonary carcinomas and 1 case nontumoral SVC thrombosis.

We also analysed the presence of collateral pathways. Congenital anomalies such as persistent left SVC were found in 5 patients: isolated (1 case) or in association with inferior vena cava pathology (4 cases).

Conclusion: Using spiral CT and MR imaging, it is possible to evaluate very accurately all the pathological lesions located in the course of the SVC and its tributaries.

C-1073

Early ultrasound characteristics of angiopathy in patients receiving antitumor therapy

L.A. Krasilnikova, L.A. Tyutin; St. Petersburg/RU

Purpose: To reveal the early ultrasound characteristics (UC) of angiopathy in patients receiving antitumor therapy.

Method: The UC of arterial walls were assessed in 82 young and middle-aged male (45) and female (37) cancer patients (mean age 30.1 ± 0.9 years) receiving radiation or polychemotherapy for less than 1 year. To reveal the angiopathy we used quantitative and qualitative analyses detecting the changes in the "intima-media" complex in the different peripheral arteries (arteries of upper and lower limbs, carotid and vertebral arteries, abdominal aorta). Also we estimate the va-

soactive dysfunction of the endothelium (VDE) as the response of the brachial artery diameter to compression and nitroglycerine.

Results: We noted the early changes in the "intima-media" complex were seen more frequently in patients who underwent radiation therapy, being more pronounced in the arteries localized in the irradiation areas. VDE was observed in patients who received polychemotherapy. However, these patients did not have visible changes in the "intima-media" complex in the peripheral arteries in early stages of treatment.

Conclusion: The lesions of arterial walls evoked by radiation therapy and polychemotherapy are different. The patients should be prescribed vascular protective treatment in depending on type of antitumor therapy.

C-1074

Follow-up of the aneurysm neck diameter after endovascular repair of abdominal aortic aneurysms

A. Bravo, M. Martí, G. Garzón, A. Alvarez Luque, B. Rodriguez-Vigil, M. Allona; Madrid/ES

Purpose: To assess aneurysm neck diameter change after endovascular repair (EVR) of abdominal aortic aneurysms.

Methods and Materials: 95 patients with abdominal aortic aneurysm who underwent EVR were studied with multislice CT following a standardised protocol. A preoperative study, an immediate postoperative, and a six month and one year follow-up were always performed. The volume of interest comprised from the supraceliac aorta to the femoral artery bifurcation, and 120 ml of contrast was administered at 3 ml/sec. A 3 mm collimation, table speed of 16 mm per rotation, pitch of 4, and 2 mm reconstruction interval were used. The images were post-processed and multiplanar reformations obtained on a workstation. The aneurysm neck was measured from adventitia to adventitia, 6 mm below the lowermost renal artery, in planar images performed perpendicular to the vessel axis (real axial section). For the statistical analysis a one-way ANOVA with repeated measures was used.

Results: The average neck diameter was 22.38 mm (16-32.5) on the preoperative study, 23.35 mm (17-33.9) on the immediate postoperative, 24.35 mm (18.2-34.5) on the 6 month, and 24.36 mm (18-34.5) on the one year follow-up. A statistically significant increase in the average neck diameter between the preoperative, immediate postoperative control, and the six month follow-up was observed. There was no significant increase in the average neck diameter between the six month and the one year follow-up.

Conclusions: An enlargement of the infrarenal aneurysm neck occurs during the first six months after EVR. No significant variation in the neck diameter occurs between the six month and the one year follow-up.

C-1075

The diagnosis and endovascular treatment of carotid artery and vertebral artery dissections

C.M. Flis, H.R. Jager, P.S. Sidhu; London/UK

Learning Objectives: To describe the clinical presentation of extra-cranial arterial dissections. To illustrate and describe the imaging findings on angiography, ultrasound, computed tomography (CT) and magnetic resonance imaging (MRI) and to emphasize the advantages and limitations of each modality. To describe the various management options and the current opinion on each form of treatment.

Background: Extra-cranial arterial dissections are a recognised cause of stroke in young adults. Clinical diagnosis may be difficult. The classic triad of presentation occurs in less than 1/3 of patients and so there must be a high degree of suspicion for the diagnosis not to be missed. Conventional angiography has been the reference standard for diagnosis. It will demonstrate stenosis, occlusion or a pseudoaneurysm. Other imaging modalities are now available. MR techniques provide a useful overview of the extent of a dissection and document cerebral ischaemia. Ultrasound gives haemodynamic information. CT angiography allows excellent visualization of the carotid arteries and allows data to be displayed using a MIP algorithm, providing angiography-like images. Surgery has a limited role in the management, whilst endovascular stent insertion and embolisation is the treatment of choice in failed medical management. Anticoagulation, however, remains the mainstay of medical treatment.

Conclusion: A combination of MRI is the most useful adjunct to diagnosis, but ultrasound provides a practical method for follow-up of arterial patency. Angiography is reserved for cases where endovascular management is considered. Endovascular management should be considered when medical treatment fails or there is disease progression.

C-1076

Deep venous thrombosis of the lower limb on screening with colour Doppler: Incidence and correlation with clinical history

M. Chalkia, I. Kirimlidis, A. Spanos, A. Mountzouoglou, P. Chalkia, N. Vougiouklis; Thessaloniki/GR

Purpose: Our purpose is to study the incidence and location of Deep Venous Thrombosis (DVT) of the lower limbs on screening with colour Doppler and to correlate it with the clinical history.

Methods and Materials: We performed colour Doppler examination of lower limb veins in 535 consecutive patients, 349 women and 186 men, (10- 84 years old, mean age = 55). Bilateral screening was performed in 260 patients and unilateral in 275.

Results: DVT was found in 126 patients (23.46% of the examined patients), 57 were women (45.23%) and 69 men (54.74%). DVT was unilateral in 122 patients (85 on the left and 37 on the right), while it was bilateral in four patients (3.14% of the patients with DVT). DVT was confined to the calf veins in two patients only (1.5% of the patients with DVT). Eleven patients (2% of the examined patients) had superficial vein thrombosis, while in one patient DVT and SVT coexisted. Forty-eight of the 126 patients with DVT (38%) had a predisposing factor for thrombosis; pregnancy-puerperum:13, neoplastic disease:8, varices:6, recent surgery:6, bedridden:5, fracture:3, contraceptive pills:2 and IV drug abuse:1.

Conclusion: DVT of the lower limbs is a common finding during examination with colour Doppler ultrasonography. The possibility of DVT confined to the calf veins is small, so screening of them can be avoided if examination of the more central veins is negative. A predisposing factor for thrombosis was present in 38% of the patients with DVT, pregnancy and neoplastic disease being the most commonly encountered.

C-1077

Technical optimization of diffusion tensor sequences: Evaluation of three dimensional white matter tractography in various neurologic disorders

N. Papapanikolaou; Iraklion/GR

Non-invasive in-vivo visualization of white matter fiber tracts is nowadays feasible by means of diffusion tensor imaging (DTI) techniques. Technical optimization of diffusion tensor sequences including signal to noise ratio and spatial resolution was performed. Parameters that were optimized for white matter tractography included b-value, slice thickness, scan matrix, number of slices and acquisition time. Two different DTI protocols applied on 20 normal subjects were compared in terms of signal to noise ratio, spatial resolution and scan time while fractional anisotropy (FA) and apparent diffusion coefficient (ADC) maps were reconstructed. A voxel based statistical analysis was made to reveal any potential regions with statistically significant differences between FA and ADC maps generated by the two different DTI protocols. Additionally, cortico-spinal tracts and the splenium of corpus callosum were reconstructed by using fiber-tracking algorithms and a qualitative comparison was performed. The optimized diffusion tensor sequence was applied in 10 patients with various brain tumors, 8 patients with multiple sclerosis, 7 patients with stroke and 2 patients with dementia. Examples of white matter tractography reconstructions along with its current limitations are presented.

C-1078

Characterisation of carotid atheroma in symptomatic and asymptomatic patients using high-resolution gadolinium-enhanced MR imaging

J.M. U-King-Im, R.A. Trivedi, M.J. Graves, P.J. Kirkpatrick, N.M. Antoun, J.H. Gillard; Cambridge/UK

Purpose: Risks of stroke secondary to carotid atheroma may be better predicted using plaque characteristics rather than luminal stenosis. The aim of this study is to explore plaque morphology in symptomatic and asymptomatic patients using high-resolution MR imaging and histology.

Materials and Methods: 9 patients (mean age 71, 3 women) with carotid artery territory symptoms within the previous 6 months and 8 asymptomatic patients (mean age 68, 1 woman), enrolled in the Asymptomatic Carotid Surgery Trial, were prospectively recruited to have high-resolution (0.39 x 0.39 mm) MR imaging prior to surgery. Imaging protocol consisted of a T2-W, PD-W, STIR, TI-W and post-gadolinium T1-W sequences using a 4-channel phased array coil (Flick Engineering Solutions) at 1.5 Tesla. Histological analysis of excised carotid specimens was independently performed using EVG, H&E and CD 31 (vascular endothelial marker) stains.

Results: MR imaging analysis show that 5 out of 8 asymptomatic plaques were mainly fibrous in composition with no evidence of necrotic lipid core while all 9 symptomatic plaques showed complex patterns with relatively large lipid cores separated from the lumen by fibrous caps (which were either thin or ruptured in 5 cases). Findings were confirmed on histological analysis. Visible patterns of enhancement post-gadolinium were observed in 12 out of 17 cases but appear confined to fibrous regions.

Conclusions: Symptomatic and asymptomatic carotid plaques show different morphological characteristics. Current work is under way to quantify fibrous cap thickness and lipid core areas as well as correlate histological areas of neovascularisation to regions of enhancement on MR imaging.

C-1079

Automatic segmentation of airway wall area for quantitative assessment at MDCT: Preliminary results in asthmatics

P.-Y. Brillet¹, C. Fetita², C. Beigelman-Aubry³, D. Perchet², F. Prêteux², P. Grenier³; ¹Bobigny/FR, ²Evry/FR, ³Paris/FR

Objective: We developed a CT lung analysis software based on mathematical modeling to provide automatically: 1) 3D segmentation of the bronchial lumen, 2) extraction of the central axis of the airway tree, 3) cross sectional image reconstruction orthogonal to the bronchus axis, 4) 2D segmentation of the outer contour of the bronchus for quantification of the luminal and wall (WA) areas. The objective was to determine the number of segmental and subsegmental bronchi correctly segmented by the software and to define criteria for accurate measurement of WA.

Methods and Materials: Eighteen thin collimation MDCT examinations (16 x 0.6 mm), performed in mild persistent asthmatics were retrospectively used for analysis of the airways. Acquisitions were performed at spirometrically controlled lung volume (65% TLC). Reconstructions were targeted on the right middle and

Scientific Exhibits - ECR Research Grant Winners

lower lobes (reconstruction interval: 0.3-mm, FOV: 18-20 cm) and all segmental and subsegmental bronchi were included for analysis. A confidence index (CI) defined as the percentage of the bronchus surrounded by lung parenchyma without apposition of vessels or soft tissue was calculated.

Results: The software correctly segmented 349/396 (88%) of bronchial lumen and correctly extract the central axis of 347/349 (98%) of the bronchi. By imposing a CI > 55% on 10 contiguous cross sectional images as a condition for an accurate segmentation of the outer contour, the software selected 48% of the segmented bronchi. B10b was the most frequently (87%) selected bronchi.

Conclusion: The developed software allows an adequate segmentation of the airways for quantitative assessment of WA at a segmental and subsegmental level.

C-1080

Proposal of an appropriate mathematical model to represent replenishment kinetic after microbubble destruction of an imaged renal volume to quantify renal perfusion

E. Quaia, L. Torelli; Trieste/IT

Purpose: To propose a mathematical model representing the replenishment kinetic of renal parenchyma after microbubbles destruction.

Methods and Materials: For this problem the biological models theory about diffusion and progressive volume filling was employed and *in vitro* and *in vivo* models were analysed. After sulfur hexafluoride - filled microbubbles injection (1 ml/min infusion rate), microbubbles filling the imaged volume were destroyed by high transmit power (8 pulses; mechanical index: 1.2-1.5) and the progressive volume replenishment was assessed by low transmit power (mechanical index: 0.02-0.08). The US video-intensity was measured by one region of interest encompassing entirely the kidney. Through mathematical approximation, renal flow was related to the slope of the first ascending tract of the obtained curve, while renal fractional blood volume was related to plateau intensity.

Results: The imaged renal volume (thickness of the US beam = 5 mm) was considered as the not conservative variable of state (volume replenishment is dependent from the grade of filling), while microbubbles velocity entering the volume (bi-compartmental model) were considered as bi-directional variable of control. After converters (equations transforming input in output values) and constants addition, a system of partial differential equations was derived including the velocity of volume replenishment, time, the volume percentage occupied by microbubbles, the percentage of microbubbles destroyed in the volume and of microbubbles leaving the volume and not replaced.

Conclusion: A system of partial differential equations was proposed to represent replenishment kinetic of renal parenchyma. Mathematical parameters are derived from this model through approximation procedures.

C-1081

The study of the human auditory system using combined fMR imaging and DTI at 3 T

S. Sunaert; Leuven/BE

Purpose: The combined fMR imaging and DTI study of the auditory system in normal and pathological conditions.

Methods and Materials: Fifteen normal subjects and 43 patients with non-pulsatile tinnitus (12/19 with right/left unilateral, 12 with bilateral) were enrolled. Imaging was performed on a 3 T imager using BOLD fMR imaging (GE-EPI, TR/TE = 5000/33 ms, 3x3x3 mm) with sparse temporal sampling to minimize interaction between auditory stimuli and scanner noise. A DTI dataset (SE-EPI, b = 800, 15 directions) was acquired in the normal volunteers. Auditory fMR imaging consisted of a blocked design with binaural musical stimulation and an event-related presentation of sinusoidal tones, either unattended or attended (1-back discrimination task). Analyses were performed using SPM2 (FIL, London) and PRIDE software (PMS, Best, NL).

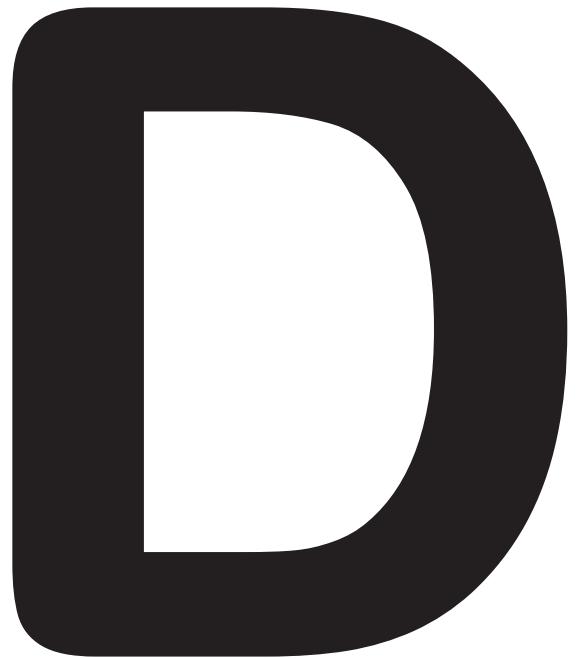

Results: 1. Significant ($p < 0.05$ corrected) (sub)cortical activity was present bilaterally in A1, A2 and the inferior colliculus in all subjects and in > 70% of subjects in medial geniculate body and superior olivary complex. 2. Tonotopy: within A1 an anterolateral to posteromedial tonotopic organisation was clear for low to high frequency stimuli (sinusoidal tones of 120, 800, 2000, 4000 and 6000 Hz); in A2, this organisation is reversed. 3. Task effects: A 1-back pitch discrimination task enhances activity in A2, but not in A1. 4. In patients with unilateral tinnitus a significant decrease of activity was found in the contralateral inferior colliculus, medial geniculate body and A1. A significant correlation exists between the reduced activity in A1 and the perceived loudness of the phantom sound. 5. DTI fiber tracts were identified from subcortical to cortical areas.

C-1083

Diagnostic accuracy of gadolinium-enhanced MR-angiography vs. contrast-enhanced helical CT in the diagnosis of pulmonary embolism in the presence of lung infiltrate: An animal study

T. Franquet¹, S.E. Kaloger², A. Oikonomou², S.L. MacDonald², E.M. Baile², J.R. Mayo²; ¹Barcelona/ES, ²Vancouver, BC/CA

Ten female juvenile pigs were used. Human sub-segmental sized pulmonary emboli were introduced by injecting 4.5 mm methacrylate beads into the external jugular vein. Lung infiltrates were simulated by intra-bronchial injection of 100 ml of human plasma. Animals were imaged in the supine position at suspended inspiration with 15 cm H2O PEEP. Contrast media was injected via brachial vein. Dual gradient (TwinSpeed) 1.5 T MR images were acquired using a 3 dimensional spoiled gradient-echo time of flight sequence; TR 4.8 msec, TE 1.2 msec, 45° flip angle, 6 mm section thickness, 32 cm FOV, 256x160 matrix, one average. Two MRA sets, pulmonary arterial and venous, were acquired in 39 seconds. Contrast enhancement was provided by 20 mL of Gd dimegloamine followed by 20 ml of normal saline, injected at 2 mL/sec. Non-contrast and contrast enhanced CT images were obtained using an 8 track spiral CT; 1.25 mm detector aperture, 90 ml contrast at 3 ml/sec. Subtraction perfusion images were calculated by subtracting contrast enhanced from non-contrast CT images. After imaging the pig was euthanized and a methacrylate cast of the pulmonary vasculature was obtained and used as a "gold-standard". All images were independently interpreted by two observers in a blinded fashion. No significant difference ($p > 0.05$) was seen between CTA, CTA with subtraction perfusion images and MR for sensitivity (86%, 88%, 68%) or specificity (94%, 94% 73%), respectively. No significant difference ($p > 0.05$) was seen in sensitivity or specificity between pigs with and without infiltrates.

B-ROB II: A robotic system for percutaneous interventions

J. Kettenbach¹, G. Kronreif², M. Figl¹, M. Fuerst², W. Birkfellner¹, R. Hanel¹, J. Hummel¹, H. Bergmann¹; ¹Vienna/AT, ²Seibersdorf/AT

We developed a robotic system (B-Rob II) in order to assist ultrasound (US)- and CT-guided percutaneous interventions such as biopsies and to provide the physician with a needle guidance tool that enables very stable access to lesions even difficult to reach. The robotic system will be cost-effective, has a plug-and play design and can be used with all currently available imaging modalities used for interventions.

Preliminary phantom tests so far demonstrated that with only one needle pass necessary a successful biopsy of peas (mean diameter 9.3 ± 0.1 mm) was performed using US-, and CT-guidance. In the first experiment positional data of an US transducer was recorded by an optical tracking system while targeting peas embedded within a custom-made gel-phantom. In the second experiment the same phantom was used and peas were localized using a spiral-CT scanner. The average radial distance between the needle tip and the center of the target was 1.9 ± 1.1 mm using US-guidance, and was 1.3 ± 0.9 mm using CT-guidance. So far we have proven that robotic assisted biopsies using US-, or CT-guidance were feasible with high accuracy. The visitor of IMAGINE will be able to perform US-guided roboter-assisted biopsies of a phantom on-site.

D-02

Unified patient: A medical media database supporting surgical planning and interdisciplinary meetings

P. Pokieser¹, J. Brandstätter², M. Wernig¹, J. Berger¹; ¹Vienna/AT, ²Wr. Neudorf/AT

The Unified Patient (UP) system is a web based software and database in order to provide as a multimedia storage for medical imaging data as well as for patient records. Available with a standard web-browser by the hospital's intranet radiological and clinical data are integrated into a "time-line". Thus patient data are demonstrated chronologically - every medical event is enhanced by radiologic, endoscopic, histopathologic, surgical or other relevant images, movies, sound files, laboratory findings as well as complementary text files and tables, approximated to a one stop shopping fashion for the use in routine, education and science.

Data collection starts at various stations of patient care: UP workstations in the operation theatre allow easy handling of images obtained during surgery, a PACS interface allows to export relevant images to UP.

At our institution UP is currently used to "submit" patients for weekly interdisciplinary oncologic meetings, as well as for plastic surgery and emergency medicine (www.univie.ac.at/interdis, www.unifiedpatient.org). At these meetings selected images of various tumor sites stored earlier are compared with current follow-up images obtained from PACS. Thus, large imaging files from MR imaging, MSCT, PET etc. can be reduced to relevant images from tumor sites treated by surgery, oncology, radiation therapy or interventional radiology.

Furthermore, relevant clinical information and the decision how to proceed with treatment are added to each patient's record in the UP system, which can be accessed anytime by authorized group members. We will further demonstrate how to submit teaching files from remote hospitals into the UP system and will offer remote-control instructions using a client-server TCP/IP software to improve radiologic service for clinicians located at distant sites such as intensive care units or operation theatre.

D-03

A novel navigation systems for percutaneous interventions

R.J. Bale¹, R. Petzold¹, M. Nagel¹, M. Voegeli², W.A. Kalender³, W. Jaschke¹;

¹Innsbruck/AT, ²Schwabmünchen/DE, ³Erlangen/DE

A novel immobilization and registration device (CAPPA® IRAD) for image-guided percutaneous interventions is presented. In addition novel registration algorithms for accurate fusion of various pre-operative imaging modalities such as CT, MR, SPECT, PET and ultrasonography will be shown. After planning of the pathway, the targeting device will be calibrated and adjusted according to the most accurate and safest access to a lesion (target) anywhere in the body. Next, our immobilization- and autoregistration device will be used to match the lesion coordinates with the adjusted targeting device without using any imaging modality. Once the targeting device is in place, puncture of the lesion for diagnostic or therapeutic

purpose can be performed quickly and safely. For safety reason, the position of the needle tip can be then confirmed by intraoperative imaging. Our system provides accurate guidance of an instrument along the desired trajectory to the target with minimal computational effort and time. Image fusion, planning, adjustment of the targeting device and puncture will be simulated using a phantom during the IMAGINE exhibition.

D-04

The virtual liver surgery planning system

E. Sorantin¹, G. Werkgartner¹, R. Beichel¹, A. Bornik¹, B. Reitinger¹, M. Riccabona¹, R. Wegenkittl², A. Fuhrmann², M. Sonka³, A. Koll¹; ¹Graz/AT, ²Vienna/AT, ³Iowa, IA/US

In patients suffering from liver tumours, the operability and choice of a surgical approach depends on the correct interpretation of preoperative imaging data. In particular, the correct assessment of the involved liver segments, the topographic relationship of the tumour to vessels, and the residual liver volume following liver surgery play a major role in patient outcome. Since cross sectional imaging such as CT or MR imaging represents an integral part of the preoperative assessment a virtual liver planning system was developed, which provides visualization of the underlying anatomy, pathology. Using a head mounted display (HMD) and passive registration tools (Polaris tracker) interactive 3D visualization as well as virtual planning of liver surgery is achieved. The semi-automated segmented tumour, liver segments and portal vessels can be evaluated from any direction including a pre-defined safety margin around the planned tumor resection. Moreover, distance measurements within the 3D-space as well as volumetric analysis of individual liver segments and the tumour itself can be obtained. Essential components of this project will be demonstrated at the exhibition.

D-05

Patient-specific computational analysis of transvenous defibrillation

D. Mocanu¹, J. Kettenbach², M.O. Sweeney¹, R. Kikinis¹, B.H. Kenknight³, S.R. Eisenberg¹; ¹Boston, MA/US, ²Vienna/AT, ³St. Paul, MN/US

The goal of this project is to assess the predictive capacity of computational models of transvenous defibrillation by comparing the results of patient-specific simulations to clinical defibrillation thresholds (DFT). Nine patient-specific models of the thorax and *in situ* electrodes were created from segmented CT images taken after implantation of the cardioverter-defibrillator.

The defibrillation field distribution was computed using the finite volume method. The DFTs were extracted from the calculated field distribution using the 95% critical mass criterion. The comparison between simulated and clinical DFT energy resulted in a rms difference of 12.4 J and a 0.05 correlation coefficient (cc). The model-predicted DFTs were well matched to the clinical values in four patients (rmsD1 1.5 J; ccD0.84). For the remaining five patients the rms difference was 18.4 J with a ccD0.85. These results suggest that computational models based solely on the critical mass criterion and a single value of the inexcitability threshold are not able to consistently predict DFTs for individual patients.

However, inspection of the weak potential gradient field in all nine patients revealed a relationship between the degree of dispersion of the weak field and the clinical DFT, which may help identify high DFT patients.

D-06

Computer aided diagnosis (CAD) in rheumatoid arthritis

P. Peloschek¹, G. Langs¹, F. Kainberger¹, H. Bischof², W.G. Kropatsch¹, H. Imhof¹; ¹Vienna/AT, ²Graz/AT

The aim of this project is to develop an automated analysis software of serial hand radiographs in patients with rheumatoid arthritis.

All software calculations are performed on a commercially available laptop using digital radiographs (DICOM). No manual initialisation is required for the localisation procedure. The training of the contour delineation algorithm was performed on two training sets T 15 and T 30 consisting of n = 15 and n = 30 sample radiographs. Statistical analysis for the localizer procedure was done on the CMC-, MCP- and DIP-joints of 10 subjects. Evaluation of the automated bone contour delineation was done using 42 landmarks per metacarpal bone on 10 different radiographs leading to a sample data set of 420 measurements.

Automated joint localization was found to be sufficiently robust (mean position error 2.7 mm) by means of further processing. The bone contour was found with high accuracy. Median error orthogonal to the contour was 0.113 mm, 74.6% of the landmarks in the test set lie within a 0.25 mm error corridor. Features extracted from the algorithm show good discriminative properties for the automated detection of bone erosions.

We conclude that our software provides an interactive robust automated quantification of bone lesions and an automated estimation of the bone contour is proposed. The software can be used interactively at the *IMAGINE* exhibition.

D-07

Advanced clinical applications for the digital hospital

J. Peters¹, R. Truyen¹, M. Quist¹, P. Ermes¹, R. Habets¹, M. Breeuwer¹, H. de Blieck¹, L. Spies², S. Deckers¹, F.A. Gerritsen¹; ¹Best/NL, ²Aachen/DE

This IMAGINE exhibit will be a 'behind-the-scenes' of our current research and advanced development activities in new clinical applications for medical imaging. A selection of innovations will be highlighted, where the common theme is our drive towards automated analysis and intelligent integration of clinical and image information. Work at various stages of the research and development cycle will be presented in the form of live demonstrators.

Digital osteotomy planning is a first in a range of orthopaedic tools that run as an advanced PACS application: starting from a worklist images are retrieved from the PACS, the tool starts and the orthopaedic surgeon can plan his procedures, subsequently the planned and simulated osteotomies are stored to the PACS where the orthopaedic surgeon can view and use the documented plan in his further procedure.

Fast and reliable methods are required for the comprehensive visualization and quantification of cardiac MRI images. We have developed software that has a simple and intuitive user interface enabling fast 3D visualization of the complete coronary-artery tree together with the heart that will work in concert with the new ViewForum software for the semi-automatic quantification of myocardial 1st-pass perfusion and myocardial viability.

Important drivers for innovation in virtual colonoscopy are patient compliance, dose-hygiene, time efficiency, sensitivity and specificity. Several validation prototypes addressing these issues are demonstrated: no-click automated path-tracking, matching of prone and supine paths, electronic cleansing of tagged stool, computer aided detection and quantification and XML based automated reporting for easy transfer of results.

Pulmonary embolism is a widespread and often deadly condition that is increasingly assessed using contrast enhanced CT. Although this method is successful in emboli detection, reading the large MD-CT volumes is still a laborious and time-consuming task. We will present detection and advanced visualization algorithms aimed at a more efficient and reproducible detection and delineation of pulmonary emboli.

In our Patient-specific hemodynamic modelling for diagnosis & therapy project we investigate how modern cardiovascular imaging can be combined with the latest techniques in hemodynamic modelling. Highlights will be shown for the recently started validation for modelling the prediction of the risk of rupture of abdominal aorta aneurysms.

Finally we will share the Philips vision on how software intelligence together with targeted imaging agents can convert multi-modality imaging equipment into molecular information, where we have created a molecular imaging toolbox that offers ease of use and seamless integration with the clinical workflow.

D-08

IMAGINE: Your heart - ONE-STOP-SHOP - in digital cardioradiology

R. Rienmüller, J. Teubl, T. Rienmüller, K. Kovaleva, G. Reiter, H. Mächler, M. Zink, W. Klein; Graz/AT

The present state of digital tomographic imaging methods as CT and MR enables to image complete cardiac morphology and function simultaneously. It means nowadays we can answer cardiac questions like in an ONE-STOP-SHOP replacing previous diagnostic methods and improving the quality of medical information. This however makes it necessary to be aware and to use the present understanding of the anatomy, patho-anatomy, physiology and patho-physiology of the cardio-vascular system inclusively the aorta and its central neuro-humoral regulation.

As permanent adequate myocardial perfusion is required for the heart as cardiac pump - the meaning of direct and derived key-factors of myocardial perfusion will be explained and discussed in the relationship to coronary morphology and function. The methods of myocardial perfusion measurements and of the evaluation of coronary vessel resistance will be extensively elucidated.

The goal of the exhibition is to demonstrate and to discuss with the visitors the results of a multi-variant-analysis of morphological and functional cardiac images and parameters and their meaning for the daily clinical diagnostic, therapy and as approach to evidence based medicine.

These results are based on more than 3000 patients studied by CT and above 500 studied by MR.

All studies were performed by standardized protocols evaluating the coronary and myo-, peri- and endocardial morphology, myocardial perfusion (ml/100 g/min) and cardiac functional parameters as EDV, ESV, EF, LVM, contractility and aortic compliance. Additionally in all patients the heart rate and the blood pressure were measured and the rate pressure product calculated.

Intracardiac, -coronary and -aortic blood flows were measured by MR whenever possible.

All images were digitally archived and integrated in a digital data bank with all morphologic, functional and clinical data as age, sex, blood pressure, pulse rate, ECG etc.

It means this data bank contains about 100 data per patient. A data bank is a prerequisite of a suitable understanding and interpretation of individual cardiac function and represents the basis for development of new strategies in risk stratification.

The structure of this data bank enables to perform any statistical evaluation with respect to age, sex, disease entity, and additionally a multi-variant-analysis of interrelationship of the various functional parameters as myocardial perfusion, blood pressure, pulse rate, stroke volume, myocardial wall tension, aortic compliance etc.

This multi-variant-analysis enables to recognize cardiac abnormalities (functional and morphologic deviation) in a very early stage of a disease and to classify a variety of cardiac diseases in a new digital quantitative manner.

This results in a better understanding of the control mechanisms of cardiac function and in direct concrete therapeutic recommendations.

The studied and digitally completely archived group of patients consists of:
Healthy volunteers, coronary heart disease (before and after bypass surgery or dilatation), congenital and acquired cardiac diseases, valvular diseases (before and after surgery), cardiomyopathies, hypertension, diabetes mellitus, renal failure with haemodialysis, pericardial disease, cardiac tumours, and cardiophobia.
The visitor of the IMAGINE exhibition will learn:

A

1. Past, present and future of digital cardio-radiology
2. The characteristics of the heart in young, adult and older people
3. The characteristics of woman heart
4. The characteristics of cardiac function at rest, at stress and in active sports-men.

B

1. How to use the CT- and MR-technology for cardiac imaging
2. How to perform morphologic image analysis
3. How to perform quantitative functional image analysis
4. How to organize and handle a data bank
5. How to perform multi-variant-analysis.

D-09

Computer aided image based diagnosis and therapy planning

S. Behrens, T. Boskamp, L. Bornemann, H. Bourquain, V. Dicken, J. Drexl, H.K. Hahn, A. Hennemuth, M. Hindennach, S. Kohle, S. Krass, B. Kümmelken, S. Kuhagen, J.-M. Kuhnigk, M. Lang, F. Link, G. Pausche, T. Preusser, R. Rascher-Friesenhausen, J. Rexilius, A. Schenk, M. Schlüter, A. Weihusen, S. Zidowitz, H.O. Peitgen; Bremen/DE

The research and development institute MeVis - Center for Medical Diagnostic Systems and Visualization - is dedicated to computer assistance for image based diagnosis in medicine. All applications described below are based on the software platform MeVisLab and result from various projects with more than 50 clinical and a number of industrial partners.

Software Platform MeVisLab: We present a software platform for rapid prototyping in R&D for computer aided image based diagnosis and treatment planning. It provides efficient image processing and visualization tools. MeVisLab allows a highly flexible software development on various levels (C++, graphical programming, application development with JavaScript) and offers substantial DICOM integration. MeVisLab is used by more than 40 partners. It is available for Windows and Linux.

Radiological and surgical interventions: We present projects for planning and preoperative risk assessment in oncological liver surgery (e.g., functional remaining volume), for living donor liver transplantation (e.g., functional graft volume), for percutaneous thermoablation of liver tumors (e.g., risk of incomplete tumor destruction), and for surgery of primary lung cancer (e.g., degree of impaired postoperative lung function based on CT data).

Distant service for surgical interventions: In this project, MeVis offers a distant service for the preoperative planning in liver surgery. Preoperative CT data are transmitted to MeVis, analyzed and the results are returned to liver centers worldwide where the computer aided surgery planning is performed. The service

has been used by more than 35 clinics in Asia, Europe and the US for more than 600 cases and is now part of the standard procedure for preoperative planning of LDLT in leading centers.

Neurological diseases: We present software applications to support diagnosis, intervention planning, and therapy monitoring in neurology, neuroradiology, and neurosurgery. Diagnosis and intervention planning are supported by multidimensional fusion of anatomical (MR imaging, CT), functional (Gd-MR imaging, fMRI), and structural (DTI, DWI, MTR) information. To assess brain atrophy, e.g., in AD or MS, we present fast, reproducible, and accurate volumetry of total brain, gray and white matter, cerebellum, cerebral ventricles, and temporal horns. Visualization and quantification of diffusion tensor characteristics facilitate the assessment of both tumor infiltration and white matter degeneration.

Oncological diseases: We present software applications for morphological and functional analysis of tumors. The morphological analysis is based on CT data and includes exact and reproducible tumor volumetry for chemotherapy of metastatic diseases. Functional assessment of tumor vitality is performed based on contrast enhanced dynamical MRI.

D-10

MARVIN: A modular image archive; ASENA: A web based RDE-tool, and secure DICOM-communication

D. Emmel, A. Haderer, N. Yakan, M. Gutberlet, K. Klimes, M. Werk, J. Ricke;
Berlin/DE

Purpose: The remote data entry (RDE) system ASENA together with the modular image archive MARVIN allows clinics and hospitals to establish digital image archiving and remote data collection including secure exchange of DICOM images. By using standard protocols for data transfer ASENAs and MARVIN integrate seamless into existing network infrastructures. MARVIN offers an everything online (EOL) DICOM image archive with an integrated web interface for image retrieval. The implementation of secure DICOM protocol allows image communication over insecure networks like the internet. ASENAs enables users to setup customized web based applications for RDE. Users enter data into the central ASENAs database using standard web browsers. Through the integration of MARVIN archiving components into ASENAs a seamless integration of DICOM image data and RDE is realized. This approach brings together textual and numerical information with DICOM images.

Methods and Materials: *DICOM image archive MARVIN:* MARVIN is set up as a modular EOL DICOM image archive. All image data is stored on mirrored hard-disks. EOL guarantees immediate access to all stored image data without delay, as there is no need to move image data between different storage media. By exchanging the hardware modules after three years of use, expensive and complicated migration of image can be avoided. Users access MARVIN either via web browser or by DICOM query/retrieve.

Remote data entry system ASENAs: ASENAs creates web applications out of customized HTML-forms for data entry into a central database. To realize a first step validation constraints can be attached to form elements. Fine granulated permissions can be given to individual users for role based access rules. Through the integrated MARVIN archiving component DICOM images can be attached directly to the database records. The database contents can be downloaded in a standardized format for further statistical evaluation with common analyzing tools.

Results: MARVIN realizes the storage and image distribution infrastructure for the department of radiology at Charité Campus Virchow-Klinikum in Berlin-Germany. Growing by 20 GB/day MARVIN currently stores 15 terabyte of image data (Sept. 2004) accessed by more than 300 users. The integrated secure DICOM protocol allows image exchange with external partners over insecure networks. Using ASENAs successful projects are established within the Charité as well as with external partners. The integration of DICOM images together with textual information in a central database system is a major feature of ASENAs.

Conclusion: ASENAs and MARVIN are well accepted and reliable systems. The growing importance of inter-hospital data exchange can be achieved by using the communication abilities of ASENAs and MARVIN. Using standard protocols makes integration into existing infrastructures easy.

D-11

Atlas-assisted analysis of brain scans

W.L. Nowinski¹, Q. Hu¹, B. Prakash¹, I. Volkau¹, G. Qian¹,
A. Thirunavukarasu¹, J. Liu¹, A. Aziz¹, R. Baimouratov¹, Z. Hou¹, S. Huang¹,
S. Luo¹, S. Minoshima², V. Runge³, N. Beauchamp²; ¹Singapore/SG, ²Seattle,
WA/US, ³Texas, TX/US

Two trends are observed in radiology: 1) the number of scans is increasing dramatically (e.g. 50% by 2010 in the US) while at the same time the number of radiologists will be growing much slowly (e.g. 20% in the US); and 2) about 65% of the world is radiologically void and another 30% has only basic technologies. Therefore, new approaches for facilitating and speeding up the interpretation of scans as well as reducing the learning curve of radiologists are needed. In our opinion, model-enhanced radiology may be one of solutions.

Our exhibit contains three computer demos: 1) Rapid and automatic atlas-based interpretation of MR imaging normal brain scans, 2) Assistance in interpretation of stroke images by means of anatomical and blood supply territories atlases, and 3) Atlas-assisted interpretation of PET/SPECT brain images.

Interpretation of normal brain scans is achieved by using a deformable anatomical atlas with a fast method of overlaying the atlas onto the scan. An electronic version of the Talairach-Tournoux (TT) brain atlas, fully segmented and labelled, was developed earlier [1,2]. The TT atlas is interpolated to provide a high resolution volume. A fast transformation of the TT atlas to the scan is developed based on the modified Talairach landmarks [3]. This transformation is done in five steps: extraction of the midsagittal plane [4], identification of the anterior and posterior commissures [5], extraction of the cortical landmarks [6], interpolation of the scan along the intercommissural plane, and overlaying the warped atlas images on the scan.

Assistance in interpretation of stroke scans is achieved by using both the TT atlas and a deformable atlas of blood supply territories with a fast method of overlaying them into the scan. The blood supply territories atlas is derived from a 3D vascular atlas constructed from MRA images [7].

The TT atlas with a fast technique for atlas-scan warping is used for assisting interpretation of PET and SPECT brain images.

D-12

The Cerefy Atlas of Brain Anatomy in Chinese

W.L. Nowinski¹, A. Thirunavukarasu¹, Y. Fu², M. Xin¹, Z. Lin², S. Wang²,
¹Singapore/SG, ²Harbin/CN

About 65% of the world is radiologically void and another 30% has only basic technologies (*Diagnostic Imaging*, special edition, 2003). One of major reasons of this situation is the lack of expertise and resource to interpret scans. This may be improved by providing tools affordable and acceptable in terms of cost, user-friendliness, and language. The most prevalent language on earth is Chinese. This work aims at development of a Chinese version of our neuroeducational bestseller *The Cerefy Atlas of Brain Anatomy* (CABA) [1].

Electronic brain atlases provide means for learning neuroanatomy. However, their common limitation from a radiology standpoint is the lack of radiological images. The CABA overcomes this limitation by providing MRI images which are co-registered spatially with an electronic atlas of gross anatomy. The CABA contains more than 1500 individual structures on 100 images. The anatomical index has 135 names of subcortical structures and cortical areas. The application runs on personal computers and provides functions for atlas-based labeling of MRI images with structure's name and description; testing against location and name of cerebral structures; triplanar image display and manipulation on axial, coronal, and sagittal orientations; mensuration useful to study spatial relationships; structure searching; and saving of labeled images useful to prepare teaching materials.

The CABA works in two modes: *explore* and *test*. In the explore mode, the atlas and data are explored on the triplanar images. In the test mode, the user is tested against either location or name of atlas structure.

The CABA is a useful tool for students and residents as well as teachers and researchers. For students it provides testing and scoring capabilities for exam preparation, while for teachers it helps in preparation of teaching materials.

The Chinese anatomical index and the descriptions of all anatomical structures have been compiled. These materials have substituted the English ones in the CABA. In addition, all textual information in the user interface has been translated into Chinese.

D-13

New applications for computed tomography

D. Rinck, L. Gündel, A. Bakai, E. Klotz, H. Fichte, H. Ditt, C. Süß, F. Trappe, T. Flohr; *Forchheim/DE*

We present new and innovative applications for computed tomography. The colonography application visualizes the entire colon in both 2D (MPRs) and 3D (endoluminal view) modes. It supports the search for polyps and detection of colon cancer. Prone and supine data sets can be displayed and the detection results can be documented in the integrated reporting tool. The colon CAD tool (under development) searches suspicious structures in the colon and lists them in addition to the lesions marked previously by the radiologist. The cardio-vascular evaluation application consists of a robust vessel segmentation and a stenosis quantification tool with plaque visualization and quantification, including color-coding of the different plaque compartments and sub-volume calculation. Cardiac function parameters such as ejection fraction and stroke volume are calculated. Using an advanced active shape model regional myocardial wall thickening is determined. A myocardial enhancement tool is integrated, which isolates the myocardium and visualizes ischemic regions by color-coding techniques. The fast detection of pulmonary embolism (PE) is supported with a new visualization tool using contrast enhanced CT data of the lung. The HU values of the vessels are mapped onto an interactive 3D vessel structure. Regions with suspicious PE can be examined on the original CT data, rendered CT planes, or by visualization of a simplified subtree or subtree analysis. For ground glass opacities (GGOs) common segmentation methods cannot be applied because of their small size and poorly defined boundaries. Enhanced algorithms, however, can be used for accurate and reproducible measurements of GGO size and doubling time. The fast volume acquisition capabilities of multislice CT scanners also allow scanning whole volumes repeatedly in relatively short scan times. Using dedicated organ adapted registration and post processing techniques we currently investigate 3D perfusion assessment of brain, lung, and liver based on multiple volume acquisition. Another important application is bone subtraction CTA of the cerebral vasculature. It is based on co-registration of an additional low dose plain CT scan in order to remove the complex bone structures of the skull base. This significantly simplifies and improves the analysis of pathologies such as aneurisms. A prototype platform allows the assessment of perfusion changes of organs, such as liver and pancreas, and tumors based on a three dimensional tracking of relevant object structures during multislice data acquisition. Dynamic volume data sets are evaluated with the 'maximum slope' model to quantify the perfusion of tissues and whole organs, including dedicated modelling of the complex blood flow dynamics of the liver. The implementation of the 'Patlak model' allows to measure permeability and blood flow of various tumors. Combining the body perfusion models with a 3-D volume registration allows to extend the application to the diagnosis of lung disorders and lung tumors. First clinical results are promising.

D-14

Advanced 3D image rendering and multi-level, clinically-focused PACS integrations

C. Chin, G. Jones, J. Archer, J. Field, M. Dimmock, P. Papageorgiou, R. Moffett; *Edinburgh/UK*

Modality advances are driving the need to routinely visualize and analyze high-resolution images using MPR and 3D volumetric software. This is placing a new demand on PACS to visualize and analyze studies containing over 1000 images. Radiologists need to rapidly load and manipulate these studies using advanced MPR and 3D tools within an integrated PACS diagnostic workflow. This provides unlimited user access to full MPR and 3D functionality, wherever you need it. Radiologists also need to offer the best possible service to referring physicians who are intensive users of radiological images.

Barco will present its latest MPR and 3D toolsets and, specialized clinical application modules designed for, and integrated into, a PACS environment. The company will also demonstrate performance advances made in software-and hardware-based 3D rendering using high-performance graphics accelerators.

Multi-level MPR and 3D software integrations for PACS: It is critical that the advanced post-processing MPR and 3D tools, which are required for the rapid and effective analysis of large volume image studies are seamlessly embedded into the PACS application software. Barco will demonstrate its 3D integrations for a range of PACS architectures, which benefit radiologists by providing a single streamlined diagnostic workflow. Barco will demonstrate its 3D integrations for a range of PACS architectures, which benefit radiologists by providing a single streamlined diagnostic workflow.

Cost-effective, advanced 3D clinical applications for PACS: Advances in modality technology are driving the development of new clinical applications. Some are

now a routine part of a radiologist's daily work list. Barco's new clinical software modules provide radiologists with effective methodologies for using advanced MPR and 3D functionality to read specific types of clinical studies, including:

- Vessel analysis
- CT colonography
- PET/CT fused image display

Optimizing user performance and functionality: MPR and 3D rendering performance is significantly improved using high-performance graphics accelerators. Using new 3D accelerated graphics processing units (GPUs), Barco can display slab MPR images at a very fast cine frame rate. This is extremely beneficial for efficient and accurate diagnosis. Barco will demonstrate a number of concepts for optimizing user performance and diagnostic effectiveness with this enhanced MPR frame rate capability.

D-15

Exploiting the power of GPUs in medical imaging

F. Wessels; *Bilthoven/NL*

3mensio Medical Imaging will be showing 3viseon, a next generation workstation based on the latest and most powerful GPUs. GPUs (graphics processing units) are chips found on the latest graphics cards which are quickly becoming commodity components of the PC-platform. They are dedicated to delivering high-quality high-resolution 3D graphics at interactive frame rates and have their origins in the computer games industry.

By shifting the medical visualization from the "traditional" CPU to the GPU new levels of performance can be offered. In addition new functionality can be developed by exploiting the programmability of the GPUs which allows ever more sophisticated algorithms to be run on the GPU at very high speeds. This can be extended beyond visualization to areas such as advanced image processing. Given the larger datasets in radiology due to trends such as multi-slice CT scanners, the "traditional" slice by slice reading of datasets is becoming more cumbersome. As such new ways of handling these vast amounts of information need to be found for which the processing power of the GPUs is ideally suited. Likewise users outside the radiology department are finding more and more needs for visualization which can now be offered to them at interactive speeds on commodity PC hardware.

D-16

Towards hysteroscopy simulation: Interactive simulation components for deformable tetrahedral meshes

M. Teschner, B. Heidelberger, M. Müller; *Zurich/CH*

This project focuses on the development of interactive methods and algorithms for surgery simulation and training. We investigate approaches to tetrahedral mesh generation, deformable modeling, deformable collision handling, fluid simulation, and the simulation of surgical instruments. Based on these components, it is intended to implement a generalized real-time surgical simulator, which processes anatomical models represented with tetrahedral meshes.

Hysteroscopy simulation is a first application for the developed components. Within this hysteroscopy training project we collaborate with numerous partners of the Swiss National Center of Competence in Research on Computer Aided and Image Guided Medical Interventions (NCCR Co-Me).

Our software demonstration shows a first prototype of a hysteroscopy training tool where we focus on efficient deformable modeling and deformable collision handling using complex tetrahedral meshes with up to 10000 tetrahedrons.

In contrast to existing simulation environments, our approaches are not restricted to specifically designed models but process any anatomical structure which is represented as a tetrahedral mesh. Thus, the simulation components can potentially be applied to many training scenarios.

While existing environments only handle collisions between deformable structures and rigid surgical tools, our simulation detects and resolves all collisions even among deformable structures. Further, the deformable modeling approach is stable under all user interaction and provides interactive update rates for geometrically complex models. Details regarding the deformable model, deformable collision detection and response have been published in various papers.

In our first prototype, a user can navigate a camera inside the cavity of a uterus and interact with all deformable structures such as cavity and several polyps. Deformation, deformable collision detection, and visualization are performed at interactive rates for models of up to 10,000 tetrahedrons using a standard PC with Intel Pentium 4, 2 GHz.

D-17

Interoperability solutions for an integrated imaging and information system

G. Venturi¹, S. Selvaggio¹, A. Fiumicelli¹, A. Budge², C. Bull², R. Shaw³, P. Wilson³, A. Chippendale³; ¹Cairo Montenotte/IT, ²Bracknell/UK, ³Newcastle upon Tyne/UK

The purpose of the demonstration is to highlight the importance of interoperability and data portability of a complex medical imaging and information system inside the healthcare enterprise and to show the solutions adopted by the LifeWeb suite. The demonstration is subdivided into three exhibits, each of them dedicated to a specific key task for the interoperability: single access point, cross enterprise data portability and security.

Exhibit one: Enterprise PACS single access point

This exhibit will show how a large enterprise PACS, made by multiple, heterogeneous data repositories, can be arranged as a single virtual collaborative system where the user can retrieve data wherever they are with a single query. Peculiarity of an enterprise PACS is to include all the images produced by the healthcare enterprise and goes beyond radiology. It can be designed as a single virtual archive or a cluster of distributed archives, departmental specific, eventually designed by different vendors. We will demonstrate how it is possible, through the implementation of proxy services, to add any type of data repositories to the system from any vendor, and make the data instantly available to the user completely transparently. The user does not need to know where data is but simply queries the system and it is the system's engine that looks for the data on the repositories, checks for consistency, prepares the presentation.

The same engine can be used to perform data migration from end-of-life systems destined to be turned-off.

Exhibit two: Cross Enterprise Data Portability

This exhibit will show the implementation of new data coding to allow cross-enterprise data portability, including images, report and diagnostic documentation. Import, export and interchange of data will be demonstrated.

Data can be stored on removable media, according to the PDI (portable data for imaging) IHE profile to be delivered to the patient and/or can be queried automatically to the central system by a remote host according to the IHE XDS (Cross Enterprise Clinical Document Sharing) profile.

An "in-progress" demonstration of an Electronic Healthcare record implementation, made according to the HL7 EHR-CR and EHR-LR model, will be presented.

Exhibit three: Secure distribution and visualisation of images and data through the web.

This exhibit will show the use of secure web technology to distribute and visualize images and in a heterogeneous network environment made by a local intranet, the internet and wireless network. Information and images can be accessed according to routing tables that, together with user's profile, set the privileges, i.e. the functions, that can be used locally at the department, inside the distributed healthcare enterprise or remotely in any place of the world.

This demonstration will cover security issues in the broadest way, including transmission security, wireless network security, access control, data preservation and error disaster policies. Moreover it will cover privacy issues, data integrity issues and data consistency issues. Finally, it will demonstrate how to solve the patient identifier issues to reconstruct a healthcare record merging data from different institution.

D-18

Fused deposition modeling for operation planning, multimodal matching of functional and anatomical data and development of a lung atlas/model

M. Verius, R. Huttary, W. Recheis, W. Eisner, S. Felber, D. zur Nedden; Innsbruck/AT

Our research field reaches from planning and construction of fused deposition models (FDM) which are used for operation planning in oral and plastic surgery, to datafusion of preoperative CT and MR-datasets, preoperative functional MR-data and by means of a 3D-digitizer scanned intra-operative cortical stimulation points (ICS).

1. On the basis of CT or MR data a corresponding virtual model in stl-format (stereolithographic file format) is calculated and by means of a "3D-printer" a plastic model is built layer by layer. The so originated model can be treated by the surgeon like sawing, drilling etc. to plan the optimal operation and access technique.
2. The project 'Planning of minimally destructive neuro-surgical operations: Correlation of functional magnetic resonance tomography and intra-operative cortical stimulation' is a data fusion project which is supported by a grant of the Austrian National Bank (No. 9044). Therefore datasets of MR, CT, functional MR and intraoperative cortical stimulation points are superposed in

one volume dataset. It should be determined if and in what way corresponding functional MR data agree with the intra-operative cortical electrostimulation points. The patient has to execute specific paradigms within the MR-scanner (for example motor paradigms as fingertapping, arm bending, biceps contraction or similar paradigms) to monitor the active areas. During the neuro-surgical operation the patient is electrical stimulated by means of a bipolar stimulation tweezers at previously marked points and the physiological answer of the patient (finger movements, biceps contractions etc.) is registered. These functional data are overlaid with the anatomical datasets performed with ANALYZE© and CURRY© software package. After 7 patients we conclude that a good correlation between ICS and functional MR imaging can be observed but still inaccuracies due to brainshift and low spatial resolution in the fMR imaging data occur. The goal of this project is a shortening of operation time and on the other side to establish a patient friendly operation method by avoiding the patients alertness during neuro surgery.

3. A third research project in cooperation with the University of Iowa is the building of a model or atlas of the normal human lung based upon X-ray CT scanning. This atlas includes the lungs, lobes, sublobar segments and airway and vascular branching structures of the lung and attached to each level of this structure will be the normal range of the CT-based measures of regional lung physiology including ventilation, perfusion, and specific compliance. This model/atlas of the normal human lung, developed for three decades of adult age, is providing the comparative basis for detecting and quantitating pulmonary pathology.

AngioVis: Computer graphics for clinical visualization of peripheral arterial occlusive disease

D. Fleischmann¹, M. Straka², M. Sramek², A. La Cruz², A. Koechl², A. Kanitsar², T. Rakshe¹, S. Napel¹, J. Lammer², E. Gröller²; ¹Stanford, CA/US, ²Vienna/AT

Purpose: The 'AngioVis' exhibit illustrates the 'bench-to-bedside' research equivalent in the field of computer aided diagnostic imaging, exemplified by the development of visualization tools for CT angiography of peripheral arterial occlusive disease (PAOD).

Background: Continuously evolving multiple detector-row CT (MDCT) technology allows the acquisition of large, high-resolution volumetric CT angiographic datasets of the entire lower extremity arterial tree. The development of adequate tools to extract and visualize the clinically relevant complex manifestations of peripheral arterial occlusive disease requires both, knowledge of disease morphology and therapeutic options, as well as expertise in computer sciences, image segmentation and computer graphics.

Methods and Materials: Several interconnected topics - ranging from clinical background and image acquisition technique, over different methods of image segmentation and visualization, to finally image evaluation and interpretation of routine clinical datasets - will be part of this interdisciplinary exhibit:

Imaging technique:

- CT acquisition and contrast medium injection: Strategies to optimize the spatial resolution of the CTA datasets, and to achieve adequate opacification of the peripheral arterial tree in patients with sometimes severely altered flow dynamics will be presented.

Visualization technique:

- Bone segmentation is an important pre-processing step when maximum intensity projections (MIP) are used for vessel visualization. We present a semiautomated density based technique, and a statistical approach using a bone atlas. One limitation of MIP is, that vessel wall calcifications, calcified plaque, and also endoluminal stents obscure the clinically relevant flow channel of a diseased artery.
- Another key pre-processing step is the definition of the medial axis of the branching vessel tree. We present a density/gradient based 'vessel-tracking' algorithm to identify the peripheral arterial tree from the aorta down to the crural and pedal arteries.
- Because automated vessel tracking may fail in severely diseased and occluded arterial segments, we will demonstrate the initial results obtained from a Knowledge based vessel tracking algorithm, which estimates the course of an occluded arterial segment based on a statistical comparison with reference datasets.
- In the presence of atherosclerotic change (plaque, calcifications, stenoses), it is difficult to accurately identify the vessel centerline. Several algorithms (ray-casting, block matching, template matching, fitting of elliptical cylinders) will be presented and their performance in normal versus diseased arteries of variable size will be illustrated.

- Curved planar reformations are longitudinal cross-sections through a vessel centerline, and allow the clinical evaluation of the flow-channel of a diseased arterial segment. We will present several variants of CPRs (thin/thick, projected-stretched-straightened). One disadvantage of CPRs in the setting of PAOD is the limited spatial perception. This can be overcome by creating 'MultiPathCPRs', which simultaneously display multiple longitudinal cuts through the entire peripheral arterial tree in a single image. This technique is currently our preferred visualization technique for percutaneous treatment planning.
- The vessel glyph: represents an abstract notation of combining different visualization techniques for focus & context rendering in the same image. This allows, for example, to display diseased arterial segments ('focus') as CPRs, while rendering the anatomically relevant 'context' using direct volume rendering.

Clinical integration:

- The AngioVis toolbox is the software platform which hosts the above algorithms as separate plug-ins. In the clinical environment, it also connects to the CT scanner and the PACS system, using DICOM communication software. This allows 'online' evaluation of new techniques and algorithms on a large spectrum of clinical cases.
- Interpretation of clinical datasets, using the above visualization techniques will be demonstrated with angiographic correlation.

Conclusion: Close interdisciplinary collaboration between clinical and computer scientists is an effective platform for both, basic image processing research as well as for the development of dedicated clinical applications in the field of medical imaging.

Real-time virtual sonography (RVS)

Moderator:

F. Frauscher; Innsbruck/AT

E-01

Technical principles of RVS

H. Frey; Zug/CH

Ultrasound imaging is a convenient and non-invasive examination method. However it is sometimes difficult to acquire the image of organs and lesions through bones or gas in gastrointestinal tract. The ultrasound probe is manipulated by freehand during examinations, so its cross section is less objective compared with other modalities. The real-time virtual sonography combines the advantages of CT and ultrasound. The system is able to display multi-planar reconstruction images (MPR) which indicate the same cross section as the live ultrasound image from the CT volume data set in real-time. The real-time virtual sonography is available for the HITACHI EUB-8500 digital ultrasound scanner. The CT volume data set is received via DICOM network or CD/DVD by the ultrasound unit. A magnetic positioning unit detects the position of the probe during the examination. The system processor of the ultrasound scanner calculates MPR images from CT volume data and displays them side by side with the ultrasound image. MPR image can be visualized in more than 10 frames per second as 256 by 256 pixels image. As a result, it becomes possible to compare ultrasound images with MPR image in real-time.

E-02

Real-time virtual sonography is not only a novel navigation tool in radiofrequency ablation, but also a novel evidence-based imaging for hepatocellular carcinoma

T. Iwasaki; Miyagi/JP

Because ultrasound is simple, noninvasive and real-time, percutaneous radiofrequency ablation of hepatocellular carcinomas is usually performed under ultrasound guidance. However, it is often difficult to detect residue or recurrence after ablation. To solve the problem without spoiling the advantages, utilizing virtual reality technology and multi-detector row CT, which acquires volume data and shows any MPR images, we developed real-time virtual sonography (RVS). This lecture is to demonstrate the clinical value of the RVS system. The RVS system is composed by magnetic motion tracking device, image-processing workstation and ultrasound equipment. The magnetic sensor mounted on the ultrasound probe registers and transmits the spatial location and orientation of the probe to the workstation which possesses CT volume data. The workstation computes and displays the MPR image corresponding to the ultrasound image in more than 10 frames per second. When starting RVS, the position adjustment is performed at the xiphoid process. Discrepancy by respiration is rectified by adjust system. RVS was performed in 62 hepatocellular carcinoma patients. MPR image of target tumor was displayed under good position correspondence with ultrasound image in all the patients. Ablation was successfully performed. RVS was useful for the identification of residue after ablation. The real-time existence of virtual MPR imaging, which must be the most convincing evidence imaging, enabled us to perform safe and definite ablation at ease. RVS is not only a novel and effective navigation tool in percutaneous radiofrequency ablation, but also a novel and persuasive evidence-based imaging for hepatocellular carcinoma.

Impact of detection and characterization of liver lesions

R. Hammersting¹, J. Breuer², T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Berlin/DE

Introduction: Staging of malignant tumours is getting more and more important, especially because of new therapeutic strategies. Metastatic involvement of the liver in extrahepatic malignant disease alternates the therapeutic approach significantly in many cases and has to be ruled out with high confidence. Detection of focal liver lesions is determined by conspicuity and is related to the degree of tumour-to-liver contrast. As known tumour characterization is mainly based on the lesion contrast uptake at the different enhancement phases. Magnetic resonance imaging has proved to be a reliable diagnostic tool for the work-up of patients suffering from liver tumours. The use of different contrast agents enables good detection and precise characterisation of focal liver lesions, especially when liver-specific contrast agents are used.

New hepatobiliary contrast agent Primovist® for MR imaging of the liver: Gd-EOB-DTPA (Primovist®) is a new liver-specific magnetic resonance contrast agent for T1-weighted imaging. It consists of a gadolinium derivate linked to lipophilic ethoxybenzyl combining good hepatocellular specificity with excellent T1-relaxivity. After intravenous injection the new liver-specific Gd-Chelate is taken up by the hepatocytes via an organic anion-transporting polypeptide. It is excreted unmetabolized up to 50% via the kidneys and 50% via the bile. Renal excretion can be substituted by the hepato-biliary excretion and vice versa. The substance is a ready-to-use contrast agent which is administered intravenously in a concentration of 0.25 mmol/ml and a dosage of 0.1 ml/kg b.w. or 25 µmol/kg b.w.

Contrast mechanisms: After intravenous bolus injection of Gd-EOB-DTPA dynamic imaging (arterial, portal venous and equilibrium phase) as known from standard gadolinium-chelates can be performed. In the liver-specific phase (around 20 minutes post injection) the agent is taken up by normal liver parenchyma and hepatocyte-consisting liver lesions e.g. FNH or adenoma. Tumours without hepatocellular elements of the liver e.g. metastases do not show any hepatocyte uptake.

Results from the clinical development programme: The contrast agent has shown good safety properties in phase I - III clinical trials in up to now more than 1500 persons. In the detection study (European phase III clinical trial) 302 lesions were detected in the 131 patients (included in the final efficacy analysis). Histopathologically 215 lesions were malignant and 80 lesions were benign. 7 lesions could not be classified by histopathology. Gd-EOB-DTPA-enhanced MR imaging (EOB-MRI) was equivalent to spiral computed tomography in detection of focal liver lesions in the overall analysis. Lowest rate of false positive and false negative lesions was documented for EOB-MRI compared to CT and pre-contrast MR imaging. Highest rate of correctly detected lesions with a diameter below 1cm was achieved by EOB-MRI. A change in surgical therapy was documented in 14.5% of patients post EOB-MRI. In the characterization study (European phase III clinical trial) 176 patients with known or suspected focal liver lesions were included. The number of lesions correctly diagnosed by combined MRI (pre-contrast and EOB) was higher than for pre-contrast MRI in the on-site evaluation. The proportion of correctly characterized lesions was significantly higher for combined MR imaging compared to biphasic CT. In the overall analysis, sensitivity, specificity and accuracy for lesion classification improved with combined MRI by 3-14%. The proportion of lesions with a correct classification was superior for liver-specific MRI compared to CT, but not statistically significant.

Conclusion: Primovist® is a safe and well tolerated contrast agent for the diagnostic work-up in patients with focal liver lesions. It enables dynamic non-specific and hepatocyte phase imaging with improved detection and characterization of liver tumours.

E-06

Performance of high-concentrated contrast in MR imaging

B. Tombach; Münster/DE

The 1.0 molar Gd-chelate gadobutrol (Gadovist®, Schering AG, Germany) offers the potential to be injected as a more compact bolus for contrast-enhanced MR compared to other commercially available 0.5 M formulations. Modern MRA sequences using central k-space acquisition, half-fourier and parallel imaging techniques as well as MR perfusion techniques may therefore profit from the increased intraarterial Gd concentration during first pass. Our experience in clinical routine using conventional 1.5 T clinical MR systems (Gyroscan Intera, Philips Medical Systems, Best, The Netherlands) covers more than 7000 injections of Gadovist® for any indications and 1500 injections of gadobutrol for CE-MRA of the arterial vasculature from the cranial base to the run-off vessels of the lower extremities during the last 3 years.

Due to our experience Gadovist® can be safely applied in clinical routine for any indication offering excellent imaging properties. Fast imaging techniques, e.g. brain perfusion studies and CE-MRA seem to profit mostly from the higher concentrated agent. With respect to the small injection volume a manual bolus timing (1 ml) procedure is recommended to adapt the single dose injection precisely to central k-space data acquisitions for high resolution 3D-GE sequences in a single station MRA. For multi station bolus chase techniques like peripheral or whole body MRA a fixed volume of 20 ml result in diagnostic image qualities using biphasic injection protocols. Using modern high resolution keyhole techniques for MRA of the run-off vessels, and even for intracranial CE-MRA, 1 M gadobutrol offers the potential to separate precisely the arterial and venous phase combined with excellent imaging properties.

E-07

An important step forward in the evolution of MRA techniques

T. Grist; Madison, WI/US

Widespread dissemination of the gadolinium-enhanced MRA technique is limited by several factors, including the fact that the methods involve an off-label use of MR contrast media, complexities associated with acquisition of the images, and limited spatial resolution/coverage of the imaging sequences. The emergence of MS-325 (Schering AG/ EPIX) offers to overcome many of these limitations in clinical practice, and represents a significant potential step forward in the diagnosis of vascular disease.

First, MS-325 demonstrates higher relaxivity than conventional gadolinium contrast agents, resulting in a greater signal enhancement for a given dose of the agent. The greater degree of signal enhancement has important implications for contrast-enhanced MRA, since the increased signal may be translated into better image quality or a lower dose of the contrast media relative to conventional agents.

Second, MS-325 demonstrates protein binding to human serum albumin immediately upon injection, and this contributes to the long blood pool phase of the contrast agent. The long vascular half-life allows for prolonged image acquisitions of several minutes or more, as compared to the relatively short (30 second) acquisitions for conventional gadolinium contrast agents. In addition, the long blood half life allows for steady-state imaging of vascular territories that may be inadequately imaged on the initial first-pass MRA exam.

In summary, MS-325, an MRA-specific contrast agent, is a welcome advance in the diagnostic imaging of patients with vascular disease. MS-325 offers several potential advantages, including high relaxivity (greater signal enhancement), prolonged blood pool retention, and documented safety and efficacy for bolus injection MRA.

E-08

A new generation of contrast agents meets brand new MR imaging technology

S.O. Schönberg; Munich/DE

Numerous diseases affect multiple vascular territories in various regions of the body requiring diagnostic imaging with large anatomic coverage for comprehensive evaluation of the disease manifestations. Examples of such diseases include diabetes, vasculitis, and systemic manifestations of atherosclerosis. MR angiography has established its role for the diagnostic evaluation of almost all vascular territories as the primary modality of choice. However, different requirements for temporal and spatial resolution may exist for different vascular territories. In this situation accurate first pass contrast-enhanced MRA with global coverage is difficult because numerous bolus injections of extracellular contrast agents would be required. The recent introduction of multi-channel MR imaging

scanners with greater than 30 channels and capabilities for whole body imaging can now resolve these conflicts by accelerating the image acquisition with parallel acquisition techniques, providing high signal-to-noise ratio in all vascular territories. In combination with a new class of intravascular contrast agents, that can be used both for first pass imaging and imaging in the steady state, high resolution first pass imaging of a critical target area such as the carotid arteries or the arteries of the lower leg can be obtained. These acquisitions can be combined with steady state imaging of the remaining vascular areas, possibly even coronary arteries. Imaging in the steady-state has the potential to provide accurate evaluation of critical vascular structures with ultra high resolution, less than 100 µm³, gaining insight into pathologic changes of small arteries. This approach could be used to evaluate distal microangiopathy in diabetes or inflammatory changes in diseases such as vasculitis. In addition, up to ten fold decreases in voxel size with steady-state imaging would facilitate artery-vein-separation. Due to the high relaxivity of intravascular agents compared to standard gadolinium chelates, in combination with the dedicated surface coils excellent SNR performance can be preserved. In conclusion, the combination of new scanner technology and bolus injectable intravascular contrast agents allows comprehensive assessment of vascular disease manifestations by addressing different requirements for temporal and spatial resolution.

Implementation of clinical system solutions in an e-health environment

Moderator:

H. Pohjonen; Espoo/FI

E-09

Cross-border eRadiology

J.G. Blickman; Nijmegen/NL

As part of the eHealth initiative and action plan of the European Commission, procurement and implementation of healthcare IT systems is undergoing radical change.

As the entire imaging field can be seen as a microcosm of this process, it is useful to review the added value of the digital data movement/management and its changes: where are we in eRadiology?

We will review how building the infrastructure consisting of PACS, RIS towards an EPR in a major academic teaching hospital can gain valuable insight as to how cross-border radiology services might be conceived and executed. Ingredients such as the shortage of radiologists/radiographers, low reimbursements by national health insurers and the increasing part-time medical profession are drivers for change. Efficient workflow practices, long present in the business world, can be implemented and made 'profitable' in most of the medical world as well. The digital workplace knows no boundaries: remote reporting, off-hour coverage, the 'virtual' staff radiologist are all ways to offer imaging services in a non-traditional way.

These developments need to be balanced against legal, quality control and insurance issues, as well as cultural, language and protocol differences between locales.

This discussion will make the listener review, understand and learn from the above named concepts and experiences.

E-10

Electronic medical record: The distribution of patient-based e-health information in a regional context. The Legnano experience

V. Lombardo; Legnano/IT

The move from single-department architecture, based on stand alone systems, to the need for integrated communication between multi-modality legacy systems, in order to create an EPR-based hospital information system, has led to a significant reappraisal of organisational and technological choices at the Legnano Hospital in Milan, Italy.

The 1600-bed hospital, which covers four linked sites (with high capability WAN) in the north east of the city, employs some 4000 staff and has an annual turnover of around €250 million. Each site is linked by LAN (Gb Ethernet) which connects all clinical and administrative units.

The solution adopted at Legnano is based on a solid architecture of centralised, MPI-oriented patient demographics and on the implementation of a clinical/health data repository which is dynamically integrated with systems within individual departments, such as the LIS, RIS, Booking Centre, ADT and First Aid, through the use of specific HL7 compliant middleware.

The application of interoperability standards such as HL7 and DICOM has led to the creation of an on-line data base, directly accessible both by patients and authorised professionals.

Since September 2004, the new technology at Legnano has allowed the hospital to integrate with the CRS-SISS health project created by the Lombardy Region of Italy, designed to enable the accessibility of patients' clinical information between the hospitals, general practitioners, clinics and laboratories within the regional network.

UK national programme for IT: Delivering diagnostic imaging for the north west and west midlands in England

G.D. Larson; Hemel Hempstead/UK

In May 2004, Kodak participated in a CSC-led alliance that was awarded a 10-year contract with the UK National Health Service (NHS) for delivering diagnostic imaging services for a substantial portion of England. Under the contract, the alliance is designing, building, delivering and operating new Picture Archiving and Communications System (PACS) across the North West and West Midlands cluster.

The system is being established as part of the Department of Health's £6 billion National Program for IT (NPfIT) that will help millions of patients receive treatment more quickly and efficiently. There are four primary goals of the programme: an electronic appointment booking system, an electronic care records system, electronic transmission of prescriptions, and a fast, reliable underlying IT infrastructure.

This presentation will concentrate on some of the unique aspects of this programme that differentiate it from the delivery of a more traditional PACS. Together with other participants in the alliance, we are delivering a managed service for diagnostic imaging that is tightly coupled with the overall core services in the NPfIT. Using KODAK DIRECTVIEW Versatile Intelligent Patient Archive (VIPArchive) technology, we are delivering a single, data center-based archive for a population of approximately 12 million patients. Finally, in addition to KODAK DIRECTVIEW CR and DRYVIEW printing solutions, KODAK RIS 2010 is being used to electronically integrate the radiology workflow across hospitals in the cluster to optimize the utility of their assets in the delivery of patient care.

E-16

CE-MRA of intracranial vessels

N. Anzalone; Milan/IT

Despite the possibility to perform high quality and diagnostically useful examinations of the intracranial vasculature using time-of-flight (TOF) and phase contrast (PC) MR angiography (MRA), there are still some intrinsic technical problems that limit the application of these techniques. With TOF techniques the main problems are related to saturation effects and to spin dephasing, while for PC acquisitions the appropriate choice of the velocity encoding gradient can be crucial. Moreover, both techniques are limited by the lack of adequate spatial and temporal resolution which is essential for appropriate diagnostic evaluation of cerebral vascular malformations. Many of these problems, particularly those related to flow effects, can be avoided by the use of a suitable contrast agent. However, while the use of contrast agent can raise the signal-to-noise ratio, a major problem, particularly in conjunction with TOF acquisitions, is the superimposition of venous structures. To avoid this problem, ultrafast gradient echo MRA techniques with very short TR and TE have been developed. These sequences are designed to enable the acquisition of either small volumes with almost isotropic voxels in few seconds or larger volumes with longer scan times, and permit high quality images with good spatial resolution and high signal-to-noise ratio to be obtained. Alternatively, dynamic acquisitions with high temporal but low spatial resolution may be acquired. Although the precise sequence parameters vary between different manufacturers, the CE-MRA techniques are basically similar. It is important to target the arrival of the contrast bolus and again, different bolus timing methods are available for different makes of MR equipment.

The choice between a time resolved or high spatial resolution CE MRA technique is dependent upon the precise clinical application. The most common applications include the study of cerebral aneurysms, arterio-venous malformations, dural arterio-venous fistulas and dural venous sinus diseases. This presentation will focus both on the technical aspects of CE MRA for clinical applications concerning the intracranial vessels, and on the clinical application of different imaging techniques.

E-17

MRA of the carotid arteries

S.A. Thurnher; Vienna/AT

Magnetic resonance angiography (MRA) of the carotid arteries has undergone a long period of evolution to become a routine imaging modality. Contrast-enhanced (CE) MRA, which combines fast 3D spoiled gradient echo sequences with the intravenous bolus administration of paramagnetic contrast materials, has proven a highly capable replacement for conventional MRA techniques for the evaluation of extracranial carotid artery disease.

CE-MRA of the carotid arteries is uniquely challenging because the very short arterial-venous recirculation time in the brain leads to rapid jugular venous enhancement and hence the possibility of obscured visualization of the adjacent carotid arteries. Fortunately, improvements in CE-MRA technique such as randomly segmented centric k-space encoding, allow longer scans with higher spatial resolution without jugular venous contamination. Thus, the divergent demands of high spatial resolution, wide anatomic coverage, and arterial phase imaging have been reconciled.

Despite improvements in technique, CE-MRA has generally been considered to overestimate the degree of carotid artery stenosis compared to conventional DSA. Thus, in certain settings there may be questions as to whether the measured extent of carotid artery disease is sufficiently accurate as to meet surgical criteria. On the other hand, recent studies suggest a better correlation of CE-MRA with multiplanar rotational DSA than with conventional DSA in two or three planes. Compared with standard gadolinium contrast agents, high relaxivity contrast agents, e.g. gadobenate dimeglumine (Gd-BOPTA), have a substantially higher intravascular T1-relaxativity. This has been demonstrated in studies comparing Gd-DTPA and Gd-BOPTA enhanced MRA of the carotid arteries. Qualitative eval-

uation showed equivalent arterial contrast enhancement and vessel conspicuity with low-dose Gd-BOPTA compared with high-dose Gd-DTPA. Quantitative evaluation demonstrated an improvement in both signal intensity and contrast-to-noise ratio with Gd-BOPTA. Thus, the greater relaxivity of Gd-BOPTA, at lower doses, provides high intravascular signal and may permit improved accuracy in the depiction of carotid artery stenosis. In conclusion, high relaxivity contrast agents appear to be optimal for contrast enhanced MRA of the carotid arteries.

E-18

MultiHance in MRA of peripheral vasculature

P.C. Douek; Lyon/FR

Standard contrast-enhanced MRA of the peripheral vasculature employs a bolus-chase continuous infusion of gadolinium-based contrast agent at 0.3-0.5 ml/s, with a total contrast agent dose of 0.2 mmol per kilogram body weight, combined with moving table.

Recent technological advances in MRA, especially pertinent to imaging the peripheral vasculature, now permit "volume positioning", i.e. the acquisition of images of the body in three overlapping segments oriented to the natural angles of the torso and lower limbs. Other technological approaches to improving image quality include the adoption of a) dedicated coils, e.g. a phased-array coil for imaging the peripheral vasculature and a head coil for imaging the feet, b) tourniquets to reduce venous return, and c) time-resolved MRA sequences, e.g. sensitivity encoding (SENSE), two-dimensional (2D) projections, and 3D time-resolved imaging of contrast kinetics (TRICKS). A fourth approach involves use of the gadolinium-based contrast agent Gd-BOPTA (gadobenate dimeglumine, MultiHance; Bracco Imaging, Milan, Italy) since this agent offers greater imaging efficacy compared to conventional gadolinium chelates, because identical results can be obtained at lower doses: only 20-30 ml Gd-BOPTA are necessary to perform MRA of the entire peripheral vasculature, compared to 40-60 ml of a standard agent. The indications of contrast-enhanced MRA with MultiHance for the peripheral vasculature include: endovascular and surgical treatment planning, post-treatment follow-up, and emergency evaluation (when MR imaging equipment is available in emergency departments).

E-19

MRA in pediatrics

G.K. Schneider; Homburg a.d. Saar/DE

It is particularly important that vascular imaging in the pediatric age group be noninvasive without utilizing ionizing radiation or potentially nephrotoxic iodinated contrast media while at the same time providing precise anatomic and functional information. In children this can be achieved in part by ultrasound. However, to gain a complete overview of the anatomy and of accompanying vascular abnormalities in, for example, complex congenital heart disease, MR angiography (MRA), with its high spatial resolution and free choice of image orientation, is increasingly considered the noninvasive imaging modality of choice. Although unenhanced MRA still plays an important role, contrast enhanced (CE) 3D MRA has largely replaced spin-echo sequences and TOF-angiography for depiction of the vascular anatomy in pediatric subjects.

Vascular abnormalities may be found anywhere in the body although most clinically relevant malformations are found in the thoracic vasculature, comprising the thoracic aorta and its branching vessels, and the pulmonary vasculature.

The imaging protocol in newborns should include T2w and T1w sequences for the cross sectional anatomy and CINE imaging to evaluate flow effects, to quantify the maximum velocity in the great vessels or to evaluate concomitant congenital heart disease. To depict the vasculature with fast 3D gradient-echo sequences the application of Gd-contrast agents is mandatory, despite the fact that such an application is off-label. A principal advantage of Gd-BOPTA in pediatric patients is the potential to obtain high quality images using only a standard dose of 0.1 mmol/kg bodyweight. Moreover, the high relaxivity of this agent is known to be beneficial for the depiction of smaller vessels which is especially important in newborns whose vessels of interest are frequently ≤ 2 mm in diameter.

CE MRA in pediatric patients is a safe, non-invasive and accurate imaging modality for anatomical evaluation of vascular malformations and abnormalities. While sonography, echocardiography and plain film radiography are economic and widely available screening tools, MR imaging is superior in leading to a definitive diagnosis and for pre-therapeutic evaluation of malformations.

The milestones of X-ray contrast media development

U. Speck; Berlin/DE

Past important steps in the development of contrast media (CM) are easily recognised and will be briefly summarised:

1. The concept of enhancing contrast of body cavities and soft tissues by introducing either gas or dense materials which absorb X-rays more efficaciously than natural body constituents immediately after the discovery of X-rays and their use in medical diagnosis.
2. Selection of dense materials like barium, thorium, tantalum, iodine and search for suitable routes of administration.
3. Consideration of tolerance, preference for barium and iodine, first selective angiographic procedures.
4. Development of iodinated organic molecules such as lipiodol as well as the first oral cholecystographic agents and other substances for special indications.
5. Discovery of Uroselectan for intravenous urography.
6. Development of Urograffin, an almost universal CM applied in urography, selective angiography including cardiac and cerebral angiography and finally CT; development of a variety of additional CM for IV cholangiography and myelography.
7. Almost complete substitution of ionic and specific CM by nonionic CM, ongoing substitution of specific contrast-enhanced diagnostic procedures (angiography, urography, myelography, cholangiography) by CT, MR imaging or sonography.

To identify current and future directions of CM development is more difficult. Improvements of the existing nonionic CM will be welcome but won't change the practice of radiology. New CM must result in significant advantages over the currently used products that are efficacious, well tolerated and have very broad indications. The potential benefit of metal chelates, CM with different specificity and CM supporting image-guided therapy will be discussed.

E-28

Higher concentrations: Where does it make sense

J.E. Wildberger; Aachen/DE

Optimized contrast injection is an important issue for good attenuation and high contrast within a CT data set. Contrast media delivery becomes even more important, when using multidetector-row helical CT technique. A shorter imaging time permits a reduction in overall contrast volume; however, adequate total iodine levels must be preserved for certain applications. The faster data acquisition allows for optimization of organ-specific and vascular territory-specific enhancement patterns. Examinations of whole organs in dedicated contrast phases is now technically feasible (e.g. early- and late-arterial phase of the liver). A precise separation of different enhancement phases can be extremely helpful for tumor detection and characterization, especially for hypervasculär parenchymal lesions. To achieve this goal, numerous pharmacokinetic and physiologic parameters have to be considered. The relationships of contrast medium concentration, injection flow rates, injection protocols (mono-, bi-, and multiphasic injection protocols), and injection duration have to be addressed.

A high arterial enhancement is proportional to the flux of iodine: A high iodine injection rate (milligrams of iodine per second) can be realized by a high-concentration contrast medium (milligrams of iodine per milliliter) in combination with high flow rates (milliliters per second) which may be limited by viscosity as iodine concentration surpasses an optimum. The use of double-power injectors has been advocated for automated saline-flushing at the injection site. This issue becomes even more important using fast CT scanning techniques.

Accurate timing of the scanning delay, however, will also be closely linked to individual patient parameters. Therefore, test-bolus methodology and automated bolus triggering are widely used prior to the underlying CT-scan.

CT angiographies, in particular, will benefit from a comprehensive and compact

Satellite Symposia

bolus geometry. High and constant iodine contrast should be maintained throughout the whole data set for uniform vascular enhancement.

The same holds true for dedicated arterial phase CT-imaging of the body.

E-29

Multidetector CT of the kidneys and urinary tract

G. Heinz-Peer; Vienna/AT

Multidetector CT (MDCT) has expanded the utility of CT by improving longitudinal resolution and acquisition speed. In addition, MDCT technology allows for acquisition of different image thicknesses from the same acquisition data set. With MDCT it is possible to subdivide the enhancement phases of the kidney into appropriate time intervals to detect vascular and parenchymal abnormalities. Thin slice thickness in combination with multiplanar reformats and virtual endoscopy techniques is used for detection of small focal lesions of the urinary tract and bladder tumors.

This presentation will emphasize acquisition techniques and circulation characteristics to improve renal and urinary tract lesion detection and characterization. Additionally the utility of MDCT in evaluation of vascular abnormalities of the kidneys and virtual endoscopy techniques of the bladder and urinary tract will be addressed.

E-30

Cardiovascular imaging: First results on a 64 slice scanner

C.R. Becker; Munich/DE

The new 64 slice CT scanner has an improved temporal and spatial resolution compared to any former CT scanner generation. The temporal resolution and the isotropic spatial resolution are now at 165 ms and 0.4 mm, respectively. The investigation of the entire heart lasts about 10 s.

All of these parameters lead to any overall high success rate to perform a cardiac study. The investigation of the coronary arteries is possible with low and high heart rates. However, in patients with high heart rates images reconstructed in the systolic phase are superior to images reconstructed in the diastolic phase. As diagnosis is best been made in the diastolic phase, it is desirable to have a low heart rate when the investigation of the coronary arteries is performed. To achieve this, any patient without contra indications is receiving beta blocker before the investigation.

The short scan time together with a saline chaser bolus allows targeting the administration of contrast media for a selective enhancement of the left ventricular system and the coronary arteries.

Clinically the benefit of coronary CT angiography is the investigation of patients suspected for coronary anomalies and atypical chest pain. In patients with acute chest pain CT angiography may help to rule out pulmonary embolism, aortic dissection and coronary thrombosis.

With the improved spatial resolution it seems to be possible to investigate even patients with extensive calcified atherosclerotic disease and also holds promise to rule out in-stent-stenosis.

E-31

Safety of X-ray contrast agents

A.F. Kopp; Tübingen/DE

X-ray contrast agents are widely used and often the basic requirement of many imaging modalities. They are among the medicinal products with a good safety profile.

Since the introduction of non-ionic X-ray contrast media the rate of adverse drug reactions was reduced. Several substantial large contrast media studies show the better tolerance and safety non-ionic contrast agents with regard to pseudoallergic as well as organotoxic reactions. It remains difficult to determine mortality rates and the incidence of severe contrast media reactions because of the rarity of these events and the difficult assessment of the causal relationship. Adverse reactions to intravascular X-ray contrast agents can be classified into two categories; predictable reactions and unpredictable anaphylactoid reactions.

There are several important risk factors for the intravascular use of iodinated contrast media: e.g. thyroid disease, renal impairment, allergic diathesis, former CM-reaction, dehydration, diabetes mellitus. There are also different prophylactic measures and premedications which are suitable to prevent adverse reactions.

Scan and contrast administration principles of MDCT

J.P. Heiken; St. Louis, MO/US

The markedly reduced scan durations of multi-detector CT examinations have made scan timing more critical than for single detector CT. At the same time, these short scan times have provided radiologists with an opportunity to improve contrast enhancement with MDCT. It is therefore important for radiologists and technologists to 1) understand the factors that determine both the magnitude and timing of arterial and parenchymal contrast enhancement for CT, and 2) identify the modifications needed to optimize contrast enhancement for 4-row to 64-row MDCT.

Scan Timing

Technical factors: The most important technical factor that affects scan timing is the contrast medium injection duration (1-3), which is determined by the contrast volume and the rate at which it is administered. In patients with normal cardiac output, peak arterial contrast enhancement is achieved shortly after the termination of a contrast medium injection (4). As the contrast medium volume increases, the time it takes to reach the peak of arterial or parenchymal contrast enhancement also increases (5). Conversely, an increase in injection rate results in a shorter time to peak enhancement (5). Therefore, a short injection duration (i.e., low volume and/or high injection rate) protocol results in earlier peak arterial and parenchymal enhancement, which requires a short scan delay. A long injection duration (i.e., high volume and/or low injection rate) protocol results in later peak enhancement, requiring a long scan delay.

Patient-related factors: The most important patient-related factor that affects scan timing is cardiac output (6). Decreased cardiac output results in delayed arrival of the contrast bolus in the aorta, which results in delayed arterial and parenchymal enhancement. Because of variation in cardiac output among patients, it is important to individualize the scan delay for CT angiography studies, in which scan timing is critical. Scan delay can be individualized by using a test bolus (7, 8) or a bolus tracking software program (9). When using the test bolus method, calculation of the scan delay must be modified depending on the speed of the MDCT scanner being used. With 8- and 16-row MDCT, an additional delay must be added to the contrast arrival time in the aorta, if no change is made to the contrast administration protocol. The shorter the scan duration, the longer the additional delay needed to insure that imaging takes place during the peak of aortic enhancement. With 8- and 16-row MDCT, however, one can take advantage of the very short scan durations by reducing the volume of contrast medium administered.

Contrast Enhancement Magnitude

Technical factors:

Arterial enhancement:

The magnitude of arterial enhancement is determined by the rate of iodine delivery into the vascular system. The iodine delivery rate depends upon three factors: 1) contrast medium concentration, 2) injection rate, and 3) contrast medium volume (primarily through recirculation). Increases in contrast medium concentration (10), injection rate (1, 11) and volume (10) all result in increased arterial enhancement. Use of higher iodine concentration contrast material produces greater magnitude of aortic contrast enhancement, even if total iodine dose and injection rate are unchanged, by virtue of increasing the rate of iodine delivery into the

vascular system. When contrast medium volume is reduced for CT angiography with 8- and 16-row MDCT, increased injection rate and high contrast medium concentration can compensate for the somewhat decreased magnitude of aortic enhancement achieved with the smaller contrast medium volume.

Hepatic parenchymal enhancement:

Hepatic parenchymal enhancement is determined by the total iodine dose administered (3, 12-18), which in turn is determined by the contrast medium volume and concentration. Use of higher iodine concentration contrast material improves hepatic parenchymal enhancement to the extent that it increases overall iodine dose (19). Injection rate plays a much more limited role in the magnitude of hepatic parenchymal contrast enhancement.

Although a rapid injection rate (e.g., 5 ml/sec) does not increase the magnitude of hepatic parenchymal enhancement compared with an intermediate injection rate (e.g., 2-3 ml/sec), use of a rapid injection rate increases the magnitude of hepatic arterial enhancement and separates the peaks of hepatic arterial and hepatic parenchymal enhancement (1), thus improving detection of hypervascular liver masses (20). Similarly, a rapid injection rate increases pancreatic parenchymal enhancement (21, 22). Therefore a rapid injection rate is useful for dedicated hepatic and pancreatic imaging protocols. Use of higher concentration contrast material increases tumor to liver contrast of hepatocellular carcinomas during the arterial phase of enhancement, and therefore also is useful for detecting hypervascular liver masses (23).

Patient-related factors: The most important patient-related factor that affects the magnitude of both arterial and hepatic parenchymal contrast enhancement is body weight (14, 24), which is related inversely to the magnitude of enhancement. In larger patients, less contrast enhancement is achieved for a given administered contrast dose compared with smaller patients. Therefore, when imaging large patients, one should consider modifying the contrast administration protocol by increasing the contrast medium concentration, volume or injection rate.

Saline Flush

Use of a saline flush immediately after contrast medium injection has several advantages. It increases peak aortic enhancement by 1) pushing into the cardiovascular system contrast material that otherwise would be left in the injection tubing and 2) improving bolus geometry by limiting contrast medium dispersion. Thus when a saline flush is employed, one can achieve an equivalent magnitude of contrast enhancement with a smaller contrast medium volume (25-27). An additional advantage of saline flush is that it minimizes streak artifact from dense contrast material in the brachiocephalic vein and superior vena cava on thoracic CT examinations (25, 26).

E-40

How to design injection protocols for MDCTA

D. Fleischmann; Stanford, CA/US

Continuous evolution of MDCT technology requires that contrast medium (CM) injection strategies for MDCT are regularly adopted to the increasingly faster acquisition speeds. The foundation for the development of optimal injection protocols is knowledge of the physiologic and pharmacokinetic principles of arterial enhancement.

The key-rules of early arterial contrast medium dynamics are: (§1) arterial enhancement is directly proportional to the iodine administration rate (iodine flux), and can be controlled by the injection flow rate and the iodine concentration of the contrast medium. (§2) arterial enhancement continuously increases over time with longer injection durations, due to the cumulative effects of bolus broadening and recirculation. Thus, increasing the injection duration also improves vascular opacification. (§3) the strength of an individual's enhancement response to intravenously administrated CM is controlled by cardiac output and central blood volume, and correlates with body weight.

In CTA, any of the following strategies can be employed alone or in combination to achieve adequate arterial enhancement in spite of short acquisition times: Increasing the injection rate, using higher concentration CM, or increasing the injection duration (and scanning delay) relative to the scan time. For long scan times (~30 s) biphasic injections - with initially increased flow-rates - improve the uniformity of arterial enhancement over time. Both, injection volumes and flow rates should be adjusted to body weight, at least for patients ≤ 60 kg and ≥ 90 kg BW.

Rationally designed injection protocols based on physiologic concepts allow optimal CM utilization and taking full advantage of the technical capabilities offered by modern MDCT scanners.

E-41

Optimized imaging of pulmonary embolism

M. Tillich; Graz/AT

Pulmonary embolism (PE) is a common disease with considerable mortality. Therefore, early and accurate diagnosis is important. There are no specific signs or symptoms of PE, the diagnosis relies on imaging tests. The development of multi-row-detector computed tomography has led to an improvement in the diagnosis of PE due to faster scanning and improved spatial resolution along the longitudinal axis of the patient. Aside from fast scanning and thin collimation, optimal arterial attenuation remains one of the most crucial determinants of sufficient depiction of the pulmonary arteries. Arterial attenuation over time is generally determined by iodine flow concentration, which may be increased either by raising the contrast material flow rate, and/or by using a high iodine concentration contrast material.

Currently four-to sixty-four-row detector scanners are available. The scan duration necessary for imaging the whole thorax ranges from about 20 seconds with a four-row detector scanner to about 5 seconds with a sixty-four-row detector scanner. The collimation ranges from 0.5 mm to 1 mm depending on the scanner used. This enables the most detailed display of the pulmonary arteries.

The data acquisition is obtained during the plateau phase of contrast material enhancement. Bolus triggering devices are a valuable tool for accurate timing of scanning. The administration of the contrast material bolus is performed using a power injector at a flow rate of about 4 mL/sec. A saline flush immediately after contrast material administration avoids pooling of the contrast material in the arm veins and in the injection system and reduces perivenous artifacts in the superior vena cava. Based on the findings of a study we have recently performed, the use of a high concentration contrast material (such as Iomeprol 400 mgI/mL) significantly improves attenuation of the pulmonary arteries leading to a better visualization of subsegmental and lower order pulmonary arteries in multi-row-detector-CTA of the pulmonary arteries. In addition, the higher attenuation may improve the conspicuity of emboli within the pulmonary arteries.

E-42

Advances in imaging protocols for cardiac MDCT

A.F. Kopp; Tübingen/DE

Examination of the function, perfusion, and viability of the heart muscle as well as of the morphology and function of the coronary arteries is of utmost importance in the diagnostic assessment of coronary artery disease. The current gold standard to assess the degree of stenotic artery disease is coronary angiography. In Germany alone, the total number of angiographic procedures rose by 45% from 1995 to 2000, while the fraction of interventional procedures remained almost constantly low at about 30%. Although coronary angiography has become a safe procedure with only a small risk associated, the inconvenience for the patient as well as the economic burden have fueled the quest to find an alternative, non-invasive method to visualize and assess coronary arteries. The results of MDCT coronary angiography in the detection and quantification of coronary lesions with 4-row and 16-row technology obtained so far from different centers are encouraging: CTA of the coronary arteries yielded a sensitivity of 75-90%, a specificity of 90-95%, a positive predictive value of 0.7-0.9, and a negative predictive value of 0.8-0.9 for detection of hemodynamically significant stenoses in the major segments of the coronary arteries.

Ropers et al. analyzed coronary stenoses in 16-row coronary MDCTA with a reference diameter down to 1.5 mm, thus covering all lesions that may be potential targets for revascularization. Both motion and calcification rendered fewer arteries (12%) unevaluable than in most previous studies and a high sensitivity (92%) and specificity (93%) for the detection of coronary stenoses was achieved. Nieman et al. demonstrated similar results with a sensitivity, specificity, and negative predictive value of 95, 86 and 97%, respectively, in a comparable patient population using the same 16 slice CT technology. However, their analysis was restricted to the major branches with a vessel size > 2 mm. Striking about this study was that only 7% of all coronary branches were poorly assessable.

Recently new 64-slice scanners became available. With this technology a comprehensive view of the heart and coronary arteries with submillimeter resolution in 5 seconds is now feasible. The coverage possible helps reduce beat-to-beat variability resulting in more robust, repeatable procedures, greater vessel visualization and shorter breath holds for sick patients. The increased scan speed allows to rule out (or in) the three most life-threatening critical conditions in chest pain in one single scan - aortic dissection, pulmonary embolism and coronary artery disease by acquisition of an entirely ECG-gated thorax study.

E-43

Abdominal MDCT: Protocols and contrast considerations

T.J. Vogl, R.M. Hammerstingl; Frankfurt a. Main/DE

Abdominal imaging in MDCT: Since its clinical introduction in 1991, volumetric CT scanning has resulted in a revolution for diagnostic imaging. Spiral CT has improved over the last years with faster gantry rotation, more powerful X-ray tubes, and improved interpolation algorithms, but the greatest advance has been the recent introduction of multi-detector computed tomography (MDCT). Currently capable of acquiring 64 channels of helical data simultaneously, MDCT scanners have achieved the greatest incremental gain in scan speed. Fundamental advantages include substantially shorter acquisition times, creation of thin sections on a routine basis in a single-breathhold technique, retrospective calculation of thinner or thicker sections from the same raw data, and improved 3D-postprocessing techniques.

This results in an improved detection as well as depiction of tumorous tissue, relating to aspects of tumor size and to tumor/surrounding tissue contrast ratio. Enhancement characteristics described with multiphasic scanning as well as thinner reconstructed sections allow an improved diagnosis in MDCT imaging of the abdomen.

Protocols in MDCT of the abdomen: Detection of lesions of the abdomen is determined by conspicuity and is related to the degree of tumor-to-tissue contrast. As known tumor characterization is mainly based on the lesion contrast uptake at the different enhancement phases and scanning in sufficient phases is absolutely mandatory.

During the early arterial phase (20 sec post start of injection) there is avid enhancement in the arterial vessels but relatively little enhancement of the parenchyma or hypervascular lesions. Accurate CT-angiography with optimal vessel opacification can be performed in presurgical evaluation.

In the late arterial phase or portal vein inflow phase, which occurs approximately at 30-35 sec post injection, solid neoplasms will be maximally enhanced, whereas the parenchyma will be only minimally enhanced due to predominantly portal venous supply. Therefore this phase is optimal for detection of hypervascular primary liver tumors and metastatic infiltration. The pancreatic parenchymal phase begins at 40-45 sec post injection and provides highest rates of enhancement of the pancreatic parenchyma.

The phase of portal venous dominance, the hepatic venous phase or portal venous phase or hepatic parenchymal phase occurs 60-70 sec post start of injection with maximum enhancement of the hepatic and still high values in pancreatic parenchyma. The detection of relatively hypovascular tumors, such as colorectal metastases or adenocarcinoma of the pancreas, is permitted, which may be unsuspected and in some cases poorly imaged during the other two phases.

For an elective diagnosis of the colon cleansing, distension, endoluminal contrast and spasmolytics are mandatory. A very thin-sliced protocol starting appr. 60 sec post injection with medium flow velocity is the optimal imaging protocol. Post scanning the colon can be assessed in 3D by using multiplanar reconstruction combined with endoscopic views.

Contrast considerations: Having early contrast dynamics in mind it is obvious, that the traditional concept for abdominal imaging, where the injection duration equals the scanning duration cannot be used without modifications. To ensure adequate vessel opacification as well as soft tissue imaging with fast MDCT acquisitions, the iodine administration rate needs to be increased. This can be achieved either by an increase of injection flow rate or -more conveniently- by using a higher iodine concentration of the contrast medium (400 mgI/mL). Data from several clinical trials provided higher contrast densities values of vascular structures as well as hepatic and pancreatic tissue enhancement and moreover of hypervascular tumors in arterial phase imaging using a high concentration contrast medium.

Conclusion: MDCT scanning times may vary substantially in daily clinical routine use depending on the scanner type and therefore acquisition parameters have to be modified. To ensure adequate vessel opacification as well as optimal detection as well as classification of depicted abnormal soft tissue with fast MDCT acquisitions, the iodine administration rate needs to be increased. This can be achieved either by an increase of injection flow rate or -more conveniently- by using a higher iodine concentration of the contrast medium. These agents produce better enhancement of vascular structures and improved overall display of soft tissue tumors.

E-51 New challenges in MDCT from 16 to 64 channels <i>M. Prokopp; Utrecht/NL</i>		Optical imaging techniques, particularly in the near infrared (NIR) range, offer high signal to noise ratios and efficient tissue penetration in the breast. With the advent of new optical contrast agents sensitive tumor detection can now be envisioned. Perfusion type fluorochromes can help to visualize tumor physiology such as angiogenic activity. Moreover, with the increasing understanding of the molecular basis of diseases a variety of new targets have been unravelled which may help in the future to (a) detect breast cancer earlier, (b) non-invasively grade breast cancer and (c) help monitoring of treatment response. 'Target-specific' contrast agents consisting of an affinity ligand (e.g.: antibody fragment, peptide) linked to a fluorochrome can help to detect these structures non- invasively <i>in vivo</i> . The imaging of apoptosis or cancer related antigens (e.g. EGF- receptor) can thus be achieved. 'Smart' contrast agents have been developed which undergo enzyme mediated activation and thus offer better SNR's. These 'smart' probes can be exploited to detect cancer related protease activity (e.g. cathepsin-B). Three-dimensional optical imaging technologies will help to resolve these new 'molecular beacons' <i>in vivo</i> .

Highlights on contrast ultrasound in clinical practice

Moderator

T. Rettenbacher, *Innsbruck/AT*

E-60

Our experience using contrast enhanced ultrasound for uncharacteristic focal liver lesions

T. Rettenbacher; *Innsbruck/AT*

Gray-scale US is usually the first imaging modality, if diffuse or focal liver disease has to be confirmed or ruled out. It is a highly accurate method in characterizing focal liver lesions, especially if the lesions are small hemangiomas or cysts which usually have a specific appearance. However, quite frequently focal lesions appear uncharacteristic at gray-scale US, especially in steatotic livers. In such cases the established subsequent procedure is contrast-enhanced multi-phase Spiral CT or contrast-enhanced MR imaging. If conventional US of focal liver lesions fails to show specific patterns, contrast-enhanced US would be of great interest for several reasons. The lesions dynamic contrast behaviour could be evaluated for further characterization saving additional CT or MR imaging. The topographical correlation of lesions from US to CT or MR imaging would not be necessary. Furthermore, it would be convenient for patients, gaining the definite diagnosis at once.

We could show that contrast-enhanced US with SonoVue® (Bracco Imaging SpA) in cases of uncharacteristic focal liver lesions was confidently diagnostic in 72% in comparison to 56% in multi-phase Spiral CT. Even in cases of very small liver lesions (< 10 mm) contrast-enhanced US proved to be superior to CT - 50% in US versus 30% in CT.

Our experience shows that in the majority of cases of uncharacteristic focal liver lesions contrast-enhanced US may replace additional CT or MR imaging. Several studies performed by other investigators showed that contrast-enhanced liver US can reveal significantly more metastases in patients with known malignancies than conventional US. Even metastases not detected on multi-phase Spiral CT could quite often be demonstrated. However, it still remains controversial if CT or MR imaging can be replaced entirely if liver metastases have to be ruled out.

Finally, another well examined indication of contrast-enhanced US with SonoVue is chronic liver disease with hepatocellular carcinoma before treatment, after ablation and for follow-up.

E-61

Ultrasound contrast agents: The impact of EFSUMB guidelines in clinical practice

R. Lencioni; *Pisa/IT*

Worldwide, ultrasound is the most commonly used liver imaging modality. Unfortunately, it has limited sensitivity in the detection of small tumor nodules. In addition, ultrasound findings are often nonspecific, as there is enough variability and overlap in the appearance of benign and malignant liver lesions to make a definite distinction problematic. Recently, the introduction of microbubble contrast agents and the development of contrast-specific techniques have opened new prospects in liver ultrasound. Over the past few years, several reports have shown that contrast ultrasound can substantially improve detection and characterization of focal liver lesions with respect to baseline studies. The advent of second-generation agents and low mechanical index real-time scanning techniques has been instrumental in improving the easiness and the reproducibility of the examination. With the publication of the guidelines for the use of contrast agents in liver ultrasound by the European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB), contrast ultrasound enters into clinical practice. The guidelines define the indications and recommendations for the use of contrast ultrasound in focal liver lesion detection, characterization, and follow-up after tumor ablation procedures. In this presentation, the impact of EFSUMB guidelines into diagnostic protocols currently adopted in liver imaging will be discussed with regard to the following clinical situations: (1) characterization of focal lesions of

Satellite Symposia

incidental discovery; (2) early diagnosis of hepatocellular carcinoma in patients with hepatic cirrhosis; (3) detection of liver metastases in oncology patients; and (4) assessment of the local effect of percutaneous tumor ablation procedures.

E-62

Quantification of enhancement in contrast ultrasound: A tool for monitoring of therapies in liver metastases

M. Krix; Heidelberg/DE

Ultrasound techniques are presented using the contrast agent SonoVue® (Bracco, Italy) for microvascular imaging of liver metastases and for the detection of treatment-related changes in tumour perfusion.

Technical requirements and examination protocols for contrast-enhanced ultrasound (CEUS) in the detection of microvascularity are described. Procedures for the quantitative analysis of perfusion in follow-up examinations are explained. Compared to contrast-enhanced computed tomography, low-MI (mechanical index) CEUS with SonoVue® better reflected the arterial perfusion of liver metastases. Changes of tumour perfusion after stereotactic radiotherapy or chemotherapy of liver metastases could be sensitively detected using CEUS. In addition, possible changes of the liver perfusion after therapy could be assessed. Replenishment kinetics of the contrast agent allowed for a quantitative analysis of the arterial and portal venous perfusion in the tumour and the liver tissue. CEUS is a promising method to non-invasively monitor systemic or local-ablative therapies of liver metastases by sensitively detecting changes of tumour perfusion.

E-63

The use of contrast enhanced ultrasound in renal transplants: First results and potential clinical benefit

T. Fischer; Berlin/DE

Purpose: We performed a study to investigate whether it is possible to adequately diagnose rejection after kidney transplant by evaluating the arterial inflow of an echo enhancer.

Patients and methods: So far, 50 patients underwent US examination with an echo-enhancer (1.6 ml SonoVue, Bracco-Altanapharma) 5 to 7 days after kidney transplantation. The examinations were performed using the Aprio US system (Toshiba) with a 3.5-MHz transducer and contrast harmonic imaging (MI 0.1). Contrast medium (CM) inflow was determined by means of the time-intensity curve (TIC) software. An acute rejection quotient (ARQ) was defined as: slope interlobar artery / slope renal cortex. Findings in patients with large perirenal hematoma ($n = 6$), were compared with the results in the remaining patients.

Results: In 28 patients with an uneventful clinical course US demonstrated a uniform inflow of the CM. The slopes were comparable for the interlobar artery and renal cortex with an ARQ of 1.1 ± 0.5 (nonrejection group, NRG). In fourteen patients with histologically confirmed acute rejection on day 5 to 7 after transplantation (rejection group, RG) the slopes of the CM inflow curves were comparable to those of the NRG for the interlobar artery (9.4 ± 3.6 intensity units/sec vs 11.4 ± 5.6 intensity units/sec) and less pronounced for the renal cortex (4.4 ± 3.4 vs 9.8 ± 4.7 intensity units/sec).

The ARQ was twice as high in the RG (2.1 ± 0.4 , $p < 0.05$) as in the NRG (1.1 ± 0.5). The 6 patients of the hematoma group likewise had a higher ARQ (1.5 ± 0.5 , $p > 0.05$).

Conclusions: The use of echo enhancers has a potential for the early and standardized diagnosis of acute kidney graft rejection. US not only identifies perfusion loss but also provides information on the effect of a large perirenal hematoma on kidney perfusion.

E-64

Value of contrast enhanced ultrasound in rheumatic disease

A. Klauser; Innsbruck/AT

Purpose: Ultrasound (US) has proven to enable earlier detection of inflammatory changes in rheumatic disease than radiography, by delineation of synovial proliferation and early erosions. Color/Power Doppler US is further of value in the assessment of disease activity by depiction of vascularity. Contrast enhanced US (CEUS) is known to improve detection of vascularity by improving the signal to noise ratio. Sensitive detection of vascularity has impact in disease activity assessment in rheumatic diseases. Aim of this presentation is to demonstrate the value of CEUS for detection of inflammatory activity in rheumatic joint and tendon disease.

Methods and Materials: CEUS is performed by intravenous administration of 4.8-mL of SonoVue® (Bracco, Milan, Italy), flushed with 10 mL saline. For Color/

Power Doppler CEUS, continuous infusion (1 ml/min) is preferable to reduce blooming artifacts and allowing for 15 -20 minutes examination time. For gray scale CEUS, which further improves contrast and spatial resolution, bolus administration allows objective quantitative assessment of different parameters (time intensity curves, maximum peak enhancement,) when techniques such as "contrast tuned imaging" CNTI™ (Contrast Tuned Imaging) and CTET™ (Contrast Tissue Enhancement Imaging) (Esaote Biomedica, Genoa, Italy) are used.

Results: Using CEUS improved detection of vascularity can be obtained in early disease and in therapeutic follow-up compared to unenhanced US.

Conclusion: CEUS opens new horizons in rheumatological imaging allowing for sensitive detection of disease activity with a good availability in daily routine. Sensitive monitoring of decreasing vascularity is mandatory in therapeutic follow-up, as full remission is a definite aim in treating rheumatic disease.

Keywords: Contrast enhanced ultrasound - ultrasound contrast agent - rheumatic disease - inflammatory activity.

Post-radiation malignant tumors in head and neck: A review of the clinical and imaging features, C-0532

Yamaoka T., Inamoto N., Ike K., Nakagawa H.

Image degradation and pseudo-lesions from inappropriate use of post-processing techniques, C-0965

Yamaoka T., Kurita A., Azechi H., Endo Y., Nishikawa H., Noguchi M., Nakano Y.

CT findings and clinical features of portomesenteric thrombosis., C-1054

Yamashita E., Koyama T., Kotani H., Kido A., Umeoka S., Fujiwara T., Fujii S., Imai Y., Togashi K.

MRI features with pathologic correlation of uterine malignant mixed Mullerian tumors, C-0430

Yan F., Xu P., Cheng W., Wei G., Zeng X., Qian J., Fan L.

Computer-assisted evaluation of small hepatocellular carcinoma (HCC) by multiphase dynamic imaging using multidetector helical CT (MDCT) (SS 1801b), B-856

Yanagawa N., Morita F., Ochi S., Funabashi N.

Utility of triple channel injection of contrast material with mixture of saline, with upward acquisition for arterial trees using multislice computed tomography, C-1007

Yanagimachi N., Imai Y., Higashi M.

Nonenhanced peripheral MR angiography using peripheral pulse-triggered three-dimensional half-Fourier fast spin-echo in patients with chronic kidney disease, C-1035

Yang H., Kim A.

Pattern analysis of defecography in patients with chronic constipation: Analysis and its predictive value for the responsiveness of biofeedback therapy (SS 1801a), B-817

Yang H., Do K., Song K., Seo J.

Traumatic diaphragmatic hernia: Comprehensive evaluation using novel MR techniques and multislice CT, C-0310

Yarmenitis S.D., Bakantaki A., Papantoniou Y., Gourtsoyiannis N.

Comparison of B-mode and contrast enhanced ultrasound of the liver in patients undergoing chemotherapy for known primary malignancy (SS 1401b), B-608

Yarmenitis S.D., Kolios G., Papanikolaou N., Maris T., Kouroumalis E., Gourtsoyiannis N.

Integrated sonography of Crohn's disease by combining high-resolution B-mode techniques and contrast enhanced ultrasound (CEUS) perfusion studies of the involved bowel segments, C-0083

Yarmenitis S.D., Bakantaki A., Koulieraki C., Fragos C., Maris T., Gourtsoyiannis N.

Uncommon applications of contrast enhanced ultrasound, C-0400

Yekeler E., Saedi V., Yildirim Donmez F., Tunaci A., Tunaci M., Acunas G.

Evaluation of dynamic contrast enhancement pattern of solitary pulmonary nodules on 3D gradient-echo MR imaging (SS 204), B-035

Yokoyama H., Sanada S., Ohno T.

3D image of Adamkiewicz artery: Preoperative assessment of thoracoabdominal aortic aneurysm, C-1067

Yoon S., Byun J., Park S., Won H., Kim A., Shin Y., Kim P., Ha H., Lee M.

Two-phase CT findings of mass-forming intrahepatic peripheral cholangiocarcinoma in cirrhotic patients: Comparison with those in non-cirrhotic patients (SS 701b), B-419

Yoon J., Cha S., Han S., Lee S., Kang M.

Radiologic findings of gallbladder adenomyomatosis: The importance of showing Rokitansky-Aschoff sinuses, C-0008

Yoon J., Cha S., Han S., Lee S., Kang M.

MR imaging of stomach cancer and ex vivo ¹H MR spectroscopy of the resected stomach, C-0118

Yoon K., Kim E., Hur J., Kim S., Lee Y., Choi K.

Endothelial cell-targeted MR imaging using the anti-VEGFR2 and ICAM-1 antibody-conjugated Gd-DTPA, C-0405

Yoon C., Song H., Shin J.

Covered, retrievable, expandable prostatic stent: Feasibility study in dogs, C-0607

Yoon C., Song H., Shin J.

Malignant duodenal obstructions: Palliative treatment using self-expandable nitinol stents, C-0616

Yoshigi J., Ishida J., Nakamura T., Izaki K., Ando S., Kajitani T., Yoshizako T., Kitagaki H.

MRI findings following radiofrequency ablation(RFA) of lung tumors, C-0629

Yoshikawa H., Ueda T., Myoui A., Tamai N., Araki N., Kudawara I.

Imaging of extraskeletal osteosarcoma, C-0759

Young P.C.

Sacral cementoplasty using combination CT and fluoroscopic guidance: Technical approach, C-0638

Yu C.S., Li K.C.

Quantitative study of fractional anisotropy of the corticospinal tract and corpus callosum in patients with relapsing-remitting MS (SS 211), B-092

Yu J., Zhu X., Yang Z.

Endobronchial tuberculosis: Evaluation with multislice spiral CT (SS 1804), B-847

Yu J., Yang Z., Li Z.

Rare primary mediastinal tumors: Helical CT features and pathological correlation, C-0316

Yudin A.L., Abovich Y.

HRCT in differential diagnosis of types of interstitial pneumonia, C-0302

Z

Zabakis P., Santosh C., Walker L.J., Teasdale E.

Application and efficacy of non-invasive spinal multidetector CT angiography in patients with suspected dural fistula with spinal drainage (SS 1811a), B-908

Zabakis P., Lamin S., Jenkins S., Papanastassiou V., Bhattacharya J.

Cerebral proliferative angiopathy: A distinct subgroup of brain AVMs? A single centre experience, C-0855

Zabakis P., McDonald I., Hadley D., Santosh C.

CE-MRA in the diagnosis of spinal DAVF, C-0883
