A. Imaging in acute stroke

M.M. Thurnher; Vienna/AT

Although the diagnosis of acute stroke is essentially clinical, neuroimaging plays an important role in the diagnosis of acute ischemia, while it continues to improve our understanding of the underlying pathophysiology. Because of its 24-hour availability, computed tomography (CT) maintains its role as a primary modality in the evaluation of patients with acute stroke. It is still generally considered the "gold standard" for the exclusion of acute cerebral haemorrhage. Typical signs of acute ischemia on CT will be discussed. Recent investigations using perfusion CT have shown major advances in the assessment of acute stroke patients. Compared with CT imaging, abnormal findings are present earlier on magnetic resonance imaging (MR) following acute cerebral ischemia. Diffusion-weighted MR imaging (DWI) is superior to conventional MR imaging, initial CT, and follow-up CT in examination of patients with acute stroke within 24 hours of presentation. Cerebral perfusion can be measured with MR using two different technical approaches: one measures contrast agent bolus through the brain, while the other uses radiofrequency pulses to image inversion of the magnetization inside or outside the imaged slice (spin tagging). Imaging algorithm for examining patients in acute stroke, as well as the "optimal method" for stroke detection, and the "optimal time" to image stroke patient will be described. Thrombolytic therapy has been reported to be most beneficial in patients with cytotoxic edema involving 33% or less of the MCA territory. It is crucial to distinguish patients who will benefit and those who will not have any benefit from thrombolytic therapy.

Learning Objectives:

1. To review the physiology of cerebral blood flow and explain the mechanism of cytotoxic edema.
2. To review the CT imaging findings in acute cerebral infarction.
3. To review the imaging findings in acute cerebral infarction on conventional MR sequences, diffusion-weighted MR imaging (DWI) and MR perfusion.
4. To suggest the algorithm for optimal imaging protocol in acute stroke, discuss optimal time to image the stroke patient, and optimal method for infarct detection.
5. To learn how to select patients which may benefit from treatment with thrombolytics.

A-002

B. Cerebrovascular distribution territories

A. Rovira-Cañellas¹, E. Grivé¹, A. Rovira-Gols², J. Alvarez-Sabin¹;

¹Barcelona/ES, ²Sabadell/ES

Ischemic stroke prognosis, risk of recurrence, clinical assessment and treatment decisions are influenced by stroke subtype (anatomical distribution and causative mechanism of infarction). Stroke subtype diagnosis is better achieved in the early phase of acute ischemia with the use of multimodal MR imaging (diffusion-weighted imaging, and MR angiography).

The pattern of brain lesions as shown by brain MR imaging can be classified according to a modified Oxfordshire method, based on the anatomical distribution of the infarcts into six groups: 1) total anterior circulation infarcts, 2) partial anterior circulation infarcts, 3) posterior circulation infarcts, 4) watershed infarcts, 5) centrum ovale infarcts, and 6) lacunar infarcts.

The subtype of stroke according to its causative mechanism is based on the TOAST method, which classifies stroke into five major etiological groups: 1) large-vessel atherosclerotic disease, 2) small-vessel atherosclerotic disease, 3) cardioembolic source, 4) other determined etiologies, and 5) undetermined or multiple possible etiologies.

The different MR imaging patterns of acute ischemic brain lesions (topography, size and multiplicity) visualized using diffusion-weighted imaging, the pattern of vessel involvement demonstrated with MR angiography, and the presence of previous ischemic lesions detected with conventional MR imaging are essential factors that can suggest the most likely causative mechanism of infarction. This information may have an impact on decisions regarding therapy and the performance of additional diagnostic tests.

Learning Objectives:

1. To be familiarized with the different topographic patterns of ischemic stroke
2. To understand the various causative mechanisms of ischemic stroke.
3. To illustrate the capability of diagnostic imaging for establishing early stroke subtype, which has implications regarding therapeutic decisions and indication for additional diagnostic tests.

A-003

C. Carotid and vertebral artery disease

A. Goulão; Almada/PT

Ischemic strokes may have distinct aetiologies including several different intrinsic arterial pathological disorders. The diagnosis and understanding of these arterial diseases is critical for the correct management of stroke as different treatment approaches are undertaken according to the aetiology. Atherosclerosis is, by far, the most common arterial disease among adults and other pathological processes include arterial dissection, small-vessel disease, inflammatory and noninflammatory vasculopathy and vasomotor disorders. In children there are several vasculopathies responsible for vaso-occlusive disease like sickle-cell anemia, acute regressive angiopathy and Moya-Moya disease, neurofibromatosis, dissections, vasculitis associated with intracranial and systemic infections.

An overview of the major carotid and vertebral pathological diseases responsible for ischemic stroke in adults and children, highlighting the accuracy of the different imaging modalities for its diagnosis and the imaging appearance of these diseases, is given.

Learning Objectives:

1. To recognize the most common causes of carotid and vertebral pathology responsible for stroke for children and adults.
2. To learn the technical principles underling the vascular imaging modalities and realize its accuracy and limitations.
3. To comprehend the value of the different imaging modalities to evaluate the arterial system and establish an imaging protocol for the stroke study in adults and children.
4. To glimpse into the recent applications of MR vascular imaging to study the structure of arterial wall.

08:30 - 10:00

Room B

Musculoskeletal

RC 110

Sports injuries

Moderator:

V.M. Metz; Vienna/AT

A-004

A. Ligamentous injuries of the knee revisited

O. Papakonstantinou; Iraklion/GR

MR imaging of the knee is the most frequently requested MR imaging study of the musculoskeletal system. Due to its multiplanar capabilities and excellent soft tissue resolution MR imaging has provided a new insight into the specific patterns of knee injuries produced by different mechanisms of injury. Normal and abnormal appearances of the ligamentous structures of the knee will be discussed, as well as ancillary findings to the ligamentous injuries, such as meniscal tears and bone marrow contusions. Patterns of knee injuries will be identified with regard to different mechanisms of injury. In recent radiologic literature, it has been emphasized that the distribution of bone marrow contusions may be indicative of the forces that produced the injury. Awareness of the mechanism of injury results in higher detection rates of the abnormalities of the individual anatomic structures that have been involved in a knee injury.

Learning Objectives:

1. To review the normal MR imaging anatomy of the knee ligaments and to describe optimized MR imaging sequences and imaging planes.
2. To describe the MR imaging findings that are diagnostic of or associated to a specific ligamentous injury.
3. To correlate the mechanisms of injury that produce the individual ligamentous injuries, the patterns of knee instability and the patterns of MR imaging findings.

Postgraduate Educational Programme

A-005

B. Sports-related degenerative disease of joints

C. Masciocchi; L'Aquila/IT

Amateur and professional sports activities are of increasing importance in our daily life. This means a correspondingly higher frequency of sports-related injuries, leading to muscular, tendinous, ligamentous and bony pathology. Usually in these conditions, an early and correct diagnosis is required to avoid subsequent joint instability and/or functional impairment. Many of the diagnostic techniques now available play an important role in sports-related diseases; however to choose the right diagnostic protocol it is always necessary to know how traumatic forces acted. The most frequently involved joints are those provided by the largest range of motion: shoulder, knee and ankle. As this field of diseases comprehend both acute and chronic trauma we will consider only the degenerative conditions caused by long-lasting microtraumas and overloads which may lead to stress fractures, synovial hyperplastic reactions, chondral and subchondral suffering, tendinous degeneration, impingement syndromes and entrapment neuropathies (typically involves structures narrowed into bony or ligamentous channels). Plain films are usually the first examinations to perform as they allow the best detection of bony alterations as a consequence of altered loads; being able to clearly depict osteophytes, bone sclerosis and osteochondral fragments. However in many cases plain films may be completely negative as in stress fractures, impingement syndromes and ligament derangements. In these cases Ultrasound, Magnetic Resonance and Computed Tomography allow a complete evaluation of all the remaining soft joint components.

Learning Objectives:

1. To identify critical areas of the joints submitted to dynamic stress related to the athletic movements.
2. To define the different sports-related lesions by means of diagnostic imaging techniques.
3. To emphasize the relevance of the information obtained by means of diagnostic imaging techniques for the subsequent therapeutical approach.

A-006

C. Trauma of the appendicular skeleton

N. Boutry; Lille/FR

Appendicular skeleton injuries are common, often resulting from multiple forces. After a review of the main diagnostic pitfalls, different types of traumatic lesions that affect the appendicular skeleton and their common associations are described. The ability of ultrasonography to evaluate appendicular skeleton injuries is also presented.

Learning Objectives:

1. To provide an overview of the different types of traumatic lesions that affect the appendicular skeleton and their common associations.
2. To review the role of imaging techniques in clinical management and surgical planning of these injuries.

08:30 - 10:00

Room C

Special Focus Session

SF 1

Computer assisted diagnosis

Moderator:

K.-J. Klose; Marburg/DE

A-007

Computer assisted diagnosis (Introduction)

K.-J. Klose; Marburg/DE

The session will reflect basic scientific aspects and the computational background of different clinical application of Computer Assisted Diagnosis (CAD). The first presentation will concentrate on CAD in mammography, which has a long history in the science of CAD. It will highlight, which problems CAD has solved already and how it can be used today. It will also discuss still existing caveats and restriction of this exciting technology.

The second presentation will expand the application of CAD into the field of therapy planning. Radiologists are aware of the goal, that the result of a radiological examination should help the referring physicians, to treat their patients better.

Especially in the demanding field of surgery, not all surgical questions can be reflected in every single radiology report by reading the pictures in traditional

manner, even in a softcopy reading environment. In order to squeeze volume-data-sets for all their inherent information, dedicated post-processing programs (software assistants) are needed. These have to be based on diagnostic radiological aspects as well as on surgical therapy planning considerations, if they should help to reduce information to its maximal benefit in an individual patients situation.

Support of the therapeutic decision making process can also be applied to field of interventional radiology and is addressed by the principles of RF ablation planning tools.

In the last presentation, we will see that the radiologist must learn, that reading competence relies mainly on lesion detection, which can be improved by the support of dedicated CAD software tools.

Learning Objectives:

1. To learn, how CAD can help the individual radiologist to improve the quality of his diagnostic capabilities.
2. To learn, how structured reporting supports the radiological decision process.
3. To understand, that radiological findings mostly represent intermediate outcome parameters, which guide therapeutic reasoning and how this can be linked by software assistants.
4. To discuss, how CAD will alter the way, how radiologists will work and perform in a CAD-supported future.

A-008

CAD of the breast

N. Karssemeijer; Nijmegen/NL

In breast cancer screening, Computer Aided Detection has evolved into a technology that is widely used in practice to help radiologist to perceive subtle signs of cancer. Current CAD systems can achieve very high sensitivity in the detection of clustered microcalcifications. Some radiologists consider it acceptable to rely on CAD for this feature and restrict search for microcalcifications to areas prompted by CAD. In particular, with soft-copy reading of digital mammograms this can increase productivity dramatically, as time consuming user interaction to fully magnify on the displays each part of all mammograms in an exam can be avoided in that way. For detection of masses and other signs of malignancy current CAD systems are less sensitive, but gradual progress is being made to improve algorithms. In practice the use of CAD appears to be more difficult for detection of masses. Radiologists find it more difficult to dismiss false positives of CAD and appear to need much more training to learn how to use CAD for masses effectively. Detection of masses is to a large extent a problem of interpretation. Fewer errors are made in the initial detection process. Therefore, CAD systems are being developed that are aimed at helping radiologists to characterize suspect abnormalities and to help them making a more reliable estimate of the likelihood that cancer is present. In the future, CAD systems will not be restricted to mammography. New programs are being developed to deal with ultrasound and breast MR imaging.

Learning Objectives:

1. To understand the strengths and weaknesses of current CAD systems.
2. To learn about new developments of CAD technology in breast imaging.

A-009

CAD and intervention planning of the liver

H.-O. Peitgen; Bremen/DE

We will report on new software assistants for the radiological work towards surgery and intervention planning for the liver.

For oncological liver surgery, the issue at hand is to detect and quantify the lesions and evaluate the risks of compromised liver function after resection. To that end the assistant permits the user to choose variable safety margins, determines which vessels are compromised, and then computes the territories supplied or drained by these. As a result the assistant determines the parenchyma at risk from the point of view of compromised branches of the portal vein, hepatic vein, hepatic artery and bile ducts. Finally, based on volumetry and visualization the assistant supports the choice of optimal resection proposals.

For living-donor-liver transplantation the issue at hand is to quantify the risks when a graft or remnant lobe has critical volume; determine, quantify and visualize the risks when grafts or remnant lobes are left with compromised territories (parts that are not properly drained or supplied by the hepatic vascular systems); to determine the appropriate cutting lines interactively and evaluate the risks for the resulting remnants and grafts.

For intervention planning we will demonstrate a new software assistant which simulates an entire RF ablation procedure based on individual patient data. As a

Postgraduate Educational Programme

result of the bio-physical simulation the interventional radiologist can determine whether a lesion can be ablated at all, or is assisted in the optimal placement of the applicator.

Learning Objectives:

1. To comprehend compromised liver function based on CT imaging in liver tumor surgery and living-donor-liver surgery.
2. To understand the radiological role of new preoperative planning tasks for oncological liver surgery, living-donor-liver transplantation, interventional ablation procedures.
3. To become familiar with new risk assessment strategies in the radiological work up for liver surgery and intervention planning.

A-010

CAD of the chest

P. Herzog, C.R. Becker, M.F. Reiser; Munich/DE

Purpose: To assess the performance of a computer aided diagnosis tool for the detection of pulmonary nodules in comparison with three radiologist readers.

Methods and Materials: 75 datasets of MDCT studies of the chest were randomly selected, axial images of 2 mm slice width were obtained and read independently by three readers. Readers were asked to report every pulmonary nodule on a special evaluation form. Furthermore all studies were submitted to a CAD tool (ICAD L, Siemens, Princeton, USA). To evaluate the performance of the CAD tool and the performance of readers, a consensus panel of two experienced chest radiologists validated the nodules found by the readers and the CAD tool.

Results: 772 pulmonary nodules with diameters from 2.5-18 mm were confirmed by the consensus panel. Only 238 nodules were found by the readers (39%), while 402 were missed (61%). The CAD tool detected 730 candidate nodules; 515 were confirmed by the consensus panel (70%) while 223 were dismissed as false positives (30%). Each reader working alone had an average sensitivity of 39%, whereas an individual reader plus ICAD would have had an average sensitivity of 88%, an increase of 49%.

Conclusion: CAD tools have the potential to significantly increase the number of detected pulmonary nodules. Also due to the relatively high rate of false positive findings the most beneficial way of inserting computer aided diagnosis into a the clinical context appears to be in a supportive role, as an aid for experienced human readers.

Learning Objectives:

1. To learn how to use CAD-tools to detect and to evaluate pulmonary nodules.
2. To learn how to avoid pitfalls.
3. To learn how to manage screenees or patients.
4. Indications.

08:30 - 10:00

Room E1

Breast

RC 102

Breast MR imaging

Moderator:

S.H. Heywang-Köbrunner; Munich/DE

A-011

A. When and how

J. Danes; Prague/CZ

MR mammography (MRM) occupies a strong position among other diagnostic imaging methods. The task of a radiologist specialized in "breast imaging" is to rule out malignancy, staging of tumour extent or to set the diagnosis in the easiest and cheapest way, shortest possible time and with minimal patient discomfort. Combination of high quality mammography and sonography is essential. According to our experience as many as 30% of all indications to MRM are incorrect: these are mostly ambiguous focal changes (core biopsy is a method of choice) or findings of dubious microcalcifications. MRM is relatively often indicated on basis of an interpretation of low quality mammograms or substitutes an image with spot compression or magnification. In studies of comparing routine methods, mammography and sonography also underestimated and minimal signs of carcinoma are missed.

Main indications of MRM are: Exclusion of rupture of silicon implant, assessment of scarring after breast conserving therapy, exclusion of multifocality and preoperative assessment of the extent of carcinoma in mammographically dense breast. It is suitable for screening of women with quite high risk of carcinoma (BRCA1, 2

positive) and monitoring of an impact of chemotherapy. On the other hand it is inappropriate for young symptomatic women with dense breasts, in cases of clustered microcalcifications or for differentiation of inflammation from inflammatory (erysipeloid) carcinoma.

Author also describes recommended techniques of imaging and evaluation with emphasis on standardization of procedure. He shows typical examples and cases, where MR mammography was incorrectly indicated or failed.

Learning Objectives:

1. To discuss usual indications and contraindications.
2. To present basic principles and technical aspects.
3. To present analysis and interpretation criteria as well as their results.
4. To present typical cases and common pitfalls.

A-012

B. MR guided interventional procedures

T.H. Helbich; Vienna/AT

Contrast-enhanced MR imaging of the breast has proved to be a valuable tool in the detection and work-up of breast lesions. Most of these lesions are small and not visible by other imaging modalities such as mammography or US. Thus, MR-guided preoperative localization techniques or MR-guided percutaneous biopsy can provide a histologic work-up of such lesions. MR-guided preoperative localization seems to be a well-established procedure. However, MR-guided biopsy is still problematic. Although prototypic biopsy systems have been developed, considerable progress is still required. Thus, needle biopsy currently is not recommended for lesions smaller than 10 mm.

Beside the potential of MR imaging of the breast for monitoring of interventional procedures, MR imaging provides also the impetus for the development of dedicated systems for MR-guided therapy. A variety of minimally invasive procedures have already been used to characterize and treat breast lesions. These therapies include thermal treatments, percutaneous excision or breast lumpectomy, and interstitial radiotherapy.

This course reviews current techniques for MR-guided preoperative localization and percutaneous biopsy in breast lesions. The diagnostic accuracy achievable with these techniques will be discussed. Potential for new research opportunities and directions will be provided.

Learning Objectives:

1. To review current techniques for MR-guided preoperative localization and percutaneous biopsy.
2. To discuss problems related to MR guided interventional procedures (needle artifacts, tissue shift).
3. To present the diagnostic accuracy achievable with these techniques.
4. To provide potentials for new research opportunities and directions.

A-013

C. Future trends: Technique, indications, contrast media

A. Tardivon; Paris/FR

New indications of breast MR imaging are emerging, such as screening in high risk patients with several reports demonstrating its effectiveness for detecting breast cancer. Dynamic contrast-enhanced MR imaging has a high sensitivity but a limited specificity, due to the non selective extravasation of gadolinium chelates from blood into the interstitium of both normal and pathological tissues. New techniques can be added to improve these results. The high capillary perfusion of cancers can be assessed with T2*-weighted first-pass MR imaging (detection of a signal intensity loss after contrast agent injection). Hydrogen MR spectroscopy allows the detection of an abnormal choline resonance peak in cancers. First results of combined MR studies are encouraging with a reported specificity of 100%. MR elastography is an imaging-based method for quantitatively imaging the elastic properties of breast tissue. Preliminary results show a significant difference between normal and malignant tissues. New different contrast agents are under evaluation. Macromolecular contrast media (molecular weight > 10 kDa, large size) should diffuse only across the pathological endothelium of malignant tumours. These agents seem promising and allow quantitative assessment of tumor blood flow and microvascular permeability. Current clinical applications have to define the optimal MR protocols. Ultrasmall superparamagnetic iron oxide agents increase the detection of malignant axillary lymph nodes (no captation after intravenous injection, T2*-weighted sequence) and can be used in association with gadolinium chelates for the staging of breast cancers. Intramammary injection of this contrast medium seems possible for the detection of the sentinel lymph node.

Postgraduate Educational Programme

Friday

Learning Objectives:

1. To present new sequences and new techniques (MR-spectroscopy, MR-elastography, thermo IRM).
2. To focus on new indications (high risk patients, genetic risk).
3. To present new aspects in contrast media research.
4. To present the potentials of MR imaging in axillary lymph node staging.

08:30 - 10:00

Room E2

Abdominal and Gastrointestinal

RC 101

MR of the colon and rectum

Moderator:

B. Marincek; Zürich/CH

A-014

A. Contrast agents and sequences in MR colonography

N. Papanikolaou; Iraklion/GR

MR colonography (MRC) is proposed as an alternative non-invasive technique to CT colonography (CTC) to study the large bowel. The main advantages of MRC include multiplanar imaging capabilities providing cross-sectional and virtual endoscopic views of the colon, superb soft tissue contrast and absence of radiation exposure. Two MRC protocols have been proposed. According to the first, termed as "bright lumen MRC", a gadolinium spiked water solution is administered endorectally to the patient who has previously undergone colonic cleansing to distend the colon, resulting in a homogeneous high signal intensity on heavily T1 weighted 3d gradient echo images. Polyps are demonstrated as filling defects while air bubbles can be differentiated by performing the examination in both supine and prone position. According to the second approach termed as "dark lumen MRC", dense barium or tap water is used to distend the colon in conjunction with post gadolinium 3d gradient echo with fat saturation sequences. The colonic wall and the corresponding polyps exhibit high signal intensity due to gadolinium uptake while the colonic lumen presents with low signal intensity. Recent technical developments are focused on avoiding colon cleansing. According to this method the patient drinks, at each meal, a gadolinium or barium containing contrast agent, 36 hours prior to the examination. The contrast agent is mixed up with stools and consequent changes in their signal intensity resulted in masking of the fecal material during MRC. Spatial resolution of MRC needs to be increased in the future to provide equivalent image quality to CTC.

Learning Objectives:

1. To discuss the relevant merits of individual contrast agents.
2. To review the sequences used in MR colonography.
3. To consider further technical developments.

A-015

B. Clinical applications and results of MR colonography

T.C. Lauenstein; Essen/DE

Magnetic resonance colonography (MRC) has been shown to be an appropriate diagnostic tool for the detection of colorectal pathologies. Similar to contrast-enhanced three-dimensional (3D) MR angiography, MRC is based on the principles of ultra-fast, T1-weighted 3D gradient-echo acquisitions collected within the confines of a single breath-hold. Therefore, the use of an MR system equipped with high-performance gradients is crucial. Two additional requirements need to be fulfilled: bowel distension and a sufficient contrast between the bowel wall and bowel lumen. While bowel distension can be gained by the rectal administration of either liquid or gaseous media, the contrast mechanism strongly depends on the acquired MR-sequences. Initial approaches of MRC were based on the rectal application of water spiked with paramagnetic contrast (bright-lumen MRC). Recently, dark-lumen MRC has been introduced. This technique is based on the acquisition of a T1-weighted sequence after the administration of a water enema and the intravenous administration of paramagnetic contrast. Dark-lumen MRC has turned out to be more accurate and less time consuming than bright-lumen techniques.

Learning Objectives:

1. To review the procedure and performance of MR colonography.
2. To compare patient acceptance and accuracy with other imaging modalities.
3. To consider problems and pitfalls in MR colonography.

A-016

C. MR staging of rectal tumors, problems and pitfalls

R.G.H. Beets-Tan; Maastricht/NL

One of the concerns after rectal cancer surgery is the local recurrence rate. It is now proven through randomized trials that the best local control rate for rectal cancer patients taken together as a whole group is obtained by a short preoperative course of radiotherapy followed by a total mesorectal excision¹⁻³. There are however subgroups of rectal cancer patients with different risks for recurrence. On one side of the spectrum there is the stage I disease who are at very low risk for local recurrence. At the other end of the spectrum is the group of patients with a locally advanced tumor who are at very high risk and who would benefit from a more extensive neoadjuvant treatment schedule. Paramount for the selection and differentiation of treatment is a reliable preoperative test that can distinguish between these groups.

There is recent evidence suggesting that MR imaging can accurately predict the tumor free circumferential resection margin at TME⁴⁻⁷. Our study, published in The Lancet 2001, showed that phased array MR imaging is highly accurate and reliable for the prediction of the circumferential resection margin. The prediction of the T stage however was less accurate and more affected by the experience of the observer.

In this lecture, a review will be given of the different imaging methods for rectal cancer including the appropriate MR technique and problems and pitfalls in interpreting the MR images.

Learning Objectives:

1. Preparation of the patient and contrast agents.
2. To compare staging of rectal cancer by different imaging modalities.
3. To discuss problems and pitfalls in relation to MR staging.

Smoking-related diseases

Moderator:

M. Bellomi; Milan/IT

A-017

A. Emphysema: State-of-the-art

A.A. Bankier; Vienna/AT

Pulmonary emphysema is a common, dangerous, and expensive disease. Because the definition of emphysema is based on pathological morphology, imaging techniques play a major role in the in-vivo assessment of pulmonary emphysema. Beyond a descriptive approach, these imaging techniques can be used to objectively quantify emphysema. This is at the base of the rational allocation of treatment, training or surgery.

This presentation will detail the typical and atypical radiological presentations of emphysema. It will also emphasize the limitations of the subjective assessment of emphysema. To overcome these limitations, methods for the objective quantification of emphysema will be presented. Clinical and pre-clinical applications of objective quantification of emphysema will be presented. Finally, the potential impact of new technologies on the clinical work-up of pulmonary emphysema will be discussed.

Learning Objectives:

1. To increase the awareness of the epidemiological and socioeconomic importance of pulmonary emphysema.
2. To demonstrate typical and atypical radiological features of pulmonary emphysema.
3. To familiarize with the basic technical tools and parameter used and required to accurately quantify emphysema on CT.
4. To inform about the emerging role of functional imaging and the use of advanced techniques in the quantification of pulmonary emphysema on CT.
5. To suggest how emerging new tools for analyzing emphysema could affect the diagnosis and the treatment of this disease.

A-018

B. Smoking-related interstitial diseases

K. Marten; Munich/DE

The spectrum of smoking-related interstitial lung diseases (ILD) encompasses respiratory bronchiolitis, respiratory bronchiolitis-associated interstitial lung dis-

Postgraduate Educational Programme

ease, desquamative interstitial pneumonia, and Langerhans' cell histiocytosis as the most important disorders. Although traditionally being considered as discrete entities, these smoking-related ILD frequently coexist, accounting for the sometimes complex patterns encountered on high-resolution computed tomography. This refresher course discusses the radiologic and pathologic appearances of smoking-related ILD, with emphasis placed on their frequent coexistence.

Learning Objectives:

1. To recognise the variety of interstitial lung diseases that are encountered in cigarette smokers.
2. To understand the HRCT appearances of the "pure" smoking-related interstitial lung diseases.
3. To appreciate the inter-relationship between the various smoking related lung pathologies, particularly the development of interstitial fibrosis.

A-019

C. Sites of airflow obstruction in cigarette smokers

A. Oikonomou; *Alexandroupolis/GR*

Cigarette smoking accounts for most cases of Chronic Obstructive Pulmonary Disease (COPD) - a leading cause of disability and death. Anatomical sites affected in COPD are large and small airways (chronic bronchitis and bronchiolitis) and distal airspaces (centrilobular emphysema). The two major causes of airflow obstruction are: increased airflow resistance related to luminal narrowing (chronic bronchitis) and reduced outflow pressure caused by loss of elastic recoil (emphysema).

In saber sheath trachea - strongly related to COPD - the coronal diameter of intrathoracic trachea is two-thirds of the sagittal one at the same level.

Chronic bronchitis is a clinical diagnosis and radiography has little to offer. Its principal role is to exclude other diseases that may mimic chronic bronchitis. Limited information is also available about HRCT in chronic bronchitis, perhaps reflecting the nebulous nature of this clinical entity; the most common findings being bronchial wall thickening, air-trapping and bronchiolectasis.

HRCT is more sensitive than radiography and PFTs in determining the type, and severity of emphysema and is the best noninvasive technique for detecting early emphysema. Localization of smoking induced emphysema within the secondary pulmonary lobule with radiologic-pathologic correlation and distinction from other types of emphysema (panlobular, paraseptal) as well as the functional - CT correlation will be explored.

The entity of respiratory bronchiolitis - invariably associated with cigarette smoking- will be discussed as a possible mechanism of (early) mixed obstruction and restriction.

Finally the emerging role of hyperpolarized 3He MR imaging ventilation imaging in the evaluation of COPD will be briefly reviewed.

Learning Objectives:

1. To review the anatomy of the structures that can contribute to airflow obstruction as well as the pathophysiology of smoking-related COPD.
2. To discuss the radiologic and CT findings of specific diseases of the large and small airways (chronic bronchitis-bronchiolitis), and distal airspaces (centrilobular emphysema) that cause airflow obstruction in smokers and explore the functional - CT correlation.
3. To describe the entity of respiratory bronchiolitis and discuss its functional significance.
4. To summarise new imaging techniques, such as hyperpolarized 3He MR imaging ventilation imaging offering new insights in the evaluation of COPD.

Imaging of normal anatomy and function

Moderator:

P.H. Nakstad; *Oslo/NO*

A-020

A. Brain morphology and function

F. Di Salle; *Naples/IT*

Among the astonishing progresses brain imaging has undergone in the last decades, of particular importance is the unveiling of structural details and functional processes of the human brain with unprecedented sensitivity and precision, which has provided revolutionary contributions to neuroscience research. An important

role in these developments has been played by the diffusion of high field MR imaging units for humans. While a few research centres are equipped with very high field MR imaging units, up to 8 T, magnets with field intensity ranging between 3 and 5 T have become relatively common. Consequently, studies of brain structures with high spatial resolution have become possible, as well as the use of high definition 3D sequences, which further enhance the detail of structural analysis of the brain. At the same time, also favoured by the availability of high field units, functional magnetic resonance (fMRI) has become the most widely used approach for studying brain function in humans. The diffusion of fMRI has been favoured by its sensitivity in analysing brain functional phenomena and by the lack of biological invasiveness, resulting in a remarkable flexibility of use. These properties brought the functional examination of the brain within the reach of many researchers and appreciably stimulated the research on brain functional processes. The convergence in one single machine of the potential for highly detailed anatomy and for remarkably precise studies of brain function, created the fertile ground that has promoted the incredible development of our knowledge on brain functional anatomy we have witnessed in these last years.

Learning Objectives:

1. To identify the potential of the new MRI techniques in the study of brain cortical and subcortical anatomy and in the evaluation of white matter connections.
2. To integrate the growing knowledge on brain anatomy with the evaluation of brain functions with fMRI.

A-021

B. Brain stem and cranial nerves

J. Casselman; *Bruges/BE*

The nuclei of cranial nerves III-XII are located in the brain stem and cervical medulla. The nuclei cannot be identified on MR but their location can be deduced if one can visualise the surrounding myelinated structures. This is best achieved using high resolution thin proton density and T2W TSE images with a long TR. In the same way, their fascicular course inside the brain stem can be found.

The cisternal segments, surrounded by CSF, are best seen on axial high resolution GE or TSE T2W images with a thickness of 0.35-1.0 mm. The parasellar course of nerves III-VI, the complete course of the olfactory nerve and optic nerve and tract and the extracranial course of all nerves are best seen on coronal high-resolution gadolinium-enhanced T1W SE images. Axial gadolinium-enhanced MRA TOF images are used to visualise cranial nerves IX-XII inside the jugular foramen.

The function of nerves V-VII-VIII-IX and X are more complex and must be known so that the neuroradiologist is aware which nerve (segment) he must visualise to find the cause of a certain clinical sign. This is sometimes impossible as the correlation between "clinical sign" and "involved nerve branch" can be poor (e.g. trigeminal nerve). Moreover, connections exist between cranial nerves (e.g. V-VII-IX) and their brain stem nuclei (e.g. IX-X-XI). Therefore certain nerves are best imaged as a group. Small peripheral branches of the cranial nerves and the connections between the cranial nerves must be known as lesions and tumors can involve/follow these branches and connections.

Learning Objectives:

1. To learn how to localize nuclei and fascicular segments of the cranial nerves in the brain stem.
2. To find out which technique must be used to visualise the different cranial nerves and nerve segments.
3. To know the major connections between different cranial nerves and brain stem nuclei.
4. To understand which clinical sign correlates with which nerve (segment) involvement.

A-022

C. Spine, spinal cord and circulation of cerebrospinal fluid

M. Schumacher; *Freiburg/DE*

The normal anatomy of the spine and its contents will be presented in terms of function with respect to the biomechanics of the skeletal structures as well as the movements of the spinal cord and the cerebral spinal fluid. It is shown how the spinal cord is adapted to these movements by tension, stretching and displacement. The biomechanical factors that are responsible for the development of chronic vertebrogenic myelopathy as well as the meaning of the axial spinal load will be explained. The anatomical background for loading tests is elucidated. The involvement of different anatomical structures such as viscous, elastic and bony elements is analyzed with regard to the explanation of the functional spinal unit and spinal instability and regions of motion.

Postgraduate Educational Programme

Learning Objectives:

1. To learn how anatomy and function in diseases of the spine is related to each other.
2. To learn, that static investigation of the spine and spinal cord is not enough and how it has to be combined with functional tests.
3. To know, how biomechanical stress produces pain and immobilisation.

Salivary glands

Moderator:

J.E. Kabala; Bristol/UK

A-023

A. Choice of imaging technique in patients presenting with salivary gland problems

A. Borges; Lisbon/PT

A variety of imaging modalities are used to visualize the salivary glands including plain films, conventional sialography, ultrasound, CT, CT sialography, MR imaging, MR sialography and nuclear medicine studies. For a rational, cost-effective use of diagnostic imaging it is necessary to tailor the imaging approach to patient's clinical problem/presentation. Two main clinical syndromes determine the appropriate imaging approach: inflammatory/obstructive and mass lesion syndromes. Whereas patients presenting with an inflammatory/obstructive syndrome are best evaluated with ultrasound or CT and some form of sialography, patients presenting with a mass lesion syndrome are preferably evaluated with MR or CT. Sialolithiasis and infectious/non-infectious sialoadenitis are the most common entities presenting with obstructive/inflammatory syndrome whereas benign and malignant neoplasms present as a mass lesion.

Imaging differentiates sialolithiasis from other causes of sialoadenitis. It also identifies the location and number of calculi, detects post-obstructive changes and may establish the etiology of acute and chronic sialoadenitis. Patients with mass lesion syndrome present with a palpable mass. Imaging is tailored to determine its precise anatomic location, the relationship with the facial nerve and to characterize the mass (cystic/solid, single/multiple, benign appearing/aggressive); features which will help to narrow the differential diagnoses. Imaging is also used to guide fine needle aspiration.

Learning Objectives:

1. To become familiar with the most common clinical presentations of salivary gland pathology.
2. To be able to do a cost-effective imaging approach of the most common salivary clinical syndromes.
3. To understand the advantages and limitations of the available imaging modalities.
4. To be able to build a clinically useful differential list based on imaging features.

A-024

B. The value of MR sialography today

M. Becker; Geneva/CH

Similar to MR cholangio-pancreatography, MR sialography is based on the principle that stationary fluids are hyperintense on heavily T2-weighted images. This lecture will first review the different pulse sequences that can be used to perform MR sialography, such as 2D and 3D FSE, RARE, HASTE, GRASE, 3D CISS and 3D EXPRESS. It will discuss their relative advantages and disadvantages, as well as their performance in the diagnosis and management of non-neoplastic diseases affecting the major salivary glands. Emphasis will be placed on the assessment of sialolithiasis, chronic recurrent sialadenitis and sialodochitis, autoimmune diseases, sialosis and cysts. Data from the literature comparing the performance of MR sialography with conventional X-ray sialography will be discussed. Sensitivity, specificity, positive and negative predictive values of the most useful MR sialography sequences will be discussed, as well as how to integrate the information available from these imaging studies with the clinical findings and non-radiologic diagnostic tests. Emphasis will be placed on the correlation between clinico-pathologic presentation and MR sialography findings. In addition, the implications of a precise pre-therapeutic work-up, as well as the key questions that the radiologist has to answer in a specific clinical context will be discussed with respect to treatment.

Learning Objectives:

1. To understand the role, advantages and disadvantages of MR sialography for imaging of non-neoplastic diseases of the salivary glands.
2. To recognize the diagnostic features of sialolithiasis, ductal stenoses, autoimmune diseases and cysts on MR sialography images.
3. To understand the role of MR sialography for the pretherapeutic work-up of these different pathologic entities.

A-025

C. Differential diagnosis in major and minor salivary gland tumors

N.J.M. Freling; Amsterdam/NL

Differential diagnosis of salivary gland masses depends largely on the location of the lesion: preauricular area, parapharyngeal space (PPS), oral cavity (OC), sublingual /submandibular space (SMS). Depending on the tissue constituents within these specific areas, one may assume a different origin of the lesion: major or minor salivary gland, lymph nodes, bone (mandible, skull base), odontogenic, masticator muscles, PPS, subcutaneous origin, vascular. Imaging will help differentiate a solid from a cystic or vascular lesion, and solitary from multiple lesions. To differentiate benign from malignant salivary gland lesions is not always possible. Salivary gland tumours are rare and make up about 3% of all tumours in the general population. About 1% of all head and neck tumours are of salivary origin. Parotid tumours are benign in up to 75%, submandibular and minor salivary gland tumours are malignant in about 50%, sublingual gland tumours are malignant in more than 90%. The age of the patient at presentation will greatly influence differential diagnosis: although solid salivary gland tumours may also occur in children, most of the mass lesions presenting at a very young age are due to vascular or lymphatic malformations. In the adult or elderly, solid salivary tumours outweigh vascular lesions.

Learning Objectives:

1. To locate salivary gland lesions.
2. To know relevant statistical facts about salivary gland tumours.
3. To make a differential diagnosis in view of patient data, clinical data and imaging results.
4. To advise next steps in making a final diagnosis (more imaging, FNAC, biopsy, medical treatment).
5. To consider rare minor salivary gland disease at specific anatomic locations.

Harmonization of training programmes: Myth or reality?

Moderator:

P.A. Grenier; Paris/FR

A-026

Current status from a survey

A.H. Karantanas; Iraklion/GR

Harmonization of training programmes in Europe is mandatory if communication and scientific interactions-including professional contracts- among European radiologists is to be attained. To assess the possible success of this endeavour, information on the various systems of training in different countries is required. A survey has been performed in European countries with regard to their radiology training programmes. The survey included questions on the qualifications needed upon entry into training schemes; description of the training schemes; examinations and professional evaluation; current status of sub-specialties with emphasis on the opportunities; statistics on the number of both general or sub-specialized radiologists working in each country.

The survey disclosed similarities and differences on every single topic of the questionnaire. Similarities occur mostly in the duration of training, the obligatory character of formal teaching and the professional evaluation. Differences have been mainly detected in qualification requirements upon entry into training schemes, rotation in sections and departments, check list availability for the trainees, independent action of trainees, opportunities for sub-specialty training and the number of working radiologists per million.

Learning Objectives:

1. To provide information on the current status of radiology training programmes in Europe.

Postgraduate Educational Programme

2. To assess if the differences and similarities in the radiology training programmes among different European countries can be harmonized in terms of efficiency and scientific inter-communication.

A-027

Examples from the West and the East

L. Bonomo¹, A. Urbanik²; ¹Rome/IT, ²Krakow/PL

To attempt a progressive reduction in the gap currently existing between training programmes throughout European countries it is necessary to provide guidelines and curricula for harmonization of training programmes.

At the moment there are big differences of training programmes not only between Western and Eastern in Europe, but even amongst Western European countries. Examples of training programmes will be illustrated underlying some differences. Ways to reduce the main differences will be proposed.

Learning Objectives:

1. To know some examples of training programmes in Western countries.
2. To understand some big differences of training programmes.
3. To learn how it is possible to reduce the existing gaps in training programmes.

A-028

Specific issues for training in a subspecialty

J.-I. Bilbao Jaureguizar; Pamplona/ES

There is a constant expansion of the speciality of Radiology into new areas. The permanent innovation and the continuous search for new applications result in an important expansion of both diagnostic and therapeutic interventional radiology. The concept of a common trunk in the speciality is supporting that, within the homogeneity, it is favoured the training in different radiological subspecialties. Furthermore, and not less important, the multi-disciplinary involvement of radiology in the management of the patient, needs specialists trained in determined abilities and attitudes, who are capable of responding and moulding to such objectives. Therefore, sub-specialisation in radiology is the consequence of the enormous growth in knowledge, and at the same time, is the response to the needs that the new clinical scenarios require.

The radiological subspecialties are based in "organs" (e.g. gastrointestinal), "ages" (e.g. pediatric), and types of pathology (e.g. oncology) or in therapeutic intervention. A radiologist expert in one of these areas, with clinical knowledge and working within a multi-disciplinary team will be of great value to the clinical process. Nevertheless, it is likely that the most demanded sub-specialty, with a greater impact in the composition of a hospital will be the "general radiologist", expert in several areas and with knowledge of basic interventional techniques (biopsy and drainage).

Learning Objectives:

1. To understand the need for the different subspecialties to be able to provide solutions to the particular problems of each patient.
2. To recognise the need for a multidisciplinary approach in patient care and increase our responsibility in the management of patients.
3. To realise the need to focus in a subspecialty area of interest within a broad general radiology training.
4. To envisage and be ready to adapt to the changes that the future may bring.

A-029

Objectives for the future

P.A. Grenier; Paris/FR

To target a future harmonization of training programmes in Europe, EAR will offer information and services to define common education standards, to facilitate exchanges between universities and countries, and to create a European network of excellence in education. The plan of action includes: 1) guidelines and curricula for training in radiology regularly updated and available on the EAR website, 2) recommendations and common procedures for assessing training centres through Europe, 3) development of a self-assessment system and a European diploma, both computer-based and designed through the internet, 4) identification of centers of reference offering training programme in a particular field of interest during the training time (for non certified trainees), or as a CME training (for board-certified radiologists), 5) identification of centers of excellence in the different fields of imaging for teaching the teachers, 6) selection of high quality educational material and courses for recognition and awarding.

Learning Objectives:

1. To present the plan of actions of EAR in the development of a European house for education in radiology.

2. To suggest the promotion of centers of reference in Europe for training in radiology.
3. To suggest the promotion of centers of excellence in Europe to teach the teachers.

A. Thermal ablation of liver tumors

P. Cabassa; Brescia/IT

In the last 10 years different percutaneous therapies have been used in the curative management of primary and secondary liver tumors in patients not candidate for surgery. The field of image-guided tumor ablation includes chemical ablation (ethanol or acetic acid) and thermal therapies, such as radiofrequency, laser, microwave, ultrasound, and cryoablation. Radiofrequency (RF) is a relatively new image-guided procedure; results are encouraging that this minimally invasive technique could assume a primary role of in the treatment management of patients with both primary and secondary liver neoplasms. In RF ablation, a current induces ionic agitation which results in frictional heat production within the tissue. This heat induces cellular death via coagulation necrosis. Different RF devices are commercially available for RF. These include single tip electrodes or expandible hooks electrode. Electrodes can be placed under US (most frequently), CT or MR guidance.

Treatments are performed under conscious sedation or general anesthesia.

Patient selection is mandatory: Multifocal disease ($n > 5$), lesions adjacent to bowel loops, or patients with severe coagulopathy should be considered not suitable for treatment. Lesion size is the most important factor in determining local therapeutic efficacy. Lesions larger than 4 cm have a high probability of tumor persistence after ablation. The introduction of combined procedures such as RF+embolisation (to reduce blood flow) or RF+saline injection (to increase ionic conductivity) can achieve better results especially in large lesions. The procedure is safe and well tolerated. Major complications are rare and include peritoneal hemorrhage, neoplastic seeding, intrahepatic abscesses, and intestinal perforation.

Learning Objectives:

1. To understand the principles, equipment and techniques of radiofrequency ablation.
2. To know how to do an appropriate case selection.
3. To know the imaging features of the lesions after radiofrequency ablation and their follow-up with regards to local recurrence.
4. To know the place of combined procedures and their potential role in difficult case management.

A-031

B. Management of gastrointestinal bleeding

A. Denys, F. Doenz, S. Qanadli, B. Bessoud, P. Schnyder; Lausanne/CH

Embolization of digestive haemorrhage necessitate a perfect knowledge of arterial and venous anatomy of the abdominal vessels. Indications of embolization of low and upper digestive system will be discussed in the perspective of other therapeutic methods like endoscopy and surgery. Basic technique of embolization (temporary vs. definitive) will be detailed depending of the vascular territory. Follow-up of patients as well as complications will be presented.

Learning Objectives:

1. To be familiar with the arterial anatomy of celiac trunk, superior and inferior mesenteric artery.
2. To understand what are the indications of an endovascular treatment of upper and lower GI bleeding.
3. To detail the technique of embolization in these different territories.
4. To know about other endoscopic or surgical treatment options.
5. To understand how complications and treatment failure occurs in these different vascular territories.

Postgraduate Educational Programme

A-032

C. Percutaneous gastrostomy/Gastrojejunostomy

J. Seitz; Regensburg/DE

The most common indications for gastrostomy or gastrojejunostomy are malignant tumors of the throat or esophagus as well as different neurological diseases. Several conditions make the endoscopic approach of gastrostomy impossible or lead to an unsuccessful endoscopic procedure. This is the indication for radiological guided gastrostomy or gastrojejunostomy. There are two common radiological methods: (1) the fluoroscopically guided procedure and alternatively the CT-guided gastrostomy. Contra-indications for both procedures are severe uncorrectable coagulopathy and major perigastric ascites. Additional contra-indications for the fluoroscopically guided technique are hypertrophy of the left lobe of the liver, interposition of the colon and major surgical procedures of the upper abdomen. The preparation of the patient with a nasogastral catheter is the same for both procedures. The fluoroscopically guided method requires an additional enema of the colon with contrast media or an oral application of barium the day before. Before imaging an intravenous application of a parasympatholytic agent or Glucagon is required. Additionally room air must be insufflated over the nasogastral tube to distend the stomach. After local anesthesia the stomach is punctured and an anchor is placed inside. This access has to be dilated in seldingers technique up to 17 F. Next the 14 F gastrostomy catheter is inserted via a peel-away sheath. The balloon of the catheter has to be blocked with 5 ml of a mixture consisting of 0.9% NaCl and contrast media.

Learning Objectives:

1. To know the indications and contra-indications of gastrostomy/gastrojejunostomy.
2. To be familiar with the preparation of the patient and the information about the procedure itself.
3. To understand the complications, pitfalls and their management.

Imaging of the female pelvis

Moderator:

E. Kuligowska; Boston, MA/US

A-033

A. Infertility

A.J.M. Maubon¹, B. Caire-Gana¹, M. DeGraef², P. Piver¹, Y. Aubard¹, J. Rouanet²; ¹Limoges/FR, ²Montpellier/FR

Epidemiological studies show that 12-20% of couples have an infertility problem. On the female side they can be classified according to the localization of the fertility impairment - uterine factors (Müllerian malformations, DES syndrome, synechia, adenomyosis, ...), tubal factors (tubal obstruction, tubal infection, salpingitis isthmica nodosa, ...), peritoneal factors (endometriosis, inflammatory adhesions, ...), ovarian or central factors (dysovulations, pituitary adenomas, ...). Ancient and more recent imaging modalities (Hysterosalpingogram, tubal catheterization techniques, ultrasound, doppler ultrasound, sonohysterogram, MRI) play an essential role in the diagnostic and therapeutic assessment of these various infertility factors. This lecture will focus on recent developments in this rapidly evolving field, with a special emphasis on pelvic magnetic resonance. Pelvic MR is specially invaluable in the non invasive diagnosis and follow-up of infertile patients. Furthermore we shall detail how, from a medical and a financial point of view, MR imaging will modify the management of patients included in an infertility program.

Learning Objectives:

1. To review the imaging work up for female infertility (ultrasound, magnetic resonance, hysterosalpingogram).
2. To review the imaging features of the main causes of female infertility (tubal obstruction, uterine malformation, adenomyosis, endometriosis, pelvic adhesions) in relationship with their potential treatment.
3. To detail the remaining indications of hysterosalpingogram and selective tubal catheterization.

A-034

B. Endometriosis

K. Kinkel; Chêne-Bougeries/CH

Endometriosis corresponds to ectopic growth of endometrial glandular tissue associated with stromal tissue. Clinical symptoms are chronic pelvic pain, mainly menstrual, and infertility. Endometriosis of the pelvis includes superficial or peritoneal endometriosis, endometriomas or endometriosis of the ovary and deep peritoneal endometriosis which can be located posteriorly (retrocervical, uterosacral ligaments, rectosigmoid, ureter), anteriorly (bladder) or in the vagina. Ultrasound is the initial imaging of choice. Characteristic sonographic features of endometriomas are diffuse, low-level internal echoes, multilocularity and hyperechoic foci in the wall. Differential diagnoses include corpus luteum, teratoma, cystadenoma, ovarian fibroid, tubo-ovarian abscess and carcinoma. Repeat ultrasound is highly recommended for unilocular cysts with low-level internal echoes to differentiate functional corpus luteum from neoplastic ovarian cysts such as endometriomas. Ultrasound is limited in the diagnosis of vaginal and posterior endometriosis. MR imaging has shown a high positive predictive value for all locations of pelvic endometriosis and often demonstrates abnormal nodular structures of T2 low or intermediate signal intensity with occasional T1 hyperintense spots. Knowledge of the most frequent anatomical location of endometriosis and a technical imaging protocol adapted to clinical symptoms are important factors to identify lesions of deep endometriosis, often missed at laparoscopy due to subperitoneal location or presence of severe adhesions. This lecture will focus on imaging signs at ultrasound and MR imaging according to lesion localization, and include clinical case presentation.

Learning Objectives:

1. To identify features of ovarian, peritoneal, vaginal, bladder, rectal and bowel endometriosis at ultrasound and MR imaging.
2. To discuss differential diagnosis in patients with pelvic pain.
3. To compare the value of preoperative imaging modalities according to symptoms and lesion location.

A-035

C. Adnexal lesions characterization and staging

C.S. Balleyguier¹, K. Kinkel², N. Perrot³, P. Morice¹, R. Sigal¹; ¹Villejuif/FR, ²Geneva/CH, ³Paris/FR

Imaging is essential for characterization and staging of adnexal masses. The role of modern imaging is to point out the originating organ, to specify if the process is congenital, functional, hemorrhagic, neoplastic, obstructive or inflammatory and finally to adequately stage the neoplastic diseases before surgery or medical treatment. Adnexal lesions may include lesions of ovaries, fallopian tubes, broad ligament, uterosacral ligaments and their blood and nervous supply. Masses may also arise from the uterus. Non gynaecologic sources of abdominopelvic masses must also be considered.

Knowledge of female anatomy, embryology and physiology is necessary to understand adnexal diseases. Awareness of previous surgery and medical treatment are also helpful for the analysis of organs. Ultrasonography and Doppler US remain the first step to detect and characterize adnexal lesions. Nevertheless, MR imaging is often more accurate, provided an excellent technique depending on the suspected disease and based on multiplanar capability, spontaneous organ contrast and optional enhancement by contrast media. MR imaging carries a better soft tissue contrast than CT and precisely delineates pelvic organs and the pelvic wall landmarks like nodal chains and bones. MR imaging is also the best imaging method for deep pelvic endometriosis and atypical endometriomas. CT can provide useful information about the extent of disease in case of malignancy, and in some ovarian lesions, like teratomas or calcified ovarian tumours.

US and MR imaging appear to be complementary tools for the examination of adnexal diseases. Multidisciplinary approach is mandatory in order to understand the possibilities and limits, advantages and pitfalls of pelvic imaging.

Learning Objectives:

1. To list the most common ovarian tumors, benign or malignant, including main features of prognosis and natural history.
2. To understand why non neoplastic diseases like infection or endometriosis may present as adnexal masses.
3. To understand the role of Doppler ultrasonography for the detection and characterization of masses.
4. To know the standard technique for MR imaging, and to understand how to optimize spatial resolution and tissue characterization.
5. To describe the role of CT, which is mandatory for staging and follow-up of tumors, and may help for tumor characterization.
6. To understand the role of the radiologist in the multidisciplinary approach for decision making.

Infection in the Adult Today

CC 116

Spinocranial infection

Moderator:

R.D. Brüning; Munich/DE

A-036

A. Cranial viral infection

C.F. Andreula; Bari/IT

The central nervous system viral infections are very rare.

Acute encephalitides: Among them arbovirus encephalitis and Japanese B encephalitis, have diffuse lesions with the preferential sites being thalamus and basal ganglia. Enteroviruses encephalitides are very rare. Neuroradiological examination of all these forms could be negative, or in the worst diseases show edema and encephalomalacia. Herpes simplex type 1 encephalitis causes a typical necrotic hemorrhagic meningo-encephalitis. CT is often negative in the first week of infection. MR imaging discloses early initial meningeal involvement, submeningeal edema and hemorrhagic lesions.

Immunomediated encephalitis: The course of ADEM is usually monophasic with synchronous-enhancing lesions. These lesions do not differ greatly from multiple sclerosis plaques. MS lesions are mostly symmetrical, frequently involving the corpus callosum (rarely in ADEM), rarely basal ganglia and thalamus (frequently in ADEM), active plaques enhance and some inactive ones do not.

Subacute encephalitis: HIV encephalitis is caused by the virus itself with slow nervous tissue "intoxication" (atrophy and/or leucoencephalopathy) with MR imaging hyperintensity on long TRWI, with regular outer borders. PML is caused by papova with lesions often being multifocal and rarely symmetrical. MR imaging reveals zones of high signal on T2WI and almost always low signal on T1WI with finger-like outer borders.

Chronic encephalitides: These are caused by unconventional agents (spongiform encephalopathy). Lesions involve the cortex, thalamus and basal ganglia in Jakob-Creutzfeld disease whereas they are frequent in the cerebellum and brainstem in Kuru.

Learning Objectives:

1. To learn the epidemiology, neuropathology and clinical presentation of cranial viral disease in adulthood.
2. To recognise neuroradiological findings in disease, correlating these with neuropathology.
3. To know how to recommend imaging protocols appropriate to a correct examination.
4. To become familiar with differential diagnosis, pathognomonic features, and diagnostic strategies.

A-037

B. Cranial bacterial infection

P.L. Anslow; Oxford/UK

Despite many medical advances many intracranial pathologies, degenerative or neoplastic remain difficult or impossible to treat. Intracranial bacterial infection remains common, is treatable and delayed or unconsidered diagnosis is simply a tragedy.

The lecture demonstrates the various manifestations of intracranial sepsis. There are some clinical presentations which raise suspicions of the disease, other presentations which are frankly confusing. There are some radiological manifestations which are very obvious and some very subtle.

Attention should always be given to the parasite versus host question. How did the infection arrive in the cranium? How did it "beat" the efforts of the immune system to eradicate it? Are there critical numbers of bacteria which are required for an infection to become established? Blood borne infection and direct spread of infection from paranasal sinuses will be considered.

Finally how is intracranial infection treated? Despite effective antimicrobials, surgical intervention is usually required. How should this be done? Needle aspiration or excision? How often should the patient be scanned after definitive treatment?

Learning Objectives:

1. To recognise the classical radiographic features of intracranial sepsis.
2. To understand that whether infection occurs or not is a balance between the number of organisms, their virulence and the host's response.
3. To appreciate the importance of detecting intracranial infection.

A-038

C. Spinal and spinal cord infection

D. Balériaux; Brussels/BE

Spinal and spinal cord infections are severe pathological conditions that should be diagnosed in an early stage to avoid serious orthopedic and neurological complications. MR imaging has nowadays a key role to play and should be available as soon as infection is clinically suspected.

Learning Objectives:

1. To learn to identify the different types of infectious involvement of the spine and how to make an early and accurate diagnosis.
2. To be aware of the respective indications, contributions and limitations of plain films, CT, PET and MR imaging for the diagnosis of different spinal infectious diseases.
3. To be aware of the recurrence of tuberculous diseases of the spine.
4. To know how to identify severe and possibly life threatening complications of spinal infection.
5. To become more familiar with infectious diseases of the spinal cord since they are recently better disclosed by MR imaging.

08:30 - 10:00

Contrast Media

RC 106

Contrast media for MR imaging and US liver imaging

Moderator:

M.-F. Bellin; Villejuif/FR

A-039

A. Non-specific and liver-specific paramagnetic contrast media

G. Morana; Treviso/IT

Paramagnetic contrast media (CM) are able to modify the signal intensity of either the lesion or normal liver parenchyma and thus contribute towards the characterization of the lesion. Non-specific gadolinium chelates such as Gd-DTPA are most effective during the dynamic phase of contrast enhancement, which is an important tool in the identification and characterization of FLL. Unfortunately, dynamic phase imaging alone can, at times, prove unsatisfactory for the accurate diagnosis of hepatic lesions. The current availability of liver specific contrast media (LSCM) give the possibility to obtain an accurate diagnosis on studying focal liver lesions (FLL). It is possible to subdivide FLL into three main groups, according to the kinetic of contrast enhancement: Hypervascular FLL, hypovascular FLL and FLL with delayed enhancement. LSCM with a first phase of extra-cellular distribution give both dynamic (morphological) and late phase (functional) useful informations for lesion characterization. With LSCM it is possible to differentiate with high accuracy benign from malignant lesions and hepatocellular lesions from non hepatocellular ones. LSCM with exclusive distribution to the hepatocellular compartment has a very high sensitivity and specificity in differentiating malignant vs benign lesions and hepatocellular vs non-hepatocellular lesions. The lack of dynamic contrast enhancement by mangafodipir trisodium represents a major shortcoming of this agent. It is necessary to have an in depth knowledge either of the biological and histological characteristics of FLL either of the enhancement mechanism of LSCM to gain significant accuracy in the differential diagnosis of FLL.

Learning Objectives:

1. To illustrate the different possibilities of imaging the liver with paramagnetic contrast media.
2. To increase the confidence of the radiologist with lesion characterization.
3. To describe the different enhancement of the same focal liver lesion with multiple liver-specific contrast media.

A-040

B. Superparamagnetic contrast media for liver imaging

P.J.A. Robinson; Leeds/UK

SPIO contrast agents are stabilised aqueous suspensions of crystalline particles of mixed oxides of iron with magnetic properties. The particles are of colloidal size and are cleared rapidly by the reticulo-endothelial cells of the liver, spleen and bone marrow. Although there is a short-lived T1 enhancing effect whilst the particles are in the blood compartment, the main contrast effect is due to marked shortening of T2* producing a marked loss of signal from normal liver tissue. Of

Postgraduate Educational Programme

the two commercially available SPIO preparations, ferumoxide is given by slow IV infusion, whilst ferucarbutran may be given as a bolus injection. The bolus approach allows dynamic T1 acquisitions which show transient enhancement. A delayed (10 minutes) acquisition shows the T2* contrast effect. SPIO contrast depends upon susceptibility effects so GRE rather than FSE sequences are required.

SPIO is taken up only in normal liver tissue, so increased contrast between tumour and liver allows improved detection of tumours and optimum demonstration of their extent. A recent comparison with multi-slice CT has shown SPIO-enhanced MR imaging to be superior in detecting small metastases. Benign hepatocellular lesions, FNH and adenoma, take up SPIO, whilst metastases don't. In the cirrhotic liver, uptake of SPIO indicates benignity in a nodule, whilst nodules which take up no SPIO may be regarded as malignant.

A double-contrast approach combining post-SPIO T2* sequences with Gd-enhanced T1 images is particularly useful in differentiating benign hepatocellular lesions from metastases, and is the most effective technique for detecting HCC in the cirrhotic liver.

Learning Objectives:

1. To understand the mechanisms for liver contrast enhancement with spio.
2. To be able to prescribe a suitable sequence for using spio in a liver examination.
3. To select appropriate patients for examination with spio and interpret the results correctly.

A-041

C. Bubbles for US liver imaging

T. Albrecht; Berlin/DE

Several microbubble contrast agents for ultrasound (US) have been developed in recent years. In principle, all microbubble contrast agents are blood pool agents, some also have liver-specific properties. In the liver, US contrast agents are used for dynamic assessment of enhancement during the arterial, portal venous and delayed phase. The delayed phase is a specific property of US contrast agents. During this phase the bubbles pool in normal liver and spare malignant focal lesions, such as metastases. The delayed phase is of particular value for detection and characterisation of liver tumours.

The use of contrast agents dramatically improves detection and characterisation of focal liver lesions and has changed the role of US in clinical liver imaging. Contrast enhanced US is about as sensitive as CT in detecting metastases and comparable to MR imaging in characterising focal lesions.

US contrast agents can also be used as tracers for functional studies of liver perfusion. Hepatic transit time is shortened in certain diseases, such as cirrhosis or metastases, and transit time analysis of a microbubble bolus is a promising research tool for early detection of these diseases.

Learning Objectives:

1. To understand the pharmacological and technical basis of contrast-enhanced liver US.
2. To know the dynamic patterns of contrast enhancement of common focal liver lesions.
3. To understand the role of contrast agents in liver US.

Foundation Course - Chest Radiology

E3 120

Anatomy and basic signs in imaging

Moderator:

P. Vock; Berne/CH

A-042

A. Normal anatomy

J. Cáceres; Barcelona/ES

All conventional radiology is based in the interplay of four basic densities: air, fat, soft tissues and calcium. The chest radiograph is, and will continue to be, an excellent method for detecting pulmonary abnormalities, since any pathological process is manifested as an increase in density on the dark background of the healthy lung.

A conventional PA radiograph is the first step when investigating chest disease. Unless it is physically impossible, a lateral chest radiograph should be taken.

In both lungs, there are opacities that correspond to normal structures. They are

the hila, the pulmonary vessels and the fissures. It is basic to know the normal anatomy of these structures because they act as markers of pulmonary disease. A basic question when an abnormality is found is whether it is pathological or simply a normal variant. Fat is ubiquitous in the thorax and may be confused with numerous pathological processes.

Learning Objectives:

1. To demonstrate the importance of knowing normal anatomy to understand pathological changes.
2. To emphasize the value of the silhouette sign in the understanding of normal radiological anatomy.
3. To show normal variants that may be confused with pathology.

A-043

B. Basic findings and signs in imaging

T. Franquet; Barcelona/ES

The diagnostic limitations of conventional chest radiology are well known. A thorough knowledge of roentgen signs in thoracic radiology is required for the detection and diagnosis of chest pathology. Although the discovery of a chest abnormality on conventional radiography may be of great clinical importance, it does not necessarily lead to a definitive diagnosis. Despite recent major advances in thoracic imaging, conventional plain-film still remains the first radiographic study. Recognition of special radiographic signs is useful in chest radiologic interpretation. In this lecture some of these signs are described and their value discussed. Some of the most relevant described signs include the silhouette sign, the air bronchogram, the bulging septum, the extrapleural sign, the S-line of Golden, and the patent bronchus sign. With new cross-sectional technology, signs based on the CT findings have also been described. CT signs include among others the angiogram sign, the halo sign, the mucous bronchogram, and the split pleura sign. This presentation will revisit the commonest conventional and CT signs in thoracic imaging. Emphasis will be placed on the correlation between conventional radiographic presentation and CT findings. Knowledge of these signs will permit the radiologist an accurate interpretation of images as well as a confident diagnostic approach.

Learning Objectives:

1. To describe the characteristics imaging manifestations and significance of the most common radiologic signs.
2. To recognize these signs on chest radiography and/or chest CT.

10:30 - 12:00

Whole-body imaging

Moderator:

M.F. Reiser; Munich/DE

A-044

Whole-body imaging (Introduction)

M.F. Reiser; Munich/DE

The healthcare systems all over the world face major financial problems. Limited resources have to be spent as effectively as possible. Moreover, the population in industrialized countries became more and more aware of the value of early diagnosis and preventive interventions. These global trends resulted in new challenges to radiology: non-invasive, accurate diagnosis, if possible in a one-step approach, instead of a cascade of multiple different diagnostic procedures.

Recently, various modalities have been introduced, which appear to be capable to fulfil these expectations by imaging the whole body. Many diseases, such as atherosclerosis, advanced stages of malignant tumours, lymphoma and rheumatic disorders manifest in various locations rather than in one single organ or body part. Therefore, disease oriented imaging is required and "whole body imaging" may be the best approach.

In this state-of-the-art symposium, the methods for whole body imaging - multi-slice-CT, whole-body MR imaging and PET/CT - will be presented. The contribution of these methods in the early detection and comprehensive diagnosis of cardiovascular and oncologic diseases will be discussed. Even if extensive scientific research is required to explore the capabilities and limitations of different types of whole body imaging, it can be anticipated that they will play an increasing role in the field of our profession.

Postgraduate Educational Programme

Learning Objectives:

1. To describe the technical background of MDCT, whole body MR imaging and PET/CT for comprehensive diagnostics.
2. To inform about the methods and results of whole body imaging in the detection and staging of malignancies.
3. To discuss the technique and diagnostic accuracy of MR imaging in the assessment of cardiovascular diseases.

A-045

Modalities

H.-P. Schlemmer; *Tübingen/DE*

Recent progress in Radiology allows to acquire three-dimensional high-resolved data sets of the whole body within one single examination thus enabling fast one-stop assessment of systemic aspects of diseases. The presentation describes cutting-edge advances in cross-sectional imaging technology radiologists are faces with as whole-body imaging is entering everyday clinical practice. Physical and technical principles of whole-body imaging using helical computed tomography (CT), magnetic resonance imaging (MRI) and the combination of positron emission tomography (PET) with CT in one hybrid scanner (PET-CT) are demonstrated. Relative virtues and limitations of the imaging modalities are discussed against the background that these technologies may shortly become an important and even initial diagnostic approach for evaluating a wide range of diseases, e.g. in oncology or cardiovascular diseases. It is illustrated how advances in information processing and communication technology are necessary and will facilitate imaging data management for improved and accelerated image interpretation. Using high-power workstations diagnostic findings can be reported interactively making whole-body imaging a great help to other clinicians. The technologies will furthermore contribute to a more rapid throughput of patients in the Radiology department. Consequently, whole-body imaging will be an important diagnostic tool in the face of not only medically but also economically optimized patient management.

Learning Objectives:

1. To understand physical and technical principles of whole-body imaging using cross-sectional modalities CT, MRI and PET-CT.
2. To learn relative opportunities and drawbacks of the modalities.
3. To become familiar with the potentials of image post-processing for improved and accelerated image interpretation.
4. To comprehend indications in the face of medically and economically optimized patient management.

A-046

Metastases

A. Baur-Melnyk; *Munich/DE*

Until now MSCT is the method of choice for screening the cerebrum, the thorax and abdomen in patients with suspected metastases. However, new technologies in MR imaging and the development of PET/CT now also allow for a whole body screening. With the introduction of special coil devices and parallel imaging in MR imaging, a whole body imaging approach for the detection of metastases is possible within a reasonable time. Since not all tumors show a pathologic FDG uptake, indications are limited to a number of malignancies, such as bronchogenic carcinoma, head and neck cancer, esophageal cancer, colorectal cancer, lymphoma and malignant melanoma. In CT and MR imaging the detection of lymph node metastases, tumor recurrences in the peritoneal cavity and postoperative tissue changes sometimes is limited. Due to the functional approach with FDG these problems can be overcome by PET/CT. In addition, response of therapy can be monitored. With the combination of PET with CT the resolution is increased, and the definition of the exact anatomic site of "hot-spot" lesions is made possible. PET/CT has shown to be superior over PET and CT alone for the detection of metastatic lesions. Since the brain and the kidney show a strong homogeneous uptake of FDG there is a constrain for the detection of metastases in the brain and kidney. Small lesions < 1 cm in size may not show enough enhancement. MR imaging shows an advantage over PET/CT for the detection of skeletal and liver metastases. MR imaging has limited sensitivity for lymph node and lung metastases.

Learning Objectives:

1. To become familiar with the appearance of metastases in the different techniques of whole body imaging (PET/CT, MR imaging/MSCT).
2. To comprehend the advantages and disadvantages of each technique concerning metastases.
3. To understand the role of whole body imaging in patients with malignant tumors.

A-047

Vascular imaging

S.G. Ruehm; *Essen/DE*

Peripheral vascular disease (PVD) is frequently associated with coronary, renal, and carotid arterial disease. Localizing and determining the severity of arterial lesions is crucial for therapeutic decision making. Recently, whole-body 3D MR-angiography has become available. The technique which is used at our department (1.5 T MR-Scanner (SIEMENS, Sonata, Erlangen, Germany)) employs a rolling table platform (AngioSURF). Five coronal contiguous 40 cm data sets are collected each with a 3D FLASH sequence over 12 s. Taking into account 3 s for table repositioning, the total scan time is 72 s. Paramagnetic contrast agent is administered using a power-injected using a biphasic injection protocol at a dose of 0.2 mmol/kg BW.

Whole body 3D MRA-approach is characterized by non-invasiveness, three-dimensionality, extended coverage and high contrast conspicuity. It allows for a quick, risk-free, and comprehensive evaluation of the arterial system from carotid to tibial arteries in patients with atherosclerosis.

Learning Objectives:

1. To discuss the role of whole-body MR angiography in the management of patients with PVD.
2. To become familiar with typical findings in whole-body MRA.
3. To discuss the role of whole-body MR angiography as a screening tool.
4. To discuss clinical indications for whole-body MRA.

Radiology on the web

D. Caramella; *Pisa/IT*

The Internet provides access to a huge volume of medical information that is directed toward both health care professionals and the public, and that might not be readily available through traditional sources.

Radiologists are aware that a wealth of diagnostic imaging information is accessible on the World Wide Web: this material has the potential to empower the public by improving their understanding of the diagnostic procedures as well as to enhance continuing medical education for professional users.

However, there is growing concern that a substantial proportion of such information that is free from rigorous editorial control might be inaccurate, erroneous, misleading, and thereby causing potential danger.

One of the initiatives that implemented a formal anonymous peer-review process to assure the scientific and educational quality of radiological material published on the Internet is EURORAD, the on-line educational database of the European Association of Radiology (ISSN 1563-4086) that can be accessed free of charge at the address: www.eurorad.org.

EURORAD promotes interactive learning supported by the consultation of multi-modality digital images illustrating common as well as unusual pathological situations.

Presently, EURORAD contains a large variety of teaching files (published in English, French, and Spanish) encompassing all radiological subspecialties and aims to stimulate the professional use of the World Wide Web, by providing sound and up-to-date information that can assist radiological practice and education.

EURORAD exploits the powerful features of the Internet by combining co-operative work, peer review, and universal access.

Learning Objectives:

1. To appreciate the value of Internet for distributing health-related information.
2. To realize the potential risks arising from the wide availability of medical information free from proper editorial control.
3. To understand the specific features of the educational database eurorad.org.

E-mail for the radiologist

E.R. Ranschaert; s'-Hertogenbosch/NL

E-mail has become one of the most popular communication tools, and it is also increasingly being utilised in radiological practice. It is an internet service that is not only used for sending messages between two individuals, but also for participating in (radiological) discussion groups.

For sending and receiving these types of messages, the users must use either a dedicated e-mail client or one of the other mailing facilities offered on the world wide web. The principles and mechanisms of different e-mail services are explained. Several additional functionalities are highlighted, such as the possibility to attach documents and images. Potential problems and concerns, such as virus attacks, spamming and privacy matters are highlighted. It is demonstrated how e-mail can be of value in a professional radiological environment and how it can facilitate communication between radiologists and other medical professionals.

Learning Objectives:

1. To learn the principles of the different e-mail services offered on the Internet.
2. To become familiar with the advantages and disadvantages of using e-mail.
3. To learn how the most frequent problems can be solved.
4. To understand how e-mail can add value to daily radiological practice.

Quantitative imaging: The next paradigm

J.T. Ferrucci; Boston, MA/US

Data acquired from radiological imaging modalities may be described as having three qualities; i.e., anatomical (structural), physiological (functional) and metabolic (molecular). In addition to classic visual inspection, image data is being independently processed to create new windows to diagnostic information. Automated computations can display unique numerical relationships extracted from large data sets, especially from modern CT and MR scanners. Using computer science techniques such as statistical learning theory and pattern recognition, quantitative imaging is evolving as the next paradigm for Radiology.

Principle tools for quantitative imaging include segmentation (digital extraction of voxels), computer aided detection (CAD) used for cancer screening and volumetry for organ, or tumor volumes. Computations are automated, and results can be sorted and edited for reporting. Software resides on clinical diagnostic workstations, and increasingly will be PACS/RIS integrated.

Segmentation, a user defined data separation process, is the first step for both CAD and volumetry, but has its own applications especially in displaying regional anatomy (vessels). CAD is used as a decision-support tool in mammography, lung cancer screening, CT colonography, and liver tumor detection. Automated

volumetric measurements are faster and more accurate than traditional linear or planimetric estimates of volume. Volumetry has many clinical uses, including monitoring growth of liver neoplasms, lung nodules, or colon polyps, and predicting functional organ reserve.

Learning Objectives:

1. To describe quantitative imaging techniques and applications.
2. To review segmentation, computer aided diagnosis and volumetry.

Acute abdomen

G.P. Krestin¹, B. Marincek²; ¹Rotterdam/NL, ²Zürich/CH

Acute abdomen is one of the most common and diverse syndromes in medicine. In its broad sense it refers to various disorders associated with more or less severe abdominal pain of rapid onset. Imaging diagnosis plays a crucial role in differentiating the underlying cause of the symptoms. Narrowing of the differential is based upon localisation of the main symptoms. The instructors will discuss in an interactive fashion the common and more unusual cases with main symptoms localised to the right lower abdominal quadrant, the right upper quadrant, the left lower quadrant, central abdominal pain, diffuse complaints and flank pain. The audience should be able to learn how to approach these cases and use different imaging modalities for establishing the diagnosis. The main focus will be on multidetector CT.

Learning Objectives:

1. To understand the role of different imaging modalities in acute abdomen.
2. To learn possible differential diagnosis based on localisation of main symptoms in acute abdomen.
3. To recognise some selected common and more unusual findings in acute abdominal disorders.

A. Intracranial hemorrhage

T.A.G.M. Huisman; Zürich/CH

Intracranial hemorrhage is one of the most common causes of acute focal neurological deficit in children and adults. Neuroimaging including ultrasonography (US), computer tomography (CT) and magnetic resonance imaging (MRI) is essential in the diagnosis of intracranial hemorrhage. Imaging findings should guide treatment. The highly variable appearance of an intracranial hemorrhage can be challenging. A thorough knowledge of hematoma evolution and US, CT and MR-hematoma characteristics is mandatory for an adequate interpretation of findings. The purpose of this presentation is (a) to summarize the imaging characteristics of intracranial hemorrhage on various imaging techniques and (b) to review the various types of intracranial hemorrhage, and their causes.

Learning Objectives:

1. To give insight in the imaging characteristics of intracranial hemorrhage on various imaging techniques.
2. To review the various types of intracranial hemorrhage, and their causes.

Postgraduate Educational Programme

A-053

B. Intracranial aneurysms

R. Gasparotti; Brescia/IT

Intracranial aneurysms become symptomatic as a result of rupture with consequent subarachnoid hemorrhage (SAH). Unruptured aneurysms may be discovered when they cause neurological symptoms depending on the location and size. With the advent of spiral and multi-slice CT, CT Angiography (CTA) has been proposed as an adjunct to plain CT in investigating SAH and it is under debate whether it can replace intraarterial digital subtraction angiography (IAD-SA) in treatment planning.

Although MR Angiography (MRA) has given good results in detecting aneurysms in acute SAH, it is preferred as a screening modality for patients at risk and for the follow-up of aneurysms treated with endovascular coiling. MRA has the advantage of displaying cerebral vessels without contrast medium, although it provides limited coverage of the intracranial vasculature.

There are several methods to analyze CTA and MRA volumes: once the aneurysm is identified on source images, 3D reconstructions (MIP, SSD or VRT) are used for depiction of the size and orientation of the aneurysm neck and sac and characterization of arterial branching patterns. An accurate anatomical evaluation is useful for assessment of the suitability of an endovascular approach for aneurysm treatment, which has become a valid alternative to surgical clipping. IADSA is still the most sensitive tool in detecting intracranial aneurysms and should be performed within 24 hours from bleeding to ensure a correct therapeutic management of patients. The selective intraarterial injection of iodinated contrast medium ensures optimal enhancement of the intracranial arteries with superior resolution than CTA or MRA.

Learning Objectives:

1. To become familiar with the etiology and classification of intracranial aneurysms.
2. To understand imaging strategies for detecting subarachnoid hemorrhage and aneurysms.
3. To learn how to perform non-invasive screening for cerebral aneurysms.
4. To comprehend the principles, the indications and the effectiveness of the endovascular treatment of intracranial aneurysms.

A-054

C. Cerebrovascular malformations

J.V. Byrne; Oxford/UK

Arteriovenous Malformation of the Brain: The term refers to abnormal cerebral blood vessels comprising feeding arteries, draining veins and an intervening collection of abnormal vessels called the nidus. Diagnosis of large BAVM on CT and MR imaging is relatively easy. Small lesions are more difficult and recent haemorrhage may mask a small lesion. DSA remains the gold standard for excluding BAVM.

Cavernous Malformations: These occur anywhere in the brain but are usually found in subcortical white matter. They consist of closely packed thin-walled vessels without normal interposed brain. On CT they are well-demarcated hyperdense lesions but CT does not show 10% of lesions found at surgery and only 1/3rd of lesions demonstrated by MR. On MR the features are characteristic but not pathognomonic. They are not seen on DSA.

Capillary Telangiectasis: These lesions are ill-defined areas of dilated thin walled capillaries without mural smooth muscle or elastic fibres. Normal brain is found between these vessels. CT and DSA are usually unhelpful but on MR these lesions show hypointense or isointense signal.

Dural AV Fistulas: These lesions comprise arteriovenous fistula(s) situated in the meninges and supplied partly or wholly by dural arteries. CT is rarely diagnostic. Dilated vessels may be seen in the parenchyma (cortex or subcortical) on enhanced scans. Following haemorrhage the findings are those of lobar haematoma with or without subarachnoid haemorrhage. MR may show dilated vessels on the cortex (veins), meninges or extracranial tissues. CE-MRA will help. Catheter angiography is the "gold-standard".

Learning Objectives:

1. To consider 4 types of commonly encountered cerebral vascular malformations.
2. To protocol investigation of the patient presenting with spontaneous cerebral haemorrhage.
3. To logical plan imaging investigations.
4. To learn imaging features of 1. above.

Rectal carcinoma

Moderator:

S. Rafaelsen; Vejle/DK

A-055

Rectal carcinoma (Introduction)

S. Rafaelsen; Vejle/DK

Rectal cancer is a major health problem in Europe. Prognosis and treatment of the disease depend on stage at the time of diagnosis. Local recurrence, as well as liver metastases, are significant causes of morbidity and mortality. The high mortality is presumably also caused by other factors: The examinations performed, the offered treatment including operative techniques, the possible combination of operation with radiotherapy and chemotherapy and post-treatment follow-up.

The treatment of rectal carcinoma has changed over the last years, as far as surgical techniques (with introduction of total mesorectal excision) and radiotherapy are concerned. With the implementation of the new treatment options local recurrence rates have been considerably reduced. Accurate radiological evaluation of the extension of the tumour into the peri-rectal fat, distance to the mesorectal fascia, involvement of adjacent organs and lymph nodes are essential for best possible treatment planning.

Multidisciplinary teams and quality assurance are important for achievement of optimal treatment planning.

Learning Objectives:

1. To hear about the different methods in the diagnosis.
2. To understand the importance of accurate staging.
3. To discuss the possible effect of post-treatment follow-up.

A-056

Diagnosis

F.-T. Fork; Malmö/SE

Symptoms of rectal carcinoma depend on type, extent and complications, including bleeding, tenesmus, sensation of incomplete evacuation and mucous discharge. Abdominal discomfort is absent until perirectal tissue is involved.

Change in bowel habit may develop over a long period of time.
Occult blood in stool: Testing for occult blood is low in sensitivity but high in specificity and inexpensive. It demands dietary restriction. Positive tests require further examinations.

Digital exploration: Tumours in the anal part of the rectum may be explored if not soft and villous.

Flexible sigmoidoscopy: About 60 percent of colorectal cancers are within the reach of flexi sig. Rectoscopy with stiff instruments should therefore be discarded.

Total colonoscopy: If any of the above tests are positive a total colorectal exploration should be contemplated to rule out and remove suitable synchronous lesions.

Barium enema examination is sensitive for mass lesions but not for a histologically early, superficial malignancy and a protruding one less than 5-10 mm. Therefore, barium enemas ought to be replaced by colonoscopy in patients at risk for CRC.

Colonography based on CT and MR imaging techniques are still under clinical testing. Results report figures of sensitivity in detecting neoplastic lesions bigger than 5 mm in par with colonoscopy. Results based on routine studies of patients with an average risk for colorectal cancer disease show less favourable figures.

Learning Objectives:

1. To understand the role of imaging in the management of patients with colorectal cancer.
2. To understand the virtues and shortcomings of diagnostic techniques available today.
3. To select first imaging modality based on clinical patient data.

Postgraduate Educational Programme

A-057

Staging

C.I. Bartram; Harrow/UK

The Dukes classification gives an indication of prognosis, and the TNM system tumour penetration and nodal involvement. However, it does not account for the variation in T3 survival, nor relates lateral tumour extent to the mesorectal fascia, the preferred plane of surgical dissection. Fascial involvement implies total mesorectal excision (TME) will not be feasible and pre-operative chemo-radiotherapy indicated to downstage the tumour to allow TME and prevent local recurrence. Early T1 cancers may be considered for local excision provided there is no nodal involvement.

CT is valuable for large, clinically fixed lesions to determine local infiltration. Rectal endosonography (RES) remains the optimum modality for T staging, though liable to overstage T2 lesions, if an inflammatory response is not recognised. Perirectal stranding on MR imaging may be just due to desmoplastic response, though tumour infiltration is difficult to exclude. The main strength of MR is to define the mesorectal fascia and to relate the lateral tumour margin to this using high spatial resolution T2w sequences at right angles to the long axis of the tumour. The criteria for nodal involvement has been mainly size, although there is considerable overlap between reactive and involved nodes both on RES and MR imaging. Border contour and signal intensity characteristics are more discriminatory.

Learning Objectives:

1. The pathological rationale for the surgical management of rectal cancer.
2. The role of endosonography.
3. MR imaging of rectal cancer in relation to the mesorectal fascia and nodal involvement.
4. Limitations and problems imaging rectal cancer.

A-058

Post-treatment follow-up

T.J. Vogl; Frankfurt a. Main/DE

Purpose: To evaluate the role of imaging techniques and interventional procedures in the post treatment follow-up of rectal cancer.

Methods and Materials: Techniques of MR imaging protocols for the evaluation of the rectum and small pelvis are based on T1- and T2-weighted protocols and contrast-enhanced images using dynamic and diffusion imaging. MSCT protocols are based on the evaluation of raw data and 3D reconstruction protocols.

Results: Depending on the results of the primary staging, follow-up protocols will be presented using MR imaging techniques or MSCT protocols. For the evaluation of the small pelvis, PET will be discussed as well as techniques for the evaluation of distant metastases in the lung, liver, lymph nodes and bones. For the verification of a local recurrence CT- or MR imaging-based interventional biopsy techniques will be presented.

Conclusion: Cross-sectional imaging techniques allow a precise follow-up evaluation after treatment of rectal cancer. Under certain circumstances the additional use of PET and biopsy techniques is necessary.

Learning Objectives:

1. To understand the clinical question.
2. To define the examination strategy.
3. To analyze images of the rectum.

16:00 - 17:30

Imaging of the lymphatic system

Moderator:

S.C. Efremidis; Ioannina/GR

A-059

Imaging of the lymphatic system (Introduction)

S.C. Efremidis; Ioannina/GR

During the past two decades technological improvements in computed tomography (CT), advances in high resolution power Doppler ultrasonography (US), the development of tissue specific contrast media in magnetic resonance (MR) imaging and refinements in lymphangioscintigraphy have severely curtailed the use of conventional oil-contrast lymphangiography, which has long been considered the

standard of reference for lymphatic imaging. However, the techniques mentioned above have neither the ability to visualize the lymphatic vessels nor have they the accuracy of conventional lymphangiography to demonstrate the internal architecture and show metastases in normal sized nodes. On the other hand, lymphangiography in contrast to CT, MR and US is a traumatic procedure, tedious to perform and time consuming, unable to routinely visualize in its entirety, the regional lymphatic system of common pelvic malignancies. All of these reasons have contributed to its dramatic decline in popularity. Therefore, despite past and current innovations, evaluation of the lymph nodes and lymphatics remains the "Achilles heel" of imaging.

Imaging of the lymphatic system is a forgotten frontier. Yet, prognosis and treatment of neoplastic diseases are not infrequently based on this art. Moreover, this system has a major role to play in the propagation and limitation of disease processes providing both a barrier to their extent and, a conduit to their spread. Finally, visualization of the lymphatics is very important in some congenital, hereditary, circulatory, traumatic and inflammatory disorders affecting this system.

Recently there has been some research devoted to visualizing univascularly the lymphatic system and identifying micrometastases in lymph nodes.

Learning Objectives:

1. To learn the anatomic- imaging correlation of the normal lymphatic drainage systems.
2. To understand the interaction of lymph vessels and nodes in the limitation and spread of diseases.
3. To discuss the role of imaging in various lymph vessel diseases (congenital, inflammatory, neoplastic).

A-060

The lymphatics: Clinical considerations

M. Bellomi; Milan/IT

Lymphatic ducts drain interstitial fluid and macromolecules, playing a major role in many diseases involving the intercellular space. Malfunction of lymphatic drainage leads to liquid stagnation within the tissues and eventually lymphoedema. This condition is common in Filariasis but may be caused by surgery or radiotherapy.

Lymphatics play a major role in tumor spread, involving both surgical approach and staging modalities. Sectorial surgery is based on the knowledge of the lymphatic drainage pathways, resecting the tumor and extending the resection to lymphatic "bed", where the diffusion of neoplastic cells is probable: This happens today in breast and colonic tumors resections, and is under research for possibly reducing demolitive surgery in tongue tumors. Imaging of lymphatic pathways draining the tumor can be obtained by lymphoscintigraphy or by injection of dyes during operation: This not only helps to decide on the surgical margins, but also the identification of sentinel node(s).

Nodal staging is a key-point in therapeutic management of many tumors and knowing the path of lymphatics is important to target the sophisticated techniques to define nodal status. The clinical impact of N staging is very important in some tumors at early stages (prostate, ovary); in other tumors (i.e. lung, rectum, pancreas) imaging is less important, since their surgical approach already foresees loco-regional nodal dissection. The detection of distant nodal metastases is always mandatory, because they are outside the conventional surgical bed, and when imaging is aimed to staging, the entire lymphatic drainage net from different tumors has to be kept in mind.

Learning Objectives:

1. To learn the function of the lymphatic drainage.
2. To understand the clinical importance of the lymphatic drainage in surgical planning of some tumors.
3. To learn how to correctly stage Nodal status of neoplastic patients.

A-061

Normal lymphatic drainage

S.C. Efremidis; Ioannina/GR

Evaluation of the lymphatic system* requires knowledge of lymph flow pathways dictated by its anatomy. The anatomy of the lymphatic system can be separated into pathways of the upper and lower extremities, neck, mediastinum, upper abdomen, lower abdomen and pelvis. This lecture will focus on the anatomy of this system in the abdomen and pelvis with emphasis on lymph drainage because of its complexity and frequently confusing pathological configuration.

The lymphatic route is composed of afferent and efferent lymphatic vessels and lymph nodes. Lymphatic vessels in the abdomen and pelvis course within the subperitoneal space (including that of peritoneal reflections i.e. ligaments, mesenteries and omenta), providing an important natural pathway for extension of the pathological processes.

Postgraduate Educational Programme

Lymph nodes in the abdomen are also extraperitoneal lying within the retroperitoneal space or its subperitoneal continuation, where they form discrete groups. Terminal groups are the retroperitoneal nodes divided into pre-aortic, para-aortic and retro-aortic groups. These groups have their own large area of visceral drainage via lymphatic trunks of intermediary nodes representing steps of the natural lymph flow from the regional nodes of the abdominal and pelvic organs to the cisterna chyli. A key to understanding the lymph drainage in the abdomen is the lymphatic anatomy of the lesser omentum which provides a conduit for disease extension from peritoneal organs such as the stomach, liver, gallbladder, bile ducts and duodenum to retroperitoneal tissues via the hepatoduodenal ligament. *Term "lymphatic system" in this lecture is used to denote lymphatic vessels and lymph nodes only.

Learning Objectives:

1. To familiarize with localization, identification and terminology of lymphatic vessels and lymph nodes.
2. To comprehend the complex anatomy of lymph drainage in the abdomen and pelvis.
3. To understand the pathophysiology of disease extension using the lymphatic route.
4. To present certain relatively discrete configurations of nodal involvement in the abdomen.

A-062

Imaging of lymph vessel disease

S.G. Ruehm; Essen/DE

Knowledge of the status of lymphatic vessels and nodes is important for various diseases. Reflecting the small size and indistinct tissue properties of the lymphatic system, display of the lymphatic system requires contrast agents that can be delivered by using different routes.

Direct lymphography, usually performed with fluoroscopic guidance with iodinated contrast agents, permits enhancement of only those lymph nodes contained within the draining route of the cannulated vessel. Although it provides the highest accumulation of contrast agent in lymph nodes, the technique has been abandoned owing to its invasiveness, technical difficulties, and potential for side effects (pulmonary embolism, local wound infection). Indirect lymphangiography, using interstitial injection of iodinated contrast agent to delineate draining lymph vessels has been proposed. However, the technique could not find its way into clinical routine. Selected display of lymph nodes is also possible after intravenous administration of contrast agent. Authors of several studies have described the use of ultrasmall iron oxide particles (USPIO) for systemic lymph node display in conjunction with magnetic resonance (MR) imaging. Results have been mixed, as nodal accumulation of contrast agent appears unreliable, and images depict many artefacts. Alternatively, the contrast agent can be administered into the subcutaneous interstitium. Several MR imaging agents have been evaluated for this purpose, including USPIOS and Gd-based compounds. New developments in contrast agents in combination with recent sequence designs might allow the implementation of MR based imaging techniques with the advantage of combining functional information about local lymphatic drainage with high resolution data acquisition.

Learning Objectives:

1. To discuss the role of MR lymphography for the diagnosis of lymphatic disease.
2. To become familiar with possible approaches for MR lymphography and its underlying principles.

16:00 - 17:30

Room E2

Abdominal and Gastrointestinal

RC 401

Abdominal trauma

Moderator:

J.S. Laméris; Amsterdam/NL

A-063

A. The radiologist's role in the trauma team (organisation and triage)

P. Huppert; Darmstadt/DE

There is no radiological field where the radiologist is more integrated into an interdisciplinary team than in trauma management. Consequently he should be aware of general principles in trauma management and the role of diagnostic and interventional radiology for patients triage.

Radiologists have to make sure that state of the art radiography, (Multislice-) Spiral-CT and diagnostic and therapeutic angiography are available at any time and within an appropriate distance to the emergency room. Imaging procedures have to be standardized according to protocols available at any time. Accepted rules of interdisciplinary trauma management should be discussed in advance, including standards for imaging and intervention.

Radiologists have to be familiar with typical findings in trauma patients and with specific problems of critical periods: detection and management of ongoing bleeding during the first hours and complications around the 3rd week.

Radiologists have to make sure that modalities, technicians and instruments are on stand-by if patients arrive at the hospital, that studies proceed without time delay according to protocols, that positive and suspected findings are communicated immediately and that a reliable written report and complete image folders are available to all members of the trauma team at any time.

Learning Objectives:

1. To discuss the overall organisation of radiology in the trauma team.
2. To review the essential needs of personnel and equipment.
3. To describe patient triage, logistics and outcome.

A-064

B. How to image the trauma patient

O. Chan; London/UK

The advent of small portable US machines, PACS and in particular MDCT scanners, has opened new pathways for the management of severely polytraumatised patients and hence the role of the emergency radiologist (ER) has changed dramatically over the past 10 years. Clinical evaluation in the obtunded patient has been shown to be unreliable and misleading and the role of US and CT in evaluating this group of patients is now clearly established. Subsecond imaging with > 32 MDCTs, potentially allows up to 9600 images to be acquired in 1 minute. The delay in transporting patients into CT from the emergency resuscitation room is no longer acceptable in these scenarios. Patients should be transferred from the ambulance or helicopter, directly to the CT scanner, where basic resuscitation can be carried out with simultaneous imaging of the whole body.

This will allow patients to be accurately and rapidly assessed both clinically and radiologically, regardless of the patient's haemodynamic status. "Conventional wisdom"/management can now be challenged using this form of algorithm and hopefully, the doughnut of death can be renamed "The doughnut of life"!

Learning Objectives:

1. To discuss the relative merits of individual radiological techniques.
2. To learn who, when and where to image polytraumatised patients.
3. To understand the changing face of trauma imaging - role of MDCTs and the ER.

A-065

C. The role of intervention

P. Goffette; Brussels/BE

Investigation of polytraumatized patients with multidetector CT, which enables precise evaluation of solid organ trauma, leads to a more conservative management of all abdominal trauma irrespective of their grading.

Advances in CT technology have improved the identification of both contrast extravasation and non-bleeding vascular injuries and can predict the need for embolization in low-grade trauma. Contrast blush (CB) on CT after splenic fracture is not an absolute indication for immediate angio-intervention. Conversely, CB after liver trauma is associated with a significantly greater risk of mortality and needs systematic angio-embolization.

The liberal use of angiography and the technical refinements in embolization have broadened the indications and improved the results of the non-operative management in high-grade injuries.

Immediate angiography should be performed in the following settings:

1. As primary damage control modality in lieu of devastating surgery in unstable patients suspected to develop massive retroperitoneal or pelvic hemorrhage.
2. After damage control laparotomy for complex hepatic or mesenteric injuries in order to detect and treat deeply located vascular lesion not detected at surgery.
3. For all high-grade (IV-V) hepato-splenic or renal injuries, irrespective of the hemodynamic status.
4. To stop visceral bleeding in stable patients and obviate otherwise unnecessary surgery.
5. To differentiate CT findings of "ongoing hemorrhage" from small intra-parenchymal or intra-muscular CB or venous bleeding which don't require intervention.

Postgraduate Educational Programme

Endovascular hemostasis is achieved in 88 to 100% of the cases. Failures are nearly always due to delayed intervention or underestimation of the severity of injury on CT. Post-embolization complications are rare.

Learning Objectives:

1. To discuss the indications and contraindications of vascular intervention.
2. To identify the CT findings which should lead to angiographic intervention.
3. To learn the principles and technical rules of hemostatic embolization in polytraumatised patients.

16:00 - 17:30

Room F1

Cardiac

RC 403

Cardiomyopathies

Moderator:

R. Couliden; Cambridge/UK

A-066

A. Hypertrophic cardiomyopathy

J. Bogaert; Leuven/BE

The characteristic finding of hypertrophic cardiomyopathy (HCM) is an inappropriate myocardial hypertrophy in the absence of an obvious cause for the hypertrophy, such as systemic hypertension or aortic stenosis. Familial clustering is often observed, and the disease is genetically transmitted in about half of the cases. The natural history and clinical presentation of HCM are variable. Symptoms are caused by intraventricular, usually left ventricular outflow tract (LVOT) obstruction; myocardial ischemia and reduced coronary vasodilator flow reserve; diastolic dysfunction; and arrhythmias. Although patients might be completely asymptomatic, HCM is the most common identified cause of sudden cardiac death in young people, due to arrhythmia. Histologically, HCM is characterized by a disorganization and malalignment of the myofibrils, i.e., myofibrillar disarray, which is not unique to HCM but is clearly more extensive in this disorder than in secondary myocardial hypertrophy from pressure overload or congenital heart disorders. In this presentation, the contribution of new cardiac imaging modalities, such as magnetic resonance imaging, in the diagnosis, differential diagnosis and follow-up of patients with HCM will be highlighted.

Learning Objectives:

1. To give an overview of the clinical problem.
2. To learn the techniques.
3. To discuss usefulness and limitations of imaging.

A-067

B. Restrictive cardiomyopathy

O. Vignaux; Paris/FR

Restrictive cardiomyopathy, the least common form of cardiomyopathy, is defined as heart-muscle disease that results in impaired ventricular filling due to increased myocardial stiffness, with normal or decreased diastolic volume of either or both ventricles. Systolic function usually remains normal, at least early in the disease, and wall thickness may be normal or increased, depending on the underlying cause. Outside the tropics, cardiac amyloidosis is the most frequent cause. A number of other infiltrative conditions can result in restrictive cardiomyopathy such as tropical endomyocardial fibrosis and eosinophilic cardiomyopathy (Loffler's endocarditis), glycogen storage diseases, hemochromatosis and cardiac sarcoidosis. Other restrictive conditions include carcinoid heart disease, radiation-induced and anthracycline-induced endomyocardial fibrosis and idiopathic myocardial fibrosis. Clinical signs and symptoms may be similar to those in constrictive pericarditis and Cardiac Magnetic Resonance imaging (CMR) plays an important role in the differential diagnosis (pericardial thickness < 4 mm in restrictive cardiomyopathy). CMR examination with steady-state free precession and velocity-encoded sequences may show biventricular enlargement with normal left ventricular size, increased left ventricular thickness and mass, severe diastolic dysfunction (abnormal E/A velocity ratio), and normal systolic function. Infiltrative cardiomyopathies may exhibit specific CMR findings on T1- and T2-weighted black blood fast spin echo and Gadolinium-DTPA-enhanced sequences (patchy area of increased signal intensity and enhancement reflecting interstitial inflammation or granuloma in sarcoidosis, T2-weighted signal loss due to extensive iron deposit in hemochromatosis). Fibrosis or collagenous scar with expanded interstitial space appears as mid-wall hyperenhancement on delayed Gadolinium CMR.

Learning Objectives:

1. To give an overview of the clinical problem.
2. To learn the techniques.
3. To discuss usefulness and limitations of imaging.

A-068

C. Arrhythmogenic right ventricular cardiomyopathy

E. Di Cesare; L'Aquila/IT

Right ventricular dysplasia is a new entity of unknown origin in the classification of cardiomyopathies. Also known as arrhythmogenic right ventricular cardiomyopathy (ARVC) or arrhythmogenic right ventricular dysplasia, it is a disease of the heart muscle characterised by fibro-adipose atrophy mainly involving the right ventricle and responsible for cardiac electric instability. ARVC is also considered responsible for severe ventricular arrhythmias and sudden death also in young people. Symptomatology includes palpitations, syncope, congestive heart failure. Symptoms usually appear during exercise and progress over time.

MR imaging provides evidence of ventricular dilatation at the outflow tract, thinning and thickening of the wall, kinetic alterations, diastolic bulging areas (especially located at the level of the right ventricle outflow tract) and fatty substitution of the myocardium mainly at the level of the right ventricle. Many radiologists erroneously consider the previously described fatty substitution as the main sign of ARVC, even though an evaluation of fat substitution alone may be a source of error: firstly because isolated areas of fatty replacement are not synonymous with ARVC since small focal fatty areas of fat are also present in the normal patients, and secondly because the MR imaging detection of fat may be overestimated due to partial volume artefacts with normal subepicardial fat.

Moreover, considering the evolutive nature of the disease, the non invasiveness of MR imaging allows the follow-up of these patients and may be considered an excellent screening modality for the diagnosis of ARVC in family members.

Learning Objectives:

1. To give an overview of the clinical problem.
2. To learn the techniques.
3. To discuss usefulness and limitations of imaging.

16:00 - 17:30

Room F2

Neuro

RC 411

Functional MR imaging

Moderator:

M. Papathanassiou; Athens/GR

A-069

A. Technique, protocols and stimulation equipment

S. Sunaert; Leuven/BE

Functional MR imaging is a non-invasive technique capable of depicting brain activity. It is extensively used in the neurophysiological study of the human brain, and more recently clinical applications have appeared in the presurgical workup of patients with brain tumours as well as in the study of the diagnosis and treatment of different neurological and psychiatric diseases.

This refresher course will review both the MR physics and physiological principles underlying the functional MR imaging technique. The Blood Oxygen Level Dependent (BOLD) contrast, as well as other techniques will be discussed. Pitfalls regarding false positive and false negative fMRI imaging activation will be addressed.

It will review the most widely used (clinical) protocols to visualise brain activity during sensory (visual, taste, sensation, auditory, ...), motor and cognitive actions. The difference, advantages and challenges of block and event-related paradigms will be discussed. Details of acquisition and post-processing relevant to the study of specific brain activations will be elaborated on, e.g. on the use of adapted fMRI imaging sequences for the study of the auditory system, where auditory stimuli have to be delivered without interference of the MR imaging scanner noise. Finally, stimulation equipment to deliver visual, auditory, and other stimuli, as well as monitoring equipment to record responses, eye movements, etc. will be covered.

In summary, this part of the RC will introduce the audience to the basic principles, techniques, paradigms and stimulation equipment that is at present used in state-of-the art fMRI imaging studies.

Postgraduate Educational Programme

Learning Objectives:

1. To understand the basic physiological and physical principles underlying blood oxygenation level dependent functional MR imaging.
2. To understand the problems and merits of the most common imaging techniques in functional MR imaging.
3. To learn about the setup of both block and event-related fMR imaging paradigms in a clinical setting.
4. To understand imaging problems in fMR imaging and how to cope with these during fMR imaging data analysis.
5. To learn about the validity, pitfalls, accuracy and limitation of fMR imaging in a clinical setting.

A-070

B. Clinical applications of fMR imaging for intracranial tumors and epilepsy

C. Stippich; Heidelberg/DE

Preoperative fMR imaging of motor, somatosensory and language function is used worldwide by an increasing number of medical centers for safer surgery on brain tumors and epileptogenic foci. The method has not yet reached the status of a standardized diagnostic procedure. Therefore this talk provides the information that is relevant for the successful and responsible application of fMR imaging prior to brain surgery: The functional neuroanatomy of the motor and somatosensory systems and of language is summarized. Optimised clinical fMR imaging protocols and reference data are presented. Physiological and important pathological diagnostic findings are presented as well as the intraoperative validation of the functional localizations in neuronavigators using electrocorticography. Multimodality integration with MEG is presented. Important limitations and pitfalls of preoperative fMR imaging are discussed

Learning Objectives:

1. To learn about the functional neuroanatomy of motor, somatosensory and language associated brain activation.
2. To identify the indications for preoperative fMR imaging in patients with brain tumors.
3. To identify optimized preoperative fMR imaging protocols for patients with preexisting deficit.
4. To learn about normal and atypical findings in preoperative fMR imaging (illustrative cases).
5. To understand the use of fMR imaging in neuronavigation (illustrative cases).
6. To learn about the validity, intrinsic problems, pitfalls and limitations of preoperative fMR imaging.
7. To understand the possibilities of preoperative multimodality functional brain imaging using fMR imaging and magnetoencephalography (MEG) (illustrative cases).

A-071

C. fMR imaging for evaluation of brain plasticity in multiple sclerosis, stroke and trauma

A. Bizzì, V. Blasi; Milan/IT

Plasticity means different things to different scientists, but most would agree with the following definition: a change in structure over time resulting in a change of function.

Plastic changes occur at the level of the synapse, and are consequently reflected at the level of neuronal networks. It has been established that human brains show considerable plastic changes during development and that plasticity is also present in injured adult brains. In patients with lesions of the nervous system plasticity is the active or passive process of reorganizing connections and re-coordinating a network of areas while function is recovering.

Brain functions may be localised in functionally segregated brain regions but are mainly represented in extended, connected, overlapping and highly parallel processing networks. In normal subjects, it is characterised by a decrease of focal brain activity going along with an increased connectivity between the collaborating nets. Recovery of function seems to imply the "reconnection" or the recoordination of a network of areas.

Non-invasive functional neuroimaging methods such as fMR imaging offer the experimental opportunity for measuring changes in connectivity and functional segregation that accompany and underpin behavioural change or functional improvement after brain injury. This presentation will review the potential and limitations of fMR imaging to illustrate plastic changes occurring in patients after a stroke, a head injury or along the course of a relapsing remitting disease such as multiple sclerosis.

Learning Objectives:

1. To learn about acute changes in functional segregation and connectivity occurring after a focal brain lesion.
2. To learn about adaptive changes in functional segregation and connectivity occurring during recovery and their relationship with functional improvement.
3. To learn about changes in motor and language network re-organization induced by rehabilitation.

Head and Neck

RC 408

Radiological approach to stage head and neck squamous cell carcinoma

Moderator:

J.A. Castelijns; Amsterdam/NL

A-072

A. What the clinician needs to know and why

E.J. Adam; London/UK

Head and neck cancer is uncommon, accounting for only 3% of newly diagnosed cancers per annum. Benign disease far outweighs malignant disease in general ear, nose and throat surgical practice and the radiologist has an important role in alerting the clinician to the possibility of underlying malignancy.

Some "benign" presentations, for example middle ear effusions, sinus opacity and cystic neck masses, may indicate underlying malignancy and the radiologist needs to be aware of these potential pitfalls.

Once diagnosed, direct inspection provides excellent assessment of the extent of mucosal involvement by squamous cell carcinoma, but imaging is essential for evaluating the deep extent of disease and involvement of adjacent critical structures. Because these are uncommon cancers, the evidence base for treatment is small with few randomised controlled trials, and there is considerable variation in treatment strategies. The radiologist must be aware of local treatment protocols so that imaging is tailored to evaluate the critical radiological features which may affect the treatment offered to the patient.

The status of the cervical lymph nodes is the single most important prognostic factor. Clinical assessment is generally regarded as inaccurate (sensitivity and specificity 60-70%) and radiological staging is used to increase accuracy. It has a particular role in upstaging disease in the clinically negative neck and in the detection of contralateral disease, both of which will affect therapy. It is also important that radiologists and clinicians working together in this field use the same system for describing the sites of abnormal nodes for surgical planning.

Learning Objectives:

1. To appreciate the clinical context of head and neck image interpretation.
2. To be aware of radiological features which will influence treatment.
3. To understand the value of clear communication between radiologists and clinical teams.

A-073

B. Nasopharynx

M.G. Mack, T.J. Vogl; Frankfurt a. Main/DE

The nasopharynx forms an important boundary zone between the anterior and middle skull base and the parapharyngeal space. Diagnostic imaging is used in this region for morphologic evaluation, localization and staging of primary lesions of the nasopharynx.

The nasopharynx forms the upper portion of the pharynx and is continuous anteriorly with the nasal cavity. Its' roof is formed by the sphenoid bone, while its' floor and junction with the oropharynx are at the level of the soft palate. The pharyngeal recess (Rosenmüller fossa) is a pouch-like recess in the lateral wall of the nasopharynx directed toward the parapharyngeal space and lying directly adjacent to the Eustachian tube orifice. This region is a common site of origination for nasopharyngeal malignancies. Five percent of all malignant tumors of the head and neck originate in the nasopharynx and more than 90% of these are carcinomas. MR imaging is extremely helpful to demonstrate the extent of a mass in three dimensions and, most importantly, MR imaging can define the relationship of the mass to cranial nerves V, IX and X. However Multidetector CT (MDCT) is also helpful in the evaluation of the nasopharynx, especially if multi-planar reconstructions are used.

This presentation will focus on normal anatomy, benign and malignant tumors,

Postgraduate Educational Programme

congenital variations and malformations as well as the differential diagnosis.

Learning Objectives:

1. To learn the normal anatomy.
2. To learn the examination technique.
3. To know about different tumors, variants, differential diagnosis and imaging criteria.
4. To learn about tumor staging.

A-074

C. Oral and oropharyngeal cancer

R.C. Sigal; Villejuif/FR

In the oral cavity and oropharynx, cancer most often arises from the oral mucosa. Therefore the radiologist only plays a minor role in the detection of the disease but helps to define the exact extent of the lesion. Imaging plays an important role in therapeutic planning. The choice for the various types of surgery (partial or complete glossectomy, mandibulectomy) is dictated by invasion of the muscles of the tongue and the neurovascular bundle of the tongue, as well as the various subregions of the oropharynx (faucial area, soft palate, posterior oropharyngeal wall). Evaluation of the mandible is of paramount importance. Computed Tomography and Magnetic Resonance Imaging are the imaging modalities of choice. Imaging is also important in the follow-up and in the early tumor recurrence detection.

Learning Objectives:

1. To present the CT and MR techniques in the exploration of the tongue and oropharynx area.
2. To show the main patterns of tumor spread.
3. To explain the value of imaging at the posttherapeutic stage.

A-075

D. Laryngeal cancer

R. Hermans; Leuven/BE

About one quarter of head and neck tumours arise in the larynx. The majority are squamous cell carcinoma. As most laryngeal malignancies are mucosal lesions, inspection is important in staging the lesion. Imaging is needed to detect deep tumour spread into the paraglottic space, cartilage involvement and extralaryngeal tumour spread.

Criteria for tumour involvement are abnormal contrast enhancement, soft tissue thickening, presence of a bulky mass, infiltration of fatty tissue, or a combination of these features. CT can detect gross cartilage invasion, but often fails to detect early invasion. MR imaging is a more sensitive technique to detect cartilage invasion, but may yield false positive results. Overall, CT and MR imaging show comparable results in defining laryngeal tumour extent. In selected cases, these modalities may be considered to be complementary.

Surgery and radiotherapy are the only curative treatments for laryngeal cancer; chemotherapy can be used as an adjunct to one or both of these treatment modalities. Most early-staged laryngeal cancer can be cured by either surgery or radiotherapy, with similar cure rates for similar lesions. Patients with moderately advanced lesions may benefit from combined therapy. Advanced lesions often can only be treated palliatively.

The treatment plan for a particular patient is the result of a multifactorial decision process including tumour characteristics, tumour staging and volume, patient condition, and patient and institutional preferences. Objective tumour data, obtained from imaging studies, can be helpful to ensure a firm basis for informing the patient about his prognosis and for treatment decision making.

Learning Objectives:

1. To know the CT and MR appearances of laryngeal carcinomas.
2. To know the appearance of tumoral extensions into deep laryngeal structures.
3. To know the involvement of imaging modalities in the establishment of tumoural staging.
4. To understand the role of the TNM classification in the determination of the appropriate therapeutic modality.

History of contrast media

Moderator:

G. Livadas; Athens/GR

A-076

History of contrast media (Introduction)

G. Livadas; Athens/GR

This year's history session has been arranged so that it focuses on a single subject, the development of contrast media. The theoretical concept for a medium that would assist the visualisation and investigation of hollow organs is almost as old as the X-ray, since the first experimental papers on the subject appeared as early as 1896. In this session we will explore the evolution of contrast media from the primitive form of toxic and harmful compounds used in cadavers or guinea pigs, to the most sophisticated organ-specific, pathology-specific or modality-specific agents used in today's radiological practice. The speakers will present the pioneers and how they strove to excel and conquer the unknown, in an effort to understand the ideals and virtues of the talented individuals in relation to their social environment.

Learning Objectives:

1. To comprehend that any single product that commercially reaches the market is a result of a multitude of contributors' brainwork, research, trials, attempts and errors.
2. To discuss the intricate ramifications of ideas, starting as an individual conception and either ending as a failure or leading to a remarkable invention.
3. To promote the necessity of the recording and the study of all aspects of the history of radiology.
4. To stimulate younger radiologists to look into their history as a source of inspiration.
5. To stress the responsibility we all have not only to the patients but equally importantly, towards the future generations of radiologists to come.

A-077

The early years of contrast media

A.M.K. Thomas; Orpington/UK

The latter part of the 19th Century was a time of rapid development. In surgery, antisepsis was introduced by Joseph Lister and in 1865 the first operation was performed using his technique. The first anaesthetic was given in 1846 by William Morton. Unfortunately the visualization of the body prior to surgery was limited, although the first cystoscope had been introduced by Max Nitze in 1879. It was only when Wilhelm Röntgen discovered X-rays in 1895 that medical radiology was born with abdominal imaging becoming a reality. However, imaging of the abdomen was poor owing to the lack of contrast between the abdominal viscera. The use of contrast media enabled abdominal structures to be visualized, and normality and pathology defined.

In the renal tract, radiographs could be made after the passage of opaque ureteric catheters and the location of the ureters determined. This was first performed in 1901 by Schmidt and Kollscher. Opaque liquids could be injected as suggested by Klose in 1904. A suspension of bismuth sub-nitrate was initially used, however this was toxic in the renal tract. The technique of retrograde pyelography was refined in 1906 by Voelcker and von Lichtenberg and they produced the first complete outline of the ureters and renal pelvis. The problem of toxicity of the early agents was solved in 1918 when Douglas Cameron recommended the use of sodium and potassium iodide.

The retrograde contrast agents were the mainstay of renal imaging for 30 years and much knowledge of renal pathology was acquired.

Learning Objectives:

1. To understand the 19th century medical background to diagnostic radiology.
2. To learn about the development of clinico-radiological correlation in the diagnosis of normality and disease.
3. To learn about the early use of contrast material in abdominal imaging.

The classical ionic contrast media

C. de Haén; Milan/IT

Technological innovation comprises the affirmation on the market of a product that responds to a unmet societal need. Solutions of water-soluble iodinated organic compounds for intravascular injection as X-ray contrast media (CM), which in 1930 made excretion urography and angiography practical and commercially viable, responded to this criterion. The innovation process involved both institutions and individuals, who with their background contributed to constructive interference of different knowledge cultures.

By the mid 1920's CM for excretion urography and angiography assumed the character of a vision of technology, namely the locus on the perceptive horizon where the line of temporal extrapolation of feasibility meets with that of desirability. Under its spell a web of interactions between numerous academic investigators (Hryntschat, Binz, Räth, Lichtwitz, Swick, von Lichtenberg) and three industries (DEGUSSA, Bayer, Schering-Kahlbaum) with their researchers (Ossenbeck, Tietze, Hecht, Schoeller, von Schickh) formed. Since 1897 through a series of commercial injectable CM, iodine had acquired the status of a preferred constituent. Only a few months apart in 1930 two iodinated uro-angiographic CM reached the market, uroselectan (Schering-Kahlbaum) and methiodal (Bayer/IG Farben). These CM bore a salified acid function. The ratio of iodine atoms per particle formed in solution was $I/P = 0.5$. Although osmolality at the time was not considered, soon CM with ratios of 1 and 1.5, i.e. reduced osmolality, became available. Along with reduced osmolality came reduced toxicity. In particular, numerous products with $I/P = 1.5$, epitomized by diatrizoate, conquered the markets in the 1950s and are still widely used in certain parts of the world.

Learning Objectives:

1. To become conscious of the social dimension of technological innovation, contrast media in the three decades following 1925 illustrating this.
2. To recognize the interplay of multiple knowledge cultures in innovation, for contrast media in particular those of chemistry, physiology, pharmacology, pharmaceuticals, radiology, internal medicine, patenting, industrial production, project management, entrepreneurship, communication, marketing and sales.
3. To appreciate the historical heritage recognizable in modern contrast media.

A-079

The development of the non-ionic contrast agents

T. Almén; Malmö/SE

I try to remember how the concept "non-ionic contrast media with high water solubility" arose. Ingredients were:

1. A desire to reduce pain caused by the iodine contrast media of the 1950s when injected for arteriography.
2. An interest in chemistry stimulated by arteriographies in animals.

Basics: The water soluble media for arteriography were salts. Three iodine atoms (with high X-ray absorption) covalently bound to a benzene ring constituted the anion. Sodium or methylglucamine (with low X-ray absorption) constituted the cation. The media had an osmolality 5-8 times greater than plasma.

Impulses: Some episodes during clinical arteriography gave me the belief that the pain might be decreased if contrast media isotonic to plasma could be created.

Logic: The question arose: "How do you design contrast media based on three-iodinated benzene rings, which gives a higher water solubility, lower osmolality and lower viscosity for the same amount of iodine?" My naïve thinking suggested: 1) Eliminate the positive ions and make the iodo-benzenes watersoluble by covalently bonded, hydrophilic hydroxyl groups. This means a 50% reduction in osmolality. 2) For further reduction dimers, trimers, oligomers of such three-iodinated benzene rings could be tried. 3) Make the molecules small and spherical for low viscosity.

The real world: These ideas were discussed in 1968 with Dr Hugo Holtermann, head of research at Nyegaard & Co, a small Norwegian pharmaceutical company. This resulted in a non-ionic medium, metrizamide, primarily intended for the subarachnoid space. Development has continued and today various non-ionic monomers and dimers are produced by different companies for various indications.

Learning Objectives:

1. To become conscious of the social dimensions in technological innovation.
2. To recognize the interplay of multiple knowledge cultures in innovations. For contrast media this concerns chemistry, physiology, pharmacology, pharmaceuticals, diagnostic radiology, internal medicine, patenting, industrial production, project management, entrepreneurship, communication, marketing and sales.
3. To appreciate the historical heritage recognizable in modern contrast media.

A-080

MR imaging contrast agents

H.-J. Weinmann; Berlin/DE

In the early eighties NMR tomography (today MRI, Magnetic Resonance Imaging) became a new, exciting imaging technology. Lauterbur, Brady and others demonstrated that paramagnetic salts could effectively change relaxation times and create contrast in MRI.

In 1981, Gries, Rosenberg and Weinmann synthesized and characterized paramagnetic chelates as contrast agents for MRI. The Schering patents covered the fundamentals of this class of MRI contrast agents.

Independent of the activities in Berlin, paramagnetic contrast agents (e.g. Cr EDTA, ferrioxamine B, stable free radicals) were tested at the UC in San Francisco, the Vanderbilt University in Nashville, and Mallinckrodt Inc. in St. Louis. The first clinical trials started in 1983 (FU Berlin). The first successful contrast enhancements in patients were at the Hammersmith Hospital in London in 1983. In 1988, various health authorities granted marketing authorization for Gd DTPA (Magnevist®). Other gadolinium-based agents were introduced into the market several years later.

Independent of the described contrast agent technology, superparamagnetic particles were investigated. Advanced Magnetics (Cambridge, MA, USA) received FDA approval for ferumoxides, introduced in 1995 (Endorem, Guerbet, France, or Ferridex, Berlex Laboratories Inc., USA). The second generation of superparamagnetic iron oxides became available in Europe (Resovist®, Schering AG, Germany) in 2001.

Gadolinium-based contrast agents with a specific distribution in the organism are in clinical development and may reach the market within the near future. MRI technology is still in a development phase and it is very likely that improvements in technology and contrast agent development will result in more tissue- and disease-specific agents.

Learning Objectives:

- To understand the historical development of MR contrast agents.

16:00 - 17:30

Workshops on Interventional Radiology

WS 418

Arterial and venous liver intervention

Moderator:

J.B. Karani; London/UK

A-081

A. Portal venous embolization

A.J. Roche; Villejuif/FR

Curative resection of malignant liver tumors closely depends on the volume of the remnant liver (RL) after hepatectomy. The aim of portal vein embolization (PVE) is to selectively induce hypertrophy of the RL during the preoperative period. This is achieved by embolization of portal branches of the future resected liver parenchyma. Basis for understanding the mechanisms involved in inducing hypertrophy after PVE will be given. Technical choices (approach, embolic agents) will be detailed and discussed. Indications for patients with hepatocellular carcinoma or metastases will be presented as well as short and long term results. An adverse effect of PVE might be stimulation of tumor growth in the RL. This critical point will be specifically discussed. State of the art of known prognostic factors for predicting hypertrophy after PVE and liver failure after surgery will be presented for patients with normal or compromised liver (chronic hepatitis, cirrhosis, long term previous chemotherapy, cholestasis).

Learning Objectives:

1. To understand the mechanisms of induced hypertrophy after portal vein embolization.
2. To choose the appropriate technique: Surgical or endovascular proximal ligation versus distal embolization, type of embolus to use.
3. To know the indications and results in liver metastases and hepatocellular carcinoma.
4. To know the effect of embolization upon tumor growth in the non-embolized liver.
5. To know the efficiency in compromised liver (previous IV or IA chemotherapy, cirrhosis).

Postgraduate Educational Programme

A-082

B. Chemoembolization

I. Battyány; Pécs/HU

The effectiveness of intraarterial selective cytostatic treatment and chemoembolization was analysed separately and in combination with surgery and/or RF ablation in patients suffered from liver malignancies. The duration of the selective intraarterial cytostatic treatment took 5 days and ended with chemoembolization. Mytomycin (1 x 10 mg), Farmorubicin (5 x 10 mg), Carboplatin (5 x 40 mg) for intraarterial cytostatic treatment and for chemoembolization Farmorubicin (10 mg), Lipiodol Ultrafluid (3-6 ml) and Iodamide 380 (1 ml) suspension were applied. The treatment was repeated six times in period of 4-6 weeks. Results of the treatment were controlled by US and CT. The chemoembolisation applied in combination with 5 days selective cytostatic treatment showed better results than chemoembolisation applied alone or together with less than 5 days selective cytostatic treatment. The surgery or RF ablation combined with intraarterial cytostatic treatment and chemoembolization are highly increased the survival time in HCC patients and significantly in metastatic patients. In vitro effectiveness of RF treatment alone and in combination with intraarterial liver chemoembolization was also analysed with help of perfused in vitro (pig) liver model.

Learning Objectives:

1. To know how to increase the effect of radiofrequency with chemo-embolization.
2. To know what is the correct order in the combination of different oncoradiotherapy methods to improve the therapeutic result.
3. To know the benefits of multimodality treatment.

A-083

C. Budd Chiari syndrome

J.-I. Bilbao Jaureguizar, A. Martínez-Cuesta; Pamplona/ES

Budd-Chiari syndrome (BCS) is caused by obstruction of the hepatic venous flow and characterized by the presence of ascites, hepatomegaly and abdominal pain. Clinically indistinguishable from hepatic venous occlusive disease, BCS is secondary to an obstruction of the major hepatic veins or even the inferior vena cava that can be secondary to multiple clinical situations. Different surgical procedures have been described to improve the decompression of the portal system when medical treatments become ineffective. As an alternative, several percutaneous techniques have been reported for treating BCS. The reported long term results with such techniques are at least as good as with surgery.

Learning Objectives:

1. To know the different etiologies of Budd-Chiari syndrome (BCS).
2. To understand the embryologic origin of the inferior vena cava.
3. To be familiar with the different radiologic modalities for establishing the diagnosis of BCS.
4. To know the different percutaneous approaches that may be performed for the treatment of BCS.
5. To know when to place a stent or perform a percutaneous transluminal balloon angioplasty in BCS.

Imaging problem lesions (tumors)

Moderator:

A. Magnusson; Uppsala/SE

A-084

A. Adrenal imaging

G.P. Krestin; Rotterdam/NL

Clinical symptoms of adrenal diseases are due to hormonal hyper- and hypofunction and to the large size of an adrenal mass. Incidentally found asymptomatic adrenal masses are very common findings on cross sectional examinations. Therefore differentiation of "incidentalomas" is important and may be challenging. Besides non-hyperfunctioning adenomas and metastasis - the two most common adrenal incidentally found masses - other diseases like cysts and pseudocysts, fatty lesions, mesenchymal tumors, solid cortical tumors, medullary neurogenetic tumors, infections and granulomas have to be considered. Imaging features of these different entities will be presented and the differential diagnostic approach based on clinical and morphologic appearance will be discussed.

Learning Objectives:

1. To understand the clinical context that allows a pragmatic approach to imaging of adrenal lesions.
2. To become familiar with the imaging techniques and their specific features in different common adrenal tumours.
3. To learn about the differential diagnostic approach to some rare conditions affecting the adrenal glands.

A-085

B. Renal imaging

R. Pozzi-Mucelli; Verona/IT

Although diagnostic imaging modalities are extremely accurate in the diagnosis of renal masses, diagnostic difficulties are sometimes encountered with US, CT and MR imaging. The main diagnostic problem is the differential diagnosis between benign and malignant tumors, mainly in cases of complex cystic masses and in some solid masses.

A greater number of problematic masses are found with US. Diagnostic difficulties with US are due to technical limitations and/or the complexity of the lesion itself. Technical limitation are due to limited spatial and contrast resolution. Other limitations are due to artefacts and obese patients. For complex cystic masses, the difficulties in the definition of the benign or malignant nature of the lesion is due to the presence of some findings such as calcifications, septae, vegetations, blood and purulent debris. For solid masses, problems concern the identification of small tumors, the differentiation among the anatomical variants, the differentiation between benign (i.e. atypical angiomyolipoma, oncocytoma) and malignant (renal cell carcinoma) tumors. The contribution of colour-power Doppler and contrast media in the solution of some of the diagnostic difficulties will be illustrated. Problematic renal masses can be seen, although in a less number of cases, with CT and MR imaging. Indeterminate masses in CT are due to very small size, internal septae, blood, debris. Also with CT the differential diagnosis between some benign tumors (atypical angiomyolipoma and oncocytoma) and malignant tumors is difficult. MR imaging has similar difficulties but it provides a higher contrast resolution enabling better characterization of fluid content in cases of hemorrhagic cysts.

Learning Objectives:

1. To show the problematic renal masses with US, CT and MR imaging.
2. To demonstrate the possible solutions in order to differentiate benign from malignant lesions.
3. To show the importance of integration of diagnostic imaging modalities.
4. To report the advances of US, CT and MR imaging and the role of contrast agents.

Infection in the Adult Today

CC 416

Chest

Moderator:

M.-F. Carette; Paris/FR

A-086

A. Community-acquired and nosocomial infections

C.J. Herold; Vienna/AT

Pulmonary infections are among the most frequent causes of morbidity and mortality throughout the world. In the non-immunocompromised population, pneumonia is one of the top two infectious diseases and represents the most prevalent community-acquired infection (CAP). Nosocomial pneumonia (NP) is the leading cause of death from infection acquired in the hospital.

In CAP, most individuals are infected through person-to-person transmission of microorganisms bound to or suspended in water-mucus droplets. NP is the result of aspiration of gastric contents or contaminated oropharyngeal secretions.

Infections in CAP are commonly caused by gram-positive bacteria, atypical bacteria, and viruses. The most important pathogens in NP include aerobic gram-negative organisms and *Staphylococcus aureus*. Viruses, protozoa, and fungi play an increasing role in patients with impaired defense mechanisms.

In CAP and NP, the typical radiologic findings include lobar pneumonia, bronchopneumonia (lobular pneumonia), and rarely, diffuse bilateral interstitial disease. Nodules may be seen in mycobacterial infections. Complications include necrosis, cavitation, bronchopleural fistula, and pleural effusions.

Postgraduate Educational Programme

In both entities, the role of radiology includes detection and exclusion of pulmonary infiltrates (which may be difficult in NP), narrowing of the differential diagnosis, guidance of additional (invasive) procedures, and patient follow-up.

Learning Objectives:

1. To help understand the epidemiology and the causative factors of CAP and NP.
2. To elucidate the spectrum of causative microorganisms in both forms of pneumonia.
3. To present the radiologic features and patterns of different infections.
4. To discuss the role of imaging methods in the investigation of patients with suspected pneumonia.

A-087

B. Infection in AIDS and the immunocompromised patient

T. Franquet; Barcelona/ES

Pulmonary infection is a major cause of morbidity and mortality in patients with impaired immune function. In the last several decades, the AIDS epidemic, advances in the treatment of cancer, organ transplantation, and immunosuppressive therapy has resulted in large numbers of patients who develop abnormalities in their immune system. Mildly impaired host immunity, as it occurs in chronic debilitating illness, diabetes mellitus, malnutrition, alcoholism, advanced age, prolonged corticosteroid administration and chronic obstructive lung disease, has also been regarded as a predisposing factor for pulmonary infections. Although plain chest radiography, in most cases, provides adequate information and CT is usually not required for diagnosis, in some cases CT might be used as a problem-solving tool.

Learning Objectives:

1. To summarize the high-resolution CT findings of some of the most common infectious processes seen in AIDS and in immunocompromised non HIV patients.
2. To describe some complications associated with pulmonary infections.
3. To learn key points in distinguishing infectious diseases from other non-infectious pulmonary disorders.

A-088

C. The spectrum of tuberculosis and non-mycobacterial tuberculous infection

S.M. Ellis; London/UK

The spectrum of radiographic findings in pulmonary infections due to *M.tuberculosis* (TB) and non-tuberculous mycobacteria (NTM) are being increasingly discussed, primarily as a result of the increasing prevalence of these infections. NTM organisms are often overlooked as potential infecting organisms, diagnosis is often delayed and radiologists tend not to include NTM in their differential diagnosis. The literature on the imaging appearances of NTM pulmonary infections is now sufficiently large as to identify some features that would help to distinguish an NTM infection from conventional pulmonary tuberculosis (TB), allowing the radiologist at least to raise the possibility of NTM infection. This review is intended to describe the radiological features, in the immunocompetent host, that accompany TB and NTM pulmonary infections and highlight the imaging features that would favour an NTM as the causative organism.

Learning Objectives:

1. To increase awareness of radiographic appearances of mycobacterial infections in the chest.
2. To highlight features that may help distinguish different mycobacterial organisms.
3. To understand the implications the organism type has on management.

What molecular imaging actually is

C. Bremer; Münster/DE

Molecular imaging is one of the emerging research arenas for imaging related sciences. This talk intends to provide a brief definition of the term "Molecular Imaging". Selected imaging examples will be given in order to present the whole scope of this research field. Moreover an overview of the "Primer on Molecular Imaging" is provided including a presentation of the speakers and aspects covered in this new lecture series.

Learning Objectives:

1. To briefly explain the main goals of molecular imaging.
2. To introduce the speakers of the "Primer on molecular imaging".

A-090

A. Parametric and molecular MR techniques

C. Moonen; Bordeaux/FR

Molecular Imaging (MI) includes all imaging modalities and builds on the full deciphering of the human genome by looking at spatio-temporal maps of gene expression levels and its consequences. Selected examples of MI approaches using MR imaging are:

1. Visualization of tumor activity by targeting angiogenesis by directly mapping altered gene expression levels or indirectly using biomarkers such as perfusion. Processes related to apoptosis and degradation of the extracellular matrix can be mapped based on specific contrast agents targeting annexin V and Matrix Metalloproteases, respectively. Once specific markers are found, radiopharmaceuticals, and/or drugs can be attached to locally deliver therapy.
2. Local delivery of a gene therapy vector using real-time image guidance, and mapping expression of a marker gene. Spatial and temporal control of transgene expression can be achieved based on a combination of MR imaging-guided local hyperthermia and a heat-sensitive promoter.
3. Homing of stem cells as gene therapy vectors and for tissue repair. Stem cells have been isolated, labeled with MR contrast agents, then re-injected and tracked towards their target using serial MR imaging.

Recent advances have demonstrated the large potential of multi-modality MI. MR imaging requires amplification strategies to reach the high specific sensitivity of optical and Nuclear Medicine techniques. Its role in translational MI research and development of biomarkers will be significant. Further progress is needed in:

1. development of clinically relevant biomarkers,
2. specific contrast agent design,
3. development of combined diagnostic/therapeutic agents,
4. development of image-guided technologies for local drug delivery and local gene therapy.

Learning Objectives:

1. To review the emerging field of molecular imaging using MR imaging.
2. To illustrate the strategies to develop targeted MR contrast agents to evaluate endogenous and exogenous gene expression.
3. To understand the concept of MR biomarkers in the field of (anti)angiogenesis, macrophage activity, metabolism.
4. To illustrate the concept of MR image guided local molecular therapy.

A-091

B. Optical imaging

V. Ntziachristos; Charlestown, MA/US

The ability to non-invasively image molecular processes in-vivo is an emerging reality using different reporter and detection approaches. Molecular imaging has been heralded to lead to earlier detection than current anatomical imaging approaches, which typically detect late stage abnormalities. By construction the approach is highly specific as reporting probes can be engineered to be reporting on certain molecules with good discrimination capacity. Another important prospect of molecular imaging is the ability to examine and quantify treatment responses in-vivo by monitoring specific primary molecules or downstream tar-

Postgraduate Educational Programme

gets. Therapeutic efficacy could then be probed dynamically on time-scales of hours to days. This is in contrast to the mainstay of today's healthcare with traditionally late end points of drug efficacy, a practice that often impairs prompt revision and exclusion of ineffective treatment strategies with potentially lethal results. Still we are significantly limited in the ways we can accurately detect such reporter technologies in tissues associated with high photon scattering and non-linear light propagation. This talk presents the current state of the art as well as revolutionary new technologies that enable accurate and sensitive optical molecular imaging. These technologies enable practical strategies for recording of proteomics and genomics in-vivo and are designed with the clinical application in mind. Therefore they attain high potential for clinical translation and impact.

Learning Objectives:

1. To understand the basic principles of optical imaging and tomography.
2. To outline optical imaging strategies and applications.
3. To gain insights on potential clinical applications.

A-092

C. Nuclear imaging including PET

M. Schäfers; Münster/DE

The spectrum of clinically available imaging methods has a wide range of modalities capable of investigating morphology, function and molecular processes. Within this spectrum scintigraphic (nuclear) imaging modalities are widely used to characterize organ function and molecular pathways in the whole body *in vivo*. These techniques are based on the concept of labelling authentic or analog molecules with radioactive isotopes, which either are detected by direct gamma-emission (single photon emission tomography SPECT: Tc-99m, I-123 etc.) or indirect by coincidence of two high energy gamma quants (512 keV) originating from an annihilation of a positron in the tissues (positron emission tomography PET: F-18, C-11, O-15 etc.). These radiopharmaceuticals are then injected intravenously, their distribution in space and time are assessed three-dimensionally by either SPECT or PET.

Especially when used in molecular imaging, *in vivo* scintigraphic imaging approaches are uniquely able to assess molecular processes with a very high sensitivity without influencing the physiology/pathophysiology.

The state-of-the-art role of scintigraphic imaging in research and clinical applications will be reviewed.

Learning Objectives:

1. To learn about the high molecular sensitivity of scintigraphic approaches as compared to MR, CT and ultrasound.
2. To know the spectrum of currently available radiopharmaceuticals and molecular scintigraphic techniques.
3. To understand the principles and challenges of quantification (compartment models etc.) of molecular metabolism *in vivo*.
4. To hear about potential clinical scintigraphic applications.

Tele-imaging in Europe today

Moderator:

K.-J. Klose; Marburg/DE

A-093

A. Introductory lecture on teleradiology

L. Donoso; Sabadell/ES

Teleradiology is the electronic transmission of radiographic images from one geographical location to another for the purposes of interpretation and consultation. In many respects teleradiology is the best telemedicine service. It is already part of daily practice. The current clinical uses of teleradiology will be discussed from primary interpretations to on-call coverage in inter and intra-institutional scenarios.

There are many technical challenges in teleradiology, including image acquisition, transmission and interpretation. It is important to recognize that image distribution in teleradiology scenarios is only an enabling component of a much larger goal that requires both new technology (integrated information system) and new practical culture. The term "teleradiology" itself will be obsolete, remote interpretations and consultations will be such an integral part of radiology practice that referring to them will neither require nor occasion a special term.

Teleradiology clearly has a number of advantages but it also has the potential to create considerable difficulties for radiologists unless their role and the legal responsibilities involved are defined and debated.

Radiologists must now fundamentally become partners in the leadership of the process: rethink the approach to image management and distribution, promote integration of information, bearing in mind that radiology is a clinical specialty rather than just a reporting service.

Learning Objectives:

1. To discuss the impact of IT in health scenario from the radiology focus.
2. To share our experience in new working scenarios using teleradiology.
3. To recognise key factors in the process.
4. To introduce the concept of replacing teleradiology with inter-institutional networking.

A-094

B. The mobile teleradiology

J. Reponen; Oulu/FI

The development of wireless networks and terminal devices has made mobile communication to image archive systems possible. The access is nowadays possible outside the fixed hospital network and even outside physical hospital boundaries.

The mobile teleradiology units are based on different technical platforms ranging from laptop computers to mobile phones. Most promising terminal types for medical purposes are Smartphones with computer functions, Personal Digital Assistants (PDA) with phone capabilities or tablet PC devices with networking capabilities. Various wireless networks are available ranging from WLAN to GSM and GPRS.

The main limitations of current technology are relatively slow network speed, restricted computational power and a small display for image viewing purposes. For selected tasks their service is acceptable even today.

The clinical needs are basically twofold: within a hospital there is a need to serve the users of electronic patient record with radiological images. A tablet PC might be one mobile tool replacing a paper journal on wards. On the other hand, mobile teleradiology terminals have so far been used for viewing images needing a secondary consultation. A Neuroradiologist on duty can make his remarks on an emergency CT scan with a help of an image phone. A Neurosurgeon can make decisions based on image data even before entering the hospital. The benefit of mobile devices will be greatest, if they can be connected to a comprehensive electronic patient record. Especially well they perform together with a web type multimedia medical record where only a thin client software is needed.

Learning Objectives:

1. To understand the different technical platforms for mobile teleradiology and their restrictions.
2. To understand the clinical needs of multimedia terminals for radiologists and other specialities.
3. To evaluate the present and future role of mobile image viewing service.

A-095

C. Results in practice: The Norwegian experience

J. Størmer; Tromsø/NO

Norway had early pilot projects in Teleradiology (first one reported in 1984) converted to permanent services with a considerable volume per site (7,000 – 8,000 exams a year) since 1992.

PACS also has been rapidly and largely accepted in almost 100% of the 50 hospitals since the very first was installed in the Lofoten Islands in 1996.

Since 2002 the Norwegian health care system has changed fundamentally in its organisation with a shift from local/regional ownership shared between the 20 counties to a more centralized and government based ownership. Actually the country with close to 4,6 million inhabitants is divided in five independent regions, each organised as private enterprises with government as majority owner and thereby protected from bankrupts. Each region has adopted different strategies in order to create interoperability between the PACS and other clinical information systems (HIS) in their medical institutions. National authorities have since year 2,000 planned for a nationwide Health Intranet. Different local and regional initiatives (mainly proprietary Teleradiology solutions since early nineties) has resulted in a convergence ending up in an applicable and standardized National Health Net in operation since October 2004. This has facilitated and accelerated the different initiatives to interconnect PACS's. Still difficulties in interoperability between PACS and RIS from different vendors are an obstacle in the process of integration. Legal aspects are another challenge for the developers or pioneers in connecting medical information systems to the benefit for the constantly more mobile and demanding modern patient.

Postgraduate Educational Programme

Learning Objectives:

1. To discuss the basis of a nationwide teleradiology system.
2. To understand the key of the success for a teleradiology system.

Interstitial and alveolar disorders

Moderator:

C. Schaefer-Prokop; Amsterdam/NL

A-096

A. Diffuse infiltrative lung disease

D.M. Hansell; London/UK

High resolution computed tomography (HRCT) is a powerful and accepted technique which is now routinely used for the investigation of patients with suspected or known diffuse infiltrative lung disease. However, when interpreting the results of the various studies that have evaluated the diagnostic accuracy of HRCT, and encouraged its widespread clinical application, several factors need to be borne in mind: a) there is inevitably a selection bias with a relatively high proportion of conditions which have distinctive HRCT appearances. In this respect, the study populations do not reflect the case mix encountered in "normal" clinical practice, b) such studies are retrospective and are usually undertaken by highly experienced observers, and c) new or "difficult" conditions (e.g. non-specific interstitial pneumonitis) and normal individuals are under-represented.

HRCT provides a similar view of the lung as a low power scan of an autopsy or lung biopsy specimen and it is not an overstatement to suggest that HRCT images reflect histological appearances. Once the mechanism behind the generation of the basic HRCT signs is understood, interpretation is greatly facilitated. For example, the situations in which ground glass opacification on HRCT (essentially caused by nothing more or less than the displacement of air) will be encountered can readily be predicted. It must be emphasized that the *indirect* HRCT signs of fundamental pathologic processes are not wholly reliable. An appreciation of the limits of HRCT and a basic understanding of the pathophysiology of diffuse lung diseases increases the quality of HRCT interpretation.

Learning Objectives:

1. To clarify the borderland between normal state and early diffuse lung disease.
2. To understand the generation of basic HRCT features of diffuse lung disease.
3. To appreciate the limits of sensitivity and specificity of HRCT.
4. To avoid some of the obvious pitfalls in HRCT interpretation.

A-097

B. Alveolar lung disease and atelectasis

P.A. Grenier; Paris/FR

Alveolar lung diseases can manifest on chest radiographs or CT as a nodular pattern, ground glass opacification or consolidation. These features express the displacement of air from the alveoli by accumulation of fluid, cells, tissue or amorphous material.

A nodular pattern is made up of rounded opacities that measure 5-10 mm in diameter. Most often the nodular opacities have a patchy distribution and are often associated with airspace consolidation. Nodular pattern is most frequently encountered in the context of bacterial infection. Ground glass opacification is present when there is increased lung density; on CT scans, it appears as a patchy or diffuse hazy increase in lung attenuation with preservation of bronchial and vascular markings. Reticulation may be present in the same areas as ground glass opacification, giving the crazy paving pattern. Airspace consolidation is seen as homogeneous increased opacity with obscuration of underlying pulmonary vessels. This opacity extends to pleural surfaces and presents with fuzzy borders and may contain air bronchograms. Consolidation can be diffuse, patchy or lobar in distribution; it can also appear as rounded, linear or curvilinear opacities. The distribution of changes and the evolution pattern, on both radiographs and CT scans, may be helpful differential features.

Atelectasis or lung collapse is defined by a loss of lung volume. Mechanisms are obstructive, passive, cicatricial or adhesive. The imaging features of atelectasis include decrease in volume of the lobe or segment involved (movement of fissures), hilar and large airway rearrangement, mediastinal shift, compensatory hyperinflation, chest wall and diaphragm positional changes.

Learning Objectives:

1. To enhance the understanding of mechanisms and causes of alveolar lung diseases and lung atelectasis.
2. To illustrate the typical and atypical patterns at chest radiograph and CT of alveolar lung diseases.
3. To familiarize with anatomical displacement of structures in case of lobar atelectasis.
4. To illustrate the typical and atypical patterns at chest radiograph and CT scan of lobar atelectasis.

Cerebral tumors and infections

Moderator:

N. Besenski; Charleston, SC/US

A-098

A. Extra-axial brain tumors

A. Drevelegas; Thessaloniki/GR

Extra-axial are tumors with an extracerebral location. They are usually benign. Meningiomas are the most common extra-axial neoplasms in the supratentorial compartment. Other extra-axial neoplasms are: schwannomas, metastatic lesions, arachnoid cysts, epidermoids, dermoids, chordomas and eosinophilic granulomas. Schwannomas are by far the most common neoplasms of the posterior fossa.

The clinical image depends on the size and the location of the tumor. The location of the brain tumors affects treatment planning and predicts their prognosis.

In the evaluation of extra-axial brain tumors CT and MR imaging represent the two most important and commonly used imaging modalities. CT is superior for detecting areas of calcification and for evaluating bony changes related to the tumor. Multidetector CT (MDCT) is also very helpful in the presurgical evaluation of the tumors. The multiplanar capability and the superior contrast resolution of MR imaging makes it the best technique in the evaluation of extra-axial brain tumors. MR imaging permits more reliable distinction between intra- and extra-axial tumors and provides better delineation of the relationship of extra-axial tumors to the surrounding brain and vital structures involved by the tumor. Additionally MR imaging is also more useful in delineating tumors of the posterior cranial fossa where the beam hardening artifacts obscures their delineation on CT. Imaging studies play an important role in the diagnosis of extra-axial tumors and provide crucial information to the neurosurgeon in preoperative planning.

Learning Objectives:

1. To define and classify extra-axial brain tumors.
2. To demonstrate the imaging characteristics of extra-axial brain neoplasm.
3. To describe the appropriate imaging protocols.
4. To identify some clues for differential diagnosis.
5. To learn how to image the post-operative patient.

A-099

B. Intra-axial brain tumors

G. Wilms; Leuven/BE

Neuroradiology plays a key-role in the diagnosis and preoperative setup of patients with brain tumours. State-of-the-art imaging requires a standardised imaging protocol, careful and systematic study of the images and finally an attempt at characterisation of the lesion.

The radiological diagnosis and differential diagnosis of intra-axial tumours no longer relies on CT-scan and routine MR-sequences alone. Standard multiplanar imaging has to be combined with fMR imaging to allow exact anatomic location of the lesion and precise determination of the extent of the tumour. Perfusion and diffusion MR become more and more important in the differential diagnosis of cerebral mass lesions and in grading and typing of gliomas. More sophisticated techniques such as diffusion tensor imaging and spectroscopy will further enhance the value of radiological studies.

Learning Objectives:

1. To learn the standard imaging protocols for the radiological study of intra-axial brain tumors.
2. To underline the importance of new imaging techniques in the diagnosis and differential diagnosis of intra-axial brain tumors.
3. To give some clues for the differential diagnosis of intra-axial brain tumors.

A-100

C. Cerebral infections

S. Karampekios; Iraklion/GR

In spite of the development of many effective antimicrobial therapies and the general improvement in hygiene and health care systems all over the world, the incidence of central nervous system (CNS) infection has increased significantly in the past 15 years. This can be attributed primarily to the acquired immunodeficiency syndrome (AIDS) epidemic and its devastating effect on the immune sys-

tem and secondarily to various immunosuppressive agents that are being used in aggressive cancer treatment and in organ transplantations.

The brain is relatively protected from infection by the calvarium, meninges, and blood-brain barrier. However, a large number of pathogens, including bacteria, viruses, fungi, and parasites, can reach the brain hematogenously or less likely by direct extension from an adjacent infected focus. When an intracranial infection does occur, the precise localization is of great importance, because it narrows the differential diagnosis, sometimes determining the type of the pathogen, allowing institution of more appropriate treatment, and eventually leading to a more favourable outcome. Magnetic resonance imaging (MRI) is the most sensitive imaging modality in detecting focal or diffuse parenchymal infectious lesions, and today it has clearly replaced computed tomography (CT). By using advanced MRI techniques, such as Proton MR Spectroscopy (¹H-MRS), Diffusion-Weighted (DW) imaging, Perfusion-Weighted (PW) imaging and Magnetization Transfer (MT) sequences, further improvement in the detection and characterization of infectious brain lesions is possible.

Learning Objectives:

1. To become familiar with the different types of cerebral infections, using some broad categories to localize them, by the anatomic compartment involved.
2. To present the various manifestations of AIDS-related infections.
3. To understand the role of advanced MR techniques, such as DWI, PWI, MRS, MT, for the detection and characterization of intracranial CNS infections.

08:30 - 10:00

Room B

Musculoskeletal

RC 510

Osteoporosis and osteopenia

Moderator:

B. Vande Berg; Brussels/BE

A-101

A. Acquired osteoporosis

J.E. Adams; Manchester/UK

During childhood the bones grow in size, alter in shape and increase in mineral content, particularly at puberty. Peak bone mass (PBM) is reached around 20 and bone mineral density (BMD) remains stable for the next two to three decades. PBM is determined by genetic factors (80%), but lifestyle factors (physical activity, nutrition and hormonal status) are also relevant.

Bone "turnover" continues, with old bone being resorbed (osteoclasts) and replaced by new bone (osteoblasts), to maintain integrity and strength. Normal bone mineralization depends on the supply of vitamin D (1,25(OH)₂D), calcium, phosphorus and alkaline phosphatase; deficiencies cause rickets/osteomalacia. Bone formation and resorption are balanced (Basal Metabolic Unit - BMU), but in some diseases become "uncoupled". Formation may be defective (osteogenesis imperfecta, corticosteroid therapy) or resorption excessive (oestrogen deficiency, hyperparathyroidism). Bone deficiency/loss (osteoporosis), reduced BMD and insufficiency fractures result. Characteristic radiological features may have prognostic significance (a prevalent vertebral fracture predicts future fracture risk of vertebra x5 and hip x2). Bone densitometry (DXA) is important to identify those at risk before fractures occur. Effective preventative and therapeutic measures (bisphosphonates, SERMS, vitamin D and calcium supplementation) are available to increase BMD and reduce fractures.

Learning Objectives:

1. To describe the normal growth and development of the skeleton and the factors that influence the attainment of peak bone mass.
2. To explain normal bone turnover and the basal metabolic unit (BMU), and how "uncoupling" through diseases may lead to bone loss and osteoporosis.
3. To outline preventive and therapeutic measures available for secondary osteoporosis.

A-102

B. How to measure and monitor it

S. Grampp; Vienna/AT

The basis for diagnosing osteoporosis is the conventional radiograph, dual X-ray absorptiometry (DXA) (femur, lumbar spine), and quantitative computed tomography (QCT) (lumbar spine).

Conventional radiographs yield a relatively low sensitivity and cannot be used as a screening method.

Postgraduate Educational Programme

For economical reasons and because of the low radiation dose, DXA is of the most clinical relevance. After an initial radiograph of the lumbar spine either a DXA of this region (patients up to 65 and without significant degenerative changes) or at the hip (patients above 65 or with significant degenerative changes) should be performed.

In special cases or if such a device is readily available a QCT of the lumbar spine might be a first-evaluation technique.

General data for the application of densitometry with quantitative ultrasound (QUS) does not currently allow a general recommendation for its' use in diagnosis. The method is currently regarded as an additional technique and can be used for pre-screening to identify healthy women and men.

Learning Objectives:

1. To know the clinically relevant methods to measure and monitor the skeletal status such as DXA, QCT and conventional radiographs.
2. To get the ability in using strategies to apply the radiological methods in the primary diagnosis as well as in follow-up studies and in different patient groups.
3. To know about the major weaknesses and strength of each method.
4. To realize about the major pitfalls related to each method.

A-103 ♀

C. Juvenile osteopenia

T.M. Link; San Francisco, CA/US

Children are not simply small adults and bone mineral density (BMD) measurements in childhood and adolescence are an extremely complex issue. Since bone size, shape and volumetric density vary substantially with age, T-scores are of no use in this population. In addition timing of growth and puberty may also be variable. It is extremely important, however, to diagnose osteoporosis and osteopenia in these patients at an early stage since these deficits will translate into permanent deficits in bone mass in the adult.

The ideal densitometric technique should (1) provide a low radiation exposure, (2) assess true volumetric BMD, (3) provide information on fracture risk and (4) be based on normative data collected from a representative healthy population with various age ranges. Such a technique, however, does not exist at present. Currently, dual energy X-ray absorptiometry (DXA) is most frequently used, since it is fast, has a low radiation exposure and the best-established pediatric reference data. However, areal BMD is extremely dependent on bone size, which may be a big handicap in children with accelerated or delayed development. Quantitative CT (QCT) provides true volumetric density but has a higher radiation dose and there is little reference data.

Indications for bone densitometry in children and adolescents include chronic disorders such as anorexia nervosa and endocrine disorders as well as systemic diseases such as cystic fibrosis, rheumatoid arthritis, osteogenesis imperfecta and neoplastic diseases. Additionally, normal children with fractures due to low impact trauma and patients with the rare idiopathic juvenile osteopenia warrant study.

Learning Objectives:

1. To understand the limitations of diagnostic techniques in a pediatric and adolescent population.
2. To learn the strengths and weaknesses of bone densitometry techniques used for diagnosing juvenile osteoporosis and osteopenia.
3. To be aware of potential indications for BMD measurements in children and adolescents.

08:30 - 10:00

Room C

Special Focus Session

SF 5

High-field body MR imaging: The new standard?

Moderator:

G.P. Krestin; Rotterdam/NL

A-104

High-field body MR imaging: The new standard? (Introduction)

G.P. Krestin; Rotterdam/NL

High-field MR imaging is one of the most exciting, challenging but also controversial areas of development in Magnetic Resonance Imaging during the last years. While there is no doubt that for applications in the central nervous system high-field strengths have clear benefits, the use of whole body 3 T systems for imaging the heart, the abdomen or the musculoskeletal system are much more

controversial. Three experts in the area will discuss body applications of high-field MR imaging.

Learning Objectives:

1. To learn about the technical challenges of high-field body MR imaging in the three different areas of application.
2. To understand the current indications for high-field MR imaging in the cardiovascular and musculoskeletal systems and in the abdomen.
3. To learn about the future trends and developments of high-field body MR imaging.

A-105

Cardiovascular

S. Dymarkowski; Leuven/BE

The intrinsic advantage of an increased signal-to-noise ratio(SNR) at 3 T has stimulated many researchers to use this ultra-high field equipment for studies outside the brain. However, the higher field strength presents specific obstacles to 3 T MR imaging determined by the laws of physics, therefore making the transition from CMR at 1.5 T to 3 T not straightforward. The increased RF-energy deposition (SAR), the larger chemical shift and the stronger susceptibility effects have to be considered as challenges, especially in cardiovascular studies. Development of specific higher order shimming procedures, optimized surface coils and proper sequence adaptation has so far allowed highly detailed anatomical imaging, but has also opened the door for functional exams, including high quality MR tagging studies, contrast-enhanced imaging of myocardial perfusion and infarction, and offers the possibility of coronary artery imaging with formerly unseen spatial resolution.

Cardiac MR imaging exams performed at 3 Tesla are gradually finding clinical acceptance. Looking at the present results and taking in consideration the present advantages and disadvantages of using 3 T for cardiovascular work, it is still unclear to most researchers and clinicians if this is the right path to pursue. Future scientific investments will still need to tackle many currently unresolved issues and to carefully deliberate at which field strength cardiac MR imaging is best performed.

Learning Objectives:

1. To understand the signal-to-noise, imaging speed and SAR trade-offs associated with transferring cardiac MR imaging from 1.5 T to 3 T.
2. To understand how imaging at 3 T requires significant changes in pulse sequence parameters.
3. To understand how inherent benefits at 3 T can be used as an advantage in cardiac MR imaging.

A-106

Abdomen

S.M. Hussain; Rotterdam/NL

The development of a body coil and radio frequency coils for a 3 Tesla MR imaging system, and their recent approval in Europe and North America, facilitated its application as a whole body MR system. With about double the signal-to-noise ratio of a 1.5 T system, the 3.0 T MR systems dramatically improve the image quality and image acquisition speed. Higher signal-to-noise allows more imaging flexibility. Theoretically, 3.0 T can deliver half the voxel size or, in certain cases, enable one-quarter of the acquisition time of a comparable study done at 1.5 T. Additional resolution and speed could be used in a number of ways: 1) increased resolution: to visualize small structures in greater detail; 2) shorter acquisition times to reduce motion artifacts when imaging patients unable to perform extended breath holds; 3) improve both acquisition speed and resolution. Anatomy that is difficult to image at lower field strengths, such as the prostate, rectum, uterus, and ovaries, could be imaged without an internal coil, significantly reducing patient discomfort and preparation time. Faster breath-hold body imaging - with or without parallel imaging capability such as SENSE - is offered as a standard feature by several vendors. In this lecture, we will present our experience concerning the body applications of 3 T based on volunteer studies and patients, and will explain some of the difficulties that occur during sequence optimization.

Learning Objectives:

1. To review the differences between 3 T and 1.5 T for body imaging.
2. To point out the current advantages and possible future directions of 3 T for body imaging.

Postgraduate Educational Programme

A-107

Musculoskeletal

D. Weishaupt; Zürich/CH

Magnetic resonance (MR) has revolutionized musculoskeletal imaging because of high spatial resolution, multiplanar imaging capabilities and exquisite soft-tissue contrast. So far, clinical MR imaging of the musculoskeletal system is performed at magnetic field strengths ranging from 0.2 to 1.5 T with dedicated surface coils. Recently, whole body MR systems working at 3.0 T have become available for clinical use. 3.0 T MR systems provide various benefits for body MR imaging including increased signal-to-noise ratios (SNR), enhanced T2^{*} contrast, increased chemical shift resolution, and probably better diagnostic performance compared to magnets working at lower field strengths. The higher intrinsic SNR of 3.0 T systems can also be used to improve imaging speed. However, when imaging at 3.0 T there are several changes to consider including changes in relaxation time, increased artifacts and increased radio-frequency (RF) power deposition.

Learning Objectives:

1. To discuss advantages and limitations of musculoskeletal imaging at 3.0 T.
2. To understand the changes in RF- and relaxation characteristics with 3.0 T.
3. To review the differences of imaging at 3.0 T compared to imaging at lower field strength.
4. To identify potential applications of 3.0 T imaging for musculoskeletal diseases.

Open questions

Moderator:

G. Forrai; Budapest/HU

A-108

A. Technology assessment

E. Azavedo; Stockholm/SE

Technology Assessment is an important step in managing modern health care. This assessment can be divided into several parts and the most common way usually is seen from a technical point of view assessing physical details of a radiological image. The next part is assessment of the overall quality of an image to see the diagnostic details that one wishes to see. The modern approach to Technology Assessment is to assess the role and place of modern technology in a health system.

The lecture will show examples and discuss how new technology is and will be assessed by the health providers because it is a matter of economy that has to be related to the additional information that new technology may give us. We could also have new technology giving us the same old information but at a more economically attractive level and these kind of economic aspects will probably dominate the choice of future technology investments.

If a new technology needs more time and/or more total costs are involved in this new technology than the costs of existing modalities than it may be hard to convince our health providers to approve the usage of such a modality in routine clinical practice. On the other hand medico-legal implications will also force us to turn our eyes to modalities with the highest sensitivity and specificity and this type of equations are not easily solved. The lecture will cover these above mentioned aspects by showing examples of published data.

Learning Objectives:

1. To present the basics of technology assessment.
2. To discuss two cases: Introducing full-field digital mammography and large vacuum biopsy.
3. To discuss the use of technology assessment within Europe.

A-109

B. Reporting standards

H. Zonderland; Leiden/NL

In mammography, reporting a classification, based on risk assessment is the cornerstone of good patient care, as it improves the clarity of the findings and leads to optimal interdisciplinary communication. The Breast Imaging Reporting and Data System™ (BI-RADS) has been developed and revised three times since 1992 by the American College of Radiology. The newest edition also includes Ultrasound and MR imaging. It is not restricted to final assessment categories

alone, but also attempts to unify morphologic descriptive features, follow-up and outcome monitoring. It has become obligatory in accredited institutions in the US and utilization of BI-RADS in Europe is increasing. This presentation will outline considerations needed in order to consider implementing the use of BI-RADS in the European community. There are distinct advantages: Optimal inter-professional and inter-institutional communication, standardization of reporting and ease of outcome monitoring. On the other side, sometimes fine-tuning, tailored to local conditions, is missing. Also interobserver variability can hamper good comparison. One can discuss some morphologic definitions as well as definitions with respect to outcome monitoring. They are undoubtedly well-suited for the American system of health care, but sometimes need some adaptations in situations or studies performed on other grounds. The system is the product of an excellent collaborative effort between members of various committees of the American College of Radiology, but should also be discussed on European level, before full acceptance can be achieved.

Learning Objectives:

1. To discuss the need of correlation between mammography, ultrasound and pathology reports.
2. To discuss the benefits and limitations of BI-RADS.
3. To propose a method for breast imaging audit.

A-110

C. Screening planning

A. Evans; Nottingham/UK

Mammographic screening is only effective if the intervention is of high quality. To achieve this level of performance obligatory training of professional groups and a rigorous quality assurance process are essential. Screening centres have to be large enough to allow statistical evaluation of performance and for the staff to gain sufficient experience. Screening and symptomatic breast work is often best done by the same team.

Small invasive cancer detection rate is a good surrogate for overall screen performance but quality assurance visits to screening centres to assess multi disciplinary team work are also invaluable. Mammographic screen reading should be done by a limited number of high volume readers all of whom participate in screening assessment, as a number of studies have correlated performance with volume and access to feedback. Volume and performance are also seen to correlate in performance of breast pathologists and surgeons.

The best film reading practice is double reading with arbitration and given the shortage of radiologists across Europe this is often done by radiographic technicians. There is good evidence that radiographers have identical sensitivity and specificity as radiologists of similar experience. The introduction of full field digital mammography will make the use of CAD a practical possibility. As yet there is no evidence that single reading with CAD is equal to double reading with arbitration.

Learning Objectives:

1. To present the basics of screening planning.
2. To correlate with the problems of screening in Europe (enhance radiologists shortage).
3. To discuss the helping of radiographers and CAD.

Liver imaging: Characterisation and pitfalls

Moderator:

A. Palkó; Szeged/HU

A-111

A. Calcifications

C. Stoupis; Berne/CH

Although calcified liver lesions are not often seen in imaging studies in daily practice, many represent inflammatory lesions or benign and malignant liver neoplasms. Even though a specific diagnosis of a calcified mass is not always possible, there are some additional imaging features (presence of mass effect, nature of the calcified mass -cystic, solid- and the presence of scar) that may indicate the correct diagnosis. In calcified granulomatous disease (e.g., tuberculosis), the calcification (solitary, multiple) typically involves the entire lesion (no mass effect) and produces artifacts on CT. Echinococcus cysts have curvilinear or ring

Postgraduate Educational Programme

calcifications. E. alveolaris appears with calcification in a mass, mimicking malignancy. Chronic abscess may have discrete calcifications, mimicking treated metastases. In the case of hemangiomas, calcifications are solitary, large, coarse and centrally located in areas of fibrosis (CT 20%, plain film 10% of cases). In the case of hepatocellular adenoma, calcifications may be multiple, heterogeneous and usually located eccentrically within a heterogeneous mass. Primary malignant neoplasm, such as fibrolamellar carcinoma (CT 15%-25% of cases), demonstrate solitary, stellate, calcifications located in a scar (very rare, focal nodular hyperplasia, may calcify, in 1-2% of cases!). Calcifications in intrahepatic cholangiocarcinoma (18% of cases) are typically accompanied by a desmoplastic reaction and are ill defined. Calcifications in cystadenocarcinoma are associated with multiloculated, inhomogeneous cystic masses with solid components. Calcified hepatic metastases are most frequently associated with mucin-producing neoplasms such as colon carcinoma, are multiple, ill defined, amorphous and associated with a mass.

Learning Objectives:

1. To learn the pathological characteristics of calcified liver lesions.
2. To define the technical imaging aspects for the study of the liver in case of calcifications.
3. To learn the imaging characteristics of calcified liver entities.

B. Fat

C. Valls; Barcelona/ES

Diagnosis and characterization of fat in the liver is a diagnostic challenge because with most diagnostic techniques the presence of fat in the liver will significantly impair the quality of the examination. MR imaging offers significant advantages in that setting. There are two basic MR techniques that can be used to detect and characterize fatty lesions in the liver: Chemical shift imaging and fat saturation techniques. Chemical shift imaging techniques take advantage of the difference in resonance frequency between triglycerides and water protons. In in-phase images the signal from water and lipid protons is additive leading to a high signal intensity of fatty lesions. In opposed-phase images tissues containing fat and water show a significant loss of signal because the signal from water cancels the signal from fat.

Liver steatosis is defined as an abnormal accumulation of triglycerides within hepatocytes. US and CT examinations are severely impaired in cases of steatosis and the ability to detect focal lesions is decreased. Both focal fatty change and focal sparing of the liver parenchyma may have a troublesome appearance that may lead to a misdiagnosis of hepatic mass. MR imaging can readily differentiate these lesions from other tumoral lesions because focal fatty change is hyperintense on in-phase sequences and hypointense on opposed phase sequences. The differential diagnosis of incidental fat-containing liver lesions includes focal fatty change, hepatic lipoma, angiomyolipoma, liver cell adenoma and hepatocellular carcinoma. In the setting of chronic liver disease, a fat containing focal liver lesion is highly suggestive of HCC.

Learning Objectives:

1. To provide an update on technical factors and MR imaging contrast agents useful for detection and characterization of fat containing liver lesions.
2. To learn the imaging findings in fat containing liver lesions and fatty infiltration.
3. To review atypical presentations of focal liver lesions and to optimize imaging strategies in the setting of diffuse steatosis.

A-113

C. Vascular abnormalities

Y. Menu, A.-S. Rangheard; Le Kremlin-Bicêtre/FR

Flow related liver abnormalities are extremely common. Some are relevant for the diagnosis or the prognosis while others carry no clinical importance. Complexity of liver flow physiology and anatomy is the main explanation for the multiple features of liver perfusion on CT and MR imaging. Arterial obstruction or dilatation, portal or hepatic obstruction and fistulas may interfere with liver perfusion alone or in association. Liver blood volume is somewhat limited by the liver capsule, leading to a balance between different compartments. Other conditions like diffuse diseases (fatty liver disease, fibrosis or cirrhosis) or liver tumors are commonly associated with flow abnormalities. Special attention will be given to portal hypertension including portal thrombosis, arterio-portal balance, fistulas, the relationship between liver tumors and flow abnormalities, hepatic vein obstruction, peliosis and associated conditions. In this presentation, a simple method based on the recognition of anatomical landmarks and temporal analysis of liver images (plain images, arterial phase, portal phase and sometimes delayed

images) will be detailed. At the end of this talk, it should be possible to identify the abnormal flows that are clinically relevant, to recognize the most common pitfalls, to determine if an underlying disease is present and to evaluate the practical importance of flow abnormality to establish the overall prognosis.

Learning Objectives:

1. To understand normal liver flow physiology.
2. To be able to determine which vessel or flow is abnormal.
3. To understand the significance of flow abnormalities in main liver diseases.

A. Technique for imaging the great vessels

M. Rémy-Jardin, J. Rémy; Lille/FR

Volumetric techniques are greatly improved by multislice spiral CT scanners that can scan large volumes with narrow slice collimation. These new scanners confirm that they now allow the radiologists to increase the diagnostic accuracy and clinical indications of volumetric scanning not only by means of high-resolution transverse CT sections but also by means of high-quality 2D and 3D images. Multiplanar reformatting creates sagittal, coronal or curved imaging planes providing unique displays for the transverse images. Volume rendering techniques address some of the limitations of shaded-surface display techniques. MIP rendering can be applied to either the entire imaged volume or can be targeted to a thin slab of tissue. All reformatting and volume-rendering techniques provide optimal results when applied to motion-free, three-dimensional data sets composed of isometric voxels. The purpose of this lecture is to focus on practical aspects of CT angiographic techniques aimed at evaluating thoracic vessels (aorta excepted).

Learning Objectives:

1. To review the acquisition and reconstruction protocols for optimal imaging of thoracic vessels.
2. To become familiar with the most commonly used reconstructions.
3. To understand the pitfalls and limitations of postprocessing techniques used as diagnostic tools.

A-115

B. Normal and variant anatomy

M.L. Storto; Chieti/IT

The normal radiographic and cross-sectional anatomy of thoracic aorta, great vessels, and mediastinal veins will be reviewed along with a description of the most common variants.

A detailed knowledge of the wide range of congenital abnormalities that may involve the aortic arch is fundamental for a correct interpretation of mediastinum, in order to avoid misdiagnoses.

The most common anomaly of the aorta is an aberrant right subclavian artery originating from a normal left-sided arch, occurring in approximately 0.5% of the population. The proximal portion of the aberrant artery is frequently dilated, a finding known as diverticulum of Kommerel.

A right aortic arch is present in about 0.1-0.2% of subjects and in approximately 70% of cases is associated with an aberrant left subclavian artery. The presence of a left ligamentum arteriosum completes the vascular ring in most of such patients. A right aortic arch with mirror-image branching can also occur; in these cases, the left innominate artery arises as the first branch of the aorta.

In patients with double aortic arch, the right common carotid and subclavian arteries arise from the right arch, whereas the left common carotid and subclavian arteries arise from the left arch. The two arches join posteriorly to form one descending aorta.

A persistent left SVC draining to a coronary sinus is the most common thoracic venous anomaly that occurs in 0.3% of healthy subjects and 4.3% of patients with congenital heart disease. Rarely, the left SVC drains into the left atrium, thus creating a right-to-left shunt.

Postgraduate Educational Programme

Learning Objectives:

1. To describe the normal anatomy of the aorta, great vessels, and mediastinal veins.
2. To become familiar with the most common arterial and venous variants in the mediastinum.
3. To discuss possible pitfalls of interpretation.

A-116

C. Current role of CT in the evaluation of aortic diseases

M. Prokop; Utrecht/NL

For evaluation of the thoracic aorta, CT angiography became a substitute for angiography already in the mid 1990s. Multislice scanning has made it possible to improve spatial resolution for thoracic CTA and, if necessary, include the abdomen into the evaluation. Technological advances include suppression of pulsation effects by fast retrospective ECG gating or prospective triggering. Such techniques can be considered in patients with suspected type A aortic dissections or atypical chest pain. With the newest generation of 32- to 64-slice scanners, evaluation of the heart and thoracic aorta can be combined. Dose issues then become an important limiting factor. The course will discuss how radiation dose can be kept to a minimum while maintaining diagnostic image quality. Optimized techniques of contrast material administration with the new scanners can ensure evaluation of aorta, coronaries and pulmonary arteries within one scan. The course will also review the most critical clinical questions for aortic dissection, aortic aneurysm, aortic rupture as well as aortitis. Because of its speed, ease and diagnostic yield, multislice CTA is now the gold standard for the evaluation of the thoracoabdominal aorta. MRA, however, should be preferred in young individuals (radiation exposure) and in patients with impaired renal function.

Learning Objectives:

1. To learn how to choose scanning and contrast injection parameters for CTA of aortic diseases.
2. To recognize typical artifacts and learn how to avoid them.
3. To understand the most critical questions to be answered in patients with aortic dissections, aneurysms, rupture and aortitis.
4. To comprehend the relative roles of CTA and MRA for the thoracic aorta.

EFOMP Workshop

New technology in diagnostic radiology: The inescapable growth of information technology

EF 1

State-of-the-art in information technology

Moderators:

D. Caramella; Pisa/IT

S. Christofides; Nicosia/CY

A-117

Welcome address

A. Del Guerra; Pisa/IT, A. Chiesa, Brescia/IT

Information Technology (IT) has become a fundamental issue in Radiology. It opens new frontiers in diagnosis, but also creates the need for additional expertise and for new evaluation and quality control criteria. More and more advanced devices are now available with built-in capability for CAD, GRID, image analysis and quantitative image processing. Additionally PACS and Teleradiology are receiving a lot of attention in the clinical arena. This workshop is the 7th of the series EFOMP Workshop in "New Technology in Diagnostic Radiology". It has been organized by EFOMP in collaboration with ECR and COCIR to address the technological aspects, the medical requirements and the industry perspective of IT in Diagnostic Radiology.

A-118

Advances in CAD for cancer detection

N. Karssemeijer; Nijmegen/NL

Computer aided detection (CAD) of cancer is gaining acceptance as a new way of improving reader performance in radiology. In particular in screening applications the use of CAD seems to be advantageous. By using a computer that marks suspicious areas in images the risk of overlooking important lesions is greatly reduced. For effective use of CAD systems a high sensitivity is required. In general, CAD systems have a threshold for display of markers that can be adjusted

to increase sensitivity. However, display of more markers goes at the cost of specificity. Finding the right operating point is an important issue. If a CAD system has poor performance the number of false positive markers may be too high at acceptable levels of sensitivity.

The use of CAD is particularly effective in combination with dedicated workstations. On electronic display systems CAD results can be presented as overlays that can be switched on or off, allowing the radiologist to identify exactly what the computer has detected. For instance, in mammography microcalcification clusters can be displayed by highlighting individual calcifications. This allows the user to conveniently judge their spatial distribution. In lung cancer detection with CT dedicated 3D workstations allow the user to automatically move to slices in which CAD has found nodule candidates. Navigation is also possible using a 3D volume renderer in which nodules are marked. Image registration can be applied to match nodules in a temporal image pair, which greatly enhances the efficiency of the reading process.

Learning Objectives:

1. To learn about the state of art of computer aided detection of breast and lung cancer.
2. To understand the advantage of using CAD in combination with dedicated workstations for visualization.
3. To gain insight in future development of CAD.

A-119

Use of the GRID in medical imaging data management

S.R. Amendolia; Geneva/CH

A GRID can provide a seamless and secure access to distributed information and to high-level applications, a transparent use of local and remote computing resources, and constitutes a way of implementing a framework for collaborative work. GRID thus becomes a necessary tool in modern e-Health implementations: individualised healthcare requires access to all patient information regardless of place. Epidemiology demands large datasets to be addressable transparently, quality control implies quick comparison of image quality across borders, screening and early prevention rely on the possibility of exploiting in a efficient way the experts and the emerging IT tools, like CADetection systems. All this has to be carried out respecting the particularly demanding privacy and security criteria that govern the clinical data usage. Medical data are more and more based on images; multimedia, large, increasing in size and are relevant in the long term. As an example, a mammography exam can require as much as 120 Mbytes of information in terms of images, plus the associated metadata. A countrywide screening programme in a European country ends-up with terabytes of data each year on distributed storage media. Managing such an amount of information in a coherent way is outside the reach of the customary IT tools (web). This is where the GRID can make the difference, also because its intrinsic structuring in Virtual Organisations naturally matches the structure of healthcare users. Examples will be given, in particular a running GRID system for mammography data handling will be shown and discussed.

Learning Objectives:

1. To understand the basics of a GRID IT system.
2. To match the potential of GRID to the requirements of healthcare provision.
3. To verify from a practical implementation the ease of use and the scope of a GRID applied to the management of medical imaging data.

A-120 ♀

Designing image analysis algorithms for molecular imaging

B.M. ter Haar Romeny; Eindhoven/NL

Molecular imaging (MI) promises to be the next revolution in medical and biomedical imaging. As a direct extension to nuclear medicine imaging, a wide variety of molecular processes can now be monitored for the understanding of diseases and life's fundamental processes. Investments worldwide are huge, both by industry and by governmental and university research institutes.

At this moment, MI is still in the research phase. The images originate from PET, MR imaging, ultrasound and optical methods such as fluorescence microscopy. A new feature is the multi-spectral nature of the resulting image data, e.g. multiple values in a single pixel/voxel, e.g. from MR imaging scanning sequences, from different molecular target marker responses, and from combining different physical measurement parameters, e.g. fluoroscopic decay times and interaction parameters. Even full matrices and tensors become common as pixel values. Image analysis aims to answer quantitative questions by computer vision technology about the images, and visualize this complex data.

We discuss the following applications in detail:

- statistical analysis of high resolution multi-modal MR imaging data for the in-vivo classification of atherosclerotic plaque in the human internal carotid artery;

Postgraduate Educational Programme

Saturday

- visualization of tensorial data, such as for diffusion tensor imaging of human brain fibre bundles and heart muscle fibre orientation;
- analysis of functional shape parameters in remodelling vessel wall cells of the mouse from high resolution 2-photon microscopy images;
- segmentation of lysosomes in noisy 3D images of macrophages;
- the use of *Mathematica 5* as a versatile high level design language for complex image analysis algorithms by geometric reasoning.

Learning Objectives:

1. To understand the role and comprehend the design challenges of new algorithms for molecular imaging analysis.
2. To learn from examples to develop new and complex image analysis algorithms for molecular imaging.
3. To become familiar with a modern computer system for doing mathematics on images.
4. To learn the principles underlying the techniques used in the analysis of molecular images and sequences.

Imaging in cochlear implant candidates

Moderator:

P.A. Dimopoulos; Patras/GR

A-121

A. What the clinician needs to know and why

F.E. Offeciers; Antwerp/BE

I will give an overview of:

1. How and why cochlear implants function well as a replacement of the cochlear sensory function,
2. the surgical procedure,
3. the components of a cochlear implant.

The essential questions a Cochlear Implant surgeon wants answers on are:

1. Is the cochlea implantable, i.e. accessible for a standard CI electrode?
2. Is the cochlear nerve morphologically normal?
3. Are there any central auditory lesions or malformations which could hamper the normal functional outcome of a CI?
4. Is there any kind of concomitant pathology throughout the auditory system which would jeopardize safe implantation or preclude a favorable and stable long-term outcome?

Imaging also helps answering other questions. We distinguish 5 specific levels of interest, or if you will, 5 sets of goals, which are:

1. To help identifying the etiology of deafness
2. To help in selecting and counselling the CI candidates
3. To pre-operatively visualize useful surgical landmarks
4. To post-operatively evaluate the position of the CI-electrode
5. To provide important data in CI-related research

All these categories of questions will be discussed using practical examples from our clinical experience, emphasizing the impact of each set of imaging data on clinical decision making and on the functional outcome.

We will try to make this session as interactive as possible, welcoming questions from the floor throughout the session.

Learning Objectives:

1. To understand the rationale behind performing cochlear implants.
2. To be familiar with the surgical procedure and type of implants available.
3. To know which information is essential for the surgeon prior to performing a cochlear implant.
4. To know which information is essential for the surgeon in case of cochlear implant dysfunction.

A-122

B. Pre-implant imaging

J.-W. Casselman; Bruges/BE

Both CT and MR are needed in prospective cochlear implant candidates if one wants to provide the surgeon with all necessary information.

Inner ear malformations in congenitally deaf children can be seen on CT and MR. However MR better detects the intralabyrinthine malformations. In the internal auditory canal (IAC), only MR is able to detect aplasia or hypoplasia of the VIIIth nerve and its cochlear branch. Inner ear and IAC malformations are best seen on thin TSE or GE T2W images. Congenital malformations in the brainstem or audi-

tory cortex (e.g. pachygryria) can also jeopardize the success of cochlear implantation.

Meningitis is the most frequent cause of acquired deafness in children. Calcified obliterations of the cochlea can be detected on CT, whereas MR can detect fibrous intracochlear obliteration. However, MR cannot distinguish calcified from fibrous obliteration. Therefore both MR and CT are needed to tell the surgeon if cochlear implantation is possible. Acute labyrinthitis can be seen as intralabyrinthine enhancement on Gadolinium-enhanced T1W images. CT is still needed to evaluate the mastoid pneumatisation and to exclude anatomical variations/congenital malformations on the route towards the basal turn of the cochlea, even if the inner ear and nerves in the IAC are normal on MR.

In adults otosclerosis, neurofibromatosis and labyrinthitis (acquired deafness) are the most frequent causes leading to cochlear implantation. Infarction, MS, tumor or post-traumatic lesions along the auditory pathway or in the auditory cortex can also be the cause of bilateral deafness and are best seen on MR.

Learning Objectives:

1. To know which are the imaging modalities and the pertinent protocols needed to image the temporal bone and brain prior to performing a cochlear implant.
2. To know the anatomy of the auditory pathway and recognize normal and abnormal findings.
3. To know how to recognize contraindications for performing cochlear implants.
4. To be able to report the essential findings to the ENT surgeon.

A-123

C. Post-implant imaging

C. Czerny¹, W.D. Baumgartner¹, W. Gstöttner²; ¹Vienna/AT, ²Frankfurt

a. Main/DE

Introduction: This paper explains the techniques of digital radiography(DR) in one projection and Computed Tomography, presenting their indications and showing the imaging findings of normally and abnormally inserted implant electrodes in the postoperative assessment of multichannel cochlear implant (CI) patients.

Methods: To explain the radiological techniques of DR in a modified Chausse III projection and in CT imaging. To show how the position and insertion depth of the CI electrodes can be determined.

Results: The radiographic findings were found to be similar to the CT findings regarding the detection of electrode position. Excellent correlation exists between the radiological and surgical results with regard to insertion depth ($r = 0.92$). Abnormally inserted electrodes show bent electrodes, incomplete insertion, and misplaced electrodes. The radiation dose of one CT examination is about 200 times higher than that of one radiographic examination, and the examination time of one CT is 20 times longer than that of one X-ray. The costs for one CT examination are about 5.5 times higher than those of one X-ray.

Conclusions: Digital radiographs obtained in a modified Chausse III projection enable accurate assessment of the CI electrode position and insertion depth correlated to surgical results and compared to CT. The radiation dose and the costs of the examination are considerably lower than those of CT, and these facts might favour the use of digital radiographs in the modified Chausse III projection. CT might be indicated in those cases in which the radiographs can not explain any problems concerning the implant electrode.

Learning Objectives:

1. To know the modalities of exact depiction of cochlear implants and the accuracy of the different imaging modalities.
2. To know which is the most effective imaging technique for the assessment of inserted cochlear implants and to be able to recognize the features of correctly and incorrectly inserted cochlear implants by using different imaging modalities.
3. To delineate potential complications of cochlear implant insertion failure.

Endovascular treatment in female pelvis

Moderator:

E. Brountzos; Athens/GR

A-124

A. Leiomyomata

I. Pinto Pabón; Madrid/ES

Indications: The main indication for UAE is the treatment of symptomatic fibroids,

Postgraduate Educational Programme

intra-mural less than 10 cm in diameter, in a patient with no wish of future pregnancy.

Anatomy: In 77% of the cases the internal iliac artery has an anterior and a posterior trunk. The anterior trunk usually has three parietal branches (obturator, inferior gluteal, and internal pudendal) and three visceral branches (vesical, uterine, and middle rectal). We can recognize the uterine arteries, because they are highly twisted; and the characteristic course is a parietal segment, an arch part and a marginal or ascending segment.

Technique: Adequate sedation and analgesia is achieved with midazolam and fentanyl. Concerning the approach the unilateral right common femoral artery is preferred for access. Beginning with a Sidewinder catheter 4 F to catheterize the left internal iliac artery and after that, selective uterine artery catheterization is performed, with catheter tips placed within the transverse portion of the uterine artery. Embolization is performed with particles bigger than 400 μ (PVA particles or microspheres).

Complications:

* During the procedure:

- Arterial spasm (13-17%)
- Dissection or vessel perforation (5%).
- Non-target embolization.

* After the procedure: Post-embolization syndrome (15-25%), Vaginal discharge (20-50%), Sloughing Fibroids (3%-6%), Infection, piometra or uterine perforation that makes hysterectomy necessary in just 1% of cases and death (3/10,000). Amenorrhea has been reported to occur in 0%-14% of patients undergoing uterine fibroid embolization.

Follow-up: MR imaging at 3 months and after one year.

Learning Objectives:

1. To understand indications for UAE in uterine leiomyomata.
2. To discuss different uterine arteries anatomy.
3. To discuss different techniques of UAE.
4. To know possible complications.
5. To understand follow-up of UAE leiomyomata.

A-125

B. Ovarian varicocele

A. Nicholson; Leeds/UK

Chronic pelvic pain is defined as "pain that is present for at least 6 months". One third of patients have endometriosis, one third have other structural abnormalities, and one third have no obvious findings. There is often significant psychological overlay. Therefore, chronic pelvic pain can be difficult to manage and is often refractory to surgery.

Indications for ovarian venography and embolization include:

1. Unexplained chronic pelvic pain. Laparoscopy and pelvic ultrasound to exclude other pathologies is mandatory. Lack of abnormal vasculature at either of these studies does not preclude the possibility of ovarian vein reflux.
2. Lower extremity varicose veins immediately recurrent after adequate surgical treatment.
3. Severe labial/perineal varicosities. These are difficult to treat. Conservative therapy should be contemplated. If intervention is undertaken and the patient has ovarian vein reflux, these veins will recur immediately after sclerosis unless the ovarian vein "pressure column" is interrupted.

Varicosities in the pelvis secondary to retrograde flow in the ovarian vein causing pelvic pain worsening after long periods of standing or at the end of the day, labial varicosities, and dyspareunia is termed *pelvic congestion syndrome*. If the patient has reflux sufficient to cause pelvic pain, it is obvious on left renal vein or proximal right ovarian vein injection. If ovarian vein reflux is confirmed in a patient with the appropriate clinical symptoms, embolisation will cure or symptomatically improve 73%-78% of patients. This compares with 66% after surgery. Ultrasound CT and MR imaging also can aid diagnosis.

Learning Objectives:

1. To discuss the indications and technical aspects for ovarian venography.
2. To discuss the use of embolization to treat this and varicosities of the lower extremity and perineum.
3. To discuss the difference between ovarian vein syndrome and pelvic congestion syndrome.

A-126

C. Post-partum haemorrhage

J.-P. Pelage; Boulogne/FR

Post partum haemorrhage remains a major cause of maternal mortality throughout the world. Uterine atony, genital tract lacerations and abnormal placentation

account for the majority of cases. Uterine atony is usually controlled with early introduction of oxytocin or prostaglandin analogues. Surgical repair is effective to treat cervical tears and curettage may be sufficient to remove retained placental tissue. For patients whose clinical condition continues to deteriorate, arterial ligation or hysterectomy is often the favored treatment. However, surgical procedures are associated with significant failure and morbidity rates particularly in patients with coagulation disorders. The successful use of embolisation was first reported in 1979 in a patient who underwent hypogastric artery ligation and hysterectomy. Since then, many reports have emphasized the advantages of embolisation over surgery. In the majority of cases, selective embolisation of both uterine arteries is performed. In case of failure to control bleeding, additional blood supply may originate from the cervicovaginal, ovarian or round ligament arteries. In case of arterial vasoconstriction, embolisation of the anterior division of the hypogastric arteries is safe and effective. Gelatin sponge pledges, which provide a temporary occlusion are particularly suitable for hemostatic embolisation. Embolisation is effective in 70-90% of cases following cesarean section and uterine atony respectively. Pluridisciplinary management for patients with postpartum haemorrhage should be realized in highly specialized centers open 24 hours a day. If applied early in the course of events, embolisation is a valuable and safe alternative to surgery in the management of intractable postpartum hemorrhage.

Learning Objectives:

1. To understand the indications for uterine artery embolization for PPH.
2. To discuss different embolization strategies.
3. To identify and prevent failures associated with embolization.
4. To understand the need for a pluridisciplinary approach of patients with severe PPH.

Venous imaging and intervention

Moderator:

M.W. de Haan; Maastricht/NL

A-127

A. CT of thromboembolic disease

E.J.R. van Beek; Sheffield/UK

Venous thromboembolism (VTE) is now recognised as a single clinical entity, encompassing thrombosis in leg and arm veins (DVT) and their common complication of pulmonary embolism (PE). It is one of the most frequently encountered clinical problems with 3 per 1,000 population suspected of having the disease. The main diagnostic dilemma is to exclude those patients who should not run the risks of anticoagulant therapy from those where the disease can be demonstrated and treatment can take place to avoid recurrent events and late sequelae, such as chronic thromboembolic pulmonary hypertension.

After the initial start of CT for the diagnosis of PE in 1992, technology rapidly overtook the pace of clinical trials. As a result, only a few management studies have been performed using single helical CT (sCT). Subsequently, the rise of multidetector row CT (MDCT) has significantly improved the visualisation of subsegmental PE, while the increased speed of these systems allow direct imaging of the entire deep venous system. The technical aspects of sCT and MDCT will be discussed.

The findings that are characteristic of PE and DVT will be discussed, together with the findings of chronic PE. Pitfalls of diagnosis and alternative findings will also be shown. Diagnostic algorithms for the diagnosis of PE will be discussed in the context of other diagnostic tests.

Learning Objectives:

1. To be able to interpret the common findings and pitfalls of VTE.
2. To be able to make distinction between acute and chronic PE.
3. To be able to understand the literature in respect of CT for VTE.
4. To be able to integrate CT in the diagnostic management of VTE.

A-128

B. MR venography

J.F.M. Meaney; Dublin/IE

Magnetic resonance venography is a valuable cost-efficient and accurate technique for non-invasive evaluation of the venous system. Although traditional non-contrast methods are effective for evaluation of the venous system, they are

Postgraduate Educational Programme

time-consuming and prone to artefacts, predominantly because of slow flow-rates encountered in the veins. Because of rapid scan times, freedom from artefacts and high accuracy, contrast-enhanced techniques have become the reference-standard for demonstration of venous anatomy, venous anomalies and venous pathology. Depending on the anatomic location, different approaches may be appropriate. For example, injection of dilute contrast into an extremity vein allows high quality imaging of extremity veins "upstream" to the injection, however, the visceral veins (portal, mesenteric, renal) cannot be evaluated by this "direct" method and must be evaluated by other "indirect" methods (non-contrast techniques or during the "venous" phase of a contrast-enhanced MRA). Because blood T1 shortening is not as marked during the "venous" phase, elimination of fat by subtraction of a pre-contrast mask offers an advantage in most instances. Additionally, subtraction of the arterial phase from the venous phase (VESPA - Venous Subtracted Peak Arterial Phase) has the added value of subtracting not only the bright fat but also the overlapping arterial signal which results in depiction of the veins in isolation.

Evaluation of the venous component of vascular malformations can be performed using a variety of techniques.

More recently balanced sequenced (e.g. True FISP) have shown promise for venous imaging.

This presentation will describe tailored evaluation of the veins throughout the body in a time-efficient manner.

Learning Objectives:

1. To understand the clinical indications for MR venography.
2. To describe the advantages and limitations for both non-contrast techniques and contrast-enhanced techniques.
3. To explain the rationale for and technique of "indirect" and "direct" contrast-enhanced MR venography.
4. To illustrate the spectrum of findings in venous thrombosis.
5. To describe the strengths, limitations and pitfalls of MR venography in diagnosis of visceral, central and peripheral venous occlusion.

A-129

C. DVT and interventional therapy: Fact or fiction

M.J. Sharafuddin; Iowa, IA/US

Deep vein thrombosis (DVT) of the lower extremities is a common medical problem with a high risk of mortality and morbidity, and substantial immediate and long-term costs to society. Acute complications DVT include pulmonary embolism (PE), and venous ischemia. Delayed complications include a spectrum of debilitating symptoms referred to as the post-thrombotic syndrome. Anticoagulation therapy remains the mainstay of therapy in acute DVT. However, there is little data to suggest any major beneficial effect on the post-thrombotic syndrome, which is thought to be mediated by valve damage and/or occlusive chronic thrombus and venous scarring. Several experimental as well as clinical studies have indicated a potential role for early thrombolysis in preservation of venous valve function and prevention of venous occlusive pathology. Endovascular catheter-directed thrombolysis techniques using pharmacologic thrombolytic agents alone or in combination with mechanical thrombectomy devices have been proven highly effective in clearing acute DVT. In patients with underlying occlusive abnormalities, definitive management via endovascular stenting can also be undertaken. Another group of patients that benefit from endovascular therapy are those with chronic symptoms attributable to venous occlusive pathology, where endovascular stenting can play a role in alleviating symptoms attributable to venous hypertension. Management of post-thrombotic venous valve dysfunction remains one of the most formidable problems in patients suffering from chronic venous insufficiency. Although the role of endovascular techniques in the management of valvular insufficiency has been limited, a number of emerging paradigms are being explored. Endovascular obliteration is currently an effective option in solitary superficial venous insufficiency.

Learning Objectives:

1. To summarize the current indications for endovascular therapy in acute DVT.
2. To describe the current approaches and techniques for the treatment of acute DVT and chronic post-thrombotic venous disease.
3. To summarize the current outcomes of endovascular therapy in venous disease.
4. To describe the current status of endovenous ablative therapies of superficial varicose veins.

Imaging of the uterus

Moderator:

D. Babnik Peskar; Ljubljana/SI

A-130

A. Ultrasound imaging techniques

G. Serafini; Pietra Ligure/IT

A variety of examination techniques can be used for the US study of the uterus. Transabdominal sonography can still be considered the first approach to the uterus, but transvaginal sonography is the best examination technique for evaluating the endometrium and small intrauterine lesions.

A special technique called hysterosonography has been developed to obtain better analysis of the endometrial surface and uterine cavity.

Enlarged uterus: US is commonly requested to characterize structural changes of the uterus and to measure it. Fibroids are the most common tumor of the uterus and most common cause of uterine enlargement.

On US studies, uterine fibroids usually appear as solid, discrete, well-defined masses. They may be hyper, iso or hypoechoogenic related to the myometrium. Uterine leiomyosarcomas are rare and usually occur in the elderly. At US they appear as bulky uterine masses that are indistinguishable from large non-malignant fibromas. However, the clinician can be alerted to diagnosis by their rapid progression over time.

Abnormal bleeding: In clinical practice, transvaginal US is commonly employed for three main purposes:

- determining which patient should undergo endometrial biopsy. US-pathological correlation studies have demonstrated that, considering a bi-endometrial thickness cutoff value of 4 mm, in patients with endometrial measurement below this point, postmenopausal bleeding can be related to atrophy with a high degree of confidence.
- accurate analysis of the endometrium to detect polyps or submucosal fibroids.
- local staging of myometrial invasion from endometrial cancer.

Learning Objectives:

1. To understand the role of transvaginal vs. transabdominal ultrasonography in the evaluation of the uterus.
2. To be able to recognize the US findings of uterine diseases.
3. To learn the scanning technique and clinical indications of US hysteroscopy.
4. To learn the role of color Doppler in patients with uterine disorders.

A-131

B. Abnormal gynecological bleeding: What the gynecologist wants to know

R. Forstner; Salzburg/AT

Abnormal gynecologic bleeding refers to bleeding other than the expected menstrual pattern.

It is usually attributed to a uterine source, but may also arise from other pelvic sites.

In the diagnostic work-up of abnormal gynecological bleeding transvaginal sonography is the primary imaging modality in pre- and postmenopausal women. The purpose of pelvic sonography is to identify uterine or extrauterine abnormalities, and to analyze endometrial and myometrial morphology. In case of abnormal bleeding and indeterminate sonography MR imaging serves as an adjunct in localizing the source of hemorrhage, in establishing the definite diagnosis, and in determining the feasibility of conservative uterine surgery.

In patients with bleeding in childbearing age and sonographically diagnosed uterine fibroids MR imaging helps to guide to the appropriate myomectomy technique. In pre-and perimenopausal women with a sonographically enlarged uterus MR imaging allows differentiation between leiomyomas and adenomyosis.

In bleeding caused by uterine malignancies pretherapeutic MR imaging findings will directly influence the choice of therapy and guide in therapy planning.

In patients with vaginal bleeding and a large pelvic mass MR imaging helps to define the origin of the tumor and may also be able to differentiate between a neoplastic and inflammatory etiology.

Learning Objectives:

1. To become familiar with the etiologies of abnormal gynecological bleeding in pre and post menopausal patients.
2. To learn diagnostic imaging features for benign and malignant endometrial and myometrial pathologies.

Saturday

Postgraduate Educational Programme

3. To understand the value of MR imaging as adjunct to US in uterine disorders presenting with abnormal bleeding.
4. To learn what the gynecologist wants to know for treatment planning.

A-132

C. Staging and follow-up of cervical cancer

P. Petrow; Geneva/CH

MR imaging provides excellent spontaneous soft tissue contrast of all female pelvic organs, permits a multiplanar exploration of the entire pelvis including lymph nodes and the pelvic floor. Therefore MR imaging is the imaging modality of choice for the initial work-up of invasive cervical cancer. This course reviews the technical aspects of MR imaging exploration of invasive cervical cancer such as choice of sequences, slice orientation, intracavitary and intravenous contrast media injection for MR examination for initial staging, follow-up examinations during radiation therapy (external RT and brachytherapy) and suspected recurrence. The imaging features encountered during initial staging such as parametrial, bladder, ureteral and rectal invasion are reviewed with particular emphasis on findings to guide fertility conserving surgery, external radiation therapy or brachytherapy. These findings can be correlated to the FIGO classification for invasive cervical cancer. Lymph node involvement of cervical cancer and its repercussions on MR imaging are highlighted.

During follow-up, especially if cervical cancer is treated by chemoradiation, post radiation changes of the pelvic organs and spaces can render difficult the interpretation of MR images and the use of dynamic-acquisition contrast-enhanced T1-weighted SE MR images is useful to distinguish post-radiation fibrosis from recurrence.

In conclusion, MR imaging is the imaging modality for evaluation initial tumor volume and extension, response to treatment and to rule out recurrence.

Learning Objectives:

1. To become familiar with basic principles and imaging protocols to explore cervical cancer, with special emphasis on MR imaging.
2. To enhance the utility of MR imaging in the follow-up when treated with radiation therapy.
3. To show the features of recurrence.

Infection in the Adult Today

CC 516

Gastrointestinal infection: A changing scene

Moderator:

M.A. Lucic; Novi Sad/CS

A-133

A. Gastrointestinal infection in the immunocompromised patient

J.W.A.J. Reenders; Curaçao/AN

In less than three decades AIDS has become one of the most devastating illnesses in human history. The AIDS epidemic differs from most others in many ways, has challenged conventional medical thinking and has broadened the boundaries of the knowledge of human biology and medicine. The patterns of disease and pathological changes seen in AIDS patients can be perplexing and challenging, particularly in the medical imaging department. Although astonishing progress has been achieved during recent years in the treatment of patients afflicted with AIDS, with the introduction of highly active antiretroviral therapy (HAART), the epidemic still continues to spread. AIDS patients are no longer confined to a few specialized AIDS hospitals and are now seen in general hospitals and clinics everywhere. The value of imaging of AIDS is well established. This CC provides a comprehensive overview of our current knowledge about radiologic imaging features of the wide range of gastrointestinal, hepatic, splenic, biliary and retroperitoneal manifestations in the immuno-compromised patient and how the role of modern medical imaging techniques and diagnosis and treatment can be applied. The imaging aspects (conventional double contrast gastrointestinal studies, ultrasound, CT and MR) of the diseases of the luminal gastrointestinal tract, liver, spleen, biliary tract and retroperitoneum will be systematically discussed. Candidiasis, herpes, cytomegalovirus, cryptosporidiosis, histoplasmosis, isosporiasis, salmonellosis, unusual mycobacterial and viral infections account for the majority of non-neoplastic disorders. This CC is not only comprehensive, but also practical and easy to apply to daily clinical problem solving.

Learning Objectives:

1. To learn the wide range of radiological manifestations in AIDS of the GI tract.
2. To understand how modern medical imaging can assist in diagnosis and treatment.
3. To understand the needs of investigating AIDS patients in clinical practice.

A-134

B. Gastrointestinal and abdominal tuberculosis

F.M.H.M. Vanhoenacker, A.I. DeBacker, P.M. Parizel; Antwerp/BE

In this educational lecture the range of manifestations of tuberculosis (TB) of the abdomen will be discussed, including involvement of the gastrointestinal tract, the peritoneum, mesentery, omentum, abdominal lymph nodes, solid abdominal organs, the genital system and the abdominal aorta.

Abdominal TB is a diagnostic challenge, particularly when pulmonary TB is absent. It may mimic many other abdominal diseases, both clinically and radiologically. An early correct diagnosis, however, is important in order to ensure proper treatment and a favourable outcome.

Modern imaging is a cornerstone in the early diagnosis of abdominal TB and may prevent unnecessary morbidity and mortality. Generally, Computed Tomography (CT) appears to be the imaging modality of choice in the detection and assessment of abdominal tuberculosis, other than gastrointestinal TB. Barium studies remain superior for demonstrating mucosal intestinal lesions. Ultrasound (US) may be used for follow-up to monitor therapy response. The role of MR imaging has to be further defined.

Ileocaecal involvement, free or loculated high density ascites with thin-mobile septa, omental thickening, a thickened and enhancing peritoneum, a misty mesentery, low density adenopathies and focal hepatosplenic lesions are suggestive imaging findings demonstrated by either gastrointestinal series, US, CT and MR imaging.

The diagnosis of abdominal TB should be considered if suggestive imaging findings are found in patients with a high index of suspicion.

Learning Objectives:

1. To recognise the range of imaging characteristics of abdominal TB.
2. To define the strength of each imaging modality in detecting (specific) changes encountered in abdominal tuberculosis.

A-135

C. Gastrointestinal parasite infestation

M.E.A. El Bagi; Riyadh/SA

25% of the world population could be suffering from parasitic infestation. The highest prevalence is in underdeveloped agricultural and rural areas in the tropical and subtropical regions. In some areas the incidence may reach 90% of the population. In contrast, some major economic projects intended to promote local development have, paradoxically caused parasitic proliferation e.g. Bilharziasis in Egypt and Sudan and Chagas disease in Brazil. The commonest cosmopolitan gastrointestinal parasite is Entamoeba histolytica. Some intestinal parasites are endemic in temperate climates e.g. Enterobius vermicularis. The AIDS epidemic has increased the prevalence and severity of parasitic disease particularly Strongyloides stercoralis. Tropical parasites are seen in Western people who travel to tropical countries. Radiology has acquired a major role in diagnosis and management of gastrointestinal parasite infestations and their complications.

Learning Objectives:

1. To summarize the worldwide prevalence of the commonest gastrointestinal parasites.
2. To describe the various radiologic presentations of gastrointestinal parasites.
3. To highlight the role of radiology in the management of gastrointestinal parasites.

Postgraduate Educational Programme

Saturday

08:30 - 10:00	Room N/O	08:30 - 10:00	Room P
Radiographers RC 514 MR imaging/Neuroimaging <i>Moderators:</i> P.C. Maly Sundgren; Ann Arbor, MI/US F. Olsen; Trondheim/NO		Joint ECR/EAR sessions: Challenges for European Radiology ER 526 Assessment and accreditation in radiology in Europe <i>Moderator:</i> I.W. McCall; Oswestry/UK	
A-136 A. 3 Tesla whole body system MR imaging: Experiences from Lund University Hospital B. Hansson; Lund/SE		A-138 Assessment and accreditation of training centres in Europe I.W. McCall; Oswestry/UK	
In September 2003, we installed a 3 T Philips whole body scanner at the Lund University Hospital. Like our three Philips 1.5 T and our 3 T Siemens head scanners, it is mostly used to examine clinical patients. It is both interesting and challenging to be part of the development of a new technique such as the 3 T whole body system. During the first year, we received the various coils and could start to examine different body parts. We learned about the merits and disadvantages of the system, and developed techniques to work around problems. For brain examinations we already knew that 3 T was excellent e.g. in MRS (MR Spectroscopy), MRA (MR Angio) and high resolution. For other examinations, there were not many protocols optimised for 3 T and we had to explore the parameter space to find the suitable settings for a 3 T system. For example, one difficulty we encountered was to obtain a sufficient contrast between white and grey matter in a T1 weighted image. Also, to use the gradient echo instead of the spin echo produces susceptibility artefacts. One large issue with the 3 T scanner is artefact reduction. All artefacts will increase compared to using a lower field-strength. Fortunately, Philips has provided several new techniques that reduce artefacts, e.g. SENSE (SENSitivity Encoding) can help us get rid of motion artefacts by running the scan more rapidly. <i>Learning Objectives:</i> 1. To learn about the Lund university hospital experiences with 3 T whole body scanner. 2. To identify the advantages of a 3 T system. 3. To identify the difficulties with a 3 T system.		The structure of radiology training varies between and within countries in Europe. Some have a unified national training scheme, while others are managed independently by individual universities or hospitals. Practice in radiology within the EU, requires a certificate of specialist training, awarded nationally or by individual institutions. Radiologists can practice in another country or may provide services across state boundaries and patients and employers must have confidence that their training is good. To enhance and standardise training across Europe, the EAR and the radiology section of the UEMS has instigated a training assessment program. Assessment of training centres in each EAR member country are undertaken by two experienced trainers from other European countries. The host centre completes a questionnaire, which provides details of the trainers and trainees, the facilities, equipment, workload and case-mix. Information is also provided on training programs, lectures, tutorials and sub-specialty training. A separate confidential questionnaire is completed by each trainee on the strengths and weaknesses of their training. The assessors visit the centre and review the facilities, talk to both trainers and trainees and the management. Finally the assessors report to the centre identifying their strengths and weaknesses and suggesting improvements if appropriate. The reports are collated by EAR and UEMS to identify key training issues. These include instituting the EAR curriculum, providing formal tutorials and lectures and structured trainee appraisal. Provision of sub-speciality training is not available in many centres. Involvement of trainees in clinico-radiological conferences and audit is encouraged. These will be discussed. <i>Learning Objectives:</i> 1. To recognize of the need for training centre assessment throughout Europe. 2. To understand the structure and mechanisms of the EAR assessment program. 3. To appreciate the variability of training structures and opportunities in training centres in different European countries. 4. To evaluate some of the key areas where training programs may improve their structure and performance.	
A-137 B. Neuroimaging and analysis techniques for research into brain structure and function V. Sluming; Liverpool/UK		A-139 Appraisal and assessment of trainees during training C.D. Becker; Geneva/CH	
A wide range of imaging and image analysis techniques now exist for demonstrating the structure and neural activity of the living human brain. This presentation will chart the development of these techniques and describe their respective advantages and limitations. There have been major advances in recent years in analysing the structure of the human brain in-vivo using computerised statistical voxel based analysis techniques which have made the visualisation of, for example, wide spread degenerative changes of cortical tissues easier and more objective. Functional neuro-imaging is making a significant contribution to our understanding of neural substrates with studies of higher cognitive function, perception, action and emotion. Furthermore, results obtained from healthy human volunteers are leading to new ideas about depression, schizophrenia, pain syndromes, multiple sclerosis and other psychiatric and neurological disorders. The spatial mapping techniques which have been demonstrated to provide powerful insights into the structure and function of the brain include: structural and functional magnetic resonance imaging, positron emission tomography, source localisation with electroencephalography and magnetoencephalography and functional transcranial Doppler ultrasound. The physical principles underlying these techniques will be briefly outlined and important assumptions and limitations identified. A range of applications for each technique will be indicated. <i>Learning Objectives:</i> 1. To discuss the choice of appropriate imaging modality to answer a particular research question relating to structure and/or function of the human brain. 2. To appreciate the different image analysis techniques for analysing structural and functional brain data.		A primary goal of appraisal of Radiology trainees during training is to assess the adequacy of postgraduate training. The legal responsibility for the training standards vary from one country to another but the director of the training programme certainly holds a key role in this process. Appraisal must be done at each stage of training and must be based on defined methods, including regular, constructive feedback at least annually, and standardised Radiology board examinations. Assessment and feedback should be based on a written evaluation protocol containing more general as well as specific radiologic criteria. A logbook for certain invasive procedures may be helpful in order to document personal practical experience. Radiology board examinations may be written (eg, multiple-choice) or oral; their content must be based on the objectives of the postgraduate training programme in Radiology. <i>Learning Objectives:</i> To understand the process of evaluation of radiology trainees during postgraduate training.	

Postgraduate Educational Programme

A-140

Delivering a national continuing medical education programme

J. Freyschmidt; Bremen/DE

The German Academy for Continuing Education in Diagnostic Radiology was founded in 1998, 6 years before vocational training became legally mandatory for the medical profession in Germany. The Academy was founded and is supported by the German Radiological Society and the Association of German Radiologists. In Germany the fulfillment of the legal requirements which are mandatory in medical training since 2004 are being controlled by the medical associations of the individual federal states which in turn are members of the German Medical Association. The legal requirements ask for the verification of 150 CME credits every 3 years or 250 CME credits every 5 years. On recommendation of the German Medical Association, the medical associations of the federal states acknowledge 3- or 5-year-certificates of the German Academy for Continuing Education in Diagnostic Radiology, provided that the Academy can prove the fulfillment of the requirements for continuous medical education set up by the federal medical associations. Starting in 2005, the exchange of data between the Academy and the federal medical associations will run on a common server, facilitating the acknowledgement of these credits.

The German Academy for Continuing Education in Diagnostic Radiology distinguishes two categories of continuing education. Courses can only be acknowledged as category I, if they are certified by a written evaluation. The evaluation is being analysed electronically at the Academy, the participants can be identified by means of a barcode. The lecturers will receive a printout of their respective evaluations. From its beginning the Academy carried out about 15,000 evaluations. Since we started our category I courses, the level of the courses as well as that of the lecturers has risen tremendously. All category-I-courses have to be registered at the Academy, where they are also tested and rated regarding the maximum of possible credits. One training unit (1 CME-credit) corresponds to a lecture or course of 45 minutes.

Among the category-II-activities are the attendance of scientific lectures at national and international meetings, visits at medical institutions, scientific publications and lectures, basically all training activities that are not being evaluated. Private studies of scientific books and journals can be acknowledged with a maximum of 30 credits in 3 or 50 credits in 5 years. Detailed interactive studies with print media, online media or audio-visual media with a certified qualification and evaluation of the learning results are acknowledged with 1 credit per training unit. The participants of the Academy are supposed to acquire 25 CME-credits in category I and 25 CME-credits in category II per year. After 3 and/or 5 years they obtain a certificate from the Academy, which can be submitted to the German Medical Association.

From its very start, the German Radiological Academy has been extremely successful and functions as a role model for the academies of other disciplines, which were mostly initiated at a later date. In the meantime we count more than 2750 participants or, in other words, about 70% of all practicing radiologists in Germany. The Academy is directed by a board, whose chairman is the author of this abstract. It is financed mainly by fees from participants and organisers of scientific workshops and training courses, by subsidies from the German Radiological Society and the Association of German Radiologists and - after strong initial support - now only by a minor part by sponsoring from the industry.

Learning Objectives:

1. To demonstrate how a national academy for continuing education in radiology can be established on a voluntary basis, finding approval from the national medical authorities, especially as continuing education became legally compulsory for the medical profession.
2. To demonstrate that an academy run by a medical society (in this case in radiology) can stimulate its members to continuing education on a high level.
3. To demonstrate that at least 50% of the activities in continuing education should be evaluated regarding their quality in order to raise their level evidently.

A-141

Revalidation and re-certification of radiologists in Europe

A.P. Brady; Cork/IE

The concept of recertification of medical specialists was first raised in the US in 1940, and the introduction of time-limited specialist certification began there in 1969. The impetus for recertification of medical specialists comes from the desire to ensure and maintain competence of medical service delivery, driven by public demand. This demand has accelerated in recent years, at least in part, as a response to publicity relating to medical malpractice and misadventure, and an increase in litigation following adverse medical outcomes in many populations. It

is no longer publicly acceptable that lifelong competence be assumed following completion of training and passing an examination in the early years of one's medical career, and the medical profession must develop robust mechanisms by which competence of physicians can be maintained and verified throughout their careers, just as is the case with many other professions. The mechanisms developed must be unbiased and fair, appropriate to the work being done by the doctor, and acceptable to the public. This lecture will review the background behind the demand for revalidation, the arguments for and against revalidation and the methods being employed for revalidation within and outside Europe, in the context of diagnostic radiology.

Learning Objectives:

1. To understand why the demand for revalidation and recertification has arisen.
2. To understand the importance of developing unbiased and robust methods of revalidation.
3. To understand various methods of revalidation being considered or introduced.

Foundation Course - Chest Radiology

E3 520

Airways and infection

Moderator:

S.J. Copley; London/UK

A-142

A. Airway disorders and hypoluent lungs

J.A. Verschakelen; Leuven/BE

Disorder of the airways can be divided into disorders of the (large) proximal and disorders of the (small) distal airways. Chest radiograph and especially spiral computed tomography can provide very accurate information on diseases that affect the proximal airways and are often helpful for diagnosis and workup before treatment of these diseases. Small airways involvement is best seen with high resolution CT. This technique is particularly valuable in showing small airways involvement not only when it is part of widespread diseases but also when bronchiolitis is the primary finding. Focal or widespread reduction in lung attenuation is one of the important CT features of some small airways diseases and should be differentiated from other causes of hypoluent lungs.

Learning Objectives:

1. To illustrate the radiographic and CT features of airway diseases.
2. To familiarize the participants with the different causes of hypoluent lungs.

A-143

B. Pneumonia and disorders in the immunoincompetent host

C.J. Herold; Vienna/AT

Individuals with an impaired immune system are prone to a variety of infections, neoplasms, and cardio-vascular disorders. Among those, pneumonia is the most common infectious disorder, and can occur in up to 80% of patients with acute leukaemia, and in up to 50% of organ transplant recipients, respectively. Neoplasms may develop due to the primary disease, but also as a consequence of chemotherapy or radiation. Cardiovascular disorders appear most commonly as a short term or long term complication of treatment.

In this course, the underlying factors for the development of different disorders in the immunocompromized host will be revisited. Furthermore, the spectrum of causative organisms and radiologic features of various opportunistic pulmonary infections will be discussed. Specific attention will be paid towards narrowing the differential diagnosis by integrating clinical laboratory and radiologic information. Finally, the role of imaging methods in the evaluation of patients with different disorders will be reevaluated.

Learning Objectives:

1. To familiarize the audience with epidemiology, pathophysiology and etiology of infections in the immunocompromized host.
2. To elucidate the spectrum of noninfectious disorders in this specific patient population.
3. To review the morphologic findings and radiologic patterns of infectious and noninfectious diseases.
4. To illustrate the role of the radiologists in dealing with these disorders.

Postgraduate Educational Programme

10:30 - 12:00

Room A

"ECR meets" Italy

EM 1

Imaging of focal lesions

Presiding:

A. Chiesa; Brescia/IT
F. Dalla Palma; Trento/IT

A-144

Imaging of focal lesions (Introduction)

L. Bonomo; Rome/IT

Focal lesions are a common finding in daily radiological practice. In the evaluation of focal lesions, the role of imaging is different according to the diagnostic task (detection, characterization, staging and follow-up) and to the examined body organ. In "ECR meets" Italy five Italian radiologists present their experience regarding the role of different imaging modalities (conventional radiology, US, CT, MR and MN) in the evaluation of focal cerebral, pulmonary, hepatic, renal and muscular lesions.

Learning Objectives:

To introduce the role of different imaging modalities in focal lesion assessment.

A-145

Brain

G. Polonara; Ancona/IT

Neuroimaging plays a pivotal role in the diagnosis of CNS disorders. The most frequent focal pathologies of the CNS are vascular accidents, tumours and infections. The imaging techniques used for evaluating brain focal lesions include CT and MR. The multiplanar capability of MR gives better definition of the lesion extent and location. The use of a non-conventional MR technique allows for an accurate characterization of lesions compared to standard approaches. Diffusion-weighted imaging (DWI) is widely used to investigate hyper-acute cerebral ischemia, detecting early ischemic abnormalities related to reduction of ADC. DWI can also help in differentiating a brain abscess from a cystic brain tumour. Perfusion weighted imaging (PWI) provides information on the hemodynamic status of brain tissue and detects regions with impaired cerebral perfusion. PWI has been shown to be clinically useful, particularly in the initial investigation of stroke, in tumour imaging and in assessing brain tumour responses to therapies. In acute ischemic stroke patients, the difference between DWI and PWI abnormalities, termed as diffusion/perfusion mismatch, represents potentially salvageable brain tissue with timely and appropriate therapy. MR imaging is a sensitive tool for identifying space-occupying CNS lesions, but it is relatively non-specific in distinguishing between benign and malignant lesions. Proton MR-Spectroscopy can non-invasively provide a chemical profile of the lesions that help in this determination. It can also give useful information on brain tumour type and grade, even obviating stereo-tactic biopsies in some cases, and is of help in monitoring the response to therapeutic surgical/medical intervention.

Learning Objectives:

1. To become more familiar with the typical MR features of the most frequent brain focal lesions.
2. To examine the potential of new MR imaging techniques in the characterization of cerebral focal lesions.
3. To identify an acute stroke lesion with DWI and PWI.
4. To know how to distinguish between focal and infiltrating lesions.
5. To know how to differentiate a brain abscess from a cystic brain tumour.
6. To examine the potential of proton MR spectroscopy for giving useful information on brain tumour type and grade.

A-146

Chest

M.L. Storto; Chieti/IT

Pulmonary nodules are frequently detected on chest radiographs and CT scans and often represent a diagnostic challenge. As a matter of fact, all pulmonary nodules should be considered malignant until proven otherwise. However, most of them are benign, especially if their diameter is ≤ 10 mm and do not require invasive assessment.

Numerous radiographic and CT criteria have been traditionally used to differentiate benign from malignant nodules including size, morphology, contrast enhance-

ment, and lesion growth over time. Although small nodules have a higher probability of being benign, size alone is not a reliable indicator of benignity. Morphologic features are only useful in a limited number of nodules showing a benign pattern of calcification. Contrast enhancement on dynamic CT scans seems to be a valuable method to rule out malignancy in nodules enhancing less than 15 HU (negative predictive value of 96%) and can be proposed in the diagnostic workup of nodules ranging between 8 and 20 mm in diameter, which are more difficult to reach with percutaneous biopsy. Growth rate assessment, which is commonly measured in terms of doubling time, is gaining particular importance in the context of lung cancer screening trials which lead to a large number of incidentally detected small nodules. In this regard, 3D estimations of doubling time are more accurate than 2D measurements, since asymmetric nodular growth can occur in malignant lesions.

Learning Objectives:

1. To review radiographic and CT criteria most useful in characterizing pulmonary nodules as benign or malignant.
2. To discuss the role of imaging in non-invasive assessment of pulmonary nodules.
3. To provide a management algorithm for small pulmonary nodules.

A-147

Liver

L. Graziosi; Brescia/IT

The last 10 years of experience demonstrate that the technological progress of non-invasive modalities has reduced the need for liver biopsy or other invasive diagnostic techniques in the diagnosis of focal liver lesions. At present, Doppler US with echo-enhancement, fast multi-detector CT and contrast enhanced MR represent complementary tools in terms of image quality, diagnostic accuracy and functional data in the identification and characterization of focal liver lesions. Contrast enhanced US with second generation contrast material completes the ultrasound diagnostic capability through dynamic vascular evaluation of focal liver lesions, offering additional morphologic elements useful for the final diagnosis.

Imaging multirow detector technology can provide enhanced focal lesion detection and characterization, as well as high-quality vascular studies increasingly requested in the context of liver transplantation. The most flexible applications in liver imaging result from the clear separation of the three distinct phases of contrast enhancement: the arterial, the portal venous in flow and the venous phase of parenchymal enhancement, which are very useful for differential diagnosis of focal liver lesions considering their different vascularization.

Recent technological developments have considerably broadened the role of MR imaging in the evaluation of liver pathology. Today, MR imaging is not looked upon merely as a problem-solving technique, but is widely considered the principal imaging modality for both the detection and accurate diagnosis of focal liver lesions. Advances in hardware and sequence design, and the advent of novel contrast agents with liver specific properties, have contributed towards making MR of the liver a routine clinical application.

Learning Objectives:

1. To describe US, CT, and MR imaging techniques to optimize detection and characterization of focal liver lesions.
2. To identify characteristic US, CT, and MR features of various primary and secondary hepatic neoplasms.

A-148

Kidney

M. Bertolotto; Trieste/IT

New and improved imaging modalities have increased the proportion of focal renal lesions discovered during US, CT and MR imaging. The main diagnostic problem is to differentiate benign from malignant lesions.

Among solid renal lesions, imaging modalities enable one to distinguish typical pseudotumors (normal variants), typical RCCs and show some distinctive features for angiomyolipomas in most cases. No definite imaging features have been described that allow adenoma to be differentiated from adenocarcinoma. Similar difficulties occur with oncocytomas, which may exhibit some specific features only in few instances. The clinical history and CT findings may help suggest the histopathologic nature of an indeterminate renal mass in chronic or acute inflammatory lesions, renal lymphoma, metastasis and multiple hereditary renal neoplasms.

Characterization of cystic masses relies on Bosniak's classification which consists of four categories: Benign (I) and minimally complicated cysts (II), Indeterminate cystic masses (III) including cystic tumors and complex cysts and Cystic RCCs (IV).

Saturday

Postgraduate Educational Programme

With the exception of typical renal cysts, most renal masses remain indeterminate at grey-scale US. Color Doppler US can allow identification of pseudotumors when the vascular architecture of the normal renal parenchyma is identified. MR imaging can be used in characterising very small cysts and some complex cystic or pseudo-cystic indeterminate masses. It provides higher contrast resolution compared to CT enabling better characterization of the fluid content of atypical hemorrhagic cysts. MR imaging and contrast enhanced US can be useful in demonstrating minimal contrast enhancement in solid tumors with poor vascularity or within the wall of cystic RCCs.

Learning Objectives:

1. To be aware of the capabilities of CT and the role of US and MR imaging in diagnosis of focal renal lesions.
2. To know the CT appearance of solid and cystic focal renal lesions.
3. To be aware of the difficulties in the differential diagnosis of benign and malignant focal renal lesions.

A-149

Muscles and tendons

C. Martinoli, R. Podestà, G. Succio, C. Gauglio, F. Zuccarino; Genova/IT

Diagnostic imaging plays an important role in directing the work-up of space-occupying lesions affecting muscles and tendons. The objective of this lecture is to provide an overview of the ultrasound and MR imaging appearances of a spectrum of tumors and tumor-like conditions affecting muscles (including intramuscular lipoma, haemangioma, ganglion, mixoma, desmoid tumor, sarcoma and metastasis) and tendons (including giant cell tumor of the tendon sheath and intratendinous ganglia). Epidemiology and clinical features of these tumors will briefly be discussed. Although a certain overlap is observed, ultrasound and MR imaging are able to demonstrate several characteristic features of these masses that may lead, in some instances, to a conclusive diagnosis. When imaging findings are non-specific, these techniques may help to differentiate benign from malignant forms and to establish the indication for a biopsy. Potential pitfalls in imaging interpretation of pathology and the advantage of one imaging technique over the other will be discussed.

Learning Objectives:

1. To learn the ultrasound and MR imaging appearance of a wide variety of benign and malignant tumors of muscles and tendons.
2. To understand potential advantages and limitations of ultrasound and MR imaging in characterization of tumors of muscles and tendons.
3. To identify other pathologic entities mimicking these tumors.
4. To discuss the imaging features so that when a tumor arising from a muscle or a tendon is encountered the diagnosis may be considered.

Nanotechnology

Moderator:

M.J. Lee; Dublin/IE

A-150

Nanotechnology (Introduction)

M.J. Lee; Dublin/IE

Nanotechnology refers to the process of building devices from the bottom up i.e. when a large product is constructed atom by atom into larger more complex structures. All this takes place on the nanoscale, which refers to one-billionth. One of the main requirements for doing this is the scanning tunneling microscope, which has allowed nanotechnology to develop. Properties of materials constructed from nanoscale objects are often different from properties of the same material created from larger molecules. Strength, melting point, electrical conductivity and magnetic properties may all change at the nanoscale level. Nanoscience therefore, can create novel products with unique characteristics. Examples of objects made from nanoparticles include: materials used in the computer industry to decrease the size required for storing memory, electronic circuitry, CD players and LED-based traffic signals.

In the area of Medicine and Health: proteins, nuclear gases, lipids etc. have properties at the nanoscale level. Medical research is currently underway to develop tools capable of probing this biologic nanometer world. Non-invasive sensing systems are being developed in an attempt to try and detect emerging diseases.

Treatment in terms of nanoscale drug delivery devices are being developed as well as implantable drug synthetic systems and others.

This New Horizons Series will provide a basic understanding of nanotechnology concepts and will also detail the implications of nanotechnology for medicine and health and for imaging sciences.

Learning Objectives:

1. To provide a basic understanding of the fundamentals of nanotechnology.
2. To describe in general, current and future interactions with medicine.
3. To describe possible interfaces between nanotechnology and diagnostic imaging.
4. To stimulate future areas of research.

A-151

Basic tools and concepts

D. Fitzmaurice; Dublin/IE

Nanotechnology has emerged as a key enabling technology, which will impact on all areas of science and engineering, including those that underpin the field of radiology.

This presentation will provide a societal and economic context for nanotechnology. It will present and illustrate a practical definition of nanotechnology. It will consider current and possible future applications of nanotechnology in diverse fields.

In doing so, the basic concepts and tools that have underpinned the emergence of nanotechnology will be reviewed.

Learning Objectives:

1. To be able to define nanotechnology and illustrate this definition by reference to both the underpinning concepts and tools and by reference to recent developments in areas of science and engineering that are relevant to the field of radiology.
2. To be able to discuss the current and possible future social and economic impacts of the emergence of nanotechnology as a key enabling technology.

A-152

Implications for medicine and health

D. Kelleher; Dublin/IE

Nanoparticle technology offers many new and exciting advantages in biomedicine with particular applications both in laboratory and radiological diagnostics and potentially in therapeutics. Nanoparticles can be generated from a variety of materials and constructed to dimensions that have the potential to mimic the size of viruses, proteins or genes. Nanoparticles have significant advantages as fluorescent probes, including wide absorption profiles, allowing excitation of varying particles at different times simultaneously, large linear absorption cross-section, narrow emission spectra which are tunable by size and excellent photo stability. One of the major advantages of nanoparticle technology is the capacity to synthesise in organic solvents and functionalise for biological use including biologically labelling with proteins, antibodies, genes, antisense or RNAi. Latterly, nanoparticles have been designed to target cellular and subcellular compartments.

Overall, therefore, such technology offers significant advantages in biomedicine. In terms of drug delivery, the wide tissue distribution of nanoparticles permits selective localisation of pharmaceutical agents carried on pre-tagged nanoparticles. In addition, magnetic carriers have also been used in imaging, and for similar reasons, may permit detection of specific tumours based on their physical and/or antigenic properties. Lastly, the capacity to generate self-assembling nanowires in physiological solution from nanoparticles has enormous potential in a range of both neurological and inflammatory conditions. Finally, nanoparticles are currently at a relatively early stage of development and it is anticipated that major breakthroughs in the coming years will have a significant impact on human health care.

Learning Objectives:

1. Basic principles of nanoparticle composition and synthesis.
2. Potential for functionalisation of nanoparticles with drugs, proteins, DNA, RNAi.
3. Applications of functionalised nanoparticles in diagnostics, imaging and therapeutics.

A-153

Nanotechnology and diagnostic imaging

M. Harisinghani; Boston, MA/US

Magnetic nanoparticles containing superparamagnetic iron oxides are providing researchers with exciting new opportunities to study molecular and cellular proc-

Postgraduate Educational Programme

esses in various diseases. On the basic science front, derivatives of these nanoparticles have been modified into "smart" sensing probes allowing us for the first time to detect DNA mismatches or proteins/protein interactions. In some more applied research, derivatized nanoparticles have also been used to target the growth of new blood vessels (angiogenesis), cell death (apoptosis) or specific cell types (stem cells, immune cells). Specifically, a new physiologically inert nanoparticle (highly derivatized crosslinked iron oxide nanoparticle derivatized with tat peptide sequences; CLIO-HD) has been shown to allow in-vivo MR imaging tracking of systemically injected cells at near single-cell resolution. On the clinical front a commercial preparation of magnetic nanoparticle is being successfully used for the MR detection of minimal nodal metastasis disease and study early perfusion changes in the pancreas of patients with type I diabetes. The proposed talk will provide a systematic overview of magnetic nanoparticle applications from bench to bedside as well as emerging techniques. Clinical applications such as detection of minimal metastatic disease in lymph nodes, imaging of angiogenesis, imaging inflammation will be covered.

Learning Objectives:

1. To provide a broad overview of the current and emerging applications of nanoparticles.
2. To become familiar with the potential clinical applications of nanoparticles.
3. To understand the optimal techniques for imaging with nanoparticles.

PACS and teleradiology in Europe

D. Caramella; Pisa/IT

The 22nd International Conference of EuroPACS, that was held in Trieste in September 2004, offered a comprehensive update on the development of PACS and teleradiology in Europe (www.europacs.org).

The conference showed that a wealth of experience has been gathered both from the clinical and the research points of view in many European countries, including those of central and eastern Europe. Topics of relevant interest included the development of regional PAC systems with innovating networking strategies and the progressive convergence between PACS and teleradiology. The purchase of PACS services is no longer limited to traditional approaches, as ASP is emerging as a possible alternative attractive to both vendors and hospital managers. Another important aspect is the increasing role of standards in supporting filmless hospitals: in the past, interface standards such as HL7 and DICOM already facilitated systems integration, now integrating the health enterprise (IHE) promises to allow functionally driven system integration. Finally, there is an increasing interest towards the E-learning applications that use PACS systems as tools for fostering education in radiology.

Learning Objectives:

1. To analyze the organizational and networking strategies needed for the development of regional PACS.
2. To evaluate if ASP is a viable alternative in the purchase of PACS services.
3. To verify the importance of the IHE standard initiative.
4. To assess the value of PACS as a learning tool for radiologists.

A-155

Quantitative image processing

A. Jackson; Manchester/UK

The lecture should provide an understanding of the basic concepts of quantitative image analysis. In particular the lecture is intended to provide the radiologist with some insight of the potential errors that can occur in quantitative image analysis techniques.

Background: The increasing availability of stable digital imaging platforms has led to an explosion in the use of quantitative image analysis techniques many of

which are now available on commercial platforms. Typical examples include software to perform tissue segmentation, measurements of tissue perfusion or to detect differences between scans over time. All of these techniques are designed to produce quantitative data so that an understanding of the potential errors which may occur is essential.

Procedure Details: This talk will introduce the basic generic concepts of image processing using tissue segmentation and dynamic contrast enhanced MR techniques as examples. We will focus on commonly commercially available techniques and examine in detail the potential advantages and disadvantages of them by illustrating the analysis process. We will also discuss the concept of the generation of models underlying analysis techniques and the implications of their use.

Conclusions: Clinical use of quantitative image analysis techniques is increasingly common. This lecture will highlight generic issues associated with this type of analysis which must be appreciated by clinicians intending to use these methodologies.

Learning Objectives:

1. To understand the basic approaches that can be taken to segment individual tissues from MR image.
2. To understand the advantages and disadvantages of different approaches.
3. To understand the concept of dictated model based analysis of imaging data and its advantages and disadvantages.
4. To understand the basic analysis concepts applied to dynamic contrast enhanced data from MR imaging and CT.
5. To understand the range of models that can be applied to dynamic contrast enhanced data and the implications of the choice of analysis technique.

A-156

Industry, integrating solutions towards a better practice

E. Cordonnier; Rennes/FR

Due to the digitization of equipment, the medical imaging industry increasingly integrates its products, and, more, integration is becoming a crucial part of the quality of solutions.

Initially, integration was considered by vendors as:

- losing product specificity by leveraging common minimal features,
- decreasing competitive advantages by opening solutions to products from competitors,
- increasing complexity by introducing external constraints.

However, users have clearly notified vendors that without integration, products have no future. Medical imaging equipment support some of the most complex clinical processes, and data produced by devices (images, signal^{1/4}) are to be associated to and manipulated with other information originating from various sources (electronic patient record^{1/4}).

Through an increasing global and active cooperation between users and vendors, the medical imaging community has designed standards and an integration framework which enable to connect and associate multiple products without losing any advantages of any products. It has been possible to respect cultural and local clinical practices through option and configuration parameters.

The DICOM and HL7 standards, as well as general-purpose standards (Internet^{1/4}), enabled to define proper interfaces (objects, services) between systems. IHE, a worldwide initiative, defines how to implement integrated solutions complying with these standards for common clinical scenarios. This approach was first applied to radiology and then to the laboratory sector, and it is now gradually spreading to all medical sectors including cardiology and other medical imaging sectors as well as IT infrastructure, within and also across healthcare facilities. This contributes to the Cross-Enterprise Electronic Patient Record.

Learning Objectives:

1. To comprehend what is the evolution of the medical imaging industry towards integration of standards.
2. To understand what is the impact of the IHE approach for the users and clinical practice.
3. To anticipate what are the biggest challenges for the next five years around the cross-enterprise Electronic Patient Record.
4. To learn what are behind the different Acronyms: DICOM, HL7, IHE and COCIR.

A-157

Logistic implications of MSCT

A.K. Dixon, B. Housden; Cambridge/UK

The advent of Multislice CT has profoundly changed the way we practice radiology, let alone CT. The pressure to maximise throughput on modern CT systems is intense. Various novel methods of streamlining the workflow will be presented. Meanwhile the clinical indications for MSCT expand, often with little or no extra revenue for the CT unit itself. This puts yet more pressure on the hard-pressed radiographers who feel that they are running faster and faster on the treadmill and only just keeping up! Such pressures may lead to a compromise on quality. It is very hard to provide an excellent high quality, large volume service at low cost. Some of the inevitable compromises will be discussed. So too will issues related to reporting and filming/PACS storage. The single most important factor in the smooth running of a CT Unit is mutual respect between radiographers and radiologists. Only by close co-operation between the two essential groups within a modern Radiology Department will MSCT be used to its full potential.

Learning Objectives:

1. To comprehend the ever increasing indications for MSCT.
2. To understand the role and importance of vetting requests.
3. To become familiar with methods of streamlining workflow.
4. To learn the principles of archiving dilemmas and reporting practices.

L. Everse; Rotterdam/NL

A-158

How to write a successful grant proposal

L. Everse; Rotterdam/NL

Grant support is increasingly important to the radiological researcher. Yet even the most brilliant idea is not always funded. In order to score well, you have to show that your proposal fulfils the granting agency's objectives and that it is likely that your project will have an important impact on the population of interest. Some simple techniques can aid us in gaining that coveted letter of approval.

This lecture will cover the basic points inherent in determining ranking of grant proposals and make suggestions as to how grant proposals can be fine-tuned to increase their ranking. By identifying the objectives of granting organizations, you can select the most suitable granting agency and adapt your proposal to fit their priorities. By understanding the grant application process, you can identify the information that the reviewer needs to judge your proposal. Putting yourself in the reviewer's shoes teaches you to use lucid text that provides the reviewer with the required information and to use appropriate buzz-words that link your proposal to the organization's objectives and priorities. In order to show potential impact of your research, you should clearly state what the target population is and how exactly this project will change their lives. The feasibility of the project should be clear. Feasibility includes investigator expertise, predicted inclusion rates, the estimated sample size needed, and the appropriateness of the experimental design. Finally, how the project will transition from research to clinical practice should be specified (implementation plans).

Learning Objectives:

1. To identify the priorities of granting agencies from their literature.
2. To understand what the reviewer needs to know to judge your grant properly.
3. To understand the structure of grant application forms - what information goes where?
4. To optimally describe the impact that your proposal will have on the population of interest, including feasibility parameters.

Would W.C. Röntgen get along with hospital managers?

J.F. Debatin; Hamburg/DE

The work of W.C. Röntgen stands for hard work, creativity, and unrelenting curiosity spiced up by a bit of luck - ingredients which are best summarized by the term "serendipity".

Since the death of W.C. Röntgen both Radiology research and clinical Radiology have become more and more organized, requiring ever more management input. The results are evident at ECR 2005. Every angle of every new research development is being explored resulting in a vast increase in research quantity, accuracy and reliability. A visit of the industrial exhibit underscores the impact of management requirements onto clinical radiology. Thus the dominance of high tech machinery is being increasingly eroded by the omnipresence of IT management tools.

The need for structured management thus appears to be part of the Röntgen heritage. There is more, however: a modern W.C. Röntgen would insist on leaving sufficient space for creativity to assure "serendipity" not merely in research but also in clinical Radiology. Hospital managers, particularly those involved in a research environment seem well advised to consider both aspects of the Röntgen heritage. A balance needs to be struck between structured management on one hand and managed freedom on the other.

Learning Objectives:

1. To explore the skills sets required by the imaging researcher and practitioner in the 21 century.
2. To define the future role of diagnostic imagers in an evermore intriguing and complex health care system.

Vascular, emergency and ICU imaging

Moderator:

D. Fleischmann; Stanford, CA/US

A-160

A. Vascular disease and lung edema

M. Prokop; Utrecht/NL

Pulmonary embolism (PE), if left untreated, is a highly lethal disease and therefore requires a rapid diagnostic workup. There are a vast number of potential diagnostic strategies, which all prominently feature imaging techniques such as scintigraphy, CT angiography (CTA) and ultrasound. Multislice CTA has de-facto substituted for angiography as the gold standard for diagnosis of but it need not always be the first technique to be performed for this indication. The course will discuss under which conditions D-dimer assays can be used to rule out PE, and

Postgraduate Educational Programme

under which circumstances scintigraphic techniques still play a role. It will describe the dilemmas of pulmonary angiography and cover the future potential of MRA. Technical and interpretational pitfalls of CTA will be demonstrated. Radiation dose issues will also include the question which technique to use in pregnant women.

Aortic dissection and traumatic aneurysms are the most important acute diseases of the thoracic aorta and are primarily diagnosed by (multislice) CT. Chronic dissections, congenital abnormalities, aneurysms, and aortitis are diseases where MRA also plays a major role. Typical diagnostic questions and imaging pitfalls will be reviewed. In the last part, this course will provide the pathophysiologic concepts behind the development of the various types of pulmonary edema and focus on patterns that help distinguish them on plain chest radiographs. It will describe particular criteria that have to be known when interpreting bedside chest radiographs and will correlate findings with CT morphology.

Learning Objectives:

1. To learn how to diagnose pulmonary embolism and avoid diagnostic pitfalls.
2. To learn to use CTA and MRA for diagnosis of aortic disease.
3. To understand the criteria for distinguishing different types of pulmonary edema.

A-161

B. Trauma, emergency and ICU imaging

P. Schnyder; Lausanne/CH

The first part of the topic will familiarize young radiologists with the modern concept of radiological investigations of polytrauma patients, with particular focus on the impact of multidetector CT installed within or adjacent to the emergency room. The most striking life-threatening thoracic conditions will be considered, including chest wall lesions, occult and tension pneumothoraces, hemotorax, tracheobronchial ruptures, hemomediastinum and aortic lesions, diaphragm ruptures and frequently associated abdominal lesions which urge total body survey of polytrauma patients.

The second part of the presentation will deal with the importance of daily film reading sessions in the ICU held by a senior and junior radiologists together with ICU physicians. The most frequent conditions encountered daily in the ICU will be considered, including: early identification and characterization of lung infiltrates and consolidations, usual and unusual presentation of lung edema, intrathoracic fluid collections, intravascular fluid overload, postoperative complications, bone abnormalities previously missed, knowledge and identification of correct positioning of all lines or misplacement, with corresponding consequences, including mainly tracheal tubes, central venous catheters, Swann-Ganz catheters, nasogastric tubes, pleural drains, intraaortic balloon pumps and some other more specific devices.

This topic also emphasizes the importance of the close relationship between radiologists and intensive care physicians urged by ICU patients and on the role of CT applied on selected ICU patients and selected pathologic conditions for a better comprehension of physiopathological situations, for confirmation of a pending diagnosis and not infrequently for modification of the treatment.

Learning Objectives:

1. To familiarize the audience with the spectrum of findings in chest trauma.
2. To provide an overview regarding lung abnormalities in the ICU patient.
3. To present usual and unusual appearances of tubes and lines in the chest.

Epilepsy, white matter diseases and ageing

Moderator:

D. Ducreux; Le Kremlin-Bicêtre/FR

A-162

A. Epilepsy

H. Urbach; Bonn/DE

Imaging of epilepsy patients is challenging since epileptogenic lesions (defined as a structural lesions causally related to the epilepsy syndrome) may be small and often do not change during life. Prior clinical information about the epilepsy syndrome and the semiology of the seizures is needed in order to plan the examination properly. The effort to detect an epileptogenic lesion is directed to partial (focal) epilepsy syndromes whereas - by definition - no lesion is identified in

idiopathic epilepsies. Most patients with partial epilepsies suffer from mesial temporal lobe epilepsies. In these patients, 2 to 3 mm thick T2-weighted rather than FLAIR fast spin echo slices along or perpendicular to the temporal lobe length axis have the highest diagnostic efficacy. In contrast, in patients with extratemporal lobe epilepsies perpendicular FLAIR slices through the anatomic region, from which due to clinical and EEG criteria the seizures are likely to originate, are preferred. The imaging features of common epileptogenic lesions (hippocampal sclerosis, long-term epilepsy-associated tumours, focal cortical dysplasias, vascular malformations, encephalitis including limbic and Rasmussen's encephalitis, gyral scarring including ulegryia) are detailed.

Learning Objectives:

1. To become familiar with clinical informations about the epilepsy syndrome and the semiology of the seizures.
2. To use these informations as clues whether an epileptogenic lesions is likely to be present and in which part of the brain one has to look for.
3. To learn the imaging findings of common epileptogenic lesions found in patients undergoing persurgical evaluation for possible epilepsy surgery.

A-163

B. White matter diseases

E.-W. Radü; Basle/CH

This lecture will give an overview of the structure and pathology of white matter which mainly consists of myelin and supporting tissues. The presentation and specific artefacts of different examination sequences -like the spin echo sequence, the turbo spin echo sequence and the FLAIR sequence as well as other gradient echo sequences- will be discussed. Examination protocols for different types of pathologies (vascular, degenerative, inflammatory) will be introduced to make the differential diagnosis easier.

The pattern of lesions, their localization, contrast media enhancement and space occupying effects will be discussed; the lecture will present characteristic forms of congenital and acquired diseases of white matter and will suggest ways to assign them etiologically.

Furthermore the changes in white matter due to multiple sclerosis will be shown in detail. The value of T2 hyperintense areas, black holes and contrast media enhancements will be presented in connection to their distinct pathological findings. MR spectroscopy as a method of examination as well as Magnetization Transfer Imaging will be discussed. The lecture will present standardized protocols for examinations of the brain and the spinal cord in suspected multiple sclerosis and for follow-up examinations in definite multiple sclerosis. Finally, difficulties in follow-up examinations and hints on how to perform a satisfying repositioning will be shown.

Learning Objectives:

1. To demonstrate the relevant knowledge of the correlation between MR findings and histo-pathological alterations.
2. To induce a detailed report especially of alterations of the white matter.
3. To suggest a standardized examination in multiple sclerosis.

A-164

C. Normal ageing and neurodegenerative diseases

M.A. van Buchem; Leiden/NL

The most common neurodegenerative disorder is ageing. Ageing is associated with degenerative changes in the brain. With increasing life expectancy of the population, the number of elderly persons increases in industrialized societies. Therefore, radiologists in such societies will increasingly be confronted with age-related changes in the brain. Knowledge of these changes is thus essential for every radiologist. Before describing the abnormalities that occur with aging, it is important to be aware of a few facts. First, age-related abnormalities do not occur in all elderly persons. Second, age-related changes that are apparent on radiological examinations do not always have functional consequences. Third, normal ageing and neurodegenerative disorders may be difficult to distinguish. One reason is the similarity of the abnormalities that are associated with these conditions. Another phenomenon that complicates distinguishing normal ageing from other neurodegenerative disorders is the fact that due to the high prevalence of the latter, these conditions often coexist in the elderly with changes that are due to normal aging. In such circumstances it may be impossible to separate the abnormalities in terms of their origin. An important task for radiologists, when confronted with a brain study in an elderly patient, is to screen for the presence of neurodegenerative disorders. In this process, changes should not be attributed too easily to normal aging. In order to be able to separate usual ageing and other neurodegenerative disorders, a radiologist should be familiar with the changes that occur in normal ageing. In this presentation such changes will be described.

Postgraduate Educational Programme

Learning Objectives:

1. To comprehend the principles of successful, usual and pathological aging.
2. To become familiar with age-related changes in the brain that occur during usual aging.

16:00 - 17:30

Room B

Musculoskeletal

RC 810

Bone marrow disorders as a manifestation of disease

Moderator:

H. Imhof; Vienna/AT

A-165

A. How to image bone marrow

A. Stähler; Munich/DE

Introduction: MR imaging can directly visualize bone marrow. Bone marrow pathologies have low SI on unenhanced T1-weighted images and increased SI on (fat-suppressed) PD, T2w and STIR images. Differentiation of acute osteoporotic and tumor-related vertebral fracture can be difficult.

Gadolinium: The principles of percentage enhancement for bone marrow imaging and the cut-off values (> 35% in patients older 35 years) are explained. Percentage enhancement is a good and reliable tool to estimate marrow cellularity. Diffusion-weighted Imaging: On diffusion-weighted imaging benign fractures exhibit isointense or low SI compared to surrounding bone marrow, whereas metastatic vertebral compression fractures show high SI.

Whole Body Imaging: Whole body MR imaging detects more lesions than bone scintigraphy. Although bone scans tend to detect more lesions in the ribs and the skull, MR imaging detects more lesions in the clinically relevant body parts including the spine and the pelvis.

Differentiation of acute osteoporotic and tumor-related vertebral fractures:

Imaging findings characteristic for tumor-related vertebral fractures are a convex posterior cortex, diffuse low SI on T1w images, lesion extension into the pedicle, high or inhomogenous signal-intensity following Gadolinium, and a high SI of the bone marrow on T2w or STIR images. Findings indicative of osteoporotic fractures are retropulsion of a bone fragment, preservation of some fat signal on T1-weighted images, return to normal SI after Gadolinium, a horizontal bandlike signal pattern, and isointense bone marrow signal on T2w or STIR images. There is a correlation between "vacuum phenomenon" on CT and the "fluid sign" on MR imaging.

Learning Objectives:

1. To differentiate acute osteoporotic from tumor-related vertebral fractures.
2. To understand diffusion weighted imaging of bone marrow.
3. To use percentage gadolinium enhancement for bone marrow imaging.

A-166

B. Tumors

F. Lecouvet; Brussels/BE

MR imaging has a variety of roles in the setting of bone marrow tumors, depending on the patient's clinical details: unexpected observation of a tumoral lesion in patients with unknown neoplasia, confirmation of lesions detected by nuclear medicine techniques, disease staging and evaluation of response to treatment in patients with known cancer, work-up of symptoms for cancer.

Systematic screening of the bone marrow requires investigation of the pelvis and proximal femurs in addition to the spine study.

For lesion detection, T1-weighted images are often sufficient and lesions have low signal intensity. Fat-saturated T2 or intermediate-weighted images, or STIR images are also efficient in lesion detection that generally have intermediate to high signal intensity. These sequences and contrast-enhanced T1-weighted images become mandatory to differentiate diffuse neoplastic marrow infiltration from abnormally cellular albeit normal marrow.

In terms of lesion characterization, MR imaging plays little role because MR patterns of neoplastic marrow involvement are non-specific: focal lesions and diffuse infiltration are observed in metastases, lymphoma and multiple myeloma. However, some subtle features sometimes help in the differential diagnosis: concurrent observation of diffuse bone marrow signal alterations, focal lesions and compression fractures are indicative of myeloma; a combination of bone lesions with paraspinal or pelvic tumoral lymph nodes and extra-osseous tumor spread without alteration of the bone cortices suggests lymphoma.

The radiologist must be aware of some benign conditions which may mimic tumoral lesions: benign, diffuse or focal bone marrow hyperplasia, intravertebral disk herniations, acute vertebral compression fractures and infectious lesions.

Learning Objectives:

1. To illustrate general MR imaging characteristics of tumoral bone marrow involvement.
2. To describe imaging features suggestive of most frequent bone marrow tumors: Metastases, myeloma and lymphoma.
3. To underline the lack of specificity of MR imaging and illustrate several non-tumoral lesions which may mimick bone marrow tumors.

A-167

C. Non-neoplastic marrow disorders

A.H. Karantanas; Iraklion/GR

Magnetic resonance imaging is an imaging technique that allows direct visualization of bone marrow. Although MR imaging exhibits high sensitivity, we need an adequate understanding and careful choice of acquisition sequences to improve specificity. Technical improvements such as providing a moving table and developing new coils and sequences allows the study of the whole marrow in a reasonable time.

Non-neoplastic disease processes involving the marrow can induce a variety of imaging findings. These conditions are frequently undetectable by conventional radiographic techniques until they have reached an advanced clinical stage. The excellent spatial and contrast resolution provided by MR imaging facilitates early detection and evaluation of various disorders thus allowing prompt treatment. In addition, the association between marrow changes and pain such as in osteonecrosis and osteoarthritis is clinically relevant. Radiological interpretation of the marrow space requires an understanding of normal maturation, and recognition that red and yellow marrow co-exist with variable amounts depending upon age and location. With MR imaging this variability yields normal patterns ranging from very uniform and homogeneous to patchy and heterogeneous signal intensity. Signal changes also depend on the pulse sequence applied. The marrow reflects patient health and may herald developing anemia with marrow reconversion from inactive to active. Disorders to be considered include: a) marrow ischemia and infarction, b) transient osteoporosis of the hip and transient epiphyseal lesions of the knee, c) marrow oedema-like lesions secondary to trauma, stress response, osteoarthritis, tendon pathology, Sudeck's algodystrophy and previous arthroscopy, d) infection and e) marrow infiltration (Gaucher's disease - myelofibrosis).

Learning Objectives:

1. To understand the normal bone marrow reconversion observed in athletes, heavy smokers and obese patients.
2. To provide an overview of marrow changes in hemoglobinopathies, storage diseases, infection and Paget's.
3. To be familiar with the bone marrow changes in avascular necrosis and transient osteoporosis.
4. To understand the marrow changes in trauma.

Imaging ICU patients

Moderator:

L. Gattinoni; Milan/IT

A-168

Imaging ICU patients (Introduction)

L. Gattinoni; Milan/IT

The use of CT scans in ICU patients has been delayed for several years, largely because of the difficult transport of ICU patients, the cost of the technique and the absence of clear indications. The best example is ICU patients with ARDS; only in 1984 did the first report appear on the use of CT in this pathology. The CT scan images and the quantitative CT scan analysis allow us to confidently refute the common belief that ARDS is a homogeneous alteration of the lung parenchyma. Most of the more recent advances in the treatment of the patients with ALI/ARDS originated from the information obtained by CT scanning. Despite the difficulties and costs, the CT scan resulted in a change of treatment in about 30% of the patients with ALI/ARDS, making it cost-effective. Trauma, pulmonary embolism, discrepancy between clinical findings and radiological observations are all

Postgraduate Educational Programme

clear indications for CT scanning. The use of CT scan is nowadays an integral part of the assessment of most patients admitted to the ICU.

Learning Objective:

To understand the general indications for CT scanning in ICU patients.

A-169

Structure-function correlations in acute lung injury

L. Gattinoni; Milan/IT

The use of quantitative CT scanning allowed great advances in our understanding of pathophysiology of acute lung injury and ARDS. A standard voxel, characterized by a given CT number, (0.5 x 0.5 x 1.5 mm) matches the dimensions of a normal acinus at functional residual capacity, about 2,000 alveoli. If the lung collapses the same voxel may include up to 11.5 acini. In case of intra-alveolar edema the same voxel should include about 1 fluid-filled acinus. Knowing the CT number frequency and distribution, it is possible to compute the gasless, the fully aerated, the normally aerated and the hyperinflated tissue. Moreover, it is possible to compute the excess lung weight, i.e. the edema, using as reference the expected normal lung weight for any given patient. The quantitative analysis allows us to determine in ALI/ARDS if the aerated lung is small rather than stiff, and the dimensions of the baby lung are estimated by lung compliance. Regional analysis obtained at different pressure conditions led to the discovery that the lung recruitment is a continuous phenomenon along the entire volume/pressure curve. The actual modeling refers to the ARDS lung as a sponge. The increased lung mass causes the compression of the most dependent regions. The density redistribution in the prone position as well as the mechanism of positive end expiratory pressure are best explained by this model. Finally the CT scan allows an estimate of the potential for recruitment, this information may be a key clinical advance for setting PEEP and tailoring an appropriate mechanical ventilation.

Learning Objective:

To understand the use of CT scan taken in different conditions for the clinical treatment of ALI/ARDS patients.

A-170

Clinical correlation in the imaging of ARDS

L.R. Goodman; Milwaukee, WI/US

Adult respiratory distress syndrome (ARDS) is a dynamic disease due to multiple different systemic and/or local insults to the lung. Although there are some distinct differences in the imaging appearance of ARDS due to systemic insults and ARDS due to direct lung insults, in general, imaging is not specific and is used to support the diagnosis of ARDS rather than to make the diagnosis. However, in the proper clinical context, the imaging is strongly suggestive of ARDS or suggesting alternative causes for the respiratory difficulties. Imaging also aids in the understanding of the underlying clinical and pathophysiological progression. The current generation of multidetector CT scanners is also being used to study respiratory dynamics and the effect of various ventilatory measures on lung volumes and gas distribution.

Imaging's most important role is in following the progression of the disease and in the prevention and diagnosis of complications. Complications are numerous and include aspiration, nosocomial infection, atelectasis, and pulmonary embolus. Iatrogenic complications include barotrauma, fluid overload, and malposition of tubes and catheters.

Learning Objectives:

1. To understand the expected imaging progression of ARDS.
2. To understand how imaging reflects pathophysiology of ARDS.
3. To be able to detect early complications of ARDS and their treatment.

A-171

Imaging sequelae of acute lung injury

S.R. Desai; London/UK

The acute respiratory distress syndrome (ARDS) is a non-specific response to direct or indirect lung injury. Patients with ARDS are characterised by progressive dyspnoea, refractory hypoxia, decreased compliance and alveolar infiltrates on chest radiography. On histopathological examination there are progressive changes which are mirrored by the appearances on radiological studies: acutely, there are eosinophilic hyaline membranes within respiratory bronchioles and alveolar ducts. Initially, there is only a limited interstitial infiltrate. With time the interstitial infiltrate becomes more striking and there is inflammatory and haemorrhagic fluid exudation into the airspaces. In the final stages there is healing by fibrosis which, in some patients, may be marked. Imaging has an important role in the management of critically ill patients; daily chest radiography is useful for

monitoring progress and detecting complications. Computed tomography (CT) is also valuable in the acute stages: in addition to "problem-solving", CT provides insights into the pathophysiology of ARDS. The typical CT changes, in the acute stages, comprise symmetrical regions of dependent dense parenchymal opacification, non-dependent areas of ground-glass opacification and normally aerated lung parenchyma in varying proportions. In some patients it is possible to differentiate ARDS due to pulmonary and extrapulmonary injury based on CT features. Furthermore, in survivors of ARDS, there is a characteristic distribution of changes which is thought to be a consequence of barotrauma in the acute stage. The lecture will present the morphological features of ARDS both in the acute stage and at follow-up.

Learning Objectives:

1. To learn the imaging (CT) features in patients with lung injury.
2. To appreciate the relationships between histopathological changes and CT features in patients with ARDS.

16:00 - 17:30

Cardiac

RC 803

Coronary vessels

Moderator:

M. Oudkerk; Groningen/NL

A-172

A. Clinical issues and anatomy of the coronary vessels

R. Riemann; Graz/AT

Coronary vessels serve as conduit for blood flow (F) from the aorta to the myocardium and further to the right atrium.

The task of the F is to keep permanent balance between myocardial oxygen supply and demand to prevent myocardial damage. Therefore early recognition of the presence and causes of insufficient coronary F are mandatory. This means it is necessary to control and to consider all factors which may influence the F and the demand of oxygen.

Under normal anatomical conditions the individual distribution and course of the coronary vessels and their ramification play a major role. In the presence of pathohistological changes of coronary vessel walls the F is mainly influenced by the decrease of elasticity and increase of vessel wall resistance.

The loss of normal elasticity diminishes the possibility of fast F adaptation with respect to myocardial oxygen demands.

In a simplified model, coronary F may be described by Ohm's formula $F = P/R$, whereby pressure (P) and resistance (R) are controlled by the neuro-humoral system.

The present non-invasive coronary imaging methods enable the visualisation not only of the macro-anatomy of the coronary vessels and their ramification, but also directly atherosclerotic wall changes.

As their spatial, contrast and time resolution are continuously improving, they are already superior to lumeno-graphic methods as coronary angiography. The visualisation of coronary anatomy and its wall pathology will - by simultaneously performed quantitative measurements of myocardial F and by the control of neuro-humoral system - enable to generate a new approach to individual risk stratification.

Learning Objectives:

1. To give an overview of the clinical problem.
2. To describe the radiological anatomy of the coronary arteries.
3. To discuss methods of risk stratification.

A-173

B. MRA of the coronary arteries

A. de Roos; Leiden/NL

Magnetic resonance angiography (MRA) of the coronary arteries is still suboptimal for routine clinical application. Initial results have shown the potential of breath-hold and navigator approaches for visualizing coronary artery stenoses. A multicenter trial using navigator technology has shown that the exclusion of major coronary artery disease is feasible. Recently, new technical approaches have been introduced to improve coronary artery visualization. For example, whole heart MRA acquires multiple thin slices with navigator control and is displayed in various ways for improved coronary artery visualization, including with the use of volume rendering techniques. Also the recent introduction of higher field systems

Postgraduate Educational Programme

(3 T) may help to improve coronary artery visualization. In addition, a number of contrast media are tested for improved vessel delineation. Bypass imaging is also feasible with the same technology. Not only patency, but also stenosis detection in venous bypasses is feasible with MRA. Furthermore, the versatility of MR imaging also allows flow quantification in the native coronary circulation as well as in bypass grafts. Another important goal is to detect atherosclerotic plaques and to characterize plaque composition. The versatility of MRA allows anatomic depiction of the coronary vessels as well as functional assessment of the stenosis in both the coronary arteries and bypass grafts.

Learning Objectives:

1. To discuss principles and techniques of MRA.
2. To give an overview of recent clinical outcome.
3. To discuss clinical indications of MRA.

A-174

C. MDCT of the coronary arteries

C.R. Becker; Munich/DE

The combination of multi-detector rows and fast gantry rotation together with the simultaneous acquisition of the ECG signal allows for imaging the coronary arteries with a high spatial and temporal resolution by a technique called retrospective ECG gating. With every new MDCT generation, spatial and temporal resolution is getting closer to cardiac catheter. It is therefore foreseeable that a significant number of diagnostic cardiac catheter investigations will be replaced by coronary CT angiography (cCTA) in the near to midterm future.

Assessment of the atherosclerotic plaque burden by coronary calcium screening with CT is a simple and effective way to non-invasively identify asymptomatic subjects with an increased risk for a cardiac event. cCTA may have the potential to visualize vulnerable plaques that are prone to rupture and cause acute coronary symptoms.

In patients with acute myocardial infarction cCTA may be able to display the location as well as the culprit lesion in the coronary artery.

cCTA may also provide valid information in patients with vasculitis and aneurysms, fistulas or dissections. The current strength of cCTA is the high negative predictive value as compared to cardiac catheter. In patients with unspecific complaints or ambiguous stress tests, cCTA may serve as a reliable non-invasive alternative to rule out coronary artery disease. The key application of cCTA will be to perform a non-invasive triage of patients with stable angina for conservative therapy, interventional treatment and bypass surgery and limit the use of invasive coronary angiography to patients in whom coronary interventions appears necessary.

Learning Objectives:

1. To discuss principles and techniques of MDCT.
2. To give an overview of recent clinical outcome.
3. To discuss clinical indications of MDCT.

16:00 - 17:30

Room E2

Abdominal and Gastrointestinal

RC 801

Crohn's disease of the intestinal tract:

Advances in imaging

Moderator:

A. Cieszanowski; Warsaw/PL

A-175

A. US and Doppler

C. Bru; Barcelona/ES

Ultrasonography with doppler is frequently the initial imaging study performed in patients with abdominal pain and diarrhoea. Inflammatory processes affecting the intestinal wall generally result in decreased peristalsis and bowel wall thickening, both of which tend to decrease the luminal gas content that allows a better visualization of intestinal structures.

The use of graded compression or cleansing and water enema improves the capacity of the technique to evaluate all the intestinal segments. The transperineal approach can be useful for the study of perianal pathology associated with Crohn's disease.

Technical improvements in US equipment allows us to evaluate the characteristic five layer pattern of the intestinal wall, the presence or absence of haustra, the vascularity of intestinal segments as well as the flow through the superior mesenteric artery.

The following topics will be discussed during the lecture:

- Methodology of intestinal ultrasound study
- Patterns in Crohn's disease and differential diagnosis.
- Risks and benefits of the technique
- Impact on management.

Learning Objectives:

1. To describe the US examination technique and findings in chronic inflammatory diseases of the intestinal tract.
2. To discuss the value and the limits of US for the diagnosis of Crohn's disease.
3. To discuss the impact of US on patient's management.

A-176

B. CT and CT enteroclysis

E.K. Makó; Budapest/HU

The incidence and prevalence rates of inflammatory bowel diseases show an increasing tendency worldwide.

There are efforts to find a more appropriate examination technique which is able to depict characteristic and large enough pathology of the IBD is permanent.

The diagnostic flowchart in patients with known chronic inflammatory bowel disease has changed due to wide availability of spiral or multidetector CT equipment, proceeding from multi-step diagnosis toward a "one stop shop" modality such as CT or MR enteroclysis.

When compared to US the capability of CT (enteroclysis) is less patient and operator dependent. Using thin slices and narrow collimation provides excellent spatial resolution and depicts tiny pathology of the bowel mucosa over characteristic intramural or extraintestinal changes.

Although specificity and sensitivity of CT (enteroclysis) in patients with superficial Crohn's disease still remains lower than barium enteroclysis (~90% and 98% respectively), in transmural and extraintestinal IBD it provides all the relevant pathological information needed for the correct diagnosis.

CT has the advantage of allowing simultaneous depiction of possible extra-intestinal abdominal complications of IBD and playing an important role in patient's management.

Learning Objectives:

1. To describe the CT examination technique and findings in chronic inflammatory diseases of the intestinal tract.
2. To discuss the value and the limits of CT for the diagnosis of Crohn's disease.
3. To discuss the impact of CT on patient's management.

A-177

C. MR imaging

D.J. Lomas; Cambridge/UK

Techniques: Several fast imaging sequences suitable for imaging the small bowel are now available on modern MR systems, including T1W, T2W and balanced T2/T1W. Each has particular merits for studying the small bowel. Both oral and nasojejunal tube examinations may be performed with MR imaging, paralleling the same examinations using X-ray. Most tube studies have employed methyl cellulose or dilute barium as the contrast media infused by manual or automated pump systems. As for X-ray studies, debate continues regarding the merits of the two approaches and regarding the most appropriate orally administered agent to achieve adequate luminal distension. Currently many studies are performed as static examinations with initial filling of the small bowel followed by an anti-peristaltic agent and then multiple breath-hold image sets acquired with a distended small bowel lumen.

Applications: Numerous studies have shown that MR examinations in inflammatory bowel disease can demonstrate many of the morphological features of traditional X-ray studies. MR imaging also has the benefits of avoiding ionizing radiation in a typically young population and of demonstrating the extra-luminal tissues, allowing excellent delineation of fistulae and extra-luminal changes such as fatty proliferation. Current MR systems are not well designed for these types of studies and tube insertion is usually done under X-ray guidance at present. These and other factors such as availability have limited the more widespread introduction of MR imaging in routine clinical practice. Further development of "interventional" MR imaging systems may simplify the practical aspects of these procedures and encourage more widespread use in the future.

Learning Objectives:

1. To describe the MR examination technique and findings in chronic inflammatory diseases of the intestinal tract.
2. To discuss the value and the limits of MR imaging for the diagnosis of Crohn's disease.
3. To discuss the impact of MR imaging on patient's management.

A-178

A. Screening for lung cancer: Update on results of current trials

F. Laurent; Pessac/FR

Although screening studies using chest radiograph and sputum cytology examination are still the subject of debate and the use of molecular techniques an exciting area of research, CT is the current method for ongoing screening programs. This course will focus on low dose multislice CT screening studies and updates on current trials will be reported. CT studies have shown that earlier-stage lung cancer can be detected but whether this will translate into a mortality reduction remains the subject of an intense debate because of methodological biases. Randomized trials including death as an outcome are advocated to evaluate this issue. Implications of CT screening are also great especially the number of patients who require further evaluation after CT. Current practice includes the use of non-invasive procedures to evaluate indeterminate nodules in order to minimize the cost and risk of invasive methods. Recent improvements in dedicated tools for enhancing detection (CAD) and characterization (CT volumetry) may play a significant role in decreasing the concern of the indeterminate pulmonary nodule.

Learning Objectives:

1. To understand the potential role and limitation of multislice CT in lung cancer screening.
2. To update the knowledge on results of recent and current trials.
3. To become familiar with the algorithms used for managing patients with indeterminate nodules.
4. To understand the impact of CAD and volumetric measurements in screening studies.

A-179

B. Staging and follow-up with CT and MR imaging

M. Zompatori¹, G. Battista², R. Canini²; ¹Parma/IT, ²Bologna/IT

Once the diagnosis of lung cancer has been established, attention turns to clinical staging. There is a strong relationship between the anatomical extent of tumor at diagnosis and post-treatment survival. A correct staging allows the selection of patients for surgical intervention, also reducing the rate of exploratory thoracotomies. However, misclassification is still reported in about one third of cases, particularly for lower lobe tumors. Optimal lung cancer staging and follow-up is still evolving. Today, it requires a multidisciplinary approach with a combination of MDCT and FDG-PET. Other techniques, such as MR or US, can be used as problem solving tools in particular cases. In our view, the introduction of metabolic staging (FDG-PET) is probably only the first step towards an imaging directed more at tumor biology investigation. During the presentation, T, N and M status will be discussed, along with particular problems such as: Satellite nodule evaluation, pleural disease, pancoast tumor. CT technical improvements will be evaluated, in comparison with the other anatomical methods and with brief reference to the strengths and weaknesses of functional imaging. Finally, an evidence-based, algorithmic approach will be presented, which can be used as a simplified reference for the staging of a new case of lung cancer.

Learning Objectives:

1. To understand the staging system of non-small cell lung cancer and small cell lung cancer.
2. To evaluate the role of the different imaging modalities for T-, N- and M-staging of lung cancer.
3. To characterize the different therapeutic strategies at different tumor stages and its relevance for imaging procedures.

A-180

C. Staging and follow-up with PET/PET-CT

G.K. von Schulthess; Zürich/CH

FDG (Fluorodeoxyglucose)-PET has gained major importance in diagnosis and staging of lung cancers for characterization of pulmonary nodules and for N- and M-staging of NSCLC.

PET is the best imaging modality to identify malignant pulmonary nodules (accuracy > 90%). False positives are due to infection; hence the prevalence of TBC is important. There are also some false negatives, mainly in bronchioalveolar carcinomas, which may show no FDG uptake.

N and M staging with PET has shown to be highly sensitive (85-90%) and specific (90-95%) and substantially higher than CT. PET staging is now the preferred staging modality for this disease. It can identify pathological lymph nodes at sizes 1 cm and smaller, where CT criteria for pathology are useless. It identifies bone metastases which are not seen on CT, and since the lesion to background contrast in PET is exquisite, tumor manifestations are less frequently overlooked on PET compared to CT scans. PET-CT is now rapidly replacing "PET alone" scanning and provides a "one-stop-shop" exam for patients with NSCLC. Data show that PET-CT, unlike PET alone, contributes to T staging as it can demonstrate thoracic wall infiltration and distinguish tumor involvement from atelectasis. PET-CT has higher sensitivity and specificity than either PET or CT alone, and even a painstaking side-by-side viewing of PET and CT data - while useful - is less accurate than fused images. Examples where the CT part of the examination adds information not seen on PET are small disseminated metastases, pleural effusions and calcifications.

Learning Objectives:

1. To discuss therapeutic strategies at different manifestations of lung cancer recurrence.
2. To analyse the role of different imaging modalities for detection of local recurrence, lymphatic or distant metastases.
3. To understand the advantages of PET-CT compared to separate PET and CT.

Orbit and visual system

Moderator:

K. Karlinger; Budapest/HU

A-181

A. Imaging of orbital pathology

P. Sosnowski; Poznan/PL

The role of computerized methods in orbital imaging is established. CT remains the method of choice in most emergencies, especially with bony and ocular trauma, including detection of intraorbital metallic foreign bodies. In intraorbital pathologies, CT and MR are used interchangeably. MR is a more demanding and still less accessible method but has undisputable advantages, especially regarding eye, optic nerve and extraocular muscles. Its superiority in superficial orbital structures and ocular imaging are subsequent to better tissue characterization and application of local coils. MR is complementary to ultrasound in problematic cases of congenital eye abnormalities, for tissue characterization and for evaluation of secondary extraocular involvement, especially in retinoblastoma and melanoma.

Regarding the optic nerve, application of different MR sequences, fat-saturation techniques and contrast media enables detection of even subtle pathology, like MS plaques, and precise visualization of the extent of disease along the whole course of the nerve.

In the era of MSCT with precise multiplanar reconstructions, the main advantage of MR in extraocular muscle imaging is the ability to define the activity of the pathological process. It is especially helpful in thyroid ophthalmopathy, remaining one of the leading indications for computerized imaging of the orbit. The algorithm of MR study encompasses morphological sequences, with the especially important SE T1 and STIR, and short-lasting GRE scans used for quantitative analysis of eye motility disorders, especially diplopia.

Learning Objectives:

1. To understand advantages, disadvantages and the main indications for CT and MR of the orbit.
2. To define the role of MR imaging in tumoral and nontumoral eye and optic nerve pathology.
3. To identify the algorithm for MR evaluation of the extraocular muscles pathology, putting a stress on thyroid orbitopathy.
4. To comprehend the role of computerized imaging in the evaluation of the intraorbital reasons of diplopia and blindness.

Postgraduate Educational Programme

A-182

B. Imaging of optic chiasm and visual tract diseases

W. Müller-Forell; Mainz/DE

Most patients suffering from intracranial pathologies affecting the visual pathway complain of nonspecific visual deficits. Subtle neuro-ophthalmological examination discloses different visual field deficits, depending on the specific location of the involved area. Therefore this refresher course starts with a short review of the anatomical landmarks of the visual pathway, visible on MR imaging (the method of choice in the case of visual pathway lesions) and corresponding neurological symptoms.

The following presentation of different pathologies includes clinical and imaging characteristics of the three main groups of potential pathological lesions: Extrinsic lesions: these prefer the sellar region and include skull base meningioma, pituitary adenoma and craniopharyngioma. Vascular compression syndromes, caused by intracranial aneurysms are also included. The latter present with different neurological symptoms, related to their location in the circle of Willis. Intrinsic brain tumors mainly affect the visual tract and optic radiation. Imaging characteristics and differential diagnostic criteria of e.g. different types of glioma, ependymoma or metastasis are discussed.

In the last group vascular and/or inflammatory processes, affecting the visual pathway are presented.

Learning Objectives:

1. To learn about anatomic landmarks of the intracranial pathway.
2. To understand their corresponding function and neurologic symptoms in case of pathologic involvement.
3. To learn about differential diagnostic criteria of MR images concerning possible different intracranial pathologies.

Diagnostic and interventional radiology of transplants

Moderator:

M. Galanski; Hannover/DE

A-183

Diagnostic and interventional radiology of transplants (Introduction)

M. Galanski; Hannover/DE

The field of organ transplantation has grown continuously during the past decades. Kidney and liver transplantation are well established. Lung transplantation has become an accepted treatment for patients with end-stage pulmonary or vascular lung disease. Combined kidney and pancreas transplantation is the most effective treatment for renal insufficiency due to diabetes. Advances in organ preservation, development of sophisticated surgical techniques, progress in perioperative management and postoperative intensive care, and dramatic improvement in immunosuppression have resulted in higher rates of patient and graft survival. Nevertheless, the field of transplantation still presents many challenges. Whereas excellent short-time survival is readily achieved, graft loss due to chronic rejection remains a major problem. Another major barrier is the lifelong need for immunosuppression with the risk for associated complications such as infection and malignant disease. A further critical point is the shortage of donor organs. The need for transplants for qualified recipients by far exceeds the number of donor organs. Strong efforts are made to close this gap, e.g. better patient and donor selection criteria, including older donors and non-heart-beating donors in the organ pool, living donor transplantation and so on. A deeper understanding of the immunological processes responsible for transplant rejection, induction of immunologic tolerance to achieve specific graft tolerance, xenografting, cell transplantation, and gene therapy strategies are on the horizon and may one day solve the main problems.

Learning Objectives:

1. To review the current developments that have significantly improved graft and patient survival among solid-organ transplantation and addresses the main challenges in the future.
2. To learn the clinical and surgical considerations in the evaluation process for organ transplantation.
3. To understand the pathophysiology of immediate and late complications, their manifestation in imaging and their management.

A-184

Liver

J.B. Karani; London/UK

Liver transplantation is the accepted treatment of patients with irreversible liver cell failure, some metabolic disorders and a selected group of patients with hepatocellular carcinomas. Over the last decade, the major transplant centres have reported improving survival rates even though during this period more complex surgical techniques, including split liver, auxiliary and live related transplantation have been introduced and more 'marginal' higher risk patients have been treated. This successful outcome has been dependent on appropriate recipient selection, robust surgical technique and early recognition and treatment of complications. Radiologists are core members of the multidisciplinary team achieving this success.

Despite these developments there remains an organ shortage for potential recipients. Therefore appropriate selection of recipients, particularly those with hepatomas and acute liver failure, is mandatory. Inappropriate selection from inaccurate radiological diagnosis or staging will not only result in poor recipient survival, but will also deny an organ to another recipient with a better survival profile.

Improved surgical technique has decreased the more common vascular and biliary complications but the newer techniques present differing diagnostic and interventional challenges. Major developments in MR and MDCT allow these complications to be diagnosed non-invasively, reserving invasive techniques for intervention. Vascular techniques of angioplasty and stent placement may reverse the sequelae of graft ischaemia or portal hypertension and prolong graft survival in both adult and paediatric recipients. MRC allows early recognition of biliary strictures amenable to dilatation and stent placement.

This presentation will review the application and outcome of these techniques.

Learning Objectives:

1. To understand the indications and outcome of liver transplantation in an adult and pediatric program.
2. To understand the new surgical techniques and the importance of radiology in recipient and donor selection.
3. To understand the importance of a multimodality approach to the recognition of the complications of liver transplantation.
4. To understand the role of interventional radiology in providing a bridge to transplantation and treating vascular and biliary complications.

A-185

Kidney and pancreas (part 1)

J. Klempnauer, F. Lehner; Hannover/DE

Kidney transplantation is preferred over dialysis for management of end-stage renal disease complicating type 1 or 2 diabetes mellitus (DM). Simultaneous pancreas-kidney (SPK) or pancreas after kidney transplantation (PAK) is an important alternative to kidney transplantation alone for type 1 diabetes patients. Despite the significant risks, SPK/PAK is an effective treatment to reverse or minimize metabolic abnormalities and complications of type 1 DM. Candidates for SPK and PTA transplantation need to meet various selection criteria to exclude cardiac and other risk factors. SPK and PTA endocrine function is usually excellent, but common post-transplant medical complications, as well as complications unique to SPK and PTA transplantation may occur. The main post-transplant complications are pancreatitis, venous thrombosis of the graft, rejection and bleeding. Clinical diagnosis of these complications is often difficult. Therefore, diagnostic and interventional radiology play an important role in the interdisciplinary treatment concept. As a result of improved surgical techniques, immunosuppression and patient selection, one-year survival rates of 95, 83, and 88% for patient, pancreas and kidney survival are reported for patients with simultaneous pancreas-kidney transplantation. However, morbidity and mortality after SPK are still higher than for kidney transplantation alone in the first year. Main future goals are reducing postoperative morbidity, identifying relevant indications for single pancreas transplantation, adopting the best surgical technique for individual patient's needs (bladder versus enteric drainage with/without portal venous delivery of insulin), and developing immunosuppressive strategies with low nephrotoxic and diabetogenic potential.

Learning Objective:

Detection and identification of the cause of post-transplant pancreas graft dysfunction.

Postgraduate Educational Programme

A-186

Kidney and pancreas (part 2)

A. Chavan; Oldenburg/DE

Arterial DSA, which was generally used to clarify renal vascular anatomy in living kidney donors about a decade ago, has now largely been replaced by the non-invasive Duplex-Doppler Ultrasonography (US), supplemented either by contrast enhanced MRA or CTA. Due to the lack of ionizing radiation and non-nephrotoxic contrast agents, MRA is the modality of choice for this purpose in these otherwise healthy patients. As opposed to this, CTA is better suited for depicting calcification and narrowing of recipient pelvic vessels. Even in recipients, DSA is generally carried out only if an angioplasty (PTA) is necessary prior to surgery. Following renal transplantation (RT), complications of relevance to the radiologist include post-operative perirenal fluid collections compromising organ function, transplant vessel stenosis (RAS) as well as post-biopsy arterio-venous fistulas (AVF). The perirenal fluid collections are generally drained percutaneously using CT or US guidance. Besides US, MRA now has sensitivities and specificities exceeding 90% for non-invasively detecting RAS. Treatment of these stenoses as well as of intrarenal AVFs is the domain of the interventional radiologist; the technical success rate exceeds 85%.

Following pancreas transplantation (PT), organ perfusion can be determined using dynamic MRA and quantified by plotting the extent of organ enhancement against time. With increasing experience, MRA is also becoming a valuable tool in detecting vascular complications in the graft. AVFs in the transplanted organ are rare. Whereas most such fistulas are not significant, persistent fistulas affecting organ function can be treated interventional using metal coils and detachable balloons.

Learning Objectives:

1. To illustrate the advantages and disadvantages of various imaging modalities in the pre- and post-operative work-up of patients undergoing renal and pancreatic transplantation.
2. To provide tips for optimizing the technique of examination.
3. To present the entire spectrum of pre- and post-operative interventional procedures which help improve the long-term results in such patients.

A-187

Lung (heart and lung) (part 1)

A.A. Bankier; Vienna/AT

Since the very introduction of lung transplantation, lung transplant recipients have been the subject of imaging studies. Both conventional chest radiography and CT are widely applied in lung transplant recipients, with each technique having specific advantages and indications. Moreover, recent technical development in CT and the introduction of MR imaging open a window of opportunity for both morphological and functional imaging of lung transplant recipients. Finally, interventional techniques might contribute to the treatment of complications after lung transplantation. This presentation will review the role of imaging techniques in the diagnostic work-up and treatment of patients after lung transplantation and will indicate potential applications of imaging techniques currently under development.

Learning Objectives:

1. To summarize the imaging techniques used in the work-up of patients after lung transplantation.
2. To describe diagnostic and interventional methods in the management of posttransplant complications.
3. To discuss the role of imaging in the short- and long-term follow-up after lung transplantation.

A-188

Lung (heart and lung) (part 2)

M. Estenne; Brussels/BE

Since the first successful lung transplantation two decades ago, the procedure of lung transplantation has gained acceptance as a therapeutic option for a wide spectrum of lung disorders. For patients with a life expectancy limited by severe functional impairment, lung transplantation offers the potential of an improved quality of life and a longer survival. Nonetheless, complications of lung transplantation can occur and often result in constraints on long-term preservation of the graft and on patient survival. This presentation will review the current status of lung transplantation, with particular attention to the clinical indications for transplantation, the selection of patients, and the short- and long-term complications after lung transplantation.

Learning Objectives:

1. To review the clinical indications and the patient selection criteria for lung transplantation.
2. To describe the process of pretransplant evaluation and the techniques of lung transplantation.
3. To summarize common short- and long-term complications after lung transplantation.

Special issues of radiation exposure in diagnostic radiology

Moderator:

J. Walecki; Warsaw/PL

A-189

A. Minimizing radiation doses to pediatric patients

M. Raissaki; Iraklion/GR

There is considerably greater radiosensitivity of the organs and bone marrow in children, because of rapidly dividing cells. Any radiation dose, small or large, is expected to produce a response and a cumulative effect. Therefore, every effort should be made in the radiation protection area to keep the dose as low as reasonably achievable, trying to retrieve the best possible information when performing indicated, justified diagnostic tests.

Minimizing radiation doses should be a concept applied in a chain of actions, starting from the choice of equipment of the radiology department. Pediatric-oriented protocols, especially with regard to CT-protocols, regular quality assurance tests and continuous training of staff involved are important parts of this chain. Radiation protection rules should be meticulously applied in neonates and children. Justification of requested examinations, vetting of referrals for complex examinations, standardization of techniques and procedures as well as optimization of protection measures are crucial components for ensuring minimization of radiation exposure when imaging children. Special considerations include shielding of gonads, thyroid and lens, appropriate collimation, PA projections in females and grid removal. In addition, short exposure times, immobilization or sedation, entertainment or distracting devices should be applied in order to eliminate patient motion. All departments can benefit from self-audits and re-evaluation of their procedures.

Learning Objectives:

1. To emphasize dedicated clinical and radiological management when minimizing radiation doses to pediatric patients.
2. To stress the importance of multilevel training of all parties involved in the reduction of radiation exposure to pediatric patients.

A-190

B. Topics in radiation protection to be learned by radiologists

K. Perisinakis; Iraklion/GR

The recent advances in computed tomography and complex interventional radiology have lead in an exploding increase in the number of procedures which deliver high radiation doses to patients and staff. The challenge for radiologists is to maximize benefit, whilst minimizing radiation risk to patients and staff. Recommendations of international radiation protection bodies has been increasingly incorporated in national legislation and requires a rigorous approach to protecting patients and staff. In 2005, the International Commission on Radiological Protection plans to adopt a new set of recommendations that should be seen as a consolidation of earlier recommendations. However, radiation protection in medicine is not likely to be improved significantly simply with the addition of more standards. A combined approach by radiation safety professionals and radiologists is required to enhance training in radiation protection in a spirit of mutual benefit. Appropriate training should include awareness of the potential for radiation injury, equipment operational parameters, doses measurement and recording methods and dose reduction techniques.

In this presentation, the philosophy of current radiation protection policy will be illustrated and diagnostic radiology patient and occupational risks will be assessed. Current status and future advances of radiation protection training modules for radiologists will be discussed.

Postgraduate Educational Programme

Learning Objectives:

1. To review current knowledge on radiation induced effects and radiation protection philosophy.
2. To assess the level of radiation protection knowledge required by the radiologist.
3. To evaluate the future training programs for radiologists in radiation protection.

A-191

C. Pregnant employees working in diagnostic radiology

J. Damilakis; Iraklion/GR

The protection of the unborn children of pregnant employees working in diagnostic radiology is very important because the conceptus is particularly sensitive to the effects of X-rays. Efforts should be made to keep occupational radiation exposure of a pregnant worker as low as reasonably achievable. Special rules about radiation dose limits for the conceptus apply after a pregnant employee declares her pregnancy. A publication of the European Commission (EC, Radiation Protection 100, 1998) recommends that the protection of the child to be born shall be comparable with that provided for members of the public. The conditions for the pregnant woman in the context of her employment shall be such that the radiation dose to the conceptus will be unlikely to exceed 1 mSv during the remainder of the pregnancy. Once a pregnant worker declares her pregnancy, a program should be established to calculate and monitor conceptus dose and counsel the pregnant woman. This presentation will provide a methodology for accurate conceptus radiation dose anticipation and determination of the maximum workload allowed for the remaining gestation period for the declared pregnant employee who participates in complex fluoroscopic procedures. It is important that the pregnant worker receives radiation safety counselling and understands the risk to the conceptus from exposure to ionising radiation.

Learning Objectives:

1. To learn dose limits, regulations and recommendations concerning occupational exposure of pregnant women employed in diagnostic radiology.
2. To provide a methodology for establishing a program to calculate and monitor conceptus radiation dose as a result of the occupational exposure of the pregnant worker.
3. To learn the effects that radiation may have on the conceptus.
4. To understand the radiation protection measures that will ensure that the conceptus dose from the mother's occupation is kept as low as practicable.

Workshops on Interventional Radiology

WS 818

Pediatric intervention

Moderator:

D.J. Allison; London/UK

A-192

A. Oesophageal interventions in children

D. Roebuck; London/UK

Almost all oesophageal strictures in children are benign. Common causes include congenital and surgical strictures, ingestion of corrosive substances, gastro-oesophageal reflux, achalasia, immunodeficiency and dystrophic epidermolysis bullosa. The natural history, response to treatment and probability of complications all depend strongly on the underlying cause of the stricture. A number of interventional radiology techniques are used in children with oesophageal strictures. This workshop will cover endoluminal ultrasound, balloon dilatation, mitomycin application and temporary stenting. Most strictures can be treated with antegrade balloon dilatation using a simple technique. We perform this procedure under general anaesthetic, although other centres use sedation. Repeat dilatations are often necessary. In some patients this is done electively to allow progressive enlargement of the lumen. In other patients, especially those with corrosive injury or epidermolysis bullosa, repeated procedures are necessary because the stricture tends to recur. Occasionally it is impossible to cross the stricture from above. When this occurs in children who have a gastrostomy, retrograde dilatation is almost always successful. Treatment is considered successful when the interval between dilatations becomes progressively longer. Sometimes this cannot be achieved because of relentless stricture recurrence. In these patients, most of whom have corrosive strictures, mitomycin application and/or tem-

porary stenting can be performed. Clinically significant complications of oesophageal intervention are uncommon, and can usually be treated conservatively. Multidisciplinary teamwork is vital to effective treatment of oesophageal strictures in children, and the opinions and technical input of surgeons, gastroenterologists and radiologists are important. Surgical resection of oesophageal strictures is now rarely necessary.

Learning Objectives:

1. To understand the common disease processes that cause oesophageal strictures in children.
2. To be familiar with the indications for oesophageal dilatation in children.
3. To be able to discuss the anaesthetic management and perioperative care of children undergoing dilatation.
4. To understand the indications for other intervention in children with oesophageal strictures.
5. To be familiar with the results of intervention in children with oesophageal strictures.
6. To be able to treat complications of oesophageal intervention in children.

A-193

B. Treatment of vascular malformations outside the central nervous system

F. Brunelle; Paris/FR

Vascular malformations in children can be classified depending on their biological behaviour, their vascular component and their hemodynamics. Infantile haemangiomas are true vascular tumours made of endothelial cells. Two sub types are described, the classic infantile haemangioma that appears after birth and regresses slowly during the first two years of life and the RICH (rapidly involuting congenital haemangioma), that is diagnosed during pregnancy and rapidly involutes after birth. Except in rare cases with cardiac insufficiency and platelets consumption those angiomas do not need any treatment. Vascular malformations on the other hand are made of lymphatics, veins or arteries. They are called lymphangiomas, venous malformations and arterial dysplasias. True arteriovenous fistulas are rare. Arteriovenous malformations are vascular dysplasias that may involve a segment of a limb or portion of the face. Treatment depends on the macroscopic appearance, hemodynamics and localisation. Sclerotherapy of venous malformations and lymphangiomas is made thanks to injection of alcohol in the lesion. Hemodynamically active lesions can be embolised.

Learning Objectives:

1. To learn the classification of vascular malformations (VM) in children.
2. To understand the therapeutic algorithm.
3. To know the different therapeutic options and their benefit/risk ratio.
4. To learn the natural history of VM.
5. To know how to create a multidisciplinary staff.

A-194

C. Angioplasty and arterial stenting in children

C. McLaren; London/UK

There are several differences between adult and pediatric practice in angioplasty and arterial stenting. Firstly, the underlying disease processes in children are different than those in adults. Fibromuscular dysplasia is far more common than atherosclerosis, which is extremely rare in childhood. Secondly, modifications to angiographic equipment and technique are required because of the smaller size of the patients. For example, children with "mid-aortic syndrome" have a narrow aorta, and renal angioplasty and stenting are technically more difficult than in adults. In very small children the size of the femoral artery may be limiting. Thirdly, management decisions need to take into account future growth of the patient and, in most cases, a very long life expectancy. Angioplasty and stenting may be performed as definitive treatment, or with the intention of delaying surgery until the patient's growth is almost complete. Multidisciplinary teamwork is essential as this allows all treatment options to be considered. In our practice the main indication for angioplasty and stenting is renovascular hypertension. Careful patient selection is required. Children who have poorly controlled blood pressure are considered for diagnostic angiography, which provides the best information about the extent of the disease. In patients with bilateral disease, or with involvement of multiple segmental arteries, renal vein renin sampling can identify which lesion is the principal cause of the hypertension. Angioplasty is usually successful, either by reducing blood pressure on the same antihypertensive medications or by reducing the number of agents required. Stenting may be performed if angioplasty is unsuccessful.

Learning Objectives:

1. To understand the common disease processes that cause arterial abnormalities in children.

Postgraduate Educational Programme

2. To be familiar with the modern imaging modalities available for evaluation of pediatric arterial disease.
3. To be able to discuss the potential indications for angioplasty and stenting in children.
4. To be familiar with the perioperative care required in children undergoing these procedures.
5. To understand the differences between angioplasty and stenting techniques in children and adults.
6. To be able to treat complications of angioplasty and stenting in children.

Imaging of stones

Moderator:

G. Jager; 's Hertogenbosch/NL

A-195

A. Plain film, IVU and ultrasound

G. Heinz-Peer; Vienna/AT

Urolithiasis is a common problem in patients presenting to emergency departments. Radiologic imaging has always had a primary role in the work-up of these patients. Traditionally, evaluation consisted of conventional radiography (KUB) followed by intravenous urography (IVU). With the advent of ultrasonography (US) those patients who could not safely undergo IVU could be evaluated for primary or secondary (i.e. hydronephrosis) signs of obstruction. In the past several years, the introduction of unenhanced spiral CT has dramatically changed the role of the various imaging techniques in evaluation of urolithiasis. In the recent literature some authors believe that it is time for IVU to retire after 70 years of good performance. However, daily practice shows that urologists still like those "old" techniques. In addition, many patients have to undergo follow-up examinations for stone treatment. Complete replacement of IVU by CT for stone evaluation would excessively increase radiation dosages applied to patients with a high probability of disease recurrence.

This lecture will review the pros and cons of KUB, IVU, and ultrasound. In addition, aspects of radiation dosage, requirements for further imaging, impact on urological interventions and follow-up examinations, as well as aspects on diagnostic utility and the measured clinical outcome will be addressed.

Learning Objectives:

1. To understand advantages and disadvantages of the various imaging modalities.
2. To recognize the role of functional aspects in obstructive disease.
3. To know how to answer to clinical questions from the urologist.

A-196

B. CT(U) and MRU

C.C.A. Nolte-Ernsting; Hamburg/DE

Unenhanced multislice (MS) CT is considered the gold standard in the diagnosis of urolithiasis, reaching a sensitivity and specificity of nearly 100%. MSCT is able to determine location and exact size of a calculus. The rim-sign and tail-sign help distinguish calculi from phleboliths. Perinephric stranding is well seen on unenhanced images and even the grade of dilation may be assessed without using contrast material. Consequently, unenhanced MSCT provides the primary diagnostic information needed for the treatment of an acute stone colic. Contrast-enhanced MSCT urography using a low-dose scanning protocol may be employed supplementarily to obtain detailed demonstration of the urinary tract anatomy. Stones can be identified within the opacified urine. Exact knowledge of the urinary tract anatomy obtained with MSCT urography may help determine the potential of stone passage after lithotripsy or during endourologic removal. In MR urography (MRU), direct identification of small calcifications is difficult, regardless of whether unenhanced T2-weighted MRU or gadolinium-enhanced T1-weighted excretory MRU is performed. Hence, stones can only be found on MR urograms by identifying filling defects. Initial studies demonstrate that MRU may be as effective as CT in the diagnosis of ureterolithiasis, whereas data concerning the value of MRU in nephrolithiasis are still missing. Apart from its limited value in acute urolithiasis, MRU may be a promising alternative to CT in chronic stone disease in order to provide exact knowledge of the urinary tract anatomy without repeated radiation exposure.

Learning Objectives:

1. To understand CT- and MR-based imaging strategies in urolithiasis.
2. To be able to understand the role of saline, furosemide and contrast material in CT(U) and MRU.
3. To learn the imaging patterns of urolithiasis in CT(U) and MRU.

A-197

C. Radiation issues and economic aspects

F. Stacul; Trieste/IT

Unenhanced helical CT (UHCT) is now considered the gold standard for imaging patients with renal colic. However some disagreements exist on the radiation dose to patients undergoing the procedure and on the cost of the examination. Different CT techniques are used: not surprisingly the X-ray dose calculations in the literature vary to a large extent. The delivered dose can be up to 5 times higher than that delivered by excretory urography. With single-detector helical scanners the dose can be significantly decreased by increasing the pitch; some authors report that the accuracy rate for stone detection is not affected. Multidetector scanners provide an increased radiation dose if CT parameters are unchanged. The dose could be lowered by decreasing the mAs, with individual optimization related to body size or using a geometric X-ray modulation. However there is concern regarding alternate and additional diagnoses that could be missed if the dose is lowered too much.

The cost of a CT procedure in patients with renal colic can be compared with other radiological procedures following a careful analysis of the differential costs of each investigation (equipment, variable costs, personnel) and their common costs. In our environment UHCT has a cost which is 8% lower as compared to IVU.

However multiple variable factors, both for the dose and cost analysis, suggest the data cannot be simply applied to other environments and similar evaluations look worthwhile in other departments.

Learning Objectives:

1. To provide awareness of the X-ray dose delivered by single-detector and multidetector scanners.
2. To become familiar with the methodology of cost analysis.
3. To stimulate assessment of delivered X-ray dose and of financial costs in imaging patients with renal colic.

Infection in the Adult Today

CC 816

Musculoskeletal infection

Moderator:

K. Verstraete; Gent/BE

A-198

A. Vertebral infection

V. Jevtic; Ljubljana/SI

Vertebral infection represents 2-4% of all cases of osteomyelitis. An increase in the incidence of pyogenic as well as granulomatous spondylitis has been noticed. Early radiological diagnosis is of great importance for prompt treatment and prevention of clinically significant consequences which include neural compromise and late spinal deformities. The most frequent causative pyogenic microorganisms are gram-positive bacteria especially *Staphylococcus aureus*. An important form of non-pyogenic granulomatous infection is tuberculous spondylitis which represents the most common form of extra-pulmonary tuberculosis. The routes of spinal infection include hematogenous spread, post-operative infections, direct implantation during spinal punctures and spread from a contiguous focus. The role of imaging is early diagnosis, evaluation of extent of infection with special regard to potential neural compromise, differential diagnosis, guidance of diagnostic biopsy, planning of eventual operative procedures and assessment of therapeutic response. Imaging modalities include skeletal scintigraphy, plain radiography, computed tomography (CT) and magnetic resonance imaging (MRI). In practice usually a combination of a sensitive and a specific method is utilised. The only imaging modality which combines high sensitivity with satisfactory specificity is MRI. This is the reason that MRI has become the first imaging modality in clinically suspicious spinal infection. MRI is the method of choice for demonstration of direct extension of infection, especially of secondary epidural abscess or phlegmon and consequent neural compression. Using MRI, monitoring of therapeutic efficacy is possible.

Postgraduate Educational Programme

Learning Objectives:

1. To become familiar with the pathoanatomic background of vertebral infection.
2. To understand radiographic, CT and MR signs of spinal infection.
3. To comprehend the importance of Gd-DTPA MRI for early diagnosis, differential diagnosis, planning of therapy and evaluation of therapeutic efficiency in pyogenic and granulomatous spondylitis.

A-199

B. Infection in the appendicular skeleton

K. Bohndorf; Augsburg/DE

In relation to the clinical course, infection in bone can be divided into acute, subacute and chronic osteomyelitis. The diagnosis of acute osteomyelitis is challenging but can be best made by correlating radiography, bone scintigraphy and MR imaging with clinical information. Radiography should routinely be supplemented by sonography in newborns and infants, if applicable. Brodie's abscess, which is clinically a sub-acute form of osteomyelitis, is best diagnosed by the combination of radiography and MR imaging. Chronic osteomyelitis is divided into primary hematogenous forms and exogenous, mostly post-traumatic osteomyelitis. In the majority of patients, post-traumatic osteomyelitis is a clinical diagnosis; however, in a number of patients only the correlation of clinical findings, blood tests and imaging reveals the correct diagnosis. Often, MR imaging and scintigraphic methods, such as scanning with labelled leucocytes, together establish the diagnosis. Chronic recurrent multifocal osteomyelitis may mimic bacterial osteomyelitis but is a distinct disease probably associated with the SAPHO syndrome.

Learning Objectives:

1. To become familiar with the different imaging modalities which are available for diagnosing different forms of osteomyelitis.
2. To discuss the role of MR imaging compared to scintigraphic methods, including PET, to diagnose different forms of osteomyelitis.
3. To discuss the entity CRMO in comparison to bacterial osteomyelitis.
4. To define the criteria how CRMO can be diagnosed by the radiologist.

A-200 ♀

C. Soft tissue infections

D.J. Wilson; Oxford/UK

Soft tissue infection may be acute or chronic. It may involve the subcutaneous tissues (cellulitis) and/or deeper structures including muscle tendon and ligaments. Infections of bones or joints may spread to involve the soft tissues and less commonly soft tissue infection may extend to involve bones and joints.

Radiological appearances

Early, intermediate and late signs will be covered.

Specific infections

The following infection types will be discussed:

- Fungi
- HIV
- Leprosy
- Tuberculosis
- Management

The following topics will be discussed:

- Role in diagnosis, relationship to biopsy
- Role in planning treatment
- Radiological interventional techniques
- Role in monitoring treatment

Septic Arthritis

Acute pain, effusion and limitation of movement are the commonest symptoms of septic arthritis. The possibility of infection must be borne in mind to prevent severe joint destruction occurring without a concurrent strategy to manage the infection.

Radiological signs

Early, intermediate and late signs will be covered with discussion of infection in prosthetic joints.

Learning Objectives:

1. To understand the pathological basis for soft tissue and joint infections.
2. To appreciate how the radiological signs match the pathological stages of infection.
3. To recognise the role of imaging in the management of soft tissue and joint infection.

MR approaches to molecular imaging

Moderator:

P. Wunderbaldinger; Vienna/AT

A-201

A. Imaging of angiogenesis

A.R. Padhani; Northwood/UK

Several MR imaging techniques can assess the state of microscopic blood flow of tissues. These can be divided into extrinsic (contrast media enhanced) and intrinsic (non-enhanced) methods. The former can be further divided by the type of contrast medium utilized: (i) low molecular weight agents (< 1 kDa) that rapidly diffuse in the extracellular fluid space (ECF agents), (ii) intermediate (MW, 5-30 kDa) and large-molecular agents (MW, > 30 kDa) designed for prolonged intravascular retention (macromolecular contrast media, MMC, or blood pool agents) and (iii) agents intended to accumulate at sites of concentrated angiogenesis mediating molecules. This review concentrates primarily on non-invasive characterisation of human tumour neovasculature with DCE-MR imaging using low-molecular weight contrast agents and explains how perfusion and permeability related data can be extracted depending on the technique utilized. The quantification and potential human applications of MMC MR imaging will also be illustrated. Tumour angiogenesis can also be analysed using intrinsic susceptibility weighted or blood oxygenation level dependent (BOLD) contrast MR imaging. BOLD imaging can be used to monitor the effects of vascular targeting agents in humans and this application of BOLD MR imaging will be discussed. Other MR imaging techniques which provide information on tissue blood flow such as flow-related enhancement and diffusion weighted imaging will not be considered in this review.

Learning Objectives:

1. To demonstrate the differing phenomena of T1- and T2*-weighted DCE-MR imaging with low molecular weight contrast media.
 - 1.a. To explain the physiological processes that determine tissue enhancement.
 - 1.b. To show that DCE-MR imaging is dominated by tissue blood flow in tumours.
 - 1.c. Quantification of DCE-MR imaging and pathological correlates.
2. To illustrate the potential of MR imaging with macromolecular contrast agents.
 - 2.a. To show that microvessel permeability and fractional blood volume is dependent on molecular size.
3. To show that intrinsic susceptibility weighted (BOLD) contrast is sensitive to tissue oxygenation and blood flow.

A-202

B. Imaging of cell migration

M. Höhn; Köln/DE

In order to observe cell mobility in vivo using a noninvasive imaging modality, the cells must be labeled to produce sufficient contrast against the host tissue background. Depending on the chosen imaging technology, different demands on the contrast agent as well as on the labeling strategy must be considered. Selecting magnetic resonance imaging (MRI) as the imaging tool, iron oxide nanoparticles are mostly used to achieve a strong contrast on T2*-weighted images. Incorporation of the label into the cells depends on the route of labeling: i) *in vitro* labeling followed by cell implantation, or ii) *in vivo* labeling by specific injection of the contrast agent in combination with selective uptake by the desired cell population. Care must be taken to ensure that the labeling procedure is efficient enough for satisfactory contrast generation, that it is tolerated by the cells, and that, on the other hand, contrast is not lost upon dilution of the label in the wake of continuing proliferation. Finally, the technical limits of sensitivity and detectability must be considered for the lay-out of a project investigating cell migration in vivo. The learning objective is to understand the potential and limits of the above listed facets of *in vivo* cell labeling and detection using MRI. Consideration regarding application to different examples of (patho-)physiological studies are also discussed.

Learning Objectives:

1. To understand the issues of cell labeling.
2. To understand the issues of cell label efficiency for *in vivo* MRI and toxicity.
3. To understand the methodological aspects of *in vivo* cell detection with MRI.

Postgraduate Educational Programme

Saturday

4. To understand the spatial and temporal resolution requirements to observe cells *in vivo*.
5. To discuss various experimental applications under physiological and pathophysiological conditions.

A-203

C. Targeted MR contrast agents

S.A. Wickline, G.M. Lanza; St. Louis, MO/US

The next generation of pharmaceutical agents will be targeted against specific molecular pathways and/or locales within the body. Our laboratory is engaged in a multidisciplinary effort to develop systemically deliverable ligand-targeted nanoparticles for noninvasive *in vivo* image-based detection of picomolar quantities of pathological epitopes that are the sources of cancer and cardiovascular disease. We have devised strategies for the delivery of drugs or genes to those sites with the use of targeted nanoparticle carriers that can incorporate various classes of ligands (e.g., antibodies, small molecules) and selected drugs active against cancer and atherosclerosis and thrombosis. These particles also can be imaged *in vivo* with MR imaging, nuclear, CT, or ultrasound methods based on incorporation of payloads of gadolinium chelates, radionuclides, iodinated compounds, or perfluorocarbon content respectively. Drugs such as doxorubicin, paclitaxel, fumagillin can be incorporated and delivered selectively to individual cells of choice through a novel process of "contact facilitated drug delivery", which is proving to dramatically enhance tumor lysis and plaque regression.

Learning Objectives:

1. To understand the potential clinical applications of molecular imaging for early diagnosis of cardiovascular disease and cancer.
2. To understand the comparative advantages and limitations of molecular MR-imaging as a component of various imaging technologies such as nuclear, optical, ultrasound, etc.
3. To understand the role of nanotechnology in molecular MR-imaging and targeted drug delivery.

Mediastinal masses

J. Cáceres¹, J. Vilar²; ¹Barcelona/ES, ²Valencia/ES

The study of the mediastinum is performed with cross-sectional imaging (CT or MRI), due to the lack of contrast among the different mediastinal structures in conventional radiography. Nevertheless, the PA and lateral chest radiograph may be very useful as the initial examination to detect mediastinal masses and to suggest the next procedure to perform.

The study of the mediastinum starts with a thorough knowledge of the radiographic anatomy and most common variants. Differentiation of pulmonary from mediastinal masses is easily made by knowing basic semiology (pregnancy sign). To facilitate the differential diagnosis among different pathologies it is convenient to divide the mediastinum into different areas (thoracic outlet, anterior middle and posterior, including supra and infravascular compartments). The radiographic appearance and location of masses on cross-sectional imaging will contribute to narrowing the differential diagnosis.

Learning Objectives:

1. To review the anatomy and normal variants of the mediastinum.
2. To describe the signs that allow recognition of mediastinal masses and their differential diagnosis.
3. To emphasize that fat and vascular structures are not uncommon causes of mediastinal masses.

Three common neurological problems: Loss of vision, hearing loss, trigeminal and facial nerve palsy

Moderator:
G. Hur; Koyang-city/KR

A-205

A. Loss of vision: Imaging the visual pathways

H. Jäger; London/UK

Lesions affecting specific parts of the visual pathways have characteristic clinical manifestations. Radiological investigations should be tailored according to the type of visual defect, using different techniques for the examination of the orbits, sellar region, white matter tracts and occipital cortex. The type of pathology encountered depends on the location and the patient's age. Amongst tumours of the globe retinoblastomas are common in children and melanoma metastases are common in adults. The most frequent tumours of the optic nerve sheath/ complex are gliomas in children and meningiomas in adults. Other conditions involving the optic nerve/sheath complex include demyelination, orbital pseudotumour, sarcoidosis. Chiasmal lesions produce characteristically bitemporal hemianopia. Extrinsic compression of the optic chiasm may be due to pituitary tumours or giant aneurysms in adults, and craniopharyngiomas in children. Intrinsic chiasmal lesions include gliomas and granulomatous lesions. Lesions involving the optic radiation are most frequently infarcts, demyelination or tumours but other entities such as progressive multifocal leukoencephalopathy (PML) and posterior/reversible leuko encephalopathy syndrome (PRES) must also be considered. Lesions in the primary visual (striate) cortex produce homonymous hemianopia and infarcts and tumours are the commonest pathology in this region. Selective involvement of extra striate visual cortex can lead to inability to perceive movement or to recognize colours.

On the whole MR imaging is superior to CT for the assessment of visual pathways. CT is however the first line modality in orbital trauma and may be helpful to identify tumour calcification in optic nerve sheath meningiomas and craniopharyngiomas.

Learning Objectives:

1. To learn the anatomy of the visual pathways.
2. To acquire knowledge of the type of visual defects associated with lesions at specific sites of the visual pathways.
3. To become familiar with CT and MR techniques for examination of the orbits, sellar region, optic tracts and radiation and visual cortex.
4. To be able to provide a differential diagnosis for lesions of the visual pathways based on location, patient's age and imaging appearances.

A-206

B. Sensorineural hearing loss

F. Veillon; Strasbourg/FR

The aim of this lecture is to understand how to perform imaging and its results when exploring a sensorineural hearing loss.

CT is necessary for evaluating the oval and round windows and the inner ear (shape, size and bony structures). MR imaging is important for analyzing the fluid and membranous content of the labyrinth; the shape, size and structure of the VIII, VII, mixed nerves in the internal auditory meatus (IAM); the cerebello-pontine angle (CPA), the appearance of the brainstem and the cochlear pathways in the brain. Trauma may lead to injury of the oval and round windows with or without fractures (which are well documented with CT). Post operative complications in otosclerosis such as too long a prosthesis or intravestibular granuloma are studied with both CT and MR. CT and MR also used for the detection of bacterial, viral and autoimmune labyrinthitis and hemorrhage. Intralabyrinthine neurinomas are detected as solid masses with gadolinium enhancement. Malformations of the inner ear may be separated into minor and major lesions. Vestibular schwannomas must be considered but also meningioma, hamartoma, epidermoid cyst, lipoma, vascular malformation, metastases, lymphomas, meningitis, siderosis, in the IAM and/or CPA. Central brain lesions are presented in MR imaging; ischemia, hemorrhage, multiple sclerosis and tumors.

Learning Objectives:

1. To understand the method and results allowing to evaluate a sensorineural hearing loss with CT and MR imaging.

2. To know the indications of imaging (CT and/or MRI) in the evaluation of sensorineural hearing loss.

3. To learn the different signs in imaging allowing to know the etiology of sensorineural hearing loss and the consequences about the treatment.

A-207

C. Facial nerve paralysis and trigeminal neuralgia

A. Borges; Lisbon/PT

The trigeminal nerve is the largest of the cranial nerves. It provides sensory input from the face and motor innervation to the muscles of mastication. The facial nerve is the cranial nerve with the longest extracranial course and its main functions include motor innervation to the muscles of facial expression, sensory control of lacrimation and salivation, control of the stapedial reflex and to carry taste sensation from the anterior two thirds of the tongue. In order to be able to adequately image and follow the course of these cranial nerves and its main branches a detailed knowledge of neuroanatomy is required. As we are dealing with very small anatomic structures high resolution dedicated imaging studies are required to pick up normal and pathological nerves. Whereas CT is best suited to demonstrate bony neurovascular foramina and canals, MR imaging is preferred to directly visualize the nerve. It is also the single technique able to detect pathological processes afflicting the nerve without causing considerable expansion such as is usually the case in certain inflammatory/infectious conditions, perineural spread of malignancies and in very small intrinsic tumours. Because a long course from the brainstem nuclei to the peripheral branches is seen, it is useful to subdivide the nerve in several segments and then tailor the imaging modality and the imaging study to that specific segment. This is particularly true in cases where clinical topographic diagnosis can be used to locate a lesion in the course of these nerves.

Learning Objectives:

1. To become familiar with the anatomy and main functions of the trigeminal and facial nerves.
2. To become aware of the current imaging potential to visualize normal and pathologic trigeminal and facial nerves.
3. To be able to tailor the imaging approach in patients presenting with trigeminal and facial nerve dysfunction.
4. To understand the advantages and limitations of a topographic approach to trigeminal and facial nerve lesions.

A. Plain films revisited with MSCT and MR imaging

A. Blum; Nancy/FR

CT-arthrography and Magnetic Resonance Imaging are the most efficient techniques to evaluate the wrist; however, standard radiography remains a valuable method to explore this region. In most situations, it is sufficient to allow a precise diagnosis and determine therapeutic protocols. However, this method can present a real diagnostic value only when it is guided by a relevant medical history and clinical details. The purpose of this presentation is to propose a practical approach for radiographic evaluation of the wrist, suited to the main clinical scenarios. CT and MR imaging correlations will help to understand radiographic findings.

Learning Objectives:

1. To learn how to suit radiographs to the different clinical situations.
2. To know how to perform the most pertinent stress views.
3. To learn how to base the diagnostic strategy on clinical and plain films findings.

A-209

B. MR imaging and US of chronic pain

M. Zanetti; Zürich/CH

Optimal Magnetic Resonance (MR) imaging of the wrist requires a high field strength magnet and a dedicated wrist coil to achieve high-resolution images. Using current MR sequences, detailed images of articular cartilage and the sup-

Postgraduate Educational Programme

porting ligaments and tendons can be obtained. Evaluation of the triangular fibrocartilage as well as the intrinsic ligaments of the wrist is substantially improved by direct MR-arthrography. Fast inversion recovery sequences or T2 weighted sequences with fat suppression allow for detection of osteonecrosis and fractures, which are often radiographically occult. MR imaging also provides valuable information in the evaluation of tendons and synovium in rheumatoid arthritis. Normal variants (e.g. lunate II, carpal boss), pitfalls (e.g. pseudo-DISI), and findings with a high prevalence in the asymptomatic population (e.g. TFC lesion, intercarpal ligament lesion) have to be considered in the evaluation of chronic wrist pain.

With the advent of new technical improvements (high frequency probes up to 15 MHz), ultrasound is gaining acceptance as a useful modality to diagnose a variety of diseases involving the wrist. Ultrasound offers benefits in the evaluation of tendon inflammation and rupture, evaluation of palpable masses or suspected occult masses, and evaluation of suspected foreign bodies.

Learning Objectives:

1. To know the appropriate imaging technique of standard MR imaging, MR arthrography and ultrasound for triangular fibrocartilage lesions, ligament and tendon lesions, occult osseous lesions and soft tissue masses.
2. To know the diagnostic potential of standard MR imaging, MR arthrography and ultrasound for such lesions.
3. To know the differential indications for MR imaging and ultrasound in patients with chronic wrist pain.

A-210

C. Dynamic studies: MR and US clinical applications

M. Mastantuono; Rome/IT

Dynamic imaging is a mandatory step after static and morphologic assessment for the evaluation of wrist and hand. Ahead of other imaging modalities, US offers the capability of real-time depiction: continuity, position (transient dislocation) and normal sliding of the structures (stenosing tenosynovitis) are evaluated in time to assess the normal functions of tendons and muscle fibres. Kinematic MR imaging improves the diagnostic capabilities of MR imaging by allowing for the detection of dynamic instability patterns, transitory subluxation, and bony or soft tissue impingement syndromes. Dynamic MR imaging studies may passively and actively test the joint. Active movement generally provides a more physiological examination of the joint, but some techniques, like incremental passive Kinematic MR imaging, allows one to describe carpal motion and dynamic instability by using sagittal images that are acquired during progressive movement from radial to ulnar deviation. This representation is easy and directly related to the columnar concept on which the most widely accepted models for carpal instability are based. Kinematic studies performed with US and MR imaging allow one to assess pathologic conditions that are not apparent with conventional studies. They also permit an easier analysis of the radio-carpal and intra-carpal biomechanics.

Learning Objectives:

1. To choose the most suitable kinematic MR imaging protocols.
2. To review basic principles in interpreting dynamic studies (stable and unstable equilibrium in the wrist).
3. To identify the diagnostic possibility of dynamic studies in clinical applications.
4. To identify the diagnostic possibility of dynamic ultrasound studies (comparison between MR imaging and ultrasound finding).

Radiology of the elderly

Moderator:

J. Cáceres; Barcelona/ES

A-211

Radiology of the elderly (Introduction)

J. Cáceres; Barcelona/ES

In developed countries, the expected life span is 74-76 years for men and 79-82 years for women. This aging population poses new challenges for receiving medical care. The elderly behave differently to their younger counterparts. They react differently to external insults, are more prone to fractures and infection and are prey to neurological disease, such as dementia and depression. From a radiolog-

ical standpoint, handling elderly patients creates problems of logistics and interpretation that have to be addressed by the radiology department.

Learning Objectives:

1. To assess imaging changes associated with dementia in the elderly patient.
2. To evaluate the causes and differential diagnosis of dyspnea in the elderly.
3. To present an evaluation of abdominal pain in patients of advanced age.

A-212

Aging and dementia

F. Barkhof; Amsterdam/NL

When should imaging be performed?

Every patient suspected of dementia should undergo imaging at least once during the work-up. While CT may exclude surgically treatable cases (e.g. tumour, subdural haematoma), MR imaging is superior in identifying disease specific changes, such as medial temporal lobe atrophy (MTA).

A practical MR imaging protocol

To assess the pattern of atrophy, including MTA, coronal images are indispensable. Visual rating scales are available that have good predictive value. The presence of vascular pathology (infarcts, lacunes, white matter lesions, and micro-bleeds) can be assessed using T2/FLAIR and T2*-GE.

When should non-conventional techniques be considered?

Gadolinium-enhancement and DWI can be used to assess the possibility of vasculitis. Perfusion-weighted MR may reveal altered metabolism before the development of atrophy, and obviate the need for SPECT/PET studies in suspected Alzheimer's disease or fronto-temporal dementia (FTD).

Take-home messages:

- a normal hippocampus rules out Alzheimer's disease
- MTA can be indicative of AD, but does not rule out other dementias
- isolated atrophy of the temporal pole is diagnostic of FTD
- vascular pathology also occurs in AD
- small strategic infarcts (e.g. thalamic) may cause vascular dementia
- in dementia with Lewy bodies there are often hardly any abnormalities

Learning Objectives:

1. To understand normal ageing phenomena in the brain.
2. To design a robust MR imaging protocol for the evaluation of dementia patients.
3. To understand the importance of hippocampal atrophy for Alzheimer's disease.
4. To establish a diagnosis of vascular dementia

A-213

Dyspnea

J. Andreu; Barcelona/ES

Dyspnea is one of the main reasons for emergency room admission in the elderly population. The major causes of dyspnea are respiratory and cardiologic processes, but other diseases, such as abdominal and metabolic conditions have to be included in the differential diagnosis. This talk will center on the value of imaging techniques for the diagnosis and follow-up of patients with chest processes whose main presenting feature is dyspnea.

The first section will deal with common age-related limitations of the patients which can affect the quality of the technique, and the typical radiological changes seen in aging.

Following this, the most frequently encountered entities causing dyspnea in the elderly will be reviewed. Special focus will be placed on pneumonia, COPD, thromboembolism, and heart disease. The diagnostic value of the radiological features seen in each of these groups will be discussed and a practical diagnostic algorithm provided.

Chest radiology is underutilized in the elderly, but is essential for prompt diagnosis of the cause of dyspnea. The chest radiograph is still the mainstay technique for this purpose, although CT provides highly useful information in specific conditions.

Learning Objectives:

1. To present age-related features commonly seen on chest imaging in the elderly.
2. To establish a practical radiological approach to dyspnea.
3. To review the most common causes and radiological presentation of dyspnea in geriatric patients.

Postgraduate Educational Programme

A-214

Abdominal pain

W. Curati-Alasonatti; Stanmore/UK

Abdominal pain in the elderly is a symptom developing on a clinical background of aging. Aging reduces our immunity and our faculty to respond to aggression by inflammatory processes.

1. The incidence of the majority of cancers increases with age.
2. The number of cases of Multiple Malignant Tumours (MMT) increases up to the age of 90.
3. Severe inflammatory conditions may not present with significant symptoms in the elderly.

We shall present and discuss briefly at the Conference the cases of six elderly patients having presented with abdominal pain with various clinical conditions in order to illustrate the reasoning from the clinical/diagnostic problem to the result obtained.

The application of MDCT in the elderly allows for rapid and non-invasive assessment of patency (or not) of mesenteric arteries and veins, thus replacing conventional angiography. Angiography with the intention to perform an interventional procedure remains as a specific modality.

As we will illustrate in the case presentation, we are liberal with the use of MDCT in the elderly for the following reasons:

- MDCT provides a fast diagnosis or the facility to perform immediate biopsies.
- MDCT gives a complete overview of the abdomen.
- MDCT reveals all coincidental pathologies.
- MDCT is well tolerated (contrast agents limitations apply).
- MDCT is a modality of choice for teleradiology/specialist advice.
- MDCT radiation dose is relatively less significant in the elderly and,
- MDCT 2D or 3D images provide fascinating insights of the human anatomy.

Learning Objectives:

1. To comprehend the basic differences between abdominal pathologies in the adult and in the elderly.
2. To understand the principles underlying the various algorithms used in the elderly.
3. To become familiar with the arguments supporting the modality of choice.

08:30 - 10:00

Breast

RC 902

Diagnostic highlights

Moderator:

G. Svane; Stockholm/SE

A-215

A. Increased lifetime risk

I. Saarenmaa, T. Salminen; Tampere/FI

Basic life time risk of breast cancer in women in developed countries is 4% to 6%. Most breast cancers (between 65% and 80%) occur as sporadic malignancy among women without any elevated risk. The risk increases with age. Prolonged exposure to endogenous hormones increases the risk: Early menarche and late menopause, nulliparity, late first full-term pregnancy and lack of breast feeding. The breast cancer risk is elevated in women who have a first degree relative (mother, sister or daughter) with breast cancer. Inherited mutations of BRCA1 and BRCA2 genes account for a very high relative risk of breast cancer. However, only 5% of all cancers are considered to have genetic background. 10% to 20% of breast cancers are DCIS, which carries a 30% chance of developing into invasive disease. LCIS is considered not to be a precursor lesion, but it is associated with an increased risk. Some biopsy proven benign proliferative changes, in particular ADH or ALH, increase breast cancer risk. Ionizing radiation, for instance treatment for Hodgkin's disease, increases risk. Increased weight in menopause, western diet, alcohol, dense breast parenchyma, HRT and oral contraceptives are considered to have weak association to increased risk. Risk factors increase total average risk to 11%.

The risk of secondary cancer in the same (10%-35%) or in contralateral breast (1% to 15%) depends on the size, histological type and grade of the tumour, completeness of tumour removal and postoperative therapy.

Learning Objectives:

1. To introduce the increased lifetime risk factors.

2. To discuss some specific situations: Contralateral breast cancer, local recurrence, age.
3. To propose increased risk groups and best imaging modality for selected screening projects.

A-216

B. HRT and other hormone risk markers

M.G. Wallis; Coventry/UK

The major risk factor for developing breast cancer is "oestrogen". This is affected by reproductive history and exogenous hormones (oral contraceptive pill and HRT). Additionally obesity and alcohol affect oestrogen metabolism and cellular sensitivity. HRT usage in the western population has become endemic (20 to 50% of women 47-70 years of age). Oestrogen/progestogen combinations (to protect the endometrium) have superseded earlier oestrogen only preparations. More recently synthetic oestrogen (Tibolone) has been introduced.

It has been known for a long time that current HRT usage is associated with increased risk of breast cancer. But the media were sent in to overdrive by WHI study (USA) and the Million Women Study (UK). The later implicates all preparations but combined oestrogen progestogen cause 4 times as many extra cancers as oestrogen on its own. In the UK current users are 66% more likely to develop breast cancer and 22% more likely to die from breast cancer than never users. The effect on incidence increases with increasing duration of use and wears off with in a few years of stopping therapy. Additionally HRT decreases both the specificity of screening mammography (i.e. increases recall rates) and reduces its sensitivity (i.e. increases interval cancer rates). How much of this is directly related to mammographic background density remains controversial.

Increasing affluence is associated with many benefits but at what risk? All these risks are amenable to change but the choices, evidence and explanations are not necessarily straightforward.

Learning Objectives:

1. To learn about the state-of-the-art of HRT.
2. To understand the effects of HRT on the breast and imaging accuracy.
3. To understand the potentials of life style (including cultural) change on breast cancer risk.

A-217

C. Physician-patient relationship

R. Chersevani; Gorizia/IT

Radiologist-breast patient relationship may differ from that of other physician-patient situations as it is not continuous, but sometimes rather brief, or with no real meeting among the two actors. There usually is no choice on behalf of the patient; imaging production is considered a technical and rather automatic procedure - depending mostly on "machines"; the perception or misperception is that diagnosis will always be achieved as the sensitivity of imaging techniques is always 100%.

We are surely responsible for some of these issues as we have pushed women to early diagnosis indicating our best results and not the drawbacks.

Patients want to trust their doctors, but in order to achieve this they need information. Women coming for breast diagnosis differ not only as far as being symptomatic or not, but also for age, health literacy, level of anxiety and fear, and previous experiences with illness.

There must be time for dialogue: To communicate results, to explain our diagnostic workup, obtain informed consent, explain causes of false diagnosis and show care and empathy in case of "bad news".

This will not avoid the invitations women receive from the media and the web for a review of their results, nor will it change the very easy to apply hindsight analysis - no matter the bias - or pure mathematical concepts on cancer doubling time. A correct approach requires dignity, respect, understanding and caring, for the patient and her needs, and it may not necessarily be a one-way relationship.

Learning Objectives:

1. To discuss causes and rate of litigation and troubles affecting physician-patient relationship.
2. To discuss practicing breast imaging within the margins of human error.
3. To propose effective methods to increase relationships.

Abdominal and Gastrointestinal

RC 901

Impact of multislice CT on imaging of the upper abdomen

Moderator:

C. Bremer; Münster/DE

A-218

A. Technical advances

M. Prokop; Utrecht/NL

Multislice CT has been one of the most rapidly developing techniques in the history of radiology. Since the late 1980s, performance of scanners has doubled every two years. The newest developments include 32- to 64-slice scanners that can reduce acquisition time to well below 10 s for all body applications except the heart. In the abdomen, the better spatial resolution of multislice CT has improved the evaluation of vascular structures, biliary and pancreatic ducts, the stomach and bowel, and the genitourinary system. The faster acquisition times of multislice CT have made it possible to improve arterial phase imaging of the liver and pancreas. This course will provide the technological background to understand the differences between present 4- to 64-slice systems, will evaluate the effect of various acquisition parameters on image quality and radiation dose, and will discuss how to optimize intravenous contrast administration for the abdomen. New clinical opportunities and pitfalls for interpretation will be discussed.

Learning Objectives:

1. To become familiar with the systems of multislice computed tomography.
2. To comprehend the effects of different acquisition parameters on image quality.
3. To understand the impact of multislice computed tomography on performance parameters and clinical applications.

A-219

B. Bile ducts and pancreatic ducts

C.D. Becker; Geneva/CH

In daily clinical practice computed tomography (CT) retains an important role in diagnostic imaging of biliary and pancreatic disorders. Clinical findings are often unspecific and access to MR cholangio-pancreatography is limited in many institutions, especially in the emergency setting. With the advent of multislice CT with its improved resolution and reconstruction capabilities, it appears interesting to reappraise the respective role of CT and MR imaging and to define the situations in which MR imaging is clearly superior and those in which CT may be sufficient. MR cholangio-pancreatography (MRCP) is the most reliable noninvasive technique for choledocholithiasis, and the current literature provides no evidence that multidetector CT could replace it for this indication. MRCP also appears superior in the context of benign stenoses, cystic disorders and hilar cholangiocarcinoma. On the other hand, contrast - enhanced MSCT with 2D and 3D reconstructions can often provide sufficient information with regard to resectability and palliative treatment in malignant extrahepatic bile duct obstruction, including pancreatic cancer. In the context of acute and chronic pancreatitis MSCT has some advantages over MRCP because of its excellent sensitivity for detecting and localizing parenchymal and ductal calcifications.

Learning Objectives:

1. To learn about MDCT imaging protocols optimized for imaging of the pancreas and biliary ducts.
2. To learn about the usefulness of curved planar reconstructions for visualization of biliary and pancreatic abnormalities, especially for demonstration purposes.

A-220

C. Liver

C. Catalano; Rome/IT

Multidetector-row technology has completely changed the approach with computed tomography to imaging of the upper abdomen and particularly of the liver. Several technical innovations are reflected in clear advantages in the current clinical practice of liver imaging. The use of thin collimation allows us to routinely achieve high resolution studies with the possibility to visualize the liver in multiple planes, similar to that performed with magnetic resonance, using at the same time the 3D data set to perform vascular and biliary reconstructions. Further-

more, the fast acquisition allows us to scan the liver in pure vascular phases making it possible to detect significantly more lesions or diseases and increasing significantly the sensitivity. Importance of each vascular phase after contrast agent administration will be reviewed and discussed. At the same time, improvements in post-processing allows us to exactly determine anatomy, each liver segment volume, weight, arterial, portal and systemic venous vascularization and so providing important information for advanced resection, percutaneous treatment and transplantation.

Different acquisition protocols can be used and will be reviewed keeping in mind X-ray exposure to the patient. Protocols for contrast agent administration will also be examined with attention to volume, flow rate and iodine concentration.

Learning Objectives:

1. To understand the basic principles of MDCT for liver imaging.
2. To recognize the different phases of liver enhancement.
3. To become familiar with contrast injection protocols for MDCT.
4. To learn possible new clinical applications of MDCT.

08:30 - 10:00

Room F1

Joint ECR/EAR sessions: Challenges for European Radiology

ER 926

European research network in biomedical imaging

Moderator:

G.P. Krestin; Rotterdam/NL

A-221

Fundamental biomedical imaging research in Europe

D. Le Bihan; Orsay/FR

Biomedical imaging research is becoming a major issue for European health care, especially in light of soaring care costs and population aging. Furthermore, there is a need for a European basic research and technology space to fuel the European biomedical industry. This lecture will examine the different kinds of interfaces possible between basic research and radiology, based on existing examples within Europe. Obstacles and difficulties for radiologists to engage in basic research activities will be analyzed and discussed. Finally, proposals will be made to enhance biomedical imaging research in Europe, both in terms of human resources and infrastructures.

Learning Objectives:

1. To discuss possibilities and problems for radiologists to engage in biomedical imaging research in Europe.
2. To present solutions to improve the contribution of radiologists to European biomedical research.

A-222

Role of industry in sustaining European biomedical imaging research

E.R. Reinhardt; Erlangen/DE

Many innovative modalities and systems for radiology, for example CT and MR imaging, have emerged in the past few decades. These technologies have fundamentally changed medical diagnostics and have helped increase the quality of healthcare and reduce its cost. Research in European industry has played an important role in identifying and developing such technologies.

The potential for innovation in diagnostic and therapeutic technologies to continue to improve healthcare efficiency is tremendous. The field of molecular medicine is especially promising. In-vitro molecular diagnosis will be decisive for determining pre-disposition to diseases and early detection. Molecular medicine will result in more individualized therapies, making them much more effective. Information technology is crucial to leverage the benefits of molecular medicine: the integration of medical data, including information from genomics and proteomics studies, in data-warehouses with application of data-mining technologies will be essential in enabling knowledge-driven healthcare. This will also enable efficient clinical studies and therefore, translation of biomedical research results into clinical practice.

In order to realize the potential to improve healthcare efficiency, close cooperation among healthcare participants is necessary. A global network of innovation is key: it helps in defining priorities, stimulating ideas and spin-offs, shaping healthcare systems, building common knowledge databases, and attracting the most innovative and creative minds. It is important therefore, for industry to drive such innovation networks. It is also important for industry to closely partner with clinicians and scientists in the earliest phases of its R&D activities; innovation must be driven by market needs.

Postgraduate Educational Programme

Learning Objectives:

1. To highlight the input of industry to biomedical imaging research in Europe.
2. To show the key role molecular medicine will play in improving healthcare efficiency and the importance of information technology in leveraging its benefits.
3. To show the importance of close cooperation among healthcare participants - e.g. providers, academic and research centers, and industry - through a global network of innovation.

A-223

Structuring the European research area: Possibilities for biomedical research in Europe

H. Pero; Brussels/BE

The EU (and the world) is confronted with new challenges resulting from globalisation and the new "knowledge-based economy". The IT revolution has produced a fundamental change in society and knowledge is increasingly being codified and transmitted through computer and communication networks. At the same time, innovation concepts are being challenged in an unprecedented way. It is not simply a question of a tremendous increase of scientific principles to technology and the production of goods and services in general. Knowledge and skills become central issues within the economic framework. In short, there is an urgent need to capture the benefits of the new "knowledge based economies", economies which are more strongly dependent on the production, distribution and use of knowledge than ever before.

The European Research Area and its Research Infrastructures are clearly at the basis of knowledge creation, knowledge transmission, knowledge exchanges and knowledge preservation. They are also very much linked to the industrial and health related world. They offer tools and services for the development of leading-edge research, both of basic and applied character, in particular in the field of biomedical imaging. They are therefore core elements in the implementation of the Lisbon agenda. Since research infrastructures are mainly nationally-based, their development requires however more coordination efforts across Member states. In this context, the Open Method of Coordination is increasingly being used for the development of coordinated European Roadmaps.

Learning Objectives:

1. To learn about the Community research actions.
2. To reflect on European research challenges.
3. To be stimulated to participate in future European initiatives.

A-224

Towards an European institute of biomedical imaging research

G.P. Krestin; Rotterdam/NL

Since 2002 the Executive Bureau of EAR has decided to put biomedical imaging high on its agenda. Following the report of an ad hoc Committee on Research delivered during ECR 2004 a Standing Committee for Research has been created. The mission of this Committee on Research of EAR is to create an environment and infra-structure that promotes biomedical imaging research in Europe. Specific aims include:

- building of a biomedical imaging research network throughout Europe,
- encouraging excellence in basic and clinical imaging research,
- creating opportunities for research education.

It is widely recognised that the ultimate goal could be the creation of a European research centre located in one of the EU countries. In order to fulfil this endeavour a European Institute for Biomedical Imaging Research (EIBIR) should be created and formed by a network of excellence of a large number of European institutions. The network should include both fundamental research laboratories and high quality clinical research departments. A survey among many potentially participating organisations throughout Europe allows the selection and inclusion of those institutions becoming active members of the Institute. EIBIR will offer a large number of services to its member institutions and will seek endorsement from many European scientific organisations. The structure of EIBIR will allow it to fulfil the criteria for funding by the European Union and sponsorship by industrial partners. The presentation will give an overview of the first steps leading towards the creation of the European Institute of Biomedical Imaging Research.

Learning Objectives:

1. To recognise the efforts delivered by the European Association of Radiology for creating an environment in which biomedical research can flourish.
2. To learn about the ideas and activities developed by the EAR Committee on Research.
3. To recognise the necessity for creation of a European Institute for Biomedical Imaging Research.

Radiological vascular interventions

Moderator:

M. Leonardi; Bologna/IT

A-225

A. Aneurysms and vascular malformations

I. Szikora; Budapest/HU

Intracranial aneurysms are treated by both surgical and endovascular methods. Most endovascular techniques include packing of the aneurysm sac with platinum microcoils. While surgical clipping is more effective in preventing recanalization, the endovascular approach is significantly less invasive. For ruptured lesions, endovascular treatment is recommended whenever technically feasible, as recent studies (ISAT) demonstrated better clinical outcomes following endovascular than surgical aneurysm repair. Some morphological features, such as large size or poor neck to size ratio are associated with high incidence of recurrence. To avoid recanalization, special endovascular techniques are employed including tighter aneurysm packing by liquid embolus, using biologically active micro-coils that induce healing reaction inside the aneurysm, and flow modification within the parent vessel by applying vascular stents.

Intracranial vascular malformations are classified as capillary, venous and arteriovenous (AVM) lesions. The proper diagnosis is made by noninvasive MR imaging techniques. For AVMs, catheter angiography is necessary to choose the most appropriate therapeutic modality. These include surgical removal, transarterial embolization, radiosurgery and combinations of the above. The optimal technique is chosen based on the size, location and flow pattern of the malformation. Embolization is performed using adhesive and nonadhesive liquid embolus and employed either as a sole treatment, a preoperative measure to reduce intraoperative blood loss or to reduce the size of the AVM in preparation to radiosurgery. In general, 20-40% of all AVMs can be cured by embolization alone and 60-70% by combined techniques.

Learning Objectives:

1. To learn about treatment options for ruptured and unruptured intracranial aneurysms.
2. To understand techniques, indications and results of endovascular treatment for ruptured and unruptured aneurysms.
3. To learn about the classification of CNS vascular malformations.
4. To learn about clinical manifestation and imaging protocol of CNS vascular malformations.
5. To understand therapeutic decision and endovascular treatment of CNS vascular malformations.

A-226

B. Acute stroke and transarterial treatment

G. Wikholm; Gothenburg/SE

Stroke is today no longer without active treatment. Intravenous thrombolysis is an accepted treatment both in Europe and in the US. In more severe stroke and in a wider time window after the stroke transarterial embolectomy is a useful alternative to intravenous thrombolysis. A technique utilizing a standard intravascular retrieval snare will be presented in detail together with treatment results. The improvement in clinical status for patients treated has been encouraging. Our main problem today is to get the patients to the hospital quickly enough.

Learning Objectives:

1. To learn about active treatment in acute stroke.
2. To identify exempt from intravenous thrombolysis.
3. To understand technical aspects.
4. To learn about treatment results.

A-227

C. Carotid stenting

C. Cognard, H. Rousseau, P. Tall, A.C. Januel, F. Chollet, J.F. Albucher, A. Viguier, V. Larrue; Toulouse/FR

Carotid angioplasty and stenting is an alternative to carotid endarterectomy which is performed more and more worldwide in symptomatic and asymptomatic carotid stenosis. Several multicentric randomized international series are ongoing to compare both techniques and try to determine the safety and efficacy of each of

Postgraduate Educational Programme

them. In France, every patients presenting with a symptomatic carotid stenosis should be included in the EV3S study. Cases considered non surgical are the only candidate for stenting outside the trial. Treatment of asymptomatic carotid stenosis is very controversial and should be indicated in very selected cases only. The procedure is performed in most centers under local anaesthesia. The use of a brain protecting device is mandatory in the EVA3S study. Prestenting angioplasty is very rarely required.

The goal of this presentation is to discuss:

- Pretherapeutic diagnostic imaging including Doppler US, Angio CT or MR and digital substracted angiography
- Patients selections
- Therapeutic material and method
- Results of the main series published in the literature.
- Post-stenting patients medical care
- Long term follow-up

In conclusion, Carotid stenting is today a very frequent procedure which benefits from extremely rapid technological improvements and becomes more and more easy and safe to perform. Nevertheless, its advantages and drawbacks must be compared to surgery in term of evidence based medicine.

Learning Objectives:

1. To review previous and ongoing trials involving carotid angioplasty and stenting.
2. To discuss current clinical indications for carotid stenting.
3. To outline the current technique of carotid angioplasty and stenting and use of cerebral protection.

PACS pitfalls

Moderator:

N.H. Strickland; London/UK

A-228

PACS pitfalls (Introduction)

N.H. Strickland; London/UK

Our three speakers, all PACS experts from different parts of Europe, will give us the benefit of their experience using PACS in the clinical environment. PACS technology itself is now mature, and is available as an "off-the-shelf" product but many pitfalls still exist to trap those implementing PACS. Our experts draw particular attention to the pitfalls associated with: integration of PACS with other electronic systems, on-going maintenance of a PACS and its network infrastructure, reorganising clinical workflow optimally to exploit PACS, and the human factor involved in implementing a hospital-wide (or larger) PACS project.

Learning Objective:

How to avoid PACS pitfalls.

A-229

A typical PACS implementation: More than just the image! Organisational and infrastructural considerations

L. Sutton; Halifax/UK

A successful PACS Implementation requires a significant period of planning and organisational preparation if the organisation is to adapt to the changes the Implementation will introduce.

The key themes in managing this process are managing the organisational change, managing new ways of working and ensuring a robust infrastructure and well-managed network. This presentation addresses the change management issues under the following headings:

1. Realising the benefits of PACS.
2. Preparing the organisation.
3. Preparing the business case.
4. Implementation planning.
5. Post implementation support.

Educating members of the organisation of the benefits of PACS is essential if the full organisational benefits are to be realised. The types of benefits are discussed and consist of Clinical, Patient, Staff, Business and Strategic elements. In preparing the organisation there will be a greater degree of success if all members of the organisation are active participants in the planned changes rather than passive respondents.

Engaging active involvement is achieved through effective communication, training and education programmes and by addressing fears and unreasonable expectations. The involvement of the clinical community is essential for success. The formation of a Clinical Advocate Group is recommended.

Continuing success is dependent upon continuing training and education to ensure that the benefits described are actually realised. The central role of the PACS administrator is emphasised with stress being placed on effective communication skills with all members of the organisation.

The major measure of success following the implementation is that no-one would wish to go back to a film-based environment.

Learning Objectives:

1. To understand the main issues in planning and implementing a PACS into a health care organisation.
2. To recognise the importance of demonstrating the benefits of PACS to the organisation.
3. To understand the need to involve all members of the organisation as actively as possible to enable PACS to deliver all the clinical and non-clinical benefits.
4. To acknowledge that the PACS implementation process is not just simply an IMT exercise but an exercise in organisational change management.

A-230

Pitfalls when integrating HIS with PACS

W. Leodolter; Graz/AU

In the Austrian province of Styria the hospital group "KAGes" covers app. 85% of hospital beds. The group manages 22 hospitals with 6,700 beds and offers a wide range of ambulatory services. KAGes serves as example for describing pitfalls and opportunities in PACS-HIS-Integration.

Facing the dilemma of too many hospitals offering medical services close to where people are living, there is one way to manage such a group: Build a virtual hospital organisation. Uniform and interlinked hospital Information systems (HIS) with a single master patient index as entry point to an electronic patient record (EPR) and a "common language" are a prerequisite to offer patient related information exchange and telemedical services from centralized competence centers to local hospitals. PACS helps to enable the EPR, a HIS and especially teleradiology as driver for a virtual hospital organisation. Teleradiology is the most advanced field in telemedicine at KAGes.

PACS as learning opportunity for improved clinical workflow helps to prevent problems when implementing complex workflows in a HIS project afterwards. The evidence of integration issues with a Radiology information system (RIS) prevents the building of only poorly integrated "islands of information". Give your staff a taste of the benefits of an integrated HIS and EPR. Integrate the ordering-workflow from referring departments and the viewing of pictures in the ward. Experience the organisational changes involved with the intense use of EDP in your health care organisation. Teleradiology is an extension beyond the borders of the hospital organisation towards "healthcare unbound" and "e-health".

Learning Objectives:

1. To understand the role of PACS as a small part of the electronic patient record (EPR) and a hospital information system (HIS).
2. To learn why PACS is one of the driving forces and features implemented early on the way to an EPR and HIS.
3. To learn that the real and widely underestimated benefit of PACS is in clinical workflow
4. Why to address organisational changes in time when you implement the integration between PACS and HIS.

A-231

PACS implementation pitfalls: How to avoid a staff revolt!

T. Andersson; Örebro/SE

Traditional radiology is a proven and established technique, fine-tuned over more than a century. Filmless radiology, therefore, has until recently not really been considered an alternative, but more a business for pioneers, visionaries and crazy people in general. Today, however, technology makes it possible to go digital more easy and the PACS department is no longer a dream, but a reality that most hospitals have to prepare for.

Introducing a PACS is a major change of paradigm with far-reaching consequences for staff, routines and also the surrounding clinics and departments.

Dramatic changes are, in general, not popular among hospital staff, or human beings in general, and since PACS implementation is a typical and quite dramatic example of a major change one must be aware of the human side of a digitalisation process. To be able to really harvest the potential benefits from such a large change, traditional behaviours must be questioned, routines abandoned and new ways of working introduced. This is not done without pain and it is therefore im-

Postgraduate Educational Programme

portant to be prepared, not only for technical problems, but also for the human reactions and challenges.

The Pax Vobiscum project includes a total digitalisation of five independent radiology departments within Örebro County, Sweden. The human strategies, successful and unsuccessful, and lessons we learned in this project will form the basis for this presentation, which hopefully will give the audience a good view of the challenges in PACS implementation.

Learning Objectives:

1. To understand today's challenge in PACS. This is no longer the technology but rather the human side and how you organise your staff and your routines.
2. To be aware of that a successful PACS implementation must be driven from in-house, by the future users.
3. To be aware of that digitalisation is a matter for the whole hospital alone since the largest advantages can be expected outside radiology.
4. To be aware of size - small department - small problems, large department - large problems.
5. To be aware of the importance of a good system for image distribution.

Endovascular treatment of lower limb vascular occlusion

Moderator:

A. Besim; Ankara/TR

A-232

A. Thrombolysis

J.A. Reekers; Amsterdam/NL

Acute peripheral arterial thrombotic occlusion is still a limb-threatening situation, which needs acute intervention. Both surgical (thrombectomy) endovascular (thrombolysis or mechanical thrombectomy) have been widely used. There have been numerous trials to compare both treatment strategies (surgery versus thrombolysis) for endpoints like limb salvage, amputation and safety. Outcome for both groups was more or less equal, however morbidity and mortality seemed to be better in the thrombolysis group. The general opinion is that, whenever possible thrombolysis should be the first treatment option for acute arterial thrombosis. There has been a wide dispute in the literature about the way to administer the thrombolytic drug (pulsed or low-flow) and about which drug to use (rtPA or Urokinase) and the dosages. In a recent overview looking at Urokinase versus rtPA for peripheral occlusions forty-eight studies (22 urokinase, 22 rtPA, and 4 that included both treatments) were identified, encompassing 2226 urokinase-treated patients and 1927 rtPA-treated patients. The incidence of major hemorrhage varied widely, but the overall rate was lower among urokinase-treated patients (6.2%) than for patients treated with rtPA (8.4%. p = 0.007). The overall incidence of intracerebral hemorrhage was also significantly lower for urokinase (0.4% versus 1.1% for rtPA, p = 0.020). The major amputation rate was similar for both treatments (urokinase 7.9%, rtPA 7.2%), but the mortality rate was significantly lower for urokinase (3.0% versus 5.6% for rtPA, p < 0.001). The need for transfusions was less frequent with urokinase (11.1% versus 16.1%, p = 0.002).

Learning Objectives:

1. To discuss indications and practical cases concerning thrombolysis.
2. To evaluate technique and dose regimens.
3. To discuss other techniques for thrombus management like mechanical thrombectomy and thrombosuctie.

A-233

B. Uncovered stents vs covered stents

M. Sapoval; Paris/FR

Endovascular treatment of lower limb arterial occlusion can be often treated by Interventional Radiology procedures. Patients referred for non invasive imaging of leg arteries or arteriography should be carefully assessed clinically before to propose endovascular treatment. Balloon angioplasty can treat a wide range of lesions but stents can be implanted for the following setting: recanalisation of total chronic occlusion, occlusive dissection, embolic lesions. Uncovered stents should preferably be Nitinol stents and self expandable stent because of the risk of collapse in case of external compression. Covered stents are recommended for long total chronic occlusions and are now challenging the results of venous or

synthetic bypass grafts. Other techniques such as laser or atherectomy are not longer used.

Learning Objectives:

1. To understand the main clinical features of patients referred for revascularisation of lower limb vascular occlusion.
2. To choose for which patient interventional technique should be proposed.
3. To choose between covered stents, uncovered stents and simple angioplasty to ensure higher technical/clinical success.

A-234

C. Infrapopliteal lesions

A. Bolia; Leicester/UK

Subintimal Angioplasty of infrapopliteal occlusions has made a substantial impact on the treatment of critical limb ischaemia. The technique involves using a 5 French system and hydrophilic 0.035 guidewire. The wire is manipulated into a loop, which is then advanced through the length of the tibial occlusion. Then, after successfully crossing the lesion, a 3 mm balloon is used to dilate the artery. A number of publications are now available demonstrating the value of infrapopliteal subintimal angioplasty on the treatment of critical limb ischaemia. Primary success rates of over 80% and patencies of about 50% at 1 year can be expected. However, despite the relatively low patency rate, limb salvage of around 90% at 1 year has been demonstrated. Subintimal Angioplasty is safe, simple and a minimally invasive method of treating patients with chronic critical limb ischaemia. It is effective, inexpensive and a low risk alternative to distal reconstructive surgery.

Learning Objectives:

1. To discuss the management of critical limb ischaemia and include the indications, materials, technique and results of angioplasty.
2. To discuss the impact that the technique of subintimal angioplasty makes on CLI.
3. To briefly discuss the results of femoropopliteal subintimal angioplasty.
4. To grasp the basic technique of subintimal angioplasty.

Urological intervention

Moderator:

U. Patel; London/UK

A-235

A. Nephrostomy and ureteric stenting

F. Cornud; Paris/FR

Percutaneous nephrostomy (PCN) is a simple interventional procedure when it is performed on a dilated collecting system to relieve a chronic hydronephrosis. When the collecting system is not dilated, failure may occur if the Interventional Radiologist is not aware of some technical points which will be shown and which permit to achieve a PCN in virtually 100% of cases on a non-dilated collecting system. In patients with complex pelviccalyeal stones, including staghorn calculi, stones within a diverticulum, access to the collecting system is governed by a series of technical rules which will be exposed to show how to render stone-free a patient harboring the most complex renal calculi. Percutaneous stone extraction of the upper third of the ureter is also governed, in difficult cases, by technical endourological recipes which will be explained to show how to clear the ureter of stones embedded within the ureteral mucosa. Concerning ureteral stenting, most of the problems encountered are due to tight stenoses which may seem to be impassable, owing to a total ureteral obstruction. In these cases, performing an uretero-neocystostomy or using the rendez-vous technique, with a combined antegrade and retrograde approach, permits passage in 100% of cases of these totally obstructed ureters. Technical aspects of this technique will be shown. The rendez-vous technique can also very successfully be used to stent ureters in case of ureteral fistula into the retroperitoneum. Other endoureteral manipulations will be shown such as ureteral embolisation in case of intractable vesico-vaginal fistulae secondary to pelvic malignancies in female patients.

Learning Objectives:

1. To show how to solve problems in case of difficulties encountered during complex percutaneous nephrostomies.

Postgraduate Educational Programme

2. To describe the rendez-vous technique to stent ureters in case of complete obstruction or ureteral fistula.
3. To give guidelines to extract complex stones.

A-236

B. Thermal ablation of renal tumors

P.R. Mueller; Boston, MA/US

This lecture will be an updated summary of where radiofrequency ablation stands in 2004. A review of the procedure with an overview of technique, results, complications and follow-up will be given. While there have been several articles in the literature on RF ablation, there has been very little description of the process and technical difficulties of performing ablation on difficult lesions in the liver and kidney. What are the most difficult lesions to treat in the liver? What are expected results with treating primary tumors of the liver vs. metastasis disease? How difficult is follow-up? What are the problems with imaging interpretation? Similarly, in the kidney: What lesion is best suited to be treated in the kidney? What are major problems with RF of the kidney? Can you treat a metastasis? These points will be emphasized and summarized in the lecture.

Learning Objectives:

1. To become familiar with the world literature on RF ablation of kidney tumors.
2. To understand the safe techniques used to ablate kidney tumors.
3. To understand patient care issues in patients who have been or are being treated with RF ablation.

A-237

C. Renal arterial intervention

P.M.T. Pattynama; Rotterdam/NL

Renal artery stent placement has evolved as the method of choice for revascularization of atherosclerotic renal artery stenosis (RAS). The initial technical success rate is 95-100%, with only low complication rate when using the newer low-profile stent systems delivered through guiding sheaths. Complications, however, do occur and may be life-threatening: Embolisation of atherosclerotic debris in severely atherosclerotic vessels may, in the rare patient, lead to kidney loss and bowel necrosis. Stent patency approximates 90% at 6 months and 80-85% at 18 months, with little data available on more long-term follow-up. Studies are underway to establish whether patency will improve when using drug-eluting stents. Current discussion centers on the appropriate patient selection for stent placement. Proper indications include hypertension and/or renal functional impairment. There is a shift towards the latter indication, treatment to preserve renal function, given the increased efficacy of anti-hypertensive medical treatment. It has been clearly shown that RAS in the absence of hypertension or renal insufficiency should not be treated with stent placement. The importance of appropriate patient selection is shown in nearly all patient series: Stent placement will hugely benefit some patients, but will show no benefit at all in others. Controversy exists about accurate predictors of clinical success: Beneficial factors may include a relatively preserved renal function and preserved intrarenal vascular microvasculature, as evidenced by a normal resistive index of better than 80% measured with doppler ultrasound. Initial reports suggest a beneficial effect of using embolic trapping devices during stent placement, such as filter-tipped guide wires.

Learning Objectives:

1. To know the different etiologies of renal artery stenosis.
2. To discuss the indications and contraindications for renal artery revascularization.
3. To understand the evolving discussion about appropriate patient selection.
4. To discuss available techniques for, and potential complications of renal artery stent placement.

A. Large infant heads: What do we do - and when?

F. Brunelle; Paris/FR

Macrocrania in children is a common presenting clinical feature. It affects 5% of the population. Macrocrania is an associated finding in some syndromes in which mental retardation is a cardinal clinical sign. In these cases, the medical problem is of a completely different nature. However, macrocrania in some instances appears isolated. Macrocrania by definition is the consequence of an increased growth of the cranium over the brain. It cannot appear after the closure of the sutures. The role of ultrasound is to check the ventricular size and to exclude massive hydrocephalus. CT scan is usually done following the ultrasound or directly as a first procedure. It will assess the ventricular size, rule out the presence of a brain tumor and look for a chronic subdural effusion. In many cases MR imaging will be performed to make a precise diagnosis, to appreciate the extent of a tumor or to do MR angiography. Main causes of macrocrania are as follows: hydrocephalus; external hydrocephalus; brain tumors; vascular malformations; vein of galen aneurysms; metabolic diseases; idiopathic. A familial incidence is often found. Mild mental retardation is not unusual.

Learning Objectives:

1. To decide which patient should be worked-up and when.
2. To choose the technique, CT versus MR imaging.
3. To differentiate benign from conditions requiring treatment.
4. To understand the mechanisms of hydrocephalus.

A-239

B. Imaging of sensorineural hearing loss: A practical approach in children

M. Elmaleh; Paris/FR

The most frequent etiologies of sensorineural hearing loss (SNHL) are far different in children than in adults. Congenital abnormalities, infections, and trauma are, in descending order, the main causes of SNHL in children. Posterior fossa tumors are often associated with other cranial nerve involvement; IAC schwannomas are rare and, when part of neurofibromatosis type 2, manifest in the second decade of life.

Clinical and audiological data of the child (supposed time of onset, degree of the hearing loss, personal and familial history...) are essential to choose the most efficient imaging technique.

CT detects osseous labyrinth and IAC malformations, and with careful analysis of the cochlear nerve bony canal, can raise suspicion of cochlear nerve hypoplasia. Labrynthine ossification from post-meningitis deafness and temporal bone fractures are also well evaluated by CT. Recent improvements in CT technology, such as helical CT, have reduced dramatically the need for sedation. Depending on the series in the literature, CT is positive in about 20-40% in children with SNHL.

However MR imaging is the only method that looks at the cochlear nerve, the brainstem and the brain parenchyma and it can detect isolated abnormalities of the membranous labyrinth. 3D-fast spin echo technique provides sub-millimeter high-resolution T2-weighted images of the labyrinth and IAC contents. Evaluation of cochlear implant candidates include both CT and MR imaging.

Concerning congenital deafness, we would like to emphasize the increasing role of imaging in the diagnosis of deafness etiology: an increasing number of known syndromes or known genetic defects can be confidently identified by imaging.

Learning Objectives:

1. To choose the most appropriate imaging technique, CT and/or MR imaging, based on the clinical examination, history and audiologic data.
2. To propose imaging protocols, emphasising the last technical improvements in CT and MR imaging.
3. To illustrate the most frequent aetiologies of sensorineural hearing loss (SNHL) in children: Congenital abnormalities, infectious diseases and trauma.
4. To review the role of imaging in the work-up of cochlear implant candidates and after cochlear implant surgery.

A-240

C. Pediatric MR spectroscopy: Current applications and future prospects

M.J. Beer, H. Koestler; Würzburg/DE

MR-spectroscopy (MRS) has gained an established use in paediatric neuroradiology, allowing the non-invasive assessment of multiple metabolic processes. Additionally, other potential applications currently emerge outside the central nervous system e.g. heart, musculoskeletal system or liver.

The increasing use of MRS techniques is not only a result of the fascinating non-invasive approach to fundamental biochemical processes, but also a result of recent technical advances. Reproducible quantification methods, dedicated data acquisition and postprocessing methods have been introduced. Dedicated 3 T scanners pave the way for new clinical applications of MRS, with enormously increased spatial and/or temporal resolution.

1H-MRS, which is the mostly used technique in the field of neuroimaging, allows the analysis of chemical moieties as N-acetyl aspartate (NAA), creatine (Cr/PCr) and choline (Cho). An important aspect for the use in paediatrics is the normal regional variation and age dependence of the respective moieties. The main applications are characterization of brain tumours and analysis of inborn errors of metabolism.

Using 31P-MRS, the main molecules of energy metabolism, phosphocreatine (PCr) and adenosinetriphosphate (ATP), can be studied. In heart failure, both metabolites are increasingly reduced. Detection of subclinical cardiac commitment in a variety of diseases like multiple sclerosis or different forms of neurodegenerative diseases is possible. Another use is the differentiation of liver and musculoskeletal diseases and finally as a prognostic tool in oncology.

Thus, MRS may become a clinical routine tool, which offers valuable additional information for detection and assessment of various diseases.

Learning Objectives:

1. To understand fundamental biochemical processes.
2. To propose dedicated data acquisition and postprocessing protocols.
3. To illustrate possible clinical applications inside and outside the brain.
4. To review recent technical advances including (3 T/Gating/AW-CS1/DW-CS1).

Infection in the Adult Today

CC 916

Modern imaging of infective disease in the face and pelvis

Moderator:

M. Gödeny; Budapest/HU

A-241

A. Cervicofacial infection in the immunocompromised patient

K. Marsot-Dupuch; Le Kremlin-Bicêtre/FR

Head and neck lesions are encountered in more than 40-50% in patients with immunosuppression (HIV-infection, diabetes mellitus, transplant recipients, immunosuppressive drugs or post-radiotherapy). The organs affected are mainly involved by granulation tissue, perivascular and perineural inflammation, and neoplasms.

Salivary gland involvement leads to a non-specific bilateral painless enlargement of the parotid gland and xerostomia. The high rate of salivary gland involvement is related to the presence of the HIV within the saliva. Lymphoepithelial cysts, sialosis, and lymphoma may be present simultaneously in the same patient. Sinonasal diseases (66% of IS patients) are associated with a trend of decreased survival rate. Fungal sinus disease (1-10% of transplant recipients) should be suspected whether organ rejection is considered. Invasive aspergillosis (lethal in 50-80%) is defined by submucosal hyphae and tumor necrosis without host inflammatory response. MR is the best imaging modality to perform to exclude skull base involvement, extrasinonasal extension and meningeal spread. The lesion has a characteristic hypointensity on T2-WI.

The temporal bone is the most frequent target organ in the IS pediatric population. Prompt treatment may avoid complications such as lateral sinus thrombosis and skull base spread.

Kaposi's sarcoma is an indicator of the progression of HIV infection. Often multifocal at presentation, it may affect the skin and visceral organs. Cytokines and growth factors may play a role in the pathogenesis of angiogenic sarcoma.

In conclusion, immunosuppressed patients are likely to develop virulent infection with vascular complications and tumor at an earlier age than usual.

Learning Objectives:

1. To underline pathologies leading to immunosuppression status.
2. To illustrate some characteristic pathologies occurring in immunocompromised patients.
3. To describe perineural and vascular spread and complications.
4. To discuss post transplant lymphoproliferative disorders.

A-242

B. Urinary infection

W. Torreggiani, R. Browne; Dublin/IE

Urinary tract infection (UTI) in the adult is primarily based on a combination of typical symptoms of fever, as well as urinalysis. Patients with uncomplicated pyelonephritis who respond to treatment do not necessarily require radiological evaluation. In general imaging should be reserved to those patients in whom conventional treatment has failed or those who have recurrent or unusually severe symptoms. Occasionally patients may be referred for imaging at an early stage if the symptomatology or urine analysis is uncertain and if other diseases such as ureteric colic or renal infarction are suspected. In addition, in certain patients such as those with conditions predisposing to infection such as diabetes mellitus or immunocompromised states early imaging may be beneficial. Intravenous urography (IVU) and ultrasound (US) have traditionally played leading roles in the evaluation of UTI. MR imaging is an emerging modality but it is computerised Tomography (CT) that plays the pivotal role in the diagnosis of renal tract infection and its complications.

Learning Objectives:

1. To describe the role of the various imaging modalities in the investigation of UTI in adults.
2. To depict the wide range of findings that may be present in a variety of urinary infections.
3. To indicate the important role that the interventional radiologist plays in the management of these patients.

A-243

C. The spectrum of pelvic infection

A.A. Ghiatis; Athens/GR

Pelvic infection affects approximately one million women yearly with rather serious consequences such as infertility, ectopic pregnancy and pelvic pain.

Early diagnosis of pelvic infection leads to early and successful treatment with minimal if any complications. Imaging provides significant assistance to the management of pelvic infection and appropriate selection and use of different imaging modalities and techniques is essential to the diagnostic management of this pathological entity. The purpose of this presentation is to discuss the approach as well as the use of different imaging modalities such as US, MR imaging, CT and Hysterosalpingography in the management of pelvic infection.

Learning Objectives:

1. To understand the optimal use of imaging modalities.
2. To become familiar with optimal imaging protocols.
3. To comprehend an appropriate approach to imaging patients with pelvic infection.

Medical image registration: Methods, applications and validation

Moderator:

M. Kachelrieß; Erlangen/DE

A-244

A. A tutorial on algorithms and methods

D. Rueckert; London/UK

This lecture will provide attendees with a basic working knowledge of methods used to register images, and a description of some examples of the wide variety of applications for which these techniques are used. Applications of image registration include combining images of the same subject from different modalities, aligning temporal sequences of images to compensate for motion of the subject between scans, providing guidance during surgical procedures, correcting for

Postgraduate Educational Programme

soft tissue deformation and aligning images from multiple subjects in cohort studies. We will review the current state-of-the-art in image registration. We will focus primarily on algorithms that use voxel-based similarity measures to automatically register images that are related by a rigid-body transformation. We will also discuss current research trends in the development of non-rigid registration algorithms that can compensate for tissue deformation or align images from different subjects.

Learning Objectives:

1. To become familiar with the basic image registration techniques.
2. To understand the concept of rigid and non-rigid registration.
3. To understand the role of image features, image similarity measures and image interpolation in registration.

A-245

B. Applications

D. Hawkes; London/UK

Image registration has emerged as a powerful tool over a wide range of medical applications. This talk will explore how the development of this technology impacted on these applications. In multi-modal imaging, complimentary information is combined to provide synergy between two (or more) imaging modalities. Examples include the combination of structural information from MR with the functional information available at lower spatial resolution from PET or SPECT. Very accurate alignment of intra-modality data allows subtle temporal changes in structure or function to be analysed. Over short time intervals image registration improves image alignment in functional MR studies and over long time intervals allows highly accurate detection of cerebral atrophy. Image registration to the physical space of the patient in the operating room is the key enabling technology in image-guided surgery.

Non-rigid registration applications range from the measurement of change, to the generation of atlases and the propagation of segmentation in the automated interpretation of images. Applications include accurate measurement of tissue growth and destruction in the monitoring of therapy and the progression of disease by analysis of deformation fields. Atlases can be built from large numbers of example images that have been aligned and the statistics of the resulting deformation models can be used to build statistical shape models. These models can then be used to propagate organ outlines to improve measurements of size and shape.

Learning Objectives:

1. To learn how to carry out very precise measurements of change, growth, atrophy.
2. To understand how to apply image registration in motion analysis.
3. To understand how to apply image registration in shape modelling, atlas generation and segmentation propagation.
4. To understand how to use image registration in image guided interventions.
5. To understand how to use image registration in multi-modality imaging.

A-246

C. Strategies for validation

A. Todd-Pokropek; London/UK

Image registration techniques require validation, which implies the availability of a gold standard. For rigid registration this then permits the definition of a target registration error and a number of successful evaluations of rigid registration techniques have been completed. Non-rigid registration includes a model of interpolation and cannot be evaluated in such a simple manner. We are interested in the accuracy of registration at all points in image space, but "weighed" by the clinical objective to be achieved. Non-rigid registration must also include a model of the process of deformation (for example a model of tissue characteristics) and can be divided into spatial deformation and material transport. It is then possible to define the registration in terms of the deformation vector field and transport field, where some methods exist for their assessment. In general, a suitable strategy for validation of such methods starts by using real clinical data and deforming it, for example using a finite element (tissue based) method. The accuracy of restoring the data back to its undeformed state provides a baseline for evaluation, although the use of circular methods (where the forward and reverse operations match) must be avoided. Finally clinical trials are required to confirm this validation on real clinical data for real applications.

Learning Objectives:

1. To enable the understanding of the processes of rigid and non-rigid registration, of constraints such as diffeomorphism and consistency, and the choice of various particularities of different methods as appropriate for different clinical applications.

2. To understand the process of validation of rigid registration and strategies for use for non-rigid registration.
3. To become familiar with the use of and the limitations of such techniques.

Nodules and neoplasms

Moderator:

T. McLoud; Boston, MA/US

A-247

A. Solitary and multiple pulmonary nodules

A.A. Bankier; Vienna/AT

Pulmonary nodules are among the most common radiological findings. A wide array of diseases can manifest as solitary or multiple pulmonary nodules. At the edge of the differential diagnosis is the differentiation between benign and malignant nodules. This presentation attempts to propose a systematic approach to these lesions.

Learning Objectives:

1. To define the concept of pulmonary nodule.
2. To illustrate the spectrum of its radiological presentations.
3. To review the array of its differential diagnoses.
4. To present subjective and objective analytical approaches.

A-248

B. Staging of non-small cell and small cell lung cancer

P. Armstrong; London/UK

The treatment of lung cancer is highly dependent on its stage and cell type. Small-cell lung cancer is almost never treated surgically, whereas surgical resection is the optimum potentially curative treatment for non small-cell lung cancers in patients who are fit for surgery and whose tumours can be fully resected by surgery. The presentation will focus predominantly on the imaging information required by thoracic surgeons considering surgical resection of lung cancers. The practical approach, given the difficulty of accurately determining T, N and M stage and the diagnosis of metastases, will be emphasised.

Learning Objectives:

1. To inform about current staging classifications for non small-cell and small-cell lung cancer.
2. To review the spectrum of imaging features of different tumours in the TNM classification.
3. To enhance the understanding of the role of imaging in the differentiation between operable and non-operable tumours.

The present and future of Hungarian radiology: Contribution of a new generation (Introduction)

A. Palkó¹, B. Lombay²; ¹Szeged/HU, ²Miskolc/HU

Being invited by the president of ECR 2005 as one of the countries "meeting ECR" is among the most important successes in the more than one hundred year history of Hungarian radiology, thus we may be very proud to have the honor to introduce the session "ECR meets" Hungary.

The list of speakers and topics discussed by them was selected to express the concept that rich traditions of Hungarian radiology today may be best represented by those young scientists who belong to a new generation, having the oppor-

Postgraduate Educational Programme

tunity to spend the most productive period of their professional life as citizens of a new member country of the European Union.

The lectures discussing results of experiments on diffusion MR imaging and automated colon CT diagnostics, applied clinical research on epilepsy diagnostics and interventions in the liver and the carotid vessels give good samples of the wide range of ongoing scientific activity in university and hospital departments and research labs in different regions of Hungary.

We hope that the ninety minutes of the session will give a good impression and provide a lot of valuable new information regarding Hungary and Hungarian radiology at the time of our arriving back home to Europe.

Learning Objectives:

1. To introduce significance of being one of the countries invited to the "ECR meets" program.
2. To introduce principles of speaker and topic selection to the "ECR meets" Hungary session.

A-250

What do we see on diffusion MR images? A lesson learned from model experiments

P. Bogner; Kaposvár/HU

Purpose: Diffusion imaging is highly sensitive to detect the changes in water movement that are characteristically reduced in ischemic stroke as a consequence of cytotoxic edema. In addition to changes in water diffusion, the osmotic properties of ischemic brain tissue are progressively altered. In cellular model experiments the impact of cellular volume changes on water diffusion as well as the relationship of diffusive and osmotic characteristics of cellular water were investigated.

Methods and Materials: Mammalian erythrocytes with different protein hydration levels were used. Along with cellular volume changes the osmotic resistance and the amount of osmotically unresponsive water were determined. Water diffusion was measured with the Stejskal-Tanner sequence (b-factor: 0-17.684 s/mm²) on a Varian ^{Inova}Unity MR microimaging system.

Results: It was shown that a two-fold change in cellular volume (protein hydration) results in only about a 20% change in water diffusion in human erythrocytes. However, cellular volume change causes a significant alteration in the osmotic behavior of the cells that, in this experimental model, is a consequence of the change in protein hydration and most likely protein aggregation.

Conclusion: Water movement is restricted in living tissues due to three major reasons, namely 1. the presence of biological membranes, 2. molecular obstruction and 3. water binding mainly to macromolecules (protein hydration). It seems likely that the osmotic behavior is closely related to protein hydration but water diffusion depends also on other mechanisms as mentioned above. The possible mechanism of reduced water diffusion and altered osmotic behaviour in brain ischemia will be discussed.

Learning Objectives:

1. To define parameters that characterize the osmotic behavior of a cell-membrane characteristics, osmotically inactive water and protein hydration water.
2. To introduce the relationship of osmotic and diffusive characteristics of cellular water.
3. To implement experimental results in diagnostics of DWI and suggest possible therapeutic consequences.

A-251 ♀

Epilepsy patient: The complex neuroradiological approach

P. Barsi; Budapest/HU

Purpose: We created a neuroradiological protocol to answer the clinicians' questions, varying with the patient's age, epilepsy type, and treatment phase (pre/postoperative).

Material and Methods: We examined more than 1,000 epilepsy patients by MR imaging (from 0.5 to 1.5 Tesla). We used the protocol containing thin T2 and PD/FLAIR slices perpendicular to the hippocampus, and 3D acquisition with multiplanar and surface reconstructions. We used T1 IR instead of 3D under 2 years of age. We performed 3D MR imaging for the localization of intracranial EEG electrodes detecting epileptic discharges during monitoring. We used the same protocol for postoperative cases. The only role of CT was to detect calcification. We discussed our findings in detail with the clinicians.

Results: 1. The commonest causative pathologies were hippocampal sclerosis and cortical dysgenesis. 2. Focusing on the hippocampus resulted in the identification of dual pathologies and hippocampal malrotation. 3. We found evolving hippocampal sclerosis in 7 cases of SMEI. 4. We found a subtype of extensive closed lip schizencephaly with mild clinical picture. 5. We found characteristic

features in different lissencephaly subtypes. 6. MR imaging of invasive EEG electrodes proved to be useful in the focus localization of dubious focal epilepsies. 7. Postoperative analysis of unsuccessful cases is a work in progress based on a volumetric approach.

Conclusions: 1. The proper epilepsy MR imaging protocol is essential in each diagnostic phases of epilepsy. 2. The protocol should be used even in cases of other pathologies or generalized epilepsy cases. 3. Interpretation of imaging results needs close cooperation with the clinicians.

Learning Objectives:

1. To comprehend the role of MR imaging in the pre-, peri-, and postoperative phases of epilepsy patients' management.
2. To become familiar with the proper MR imaging protocol for epilepsy patients.
3. To learn the causative pathologies possibly detected by the examination.

Radiological diagnosis and treatment of carotid artery stenosis

R. Szentgyörgyi; Szeged/HU

Stroke is the No. 1 cause for disability, and No. 3 among all causes of death, behind diseases of the heart and cancer. Thromboemboli originating from stenosed carotid bifurcations are the cause of stroke in 12-60%. Non-invasive imaging techniques became widely available for the diagnosis of internal carotid artery (ICA) stenosis. Carotid artery stenting (CAS) is slowly being favoured over surgical endarterectomy (CEA) for the prevention of stroke. Observations based on the series of 250 CAS procedures performed at our institute are presented.

Duplex Doppler examination is the standard tool for screening of carotid artery stenosis. For preprocedural evaluation before CAS, however, it has to be augmented with CT angiography or MR angiography for more precise stenosis measurement and additional pathological findings in the region of supraaortic vessels. Indications for CAS are similar to those of CEA, but it is also feasible for patients considered high risk for surgery. Complication rates much lower than achievable with CEA are possible with CAS in cases with careful preprocedural planning and endovascular equipment selection. Risks of anesthesia and complications related to relatively long clamp-time is avoided with stenting. Periprocedural patient care is vital for the success of CAS. Restenosis can be successfully managed with a cutting balloon.

Improvement in equipment and expertise for CAS is expected, and will surely replace CEA in the next few years.

Learning Objectives:

1. To learn the aspects for preprocedural evaluation for carotid artery stenting.
2. To learn the indications for CAS.
3. To learn the significance of "passive protection" for CAS.

A-253

Interventional radiology in portal hypertension

I. Lázár; Miskolc/HU

Background: Viral and alcoholic induced cirrhosis are the principle causes of PH in Europe. The rest of cirrhoses are the sequelae of various metabolic or idiopathic disorders of the liver. Ultrasonography (US) is the most widespread diagnostic procedure in PH combined with invasive mesenteric angiography. In the early stages of cirrhosis PH symptoms threaten the patient more than parenchymal impairment of the liver. Transjugular intrahepatic portosystemic shunt (TIPS) is indicated at that stage or later as a bridge to liver transplantation.

Procedure Details: When clinical and endoscopic signs of PH are present an assessment of portal hemodynamics is performed by US. It is essential to reveal pre- versus post hepatic PH. Portosystemic collaterals and frequent incidental hepatocellular carcinoma are evaluated by computed tomography and recently MR. Our single center experience is 80 TIPS and 27 revisions, including 12 stent-graft procedures, a pediatric case and TIPS in a patient with portal cavernoma.

Conclusion: Interventional radiology is the method of choice in the treatment of patients with PH. Up-to-date imaging methods and continuously growing experience make the TIPS procedure safe and reproducible. The use of e-PTFE covered stent-graft, compared to bare stents, reduces the re-intervention rate by prolonging TIPS patency. Procedural technical problems seem to be mostly overcome but important difficulties like restenosis and hepatic encephalopathy has still not been solved with complete satisfaction.

Learning Objectives:

1. To remind the most frequent etiology and imaging methods of portal hypertension (PH).
2. To become familiar the indications and techniques for the interventional radiological management of PH.

Postgraduate Educational Programme

3. To illustrate the results and the complications of transjugular intrahepatic portosystemic shunt.
4. To outline the pros and cons of PTFE covered stent in TIPS procedure.

Results of the virtual colonoscopy CAD project

Z. Tarján; Budapest/HU

The aim was to develop a PC based virtual colonoscopy application which needs minimal user interaction, and with automated functions may be used as a screening tool. ColVis was developed by two universities and runs on PCs or laptop computers. Interactive real time ray casting is used, which allows high speed, high resolution volume rendering. Semiautomatic region growing segments the colon and cast or transparent view is used. For fast evaluation of suspected lesion composition an oblique image perpendicular to the virtual camera plain may be adjusted to the lesion. Automatic centerline extraction generates automated videos of the whole colon. For noisy low/ultra-low dose CT data a filter volume enhancement with edge preservation is used.

For better patient compliance the patient may eat normally in the days before the examination. Digital subtraction bowel cleansing uses the combination of selective regional thresholding and seed growing. This enables smooth, reliable endoscopic views after electronic cleansing in patients without cleansing bowel preparation. The automated lesion detection CAD, which enables us to detect polypoid lesions, is based on robust shape and density analysis algorithms. It detects all simulated polyps in plastic and pig colon fomants without false positives, and also shows promising results in patient data. The lesion size threshold may be adjusted and algorithms help to discriminate residual stool balls from polyps.

The presentation demonstrates the features of ColVis in phantom models and in patients with colonoscopic correlation. Examples of primary 2D or 3D based colon evaluation and features shortening evaluation time are demonstrated.

Learning Objectives:

1. To evaluate how PC based software may aid the reading of CT colonography data.
2. To learn the 2D and 3D based evaluation methods in colonography.
3. To understand features which are needed for greater patient compliance.
4. To get familiar with features shortening the evaluation time.

Drug-eluting stents (Introduction)

J.A. Reekers; Amsterdam/NL

Both interventional cardiologists and interventional radiologists have been facing the huge problem of intimal hyperplasia for decades. This has truly been the "Achilles heel" of percutaneous treatment of stenotic arterial disease. Introduction of stents in the late eighties of the last century has shown not to be a solution to this problem. However, stents did improve PTA outcome, due to a better starting point by elimination the recoil problem. Drug eluting stents (DES) are the next, promising step to improve the outcome after PTA by blocking intimal hyperplasia.

The fast majority of the experience and data concerning DES comes from interventional cardiology. Although DES are a very promising development for peripheral PTA, there is one important difference with all the cardiology studies. The endpoint in most cardiology studies is an angiographic parameter and deals with reduction in intimal hyperplasia compared to a placebo. For peripheral vessels however, a statistically significant effect on an angiographic primary endpoint has to translate into a significant clinical effect, as in most cases the original disease (intermittent claudication) is not life-threatening but only lifestyle limiting. DES are an exciting new tool in the battle against intimal hyperplasia, which might change the future perspective of peripheral PTA. It is therefore interesting for every radiologist involved in peripheral interventions to know about DES, and to learn about the latest development. This special session on DES is a unique opportunity to get a complete update on this topic.

Learning Objectives:

1. To understand the current role of drug eluting stents for the treatment of peripheral vascular disease.
2. To learn about ongoing research in the field of DES.
3. To become familiar with all the specific drugs currently tested against intimal hyperplasia.

A-256

General introduction drug-eluting stents

J. Rose; Newcastle Upon Tyne/UK

The restoration of peripheral vascular patency with angioplasty and stents has long been beset with the problem of restenosis. The basic mechanisms of restenosis include early elastic recoil, vessel wall remodelling and myointimal hyperplasia. The vascular stent reduces elastic recoil but tends to increase the degree of neointimal hyperplasia and late lumen loss. Several alternative technologies including anti-platelet agents, inert stent coatings, brachytherapy, sonotherapy and gene therapy have been proposed to prevent restenosis. None of these alternatives have yet been proven and drug eluting stents have attracted steadily increasing interest over the last 5 years.

The basic principle underlying the drug eluting stent is the inhibition of cellular proliferation by local delivery of an active agent with minimal systemic effect. In general a basic stent platform is coated with a matrix polymer, which may be biodegradable, and a suitable pharmacological agent is loaded within the matrix. Stents coated with a variety of anti-inflammatory or anti-mitotic agents have produced encouraging reductions of angiographic re-stenosis in the coronary circulation and appear clinically effective in the short to medium term.

The latest trends however, seem to indicate that the problem of re-stenosis is delayed rather than abolished by the use of such devices. It may be that the ideal pharmacological agent is yet to be tested and indeed the use of new stent materials, including fully bio-degradable compounds, is proceeding apace.

Learning Objectives:

1. To understand the basic mechanisms of re-stenosis.
2. To become familiar with the principles of drug eluting stents.
3. To learn the various classes of pharmacological agent carried by drug eluting stents.
4. To understand the technological differences between the current stent platforms.
5. To gain a broad picture of the current data from coronary stent trials.

A-257 ♀

Drug-eluting stents in renal arteries

M. Zähringer; Cologne/DE

The various modalities used in the treatment of renal artery stenosis (RAS) have evolved over the years. In the late 1970's, Percutaneous Transluminal Renal Angioplasty (PTRA) was introduced as an alternative to surgical revascularization. Since then, PTRA has been accepted as the initial treatment for RAS due to its minimally invasive nature. However, restenosis after PTRA still remained a problem. The introduction of stenting in renal artery treatment did improve the results. Restenosis rate after PTRA up to 9 months has been reported in various series up to 38%. A meta-analysis of the literature showed a restenosis rate at 6 months close to 17% when .035" compatible stents are used, but also showed a lack of validated angiographic follow-up data. Restenosis rate using new low profile stents have not been reported in the literature yet.

The GREAT study, presented in the lecture, is a multicenter study on the use of bare and, at the first time, drug eluting low profile balloon expandable stents in renal artery stenosis.

The study demonstrates that low profile balloon expandable stent systems allow to obtain excellent results with a low restenosis rate of 14.3% in the bare stent group. By renal artery stenting with drug eluting Palmaz Genesis stents it is possible to cut down the restenosis rate to 6.7% with a decrease in the numbers of revascularizations with 50%.

Learning Objectives:

1. To comprehend the indications for the interventional radiological management of patients with renal artery stenosis.
2. To understand the role of interventional radiology in the management of renal artery stenosis.
3. To become familiar with the relative advantages of drug eluting stents in treating renal artery stenosis.
4. To learn the principles underlying the techniques used by interventional radiologists in the management of renal artery stenosis.

A-258

Drug-eluting stents in SFA

J. Lammer, C. Kopp, M. Cejna, T. Rand, E. Minar; Vienna/AT

Purpose: Drug-eluting stents locally release drugs at high concentration to reduce intimal hyperplasia.

Method and Material: Metallic stents are covered by a polymer matrix or nanoporous ceramics to cause controlled release of the drug. The target of intervention can be blockage of receptor activation in smooth muscle cells. This prevents signal transduction by cytokines or growth factors. Immunosuppressive macrolites such as Rapamycin (Sirolimus) or FK506 (Tacrolimus) are drugs to suppress T-cell proliferation and release of proinflammatory cytokines. This also causes cell cycle arrest of smooth muscles in the late G1 phase. Another target of intervention is to block cell division in the M phase with cytotoxic drugs such as Paclitaxel (Taxol).

Results: Various animal experiments have shown that Rapamycin, FK 506 and Paclitaxel are able to prevent intimal hyperplasia. In coronary arteries large clinical trials such as the Sirius trial compared a Sirolimus-eluting stent with a bare stent in 1101 patients. At 2 years follow-up restenosis requiring target lesion recanalization (TLR) was significantly reduced (6.3% vs. 21.0%, p < 0.001). In the Taxus IV trial (n = 1314) the TLR rate at 12 month was 4.4% vs. 15.1%, p < 0.0001. In peripheral arteries only one clinical study was finished so far. In the Sirocco trial comparing Sirolimus-eluting versus bare stents in the SFA in 72 patients the 6-month binary angiographic restenosis rate was 0% vs. 11.6%.

Conclusion: Drug-eluting stents have proven to reduce the restenosis rate significantly in coronary arteries. Convincing data of studies in the peripheral arteries are pending.

Learning Objectives:

1. To understand the biological action of the various drugs.
2. To learn the clinical results of coronary artery trials.
3. To learn the clinical results of peripheral artery trials.

Uncertainty, discrepancy, and errors in radiology

R. FitzGerald; Wolverhampton/UK

Reporting discrepancies are common in Radiology, but fortunately only a minority affect patient management. Whilst one can categorise their aetiology as being due to problems of technique, perception, knowledge and judgement, in reality the origins are often multifactorial and systemic. We need to learn lessons from the airline industry in improving safety. Teamworking is fundamental to optimising performance. However, individual accountability still remains even in a systems-based culture, and we should have strategies for radiologists with difficulties. Learning from error and discrepancy is very important. We need to have a no blame reporting culture. Patients have the right to know of errors that have adversely affected their care. The communication of this information must be undertaken in a sensitive manner. A simplistic approach to accuracy in Radiology needs to be replaced with a more complete model of radiological performance. Innovations in radiological interpretive discrepancy collection should stimulate better knowledge sharing and targeted instruction.

Learning Objectives:

1. To learn how some "incorrect" radiological reports may be due to uncertainty or discrepancy rather than error.
2. To become familiar with the scale and causes of error in radiology.
3. To understand how a report can be diagnostically accurate but lack therapeutic impact.
4. To appreciate the relative infrequency of clinical effect on patients from radiological error.
5. To realize that complacency is not appropriate and how we should learn from error in a supportive environment including properly conducted discrepancy meetings.
6. To acknowledge that better knowledge sharing, targeted instruction and teamworking in radiology can improve patient safety and our own working lives.

A-261

Pitfalls in emergency radiology

O. Chan; London/UK

Large numbers of studies have been published in relation to errors in radiology. The "error rate" varies depending on numerous factors and on which imaging modality is studied. However, several factors have been identified, which consistently contribute to major errors. It is neither within the scope or intention of this talk to trawl through the literature, repeating what has already been published. The talk is based on personal experience in a busy emergency radiology department, with a strong emphasis on major trauma (HEMS). It will concentrate on how to reduce errors and improve communication in the emergency room, with quick, simple, cheap and practical advice.

The aim of this talk is to make you think and hopefully adjust/change your current practice, with an emphasis on the following:

- 1) Zero tolerance for poor quality radiography.
- 2) Interpret the radiographs with NO clinical history initially - don't be afraid to make mistakes!
- 3) Use a systematic approach - but relevant to your practice (ABCs approach).
- 4) Obtain a reliable history before giving a report.
- 5) Go and see patients!! Teleradiology is NOT the answer in trauma.
- 6) There is no point in providing a report which fails to get through the physician's skull vault.
- 7) Give your opinion, not a report!

Trauma radiology is FUN and unlike most of radiology, it SAVES LIVES!!

Learning Objectives:

1. To discuss ways of reducing errors in trauma radiology.
2. To emphasize the difference between a report and an opinion.
3. To ensure that your report is communicated to the physician.
4. To attract radiologists into emergency radiology.

A-262

Pitfalls in musculoskeletal MR imaging

W.C.G. Peh; Singapore/SG

Numerous pitfalls may be encountered in musculoskeletal magnetic resonance (MR) imaging. Those caused by imaging technical factors are potentially preventable, and include optimizing coil selection, slice selection, scan planes, pulse sequences, fat suppression, intravenous and intraarticular use of contrast agents, use of surface markers, and protocol-error artifacts. Common inherent MR artifacts include motion, truncation, chemical shift, susceptibility, fat suppression and the magic angle phenomenon. Normal anatomical structures and variants may also be a source of diagnostic pitfalls. Emphasis is placed on recognizing common potential pitfalls, identifying their causes with the aim of providing a remedy for correctable problems, improving diagnostic accuracy, and avoiding unnecessary treatment or surgery.

Learning Objectives:

1. To be aware of the various types of common potential pitfalls in musculoskeletal MR imaging.
2. To identify and if possible, correct or avoid these pitfalls in order to reduce errors in diagnosis.

The brain perivascular spaces in health and disease: 2005 update on anatomy, pathophysiology, advanced neuroimaging

A.G. Osborn; Salt Lake City, UT/US

The perivascular (Virchow-Robin) spaces (PVSs) are pial-lined structures that accompany the brain penetrating arteries. This lecture will demonstrate their anatomy and function, illustrating the relationship of the vessels and pia using both electron and transmission microscopy. Computer graphics model the normal PVSs in both the cortex and basal ganglia. The wide spectrum of their normal imaging appearance is demonstrated using 3 T MR scans. A spectrum of giant and "tumefactive" PVSs, extreme but normal variations that should not be mistaken for disease, will be shown. The contents of PVSs, interstitial fluid (ISF, not CSF), is documented and the potential role the PVSs play in regulating brain ISF and modulating immunological response in health and disease is illustrated. A variety of pathologic processes that involve the PVSs, ranging from congenital, infectious, vascular, and neoplasms is demonstrated.

Learning Objectives:

1. To understand the normal anatomy and physiology of the brain perivascular spaces.
2. To recognize the broad spectrum of normal PVSs seen on 3 T MR scans.
3. To become familiar with pathologic processes that involve the PVSs.
4. To learn to avoid mistaking giant, "tumefactive" PVSs for more ominous diagnoses such as neoplasm.

A. The skull base

J.-W. Casselman; Bruges/BE

Evaluation of the skull base requires a thorough knowledge of the skull base anatomy; the anatomy of the foramina and fissures must especially be known. The bone anatomy is best evaluated using CT. The vessels and nerves passing through the foramina and fissures and the intracranial and extracranial soft tissue structures are however best seen on MR. One can only follow or predict tumor extension along nerves and vessels and through foramina and fissures if this anatomy is known.

Many lesions occur in the anterior, central and posterior skull base and today MR is the preferred technique not only to detect but also to characterise these lesions. However, MR is only superior when the right sequences and imaging planes are used. The use of CT is more and more restricted to evaluate the presence of calcifications and involvement of thin bony walls, foramina and fissures. Many lesions can be characterised by their specific signal intensity on different MR sequences (e.g. menigioma, chondrosarcoma etc.) and by their location (e.g. esthesioneuroblastoma, glomus jugulare etc.). Nevertheless some lesions can only be characterised after biopsy. The purpose of imaging in skull base tumors remains in the first place the evaluation of the exact tumor extent and this is again best achieved with MR. Involvement of bone and sinuses, tumor spread along neurovascular structures and extension in the extra- and intracranial soft tissue structures all have their influence on the staging and therapy choice. All these extensions and involvements are again best seen on MR.

Learning Objectives:

1. To become familiar with the MR and CT technique used to study the skull base.
2. To know the normal anatomy of the bone and soft tissue structures of the skull base.
3. To understand which lesions affect the anterior, central and posterolateral skull base.
4. To learn the which routes are followed when tumor extension occurs.
5. To be able to characterize some of the lesions which are affecting the skull base.

A-265

B. Pituitary lesions

J.-F. Bonneville, F. Cattin; Besançon/FR

MR is today the only method needed for the morphological investigation of endocrine-active pituitary adenomas. In acromegaly and Cushing's syndrome, therapy is directly affected by MR data.

We present the MR aspects of pituitary adenomas according to size, sex, age, endocrine activity, and a few particular conditions such as hemorrhagic pituitary adenomas, pituitary adenomas during pregnancy, cavernous sinus invasion and postsurgical aspects.

When an intrasellar mass extending out of the sella is detected, the goal of the MR examination is to precisely locate the origin of the tumor, its extension in relation to the various anatomical surrounding structures, its structure, and its enhancement in order to help in the differential diagnosis.

Demonstration of very small pituitary adenomas remain a challenge. When SE T1 and Turbo T2-weighted sequences are non diagnostic, enhanced imaging becomes mandatory and half-dose gadolinium injection, delayed sequence, dynamic imaging can be of some help.

Learning Objectives:

1. To familiarize with the different MR techniques useful in the study of pituitary tumors.
2. To choose the MR imaging protocols according to the clinical and biological data.
3. To recognize the usual and unusual presentations of pituitary adenomas.

A-266

C. Supra- and parasellar lesions

J. Ruscalleda; Barcelona/ES

The sellar and parasellar region is an anatomically complex area that represents a crucial crossroad of important adjacent structures, e.g. orbits, cavernous sinus and its contents, circle of Willis, hypothalamus through the pituitary stalk and dural reflections forming the diaphragma sellae and the walls of the cavernous sinuses.

Although the cavernous sinus represents the most relevant parasellar structure, from the practical and clinical point of view all the structures that surround the sella turcica can be included in the parasellar region.

CT and mainly MR are the imaging modalities to study and characterize the normal anatomy and the majority of processes presenting in this region.

We present a practical short review of the most relevant CT and MR imaging characteristics such as location, nature of contrast enhancement, presence of cystic components, together with clinical findings which permit differentiation of the most frequent and less common lesions found in the parasellar region.

Learning Objectives:

1. To review the complex anatomic relationships between structures in the sellar and parasellar regions.

Postgraduate Educational Programme

2. To understand the main patterns and radiological characterisation, mainly by MR, of the many lesions that alter the structure and function of sellar and parasellar anatomy.
3. To be familiar with the description of the MR features that permit differentiation among less common lesions.
4. To learn the different protocols in the approach parasellar pathology.

Multi-dimensional imaging for guiding therapy

Moderator:
C. Bartolozzi; Pisa/IT

A-267

Multi-dimensional imaging for guiding therapy (Introduction)

C. Bartolozzi; Pisa/IT

Interventional techniques are nowadays the therapy of choice in many clinical settings and are therefore progressively substituting conventional surgical interventions.

A prerequisite for this approach is the precise anatomical display of the lesion to treat as well as the surrounding anatomical structures. This can ideally be achieved by using multi-modality volume acquisitions and advanced processing techniques (3D, image fusion, virtual reality, etc.) which allow a paramount representation of the area of interest and help to correctly plan the procedure.

Another key issue is the possibility to have a real-time feedback on the progress of the on-going interventional procedure, thus optimising the efficacy of the treatment and at the same time reducing the risks for the patient. A high degree of interactivity is therefore mandatory in these applications.

Finally, the role of computer-assisted guidance in these procedures is clearly emerging and has the potential to lead to the introduction of automated systems (robots) for performing specific interventional tasks.

Learning Objectives:

1. To discuss the role of image processing and 3D imaging in planning therapy.
2. To review the available techniques for real-time monitoring of interventional procedures.
3. To highlight present capabilities and future development of image-guided therapy and robotic applications.

A-268

3D imaging in therapy planning

A. Laghi; Rome/IT

The acquisition of volumetric data sets and the parallel development of new rendering software (in particular perspective volume rendering) allows the generation of high quality 3D reconstructions making 3D imaging part of the routine diagnostic process.

3D imaging plays a very important role in therapy planning, assisting the decisional process in conventional surgery, laparoscopic surgery and within non-surgical, interventional therapies. For upper abdominal surgery and in particular within the liver, precise definition of vascular anatomy, both arterial and venous, is determinant. The identification of a vascular anomaly, correct in over 95% of the cases, may even alter or prevent a certain type of surgery. New high-resolution data sets from 16-slice or more multi-detector spiral CT equipments allow the identification of second-order intra-hepatic branches in over 85-90% of the cases. This evaluation is particularly important in living liver donors, where some intrahepatic vascular anomalies may prevent subjects from intervention.

3D imaging offers also a better evaluation of parenchymatous lesions, in particular those small and in a sub-capsular location, thanks to the use of planes different from the axial.

Organ and lesion volumetry are two other applications of 3D imaging. Today software for automatic liver segmentation as well as calculation of segmented liver volumes are available, helping clinicians in the decision-making process regarding hepatectomy or transplantation.

In conclusion, 3D imaging does not affect the diagnosis, but it makes the diagnosis easier and faster. It offers complementary information to a simple 2D data evaluation and it facilitates the communication between radiologists and clinicians.

Learning Objectives:

1. To understand basic principles of 3D post-processing techniques.

2. To comprehend the indications for the use of different 3D post-processing techniques.
3. To understand the role of 3D imaging in different surgical planning.

A-269

Real-time monitoring of interventional procedures

A.R. Gilliams; London/UK

Successful ablation requires complete coverage of the whole tumour in three dimensions and a 1 cm margin of normal appearing tissue which often contains microscopic tumour cells. Yet, none of the available ablation techniques produce predictable zones of ablation. Tissue-mediated perfusion and adjacent vessels impact on ablation size and shape. Therefore it is important to monitor the ablation. Ideally the interventional radiologist would be provided with co-registered 3D images of the tumour with the superimposed ablation zone so that an immediate assessment can be made. Of the available techniques, CT is useful in lung ablation. A penumbra of ground-glass shadowing that encapsulates the treated lesion usually indicates successful ablation. For liver and renal ablation there are several options although the most readily available, unenhanced US, is of limited value. Contrast enhanced US has proven efficacious in the assessment of hyper-vascular tumours but is less useful in hypovascular tumours. For metastases contrast enhanced CT or MR are a better option. Ablation is indicated by absent enhancement. Intra-procedural scans can provide immediate feedback. MR has the added attraction of providing temperature mapping either by looking at changes in T1 or shifts in proton resonance frequency. This has been useful in the breast and extremities but is less useful in liver ablation where subtraction imaging is hampered by respiratory movement and tissue deformation. A more recent development uses Gadolinium-filled thermosensitive liposomes which produce T1 shortening when a specific, pre-determined temperature threshold has been reached.

Learning Objectives:

1. To understand the different options for monitoring tumour ablation, the possibilities and the drawbacks.
2. To understand how to choose the optimal technique for a particular patient.
3. To understand the importance of feedback in ensuring complete ablation.

A-270

Image-guided therapy and robotic applications

E. Sorantin¹, J. Kettenbach², R. Bale³, G. Kronreif², G. Werkgartner¹, R. Beichel¹, A. Bornik¹, B. Reitinger¹, M. Sonka⁴; ¹Graz/AT, ²Vienna/AT, ³Innsbruck/AT, ⁴Iowa, IA/US

Present capabilities of imaging modalities produce volumes of data in the range of the human genome during a single investigation. This is especially true for Multislice Computed Tomography (MSCT) and Magnetic Resonance Imaging (MRI). Together with the luckily available and affordable computer power, the development and implementation of new and challenging applications in image-guided therapy are possible.

The term 'image-guided therapy' describes applications ranging from disease quantification (e.g. tumor volumes), image fusion (e.g. functional and morphologic data - PET/CT) to intraoperative navigation. The latter, refers to a setup, where the physician can monitor the progress of a procedure by using any imaging modality (e.g. ultrasound guided biopsy). Imaging data and reality can be fused by setting up an "Augmented Reality" system, where image based 3D virtual objects can be displayed together with "Reality" around the user in real-time. Such a setup is similar to navigation systems which help aircraft pilots land an airplane safely despite unrecognizable real-life conditions (e.g. due to fog). Integration of robotics offers the possibility to exploit their precision for certain tasks such as drilling screw holes in trauma surgery or taking biopsies.

Learning Objectives:

1. To present the basics and ingredients of real time navigation and tracking.
2. To give an introduction how to set up an "Augmented Reality System".
3. To demonstrate key applications and discuss their clinical impact.

Assessment of myocardial perfusion and viability

Moderator:

A. de Roos; Leiden/NL

A-271

Assessment of myocardial perfusion and viability (Introduction)

A. de Roos; Leiden/NL

In this session, the issue of assessing myocardial viability with the use of well-accepted technology, as well as with new imaging modalities like CT and MR imaging, will be discussed. Assessment of myocardial viability is a critical clinical question for patient management. Nuclear medicine imaging is traditionally the accepted and time-honored tool for viability assessment. The role of stress echocardiography, the upcoming role of CT and the somewhat more established role of MR imaging will be discussed from different perspectives. As part of these discussions the state-of-the-art of the various technologies will be discussed. Both the current technology as well as the established or potential role of these imaging techniques for viability imaging will be put in perspective.

Learning Objectives:

1. To understand the current technical approaches.
2. To learn the current clinical applications.
3. To learn current advantages and limitations.

A-272

Ultrasound and nuclear medicine

J.J. Bax¹, D. Poldermans²; ¹Leiden/NL, ²Rotterdam/NL

Background: Assessment of viability has become an important component of the diagnostic and prognostic work-up of patients with chronic ischemic left ventricular (LV) dysfunction. This is important for risk-benefit analysis, since not all patients improve in function after revascularization. In a recent analysis with 258 consecutive patients (LVEF 29±7%), improvement in LVEF after revascularization was observed in 39% of patients.

Procedure Details: Large experience has been obtained with nuclear imaging (PET and SPECT) and stress (mainly dobutamine) echocardiography. Based on the presence of viability, it is possible to predict improvement of regional and global LV function, heart failure symptoms and exercise capacity. In addition, viability assessment carries important prognostic information. In 18 direct comparisons (563 patients) between dobutamine stress echocardiography and nuclear imaging, the sensitivity of nuclear imaging was higher than that of stress echocardiography (90% vs 74%, P < 0.05), indicating that the nuclear imaging techniques are more sensitive in detecting viable tissue.

Conclusion: Both nuclear imaging techniques and dobutamine stress echocardiography are useful techniques for assessment of viability; nuclear techniques are more sensitive to detect viability.

Learning Objective:

To explain the basics and the relative merits of nuclear imaging and dobutamine stress echocardiography for the assessment of viability.

A-273

Role of multidetector CT

J. Barkhausen; Essen/DE

Recently ECG gated multidetector spiral CT (MDCT) has emerged as a new modality for cardiac imaging. The focus of MDCT has been primarily on applications for calcium scoring and CT angiography of the coronary arteries. However, MDCT can additionally be used to assess myocardial viability and myocardial perfusion.

In the first part of the lecture different scan protocols (single- and dual-phase approaches) will be introduced. Advantages and limitations including the necessity for iodinated contrast material and radiation exposure will be discussed. Thereafter, different myocardial enhancement patterns (early defects, residual defects and late enhancement) and the clinical meaning of these findings will be explained. However, only a limited number of studies have been published so far and therefore the assessment of myocardial perfusion and myocardial viability must still be considered a challenging and controversial field of cardiac CT. Future clinical applications might include the measurement of the infarct size in

patients with acute myocardial infarction and the assessment of the success of attempted reperfusion therapy after percutaneous coronary interventions.

Learning Objectives:

1. To learn about scan protocols for the assessment of myocardial viability and perfusion.
2. To understand different myocardial enhancement patterns.
3. To discuss potential clinical applications.

A-274

Role of MR imaging

H.J. Lamb; Leiden/NL

Chronically hypoperfused and severely dysynergic myocardium in patients with chronic coronary artery disease (CAD) can maintain viability through a mechanism known as 'hibernation'. Reversal of myocardial dysfunction in patients with CAD improves long-term survival. However, revascularization is associated with a risk for complications and mortality. Therefore, it is clinically important to identify *a priori* those patients who may benefit from a revascularization procedure. Cardiovascular magnetic resonance imaging (CMR) is a new and highly reproducible technique allowing functional imaging and MR perfusion imaging of the heart at rest and during cardiac stress. For evaluation of myocardial viability, various approaches using MR imaging have been described, including assessment of end-diastolic wall thickness, assessment of contractile reserve using low-dose dobutamine and assessment of scar tissue using contrast-enhanced imaging. Recently, research has focused predominantly on these last 2 approaches. However, from a pathophysiological point-of-view, these 2 approaches do not reflect the same. While low-dose dobutamine is used to demonstrate the presence of contractile reserve in dysfunctional myocardium (and thus identifies viable myocardium), contrast-enhanced imaging identifies scar tissue. The precise relation between these 2 techniques will be explained and demonstrated in patient cases. Furthermore, prediction of therapy effect based on CMR viability imaging will be discussed. In addition, technical aspects of CMR viability imaging will be discussed.

Learning Objectives:

1. To learn about basic concepts of CMR viability imaging.
2. To obtain basic knowledge of CMR techniques for viability imaging.
3. To be able to decide what type of CMR exam answers what type of clinical question.

A-275

A. Clinical issues and US

M.R. Rees; Bristol/UK

Acute or chronic pericarditis may result from infection, malignancy, connective tissue disorders, trauma, myocardial infarction, drug therapy or AIDS where the pericarditis may be due to a fungal infection, Kaposi's sarcoma or tuberculosis. Acute pericarditis may be a result of acute myocardial infarction (Dressler's syndrome) in 10-15% of cases and may also be a cause of acute cardiac rupture resulting in haemopericardium, both syndromes usually occur within 10 days of a MI. Acute pericarditis also occurs with trauma and post pericardiectomy syndrome. Acute pericarditis often causes chest pain which usually is aggravated by thoracic motion, cough and respiration and relieved by sitting up and moving forward. The most significant finding is a pericardial rub. Fluid around the heart may muffle heart sounds. There may be characteristic ST elevation on ECG. Acute and chronic pericardial disease may also present with atrial arrhythmias particularly malignant pericardial disease. The heart may be enlarged on chest X-ray. Acute pericarditis is best diagnosed by cardiac ultrasound, detecting fluid around the heart.

Chronic pericarditis may be haemorrhagic, fibrous, adhesive, metastatic, chylous or calcific, it may follow connective tissue disease, trauma, infection or drug therapy or malignancy. Chronic pericarditis may be followed by constriction which causes raised systemic and hepatic venous pressures with signs of peripheral and hepatic congestion. The typical signs of pericardial tamponade may also be

Postgraduate Educational Programme

detected with right atrial collapse and right ventricular diastolic collapse but pericardial thickening is not easily diagnosed by ultrasound. Doppler echocardiography may help distinguish constrictive pericarditis from restrictive cardiomyopathy.

Learning Objectives:

1. To discuss symptoms and clinical relevance.
2. To review radiological investigations and evidence base.
3. To review limitations and indications of ultrasound.

A-276

B. CT and MR imaging of the inflammatory diseases

M. Midiri, M. Galia, T. Bartolotta; *Palermo/IT*

Inflammatory diseases of the pericardium are common disorders which present with pericardial thickening, with or without constrictive pericarditis, determined by multiple causes, including infection (viral or tuberculous), idiopathic conditions, uremia, rheumatic heart disease, rheumatoid arthritis, sarcoidosis and mediastinal irradiation. They are safely managed with various primary and secondary-care settings, which need accurate diagnostic evaluation.

Computed tomography (CT) and magnetic resonance (MR) imaging may provide accurate delineation of the pericardial anatomy and can aid in the precise localization and characterization of various pericardial pathological changes.

Multidetector CT enables motion-free imaging of the pericardium as well as multiplanar reformation images, allowing the detection of pericardial calcification, often associated to constrictive pericarditis, and contrast-enhancement of the inflamed thickened pericardium. Disadvantages of CT include the use of intravenously administered contrast material, ionizing radiation exposure and its occasional difficulty in differentiating fluid from thickened pericardial tissue.

MR imaging is able to distinguish pericardial effusions by pericardial thickening with the use of T1-W, T2-W and gradient-recalled echo (GRE) cine sequences. It provides depiction of the pericardium without the use of either iodinated contrast material or ionizing radiation, allowing to recognize the high signal intensity of the inflamed thickened pericardium and its enhancement after administration of gadolinium-based contrast material.

Both imaging techniques provide a large field of view, allowing the examination of the entire chest and detection of eventually associated abnormalities in the mediastinum and lungs.

Potential applications and limits of CT and MR imaging involved in the study of inflammatory diseases of pericardium will be discussed.

Learning Objectives:

1. To review aetiological classification.
2. To review patho-physiology and clinical symptoms.
3. To discuss the diagnostic possibilities of CT and MR.

A-277

C. CT and MR imaging of the neoplastic diseases

J. Bremerich; *Basle/CH*

Introduction: Neoplastic disease of the pericardium can be classified as benign, primary malignant, metastases and tumorlike lesions. Among the benign lesions are pericardial cysts and lipoma. Primary pericardial malignancies such as mesothelioma, liposarcoma, fibrosarcoma, and teratoma are rare. Metastatic disease from melanoma or cancer from breast, lung, and colon are more frequently encountered.

Methods and Results: Echocardiography is first line modality for imaging pericardial masses. But it can not characterize effusions, is limited in loculated effusions, and is unreliable in definition of pericardial thickening. Moreover, acoustic windows are not optimal in many patients.

CT is an excellent tool for morphologic assessment of pericardial masses, particularly when calcifications are present. Normal myocardium is visible as a thin line between the epicardial and pericardial fat, masses are readily identified. However, differentiation of thickened pericardium from exudative pericardial effusion with high protein content can be difficult.

Magnetic Resonance provides information on structure and function of the heart and pericardium. Free choice of imaging plane and excellent soft tissue contrast allow accurate characterization of masses, adjacent structures and cardiac function. Pericardial cysts often contain transudative fluid with low protein content and thus appear dark on T1- and bright on T2-weighted images. Lipomas will have characteristic high signal intensity on T1-weighted images. Mesotheliomas and other malignant masses will typically enhance after contrast administration.

Conclusion: Echocardiography is the first line imaging modality for pericardial masses. CT provides excellent definition of morphology, particularly when calcifications are present. MR imaging allows both specific characterization of pericardial masses and cardiac function.

Learning Objectives:

1. To understand the pathological classification and incidence of (para)cardiac neoplasms.
2. To understand the indication for various imaging modalities.
3. To understand the major differences between CT and MR imaging findings and their clinical impact.

Multislice CT of the thorax

Moderator:

Y. Pallardó; *Alzira Valencia/ES*

A-278

A. Evidence-based optimisation of standard protocols

S.M. Ellis; *London/UK*

In radiology the optimisation of imaging using ionising radiation must always consider the reciprocal relationship between radiation dose to the patient and image quality. Multi-detector CT scanners are more dose efficient than their predecessors but, with the facility to reconstruct ever thinner contiguous slices, the temptation is to use that dose efficiency to improve image quality rather than lower the dose.

Standard multi-detector CT (MDCT) protocols are to some extent evidence based, in that they are derived from protocols that have become established in clinical use, and scanner-specific modifications are performed with reference to the preferences of authoritative radiologists in the field. Alterations to these standard protocols may have a significant impact on the patient outcome therefore any "optimisation" of protocols should be rigorous and evidence based; at present there is little published data on which to base optimisation of standard protocols, a situation that should improve as MDCT scanning becomes more widespread. MDCT, more than any previous CT technology, broadens the range of alterations that can be made to scanning parameters and therefore requires careful study into how this flexibility is best utilised. I aim to outline the range of optimising techniques available, comment on the existing literature and highlight some of the problems that may be encountered when trying to optimise protocols in an evidence based manner.

Learning Objectives:

1. To review the existing literature on evidenced based multislice CT protocols.
2. To consider the relevance of evidence based protocol optimisation to an MSCT design that differs to that on which the evidence is based.

A-279

B. Dose reduction in thoracic CT

D. Tack; *Baudour/BE*

The assertion that any radiation dose, no matter how small, can cause cancer is the basis for the linear no-threshold theory of radiation carcinogenesis. However, some health scientists consider the cancer risk from low-dose radiations as used in clinical practice for diagnostic procedures as being grossly exaggerated or even negligible. The European Commission has published precautionary measures in order to limit the radiation dose, in particular from CT, because the dose from a chest CT may be 100 times higher than that by a CXR. The influence of CT parameters (number of detector-rows, beam collimation, KVp, mAs, pitch, CT-Dlw), of patient parameters (height, weight, body mass index, age, gender, and underlying conditions) as well as of radiologist-dependant parameters on the effective dose are presented. Radiation dose levels from typical standard CT protocols with single and multislice technique are compared to those of a CXR. Low-dose HRCT and multislice CT protocols enable reduction of the radiation per examination by a factor of 10 as compared to standard acquisitions, mainly by decreasing the mAs or by increasing the pitch. Potential benefit in dose reduction by the use of low KVp is presented. Newly developed automatic dose reduction systems are promising because they adapt the tube conditions to the patient's geometry. Distinction has to be made between the radiation dose delivered to one single individual and the collective radiation dose because the effect of diagnostic strategies on the individual and the collective doses may be opposite.

Learning Objectives:

1. To discuss the risk of induction of cancer through radiation exposure at chest CT.

Postgraduate Educational Programme

2. To understand how CT and biometric parameters influence the effective radiation dose.
3. To learn methods to decrease radiation exposure at chest CT by varying examination parameters maintaining diagnostic image quality.

A-280

C. The application of post-processing

J. Rémy, M. Rémy-Jardin; Lille/FR

Image processing in thoracic disorders includes multiple operations aimed at improving the diagnostic capabilities of a CT examination. Isotropic imaging, short acquisition times and data explosion have triggered the development of post-processing. One can classify postprocessing contributions into morphologic and functional approaches. Whatever the disease, a morphologic reformatting approach can be used for: a) Selective visualization of bronchial and vascular lumina and walls along their main axis with their surrounding structures. b) Virtual angiography and bronchoscopy. c) Angiographic and bronchographic renderings before interventional procedures. d) Morphological evaluation of the heart. e) Quantification and follow-up of pulmonary nodules. The functional approach using postprocessing deals with: a) Perfusion and ventilatory imaging. b) Analysis of the right ventricle. c) Evaluation of the thoracic outlet. As opposed to the aorta or peripheral arterial occlusive disease, whose evaluation can be exclusively based on angiographic renderings, investigation of a pulmonary or systemic vascular disease implies a simultaneous examination of vascular and bronchopulmonary structures which are supplied by or which have generated the abnormal circulation.

Learning Objectives:

1. To review the usual techniques of post-processing in diseases of the chest.
2. To learn their main applications in routine clinical practice: Pulmonary embolism, preoperative management of bronchial carcinoma, hemoptysis and vascular anomalies of the lung.
3. To emphasize their growing indications in the technological context of multi-slice thoracic imaging.

Diffusion and perfusion MR imaging of the brain

Moderator:

M.M. Thurnher; Vienna/AT

A-281

A. Imaging technique and protocols, post-processing

L. Østergaard; Århus/DK

Perfusion and Diffusion weighted MR imaging are becoming important tools in the diagnosis of neurological disease. In order to insure images of maximum quality of the derived parametric maps (Cerebral Blood Flow -CBF, Cerebral Blood Volume - CBV, Mean Transit Time - MTT, Apparent Diffusion Coefficient - ADC) a number of precautions must taken in the acquisition and post processing of the images. These involve tracer injection speed, saline flush volume, image acquisition rate and choice of EPI sequence in relation to the pathology. Also, the information inferred from post-processed images must be related closely to the inherent methodological problems of perfusion MR imaging (delay, dispersion).

This talk will supply a framework for acquiring and analysing perfusion data and briefly discuss issues of importance in analysis of diffusion MR imaging, especially in the context of acute stroke.

Learning Objectives:

1. To understand the problems and merits of the most common imaging techniques in perfusion imaging.
2. To discuss necessary features for imaging protocols.
3. To understand the basics of perfusion postprocessing and its limitations.
4. To discuss various pitfalls that may lead to false interpretation of perfusion weighted images.

A-282

B. Clinical applications of diffusion and perfusion MR of the brain

P. Reimer, S. Arnold, Z. Puskas; Karlsruhe/DE

Over the past 10 years, considerable experience has been accrued using both diffusion and perfusion MR imaging by means of contrast agents to measure

cerebral hemodynamics and other cerebral diseases. Diffusion and perfusion MR imaging can be performed on nearly all up-to-date clinical scanners. Imaging technology is at a stage where, in addition to morphological information, the concomitant acquisition of functional and physiological information is possible. The previous speaker will explain the techniques in detail.

The most common clinical application of both techniques is within the field of stroke imaging where diffusion MR imaging can be considered a "must do it" and perfusion MR imaging is added to solve further questions. However, imaging of neoplasm, inflammation, or infection has gained considerable interest as well. Patients presenting with possible brain ischemia are routinely imaged with diffusion MR imaging and "lesions" are also further differentiated by means of ADC maps. The combination of diffusion and perfusion MR imaging is applied when tissue at risk needs to be detected. Unfortunately, mean-transit-time and other timing maps do not appear to do an adequate task of distinguishing between levels of hemodynamic compromise. That is, the feature that makes them easy to interpret - being normal or abnormal - does not allow for the gradation of abnormalities, the difference between blood flow decreases that are mild to moderate versus moderate to severe. Perfusion techniques appear not to be able to distinguish between acute hemodynamic compromise and chronic hemodynamic compromise. Fortunately, DWI can easily make this distinction.

Learning Objectives:

1. To learn about the most common clinical applications of diffusion imaging and perfusion imaging in neuro MR imaging.
2. To understand the rationale of adding diffusion imaging and perfusion imaging to morphological MR imaging.
3. To value diffusion imaging and perfusion imaging in the scenario of a comprehensive neuro MR imaging examination.

A-283

C. Diffusion tensor imaging and fibre tracking

C. Oppenheim, J.-F. Meder, D. Fredy; Paris/FR

Diffusion tensor imaging (DTI) is generating high expectations in the study of the central nervous system (CNS) because it is currently the only way to non invasively study the 3D architecture of white matter tracts. Using DTI, diffusion anisotropy effects can be extracted and used to characterize tissue microstructure. Several scalar parameters, such as mean diffusivity and anisotropic indices, can be obtained with DTI. Their potential over routine DWI for demonstrating subtle abnormalities and improving our knowledge of brain pathophysiology will be illustrated by means of clinical applications: stroke, multiple sclerosis, tumours, dementia, epilepsy, The methods for reconstructing axonal tracts using DTI will be presented. Clinical applications, validation issues and potential future improvements will also be discussed.

Learning Objectives:

1. To understand the concept behind DTI and fiber tracking.
2. To discuss the quantitative parameters derived from DTI.
3. To identify their potential uses in clinical studies.

16:00 - 17:30

Safety considerations in MR

Moderator:

T.G. Maris; Iraklion/GR

A-284

A. MR safety, biophysical effects and the European legislation

J.M.L. Engels; Best/NL

Modern MR scanners approach the safety limits for patients for almost all relevant physical parameters for the MR scanner. More recently also legislation is accepted for the safety of MR workers (at the MR manufacturer and in the hospital). The applied dynamic gradient fields (which may create peripheral nerve stimulation), but also the acoustic noise produced by the gradients (which makes the use of ear protection essential) and the RF fields transmitted by the RF coils (which may heat up the human body), make it essential to implement safety measures on the MR scanner. Also the static magnetic field (known to create instantaneous effects such as nausea or dizziness or metal taste) may become a limiting factor for future scanners. The MR specific limits for these parameters for patients are described in the IEC 60601-2-33 international standard for safety of

Postgraduate Educational Programme

MR equipment. Recently, new European legislation is accepted which also limits these parameters for MR workers and thus has direct implications for the use of MR. Especially, high field systems and interventional MR are hindered by this new legislation and urgently call for more research, to determine the safety levels. In spite of all these potential dangerous situations MR scanners are still considered to be a most safe and patient friendly modality.

Learning Objectives:

1. To discuss the biophysical effects of static and dynamic magnetic fields.
2. To discuss the biophysical effects of RF power and related SAR.
3. To present the status of current international MR safety standards and legislation.

A-285

B. Clinical safety practice

J. de Wilde; London/UK

In MR imaging safety issues affect everyday clinical practice. Every patient and visitor to the MR suite has to be screened for implants, tattoos, eyeliner and clothing, i.e. anything which may move in the magnetic field or may heat up due to the radiofrequency field and cause injury. It is important to note that MR imaging burns are the most frequently reported incident within the UK. Patient set up within the bore of the magnet is an important safety issue, especially if there are monitoring devices involved. These issues will be reviewed in the talk. Another major cause of injury in MR is projectile hazards; ways in which to minimize the risk of this will be discussed in term of good practice within the MR suite. Currently there is a trend towards higher field strengths MR systems which means that patients and staff are likely to be exposed to higher noise levels. This talk will examine noise protection issues. Another important concern is that of pregnancy and MR imaging. The current state of play regarding imaging of pregnant patients and pregnant staff working in MR imaging will be addressed.

Learning Objectives:

1. To understand patient screening issues including implants in MR imaging.
2. To review patient monitoring issues in MR environment.
3. To understand how to minimize the projectile risk.
4. To review of acoustic noise issues.
5. To overview of MR imaging in pregnancy.

A-286

C. Interventional MR imaging: Safety considerations for patients and personnel

A. Bücker; Aachen/DE

Fast imaging sequence are a prerequisite for MR-guided interventions to speed up the procedure and allow even real-time imaging for guidance of vascular interventions. The main obstacle so far is not imaging speed but the development of interventional devices, which are MR-safe as well as MR-compatible. Using passive methods for device visualization one has to be aware of the artifact behaviour of interventional instruments in order to correctly localize the instrument tip. The artifact behaviour depends on the used imaging sequence (gradient versus spin echo) and sequence parameters like echo time and phase encoding direction. Active methods can overcome these potential problems and allow not only for device visualization but also for slice tracking. Drawbacks of active methods are more sophisticated hardware and software requirements. Furthermore safety issues concerning heating of long conductive wires have to be taken into account in order not to jeopardize the patient or interventionalist. First approaches are using fiberoptic means to achieve MR-safe active instrument visualization. While passive device visualization is sufficient for interventions like biopsies, vascular interventions will greatly profit from the possibility of slice and tip tracking of active means especially in the region of small and tortuous vessels. Performing interventions in the MR environment requires special awareness of all personnel involved in the procedure including anesthesiology. Consequently, a dedicated team should be set up in order to avoid accidents due to inexperienced handling of metallic patient support devices.

Learning Objectives:

1. To learn about imaging characteristics of interventional instruments.
2. To learn safety considerations for organizing an interventional MR suite and how to safely perform interventions.
3. To learn about safety problems of interventional instruments.

16:00 - 17:30

Aortic stent grafts

Moderator:

C. Düber; Mannheim/DE

A-287

A. Thoracic

K. Ivancev; Malmö/SE

Stent-graft (SG) treatment of conditions in the descending thoracic aorta has its own merits and limitations depending on the indications for treatment.

Material and Methods: Complicated Type B dissections were treated in 33 patients, 23 of which on emergency basis. Median imaging FU was 12 months (1-61). Traumatic transections and pseudoaneurysms were treated in 4 patients. Fusiform atherosclerotic aneurysms were treated in 34 patients at high operative risk, 8 of which on emergency basis. Median imaging FU was 22 months (3-85).

Results: In the Type B dissection group 30-day mortality was 21% in the emergency subgroup, 0% in the elective subgroup. One patient developed paraplegia. Two patients died of erosion caused by the SG during follow-up. In the group with traumatic transections and pseudoaneurysms there were no complications. In the fusiform atherosclerotic aneurysm group 30-day mortality was 26% and paraplegia 6%. Eight patients succumbed to SG-related complications during FU: Migration 2 pts, SG separation 2 pts, aortic wall erosion by the SG 4 pts.

Conclusions: SG treatment is a truly valuable alternative to open surgery in patients with traumatic transections and pseudoaneurysms and in patients with complicated Type B dissections. Extensive fusiform atherosclerotic aneurysms continue to present a challenge for SG treatment.

Learning Objectives:

1. To briefly review the literature and present the results with stent-graft treatment in the descending thoracic aorta.
2. To highlight the advantages of stent-graft treatment over open repair in complicated type B dissections.
3. To stimulate radiologists to use their imaging skills in correctly planning for stent-graft placement in the descending thoracic aorta.
4. To emphasize the limitations of current stent-graft treatment in atherosclerotic descending thoracic aortic aneurysms.

A-288

B. Abdominal

J. Lammer; Vienna/AT

Purpose: Abdominal aortic aneurysms (AAA) with a diameter of more than 6 cm have a rupture risk of 25% per year. The purpose of stentgrafts is to prevent rupture.

Materials and Methods: The indications for treatment are:

- diameter of AAA > 5 cm
- growth > 0.5 mm/year
- symptomatic aneurysm
- rupture

Specific indications for endovascular treatment are:

- patient > 75 years
- ASA 3 and 4
- > surgical risk.

Stentgrafts can be placed under epidural and local anesthesia. Arteriotomy is required because delivery systems have a diameter of 12-22 F. The stentgraft is placed below the renal arteries under fluoroscopy. Suprarenal fixation usually does not cause renal artery thrombosis or embolization.

Stentgrafts have a self expandable stent structure covered by an ultrathin polyester or ePTFE fabric. Currently only bifurcated stentgrafts are used for treatment of AAA.

Results: According to the Eurostar registry (> 4,700 patients) technical successful stentgraft placement was achieved in > 99%. Conversion to open surgery was required in 0.7%. The in-hospital mortality rate was 2.2%. At completion angiography endoleaks were demonstrated in 15.7% (type 1-4.3%, type 2 -9.0%, type 3-2.4%). Life-table analysis revealed at 1 and 5 years a survival rate of 92.3%, and 78.8%, freedom from persistent endoleaks 93% and 91%, freedom from rupture 99.8% and 98.6%, respectively.

Conclusion: AAA's can be excluded by stentgrafts with a high technical success rate of 99%. Conversion to open surgery is rarely required. Freedom from rupture is 98% at 5 years.

Postgraduate Educational Programme

Learning Objectives:

1. To understand the indications of endovascular repair of AAA.
2. To learn the technique of stentgraft implantation.
3. To get the most recent results of longterm outcome after stentgraft treatment of AAA.
4. To learn the preliminary results of endovascular treatment of ruptured AAA.

A-289

C. Bifurcated grafts

M. Maynar; Santa Cruz de Tenerife/ES

Endovascular bifurcated grafts can offer an alternative treatment for patients with symptomatic non-aneurysmal aortoiliac lesions. Indications for treatment are aortoiliac occlusion, complex aortoiliac stenotic lesions and ulcerated plaques causing blue toe syndrome. To prevent adverse hemodynamic and pathologic changes, we opted to use the Excluder® prosthesis to rebuild the aortoiliac region as it offers features like high conformability due to the flexible endoprosthesis body, a low-profile delivery system and a smooth lumen surface without metal struts or sutures. In aortas with a small distal diameter that prevent expansion of the contralateral short leg, we used a combined femoral/brachial access as the guide wire can be advanced more easily through the non-expanded contralateral leg than from a contralateral femoral access. After a through and through wire has been established, the contralateral leg can then be deployed. An angioplasty with the kissing technique is subsequently performed to ensure total expansion of the graft at the level of the bifurcation up to the maximum aortic diameter. The aortobifemoral bypass graft remains the procedure of choice for the treatment of diffuse aortoiliac disease but it is associated with a relatively high morbidity and operative mortality. Aortic uni-iliac graft combined with a femoro-femoral bypass is only considered in case of failure of the endovascular treatment, as both surgical techniques offer suboptimal clinical results. The placement of bifurcated endoprostheses is technically feasible, effective, and safe in the management of aortoiliac lesions and offers an alternative to the conventional surgical techniques.

Learning Objectives:

1. To discuss indications and patient selection.
2. To discuss graft selection.
3. To know how to work in small abdominal aortic lumen.
4. To discuss bifurcated graft vs aortic uni-iliac graft and femoro femoral bypass.
5. To know tips and tricks.

A. MRA: Basic principles and clinical applications

G.M. Bongartz; Basle/CH

MR-angiography (MRA) has evolved from cross-sectional imaging by converting artefactual flow signals into diagnostic information. So-called native techniques comprise Time-of-Flight and Phase-Contrast MRA. Today, most native MRA techniques are replaced by contrast-media enhanced MRA (CE-MRA) that combines fast imaging with high vascular contrast and easy post-processing.

CE-MRA depends on ultrafast techniques to "freeze" the arterial bolus following venous injection. The most challenging task is the timely exact coordination of the bolus and the signal collection. MR shows dedicated features during signal reading represented by the k-space. All alterations in k-space directly affect the MRA signal. Basic knowledge of k-space is therefore mandatory to achieve good results and to understand artefacts.

Bolus geometry directly affects MRA results. Especially in multi-volume imaging, the arterial bolus must remain on constant high level. The problem of conflicting venous signal is important for MRA of the lower extremities, requiring technical adaptation.

Hybrid techniques are helpful in several indications although they may suffer from decreased resolution. Recently, high speed acquisition while maintaining high contrast and high spatial resolution have been developed by using parallel imaging or ultra-high field strength and increased gradient's performance.

Learning Objectives:

1. To understand the underlying principles of the various forms of MR-angiography.
2. To learn about the physics and techniques for contrast-enhanced 3D MR-angiography.
3. To recognize and avoid common pitfalls in MR-angiography.
4. To recognize emerging applications of MR-angiography.

A-291

B. CTA: Basic principles and clinical applications

M. Prokop; Utrecht/NL

CT angiography (CTA) has been revolutionized with the advent of multislice scanning. While single slice CTA was mainly focusing on the aorta and pulmonary arteries, multislice CTA can now cover any vascular territory in the body because of a substantially increased scan coverage as well as spatial resolution. Spatial resolution is now good enough to see very small vessels like the central bronchial arteries or the arteries of the hand. This course will discuss how scanning parameters and contrast administration have to be adapted to multislice scanning. New challenges include the increased noise with thin-section imaging, the individual adaptation of radiation dose and contrast material depending on patient parameters, and the optimum timing of the scan. The course will discuss how to avoid new pitfalls introduced by the newest generation of 32 to 64 slice scanners. Postprocessing techniques will be reviewed, with a special focus on simple techniques that allow for quick and problem-oriented solutions for image display and evaluation. CTA can be used for stroke imaging, pulmonary embolism, aortic diseases, renal artery stenosis and mesenteric artery abnormalities. The latter can be examined as part of a standard arterial phase scan of the abdomen. Portal phase images allow for evaluation of portal hypertension, vascular occlusion or tumor involvement. Newer developments include CTA of the peripheral arteries of the lower and upper extremities as well as full body CTA. Compared to MRA, CTA has regained lost territory with the introduction of multislice scanning, but CTA should be used with care in young individuals and patients with impaired renal function.

Learning Objectives:

1. To learn how to adapt acquisition parameters for CTA to a specific clinical question.
2. To understand how contrast administration protocols have to be modified for multislice scanning.
3. To become familiar with the advantages and disadvantages of CTA for various clinical indications.
4. To comprehend the role of CTA relative to the other modalities.

A-292

C. Sonography: New directions

P. Landwehr; Hannover/DE

Sonography is the first procedure in the work-up of vascular disease in the majority of cases. Vascular ultrasound serves as a decision-maker in peripheral, carotid and renal arterial disease, in detection and follow-up of arterial aneurysms and in demonstration of venous thrombosis. Follow-up after therapy is mainly accomplished by ultrasound, too. CE-MRA and CTA compete with vascular ultrasound, and the results of this competition will influence clinical decision pathways under the scope of new reimbursement strategies.

This review focuses on the potential impact of new ultrasound techniques and deals with the role of signal enhancers. Transducer improvement, digital beam forming and signal processing, extended field and 3D/4D techniques, imaging modes like tissue harmonic imaging and excitation techniques (e.g., B-flow) improve resolution, spatial understanding and demonstrability. Contrast agents based on different microbubble designs are available for enhancing signals in greyscale as well as in Doppler studies. Contrast enhancers can be combined with bubble-specific modes for semi-selective demonstration of bubble location (e.g., contrast harmonic imaging).

Above all, the general technical improvements of US technology helped to improve US capabilities in vascular imaging. Many new techniques as well as contrast agents are supplementary tools (sometimes toys...) in weak signal situations like in renal arteries, tight carotid stenoses and transcranial Doppler. But: All new tools do not reduce the main challenges in vascular ultrasound: Training, standardization and establishment of cost-effective pathways for work-up of vascular disease. To underline this statement, clinical examples for the role of US in the decision-making process are demonstrated.

Learning Objectives:

1. To be familiar with all established and new techniques of vascular ultrasound.

Postgraduate Educational Programme

2. To get an overview on ultrasound signal enhancers and their limited role in vascular disease.
3. To include ultrasound in rational strategies for the diagnosis of vascular disease.

A. Multidetector CT of the chest: Guidelines and specificities in children

H. Ducou le Pointe, M. Lenoir, S. Ariche-Maman, J.-P. Montagne; Paris/FR

By combining both helical volumetric acquisition and thin slice thickness, Multidetector CT (MDCT) offers new applications in pediatric chest imaging. Concerning management of the exam, MDCT allows to reduction in numbers sedated, especially in patients older than 3. With MDCT faster coverage leads to reduction in the amount of IV contrast material. The injected quantity of contrast material is now 1 ml per kilogram of body weight. Concerning CT acquisition parameters: acquisitions are performed with 0.75 or 1.5 mm slice thickness. Isotropic viewing allows very good multiplanar reconstructions. Multiplanar reconstruction is used for all exams even in the axial plane: images are viewed with a thickness of 3 to 5 mm. Better signal to noise ratio allows lower scanning parameters to be chosen. For children under 10, lung parenchyma and airway CTs are performed with 90 kV and a tube current less than 90 mA. New applications are thoracic angiography and virtual bronchoscopy. Virtual bronchoscopy seems to produce images that correlate well with bronchoscopy.

Learning Objectives:

1. To conduct a multidetector CT exam of the chest.
2. To choose CT parameters acquisition.
3. To discuss the new applications (virtual endoscopy, angiography).

A-294

B. MR imaging of the lung

W. Hirsch; Leipzig/DE

MR imaging is not yet able to show the same precise pictures of the lung parenchyma as CT. First the principle problems that occur with imaging of the lung parenchyma in MR imaging are discussed.

Central bronchus lesions are detectable in MR imaging with the same reliability as in computer tomography. The visibility of intrapulmonary metastases depends on the size of the lesion. Peripheral metastases can be recognised from a size of 4 mm by using optimal investigation strategies. Interstitial processes show discrete findings: Fibrosis is better demonstrated on MR imaging since it shows a higher signal due to its cellular component in T2 and even in T1. Alveolar processes are very well imaged in proton MR imaging due to the high liquid content, even in small findings.

The possibilities of functional imaging by using proton MR imaging are demonstrated. Perfusion measures are the most common functional assessment in clinical use. With colour coded perfusion maps, perfusion defects are often very clear. Even the spatial resolution is much higher than in conventional perfusion scintigraphy. Imaging of the ventilation is still work in progress. Methods we used are oxygen enhanced imaging of the air space, volume estimation of the lung and imaging of trapped air by using expiration technique. A new possibility seems to be the estimation of the lung function diffusion by means of nebulized Gadobutrol. Between morphological and functional imaging MR imaging of the lung will find its place in Paediatric Radiology.

Learning Objectives:

1. To point out the principle problems that will occur when you image the lung in MR imaging.
2. To discuss what kind of morphologically lung lesions are visible reliable in MR imaging.
3. To show the present and future possibilities of functional lung imaging.

A-295

C. Cardiac MR imaging in children

A.M. Taylor; London/UK

Introduction: Cardiovascular magnetic resonance (MR) imaging is becoming commonplace in the assessment of grown-up congenital heart disease and more recently in neonates, infants and children. Not only can an accurate description of cardiac and vascular anatomy in relation to the other structures be performed, but MR can also provide accurate quantification of cardiac function and vascular flow.

Indications: In young children, cardiovascular MR is used as a second line investigation, when echocardiography cannot provide all the necessary information, and cardiac catheterisation can be avoided.

The indications for cardiovascular MR include assessment of:

- Right ventricular conduits, providing information about conduit function (stenosis and regurgitation), and the underlying RV function,
- Aortic pathology (coarctation and Marfan syndrome),
- Anomalous coronary arteries, and
- Complex congenital heart disease, where understanding the three-dimensional structure is paramount, and can be difficult with other imaging methods.

Imaging sequences: Imaging sequences can be broadly be divided into:

- 'Black-blood' spin-echo imaging - for accurate anatomical assessment,
- 'White-blood' gradient echo or SSFP imaging - for accurate anatomical and functional cine imaging (quantification of ventricular function),
- Phase contrast velocity mapping - for quantification of vascular flow, and
- Gadolinium contrast-enhanced MR angiography - for accurate assessment of thoracic vasculature.

All these sequences can be acquired in a single breath-hold, and importantly, contiguous isotropic volume datasets can be acquired enabling 3D volume rendering. Overall, cardiovascular MR can provide an accurate anatomical and functional assessment of the heart and great vessels in the majority of children with congenital and acquired heart disease.

Learning Objectives:

1. To discuss indications for cardiac MR in children.
2. To describe a MR protocol for imaging the heart in children.
3. To describe the diagnosis of congenital heart disease diagnosis using a sequential segmental analysis.

V. Donoghue; Dublin/IE

K. Eklund; Lund/SE

A-296

A. Radiographer's role in optimisation of child's radiation doses

A. Kettunen; Oulu/FI

The latest studies indicate that there may be some effects on the lower levels of radiation doses. Children are more sensitive than adults. Radiosensitive cell-forming bone marrow is present in most bones at birth. The developing breast, thyroid and gonads are sensitive to radiation detriment. The radiation doses to children must be at a minimum while the quality of the radiographic image is optimised. Wide variations have been found in techniques, equipment and radiation doses. Substantial dose reductions could be achieved without loss of image quality. Beam energy, filtration, collimation, use of grid, the anode heel-effect, low attenuation materials (carbon) in table tops, patient size, the screen-film combination and film processing conditions affect the patient dose in conventional and mostly in computed radiography. It seems that FPD gives a good resolution and no significant difference in diagnostic quality even with 50%-70% decrease in radiation dose. Lead-rubber shielding of the parts of the body next to the primary beam should always be used. A training programme, regular provision of dose information and collaboration between physicist, radiographers and radiologists can significantly reduce the doses received by children. Educated and trained staff should take X-ray examinations of children. It is important to assess image quality in relation to patient dose. The criteria for good radiographic technique must be also met. Because the weight of newborns varies widely (about 0.4 kg-6 kg), several reference levels should be set to X-ray examinations of newborns. The radiographer is in key position in dose optimisation of children.

Postgraduate Educational Programme

Learning Objectives:

1. To understand the factors effecting to the radiation risk and radiation dose of children in X-ray examinations.
2. To understand the role of the radiographer in the radiation dose optimization of children by patient care and imaging technique.

A-297

B. Radiographer reporting

D. Keane; *South Tyneside/UK*

Background: Accident and Emergency medicine brings together a complex patient group presenting with a wide diversity of pathology. The inexperience of junior doctors and emergency nurse practitioners in image interpretation can lead to inappropriate management and time delays. The introduction of a Consultant Radiographer who has undergone post graduate training in image interpretation has significantly improved the service to A&E patients and support given to A&E staff.

Procedure Details: Trauma images are 'hot reported' by the Consultant Radiographer during the normal working day. All radiographers have been given training and support in offering written opinions on trauma images out of hours, creating a 24 hour service to patients and A&E staff. All written opinions are checked and confirmed by the Consultant Radiographer during the next working day. Robust protocols, training, review and monthly audit enable the clinical governance of the process.

Conclusions: Audit results have demonstrated significant reduction in the incidence of missed fractures over the two years since the system was introduced. Other benefits include better working relationships between Radiology and A&E, improved job satisfaction and joint training initiatives to further develop practice.

Learning Objectives:

1. To identify the role of the reporting radiographer in developing A&E services.
2. To learn about new developments in the UK.
3. To identify the implications of the UK experience.
4. To identify the benefits to doctors, radiographers and patients.
5. To learn about the rationale for role development.

A-298

C. Pros and cons of radiographer reporting: A radiologist's viewpoint

P.A. Dubbins; *Plymouth/UK*

- Radiographer reporting is not a new issue - red dot reporting for A&E films in 1985, sonographers reporting ultrasound since the early 80's

- Why should radiographers report?
 - + Too few radiologists?
 - + Cheaper labour?
- Why should radiographers report?
 - + Because the service is enhanced
 - + Because the service is more timely
 - + Because they are the right individual to report the particular image
 - + Because they have the right skills for image reporting in the particular clinical environment (A&E for example)
 - + Because they understand the imaging modality and are aware of artefacts
- When should radiographers report?
 - + When they are part of a clinical team
 - + When they have clinical support from experienced radiologists
 - + When their work is carefully defined and is within defined protocols jointly developed
 - + When medical knowledge is not critical for the correct interpretation of an examination
 - + Or where this can be provided through the team
 - + Where medical support is not required for the performance of a procedure
 - + When it is cost effective, cost efficient and maintains or improves patient care within an environment that provides audit, feedback and quality improvement

Learning Objectives:

1. To learn about the nature of a clinical report and the modifications required dependant on the intended recipient.
2. To understand the responsibility of the reporter for quality and promptness.
3. To learn about the training issues affecting the nature of the report.
4. To identify the contribution of the team to quality of service and support of the individual.
5. To recognise your own limitations.

Primer: Molecular Imaging

PR 1219

Imaging of gene expression: Optical and nuclear techniques

Moderator:

R. Passariello; *Rome/IT*

A-299

A. Optical contrast agents for imaging genes and proteins

C. Bremer; *Münster/DE*

Optical imaging has emerged as a new imaging modality offering high sensitivity for detecting molecular structures *in vivo*. In the near infrared range sufficient tissue penetration is achieved for imaging small animal models as well as considerable volumes in human applications. Different absorbers such as hemoglobin, fat and water can be used to interrogate tissue characteristics (e.g. perfusion) non-invasively. Moreover, a variety of optical contrast agents are currently explored for non invasive detection of protein expression patterns *in vivo*. Fluorochromes can be linked to specific ligands (antibodies, antibody fragments or peptides) imparting probe selectivity for various targets of interest allowing e.g. the imaging of apoptosis or cancer related proteins (e.g. EGF receptor). Moreover, enzyme-sensing optical probes have been applied for the detection of protease expression *in vivo*. In these "smart" probes signal amplification is achieved by an enzyme-mediated dequenching mechanism.

For "upstream" imaging of gene (as opposed to protein) expression various fluorescent proteins (e.g. GFP, dsRed) are currently explored. Moreover, bioluminescence imaging exploiting luciferase genes can be used to sensitively detect transgene expression *in vivo*. Combined with novel 3-dimensional imaging techniques such as fluorescence mediated tomography (FMT) or surface weighted imaging tools such as fluorescence reflectance imaging these novel contrast agents will help to interrogate molecular structures *in vivo*.

Learning Objectives:

1. To elucidate the strength of optical imaging for molecular *in-vivo* diagnostics.
2. To explain different optical contrasting strategies including "intrinsic", "targeted" and "smart contrast agents".
3. To emphasize the clinical potential of this method.

A-300

B. Gene expression imaging using bioluminescence

C.W.G.M. Löwik; *Leiden/NL*

Now that the human genome project has come to completion most genes have been identified. However, the big challenge for the future is to try to discover where the genes are expressed, how they are regulated, and what their exact function is in the homeostasis of specific cell types or tissues. This will lead to a better understanding of the molecular, cellular, and biological processes involved in normal physiology and pathology in a variety of diseases. It will also allow us to find new drug targets and, consequently, better management of diseases.

In order to study the location and regulation of gene expression *in vitro* as well as *in vivo*, reporter genes (e.g. β -galactosidase, GFP, luciferase) have been widely used. They are also used for tracking the fate of cells injected systemically in small experimental animals. Until recently, the proteins translated from the reporter gene-constructs were either visualized in histological tissue sections or detected biochemically in tissue extracts after sacrifice of the animal. However, development of highly sensitive CCD camera's and bioluminescent imaging (BLI), in which luciferase is used as a reporter gene, currently allows very sensitive image recording of the topographical expression of this enzyme non-invasively and repetitively in the living animal.

In this presentation the following points will be discussed:

1. The basic principles and advantages of bioluminescent imaging.
2. How BLI can be used to image gene expression *in vivo*.
3. The broad application of the technology for other applications.

Learning Objectives:

1. To understand the basic principles and advantages of bioluminescent imaging.
2. To understand how it can be used to image gene expression *in vivo*.
3. To learn about other applications.

Postgraduate Educational Programme

C. Gene expression imaging: From bench to bedside

A.H. Jacobs, A. Winkeler, H. Li, A. Rüger, M. Klein, S. Vollmar, R. Graf, K. Wienhard, W.D. Heiss; Cologne/DE

Positron emission tomography (PET) allows a non-invasive assessment of physiological, metabolic and molecular processes in humans and animals *in vivo* (molecular imaging). With the developments in tracer technology a variety of endogenously expressed and exogenously introduced genes coding for membrane receptors and transporters or cellular enzymes can be analyzed by PET. The main and most intriguing advantage of molecular imaging is the *kinetic* analysis of a given molecular event in the same experimental subject over time. This allows a non-invasive characterization and "phenotyping" of animal models of human disease at various disease stages, under certain pathophysiological stimuli and after therapeutic intervention. Apart from *direct* detection and imaging of a certain gene product, *indirect* imaging technology is based on proportional coexpression of a PET marker gene (e.g. HSV-1-tk) with any gene of interest where specific probes are not available, yet. Moreover, certain genes can be used as *surrogate* markers, e.g. hexokinase gene expression as direct marker for glucose metabolism and as surrogate marker for cell density of a glioma or as surrogate marker for disease severity in Alzheimer's disease. The overall attractive goal of molecular imaging technology is the direct translation from *in vivo* animal data into clinical application (translations research) especially in the development of novel therapeutics.

Learning Objectives:

1. Imaging endogenous and exogenous gene expression by PET.
2. Principle of imaging-guided gene therapy of gliomas.
3. Introduction into universal HSV-1 vectors for imaging and gene therapy.

Computer Applications

RC 1205

Building an electronic patient record system

Moderator:

D. Caramella; Pisa/IT

A-302

A. Computer generated reports: A solution

P. Mildenberger; Mainz/DE

Reports are an essential part of all radiological procedures and relevant for active clinical patient management. Therefore reports should contain a description of findings and a clinical judgement. Conventional dictation has some inconveniences regarding costs, delays or strengths.

Furthermore developments like CAD, fMR imaging or fCT, Software tools for quantitative measurements using high-end workstations creates evident findings. These become part of the a complete report.

Therefore the creation of radiological reports has to incorporate different aspects like encoding or classifiers (e.g. based on ICD, LOINC, SNOMED, UMLS...), transmission and storage (e.g. XML, HL7 CDA or DICOM SR). Also structured reporting is relevant for evaluation of reports in different scenarios (scientific, economical, quality management).

Structured reporting is an important issue for Radiology, it can improve instructions for residents, turnaround time, content and interoperability with information systems outside the radiological department.

Learning Objectives:

1. To understand how a report could be partially generated on a modality or a workstation.
 - a. What are structured reports - different solutions.
 - b. How to build reports using the DICOM SR.
2. To understand how such solutions could help to solve daily issues.

A-303

B. Speech recognition

J.H. Thrall; Boston, MA/US

Speech recognition systems translate spoken words into digital text. Commercial speech recognition systems are typically tailored for specific applications with respect to vocabulary and ancillary functions such as the ability to use pre-set macros and templates. For radiology, the systems are interfaced to radiology information systems to maintain the integrity of patient demographics and information about the radiological studies.

The two most important advantages of using speech recognition are shortened cycle times for creating radiological reports and making them available for clinical use and significant cost reductions through reduced personnel requirements for transcription.

The single biggest hurdle in implementing speech recognition is overcoming the perception on the part of some radiologists that speech recognition increases the time it takes them to accomplish the interpretation/reporting process. The keys to overcoming this issue are full education of system users, full use of macros and templates, comprehensive voice training and adequate system technical support for users. Vendors should also completely integrate speech recognition systems with RIS and PACS systems to reduce work process steps.

Speech recognition reporting systems offer the rare opportunity of improving quality of care and quality of service while at the same time reducing cost. Departments of Radiology that successfully implement this technology have significant quality and cost advantages compared with departments that do not.

Learning Objectives:

1. To develop an understanding of how speech recognition works and how to incorporate speech recognition systems into the radiology interpretation workflow.
2. To learn factors that are associated with successful implementation versus failed implementation of speech recognition systems.
3. To understand the potential positive operational impact associated with implementation of speech recognition dictation of radiology reports.

A-304

C. Image distribution within the hospital and beyond

N.H. Strickland; London/UK

Electronic radiological image distribution within the hospital and beyond assumes that a PACS is in place. If non-radiological images are also to be distributed, these must be acquired in digital form, and must be entered onto the PACS (or similar system) via an electronic booking system equivalent to a RIS. Seamless integration with other hospital computer systems is an essential goal if workflow efficiency is to be improved. Requesting clinical details and previous reports must be available on the same system as the images displayed for reporting.

The purpose of image viewing at each access site in the distribution system must be precisely defined, since this dictates the appropriate technical requirements. Examples include: (1) The acceptable retrieval speed, and (2) the image viewing device: Diagnostic PACS workstation versus PC web browser verses hand-held device.

Security (firewalls and encryption) becomes an issue if public highways are used for image distribution.

Learning Objectives:

1. Electronic image distribution alone is insufficient: Seamless integration with other hospital computer systems (as part of the electronic patient record) is an essential goal.
2. A clear understanding is needed of the purpose of image viewing at every display node on the image distribution system.

A-305

A. The pleura and diaphragm

M. Maffessanti; Trieste/IT

A basic review of principal anatomical landmarks and variants of pleura and diaphragm will be offered not only to understand the images and to avoid avoidable misinterpretation of normal structures as abnormal, but also to acquire the ability to localize adjacent lesions correctly.

For the pleura, an overview of effusions and their radiological aspects, from their free fluid stage to the organized or loculated stage, will introduce the discussion of specific diseases, either focal, multiple or unique and diffuse, neoplastic or fibrotic.

For the diaphragm, the variations in shape of the muscle with the respiration have to be taken into account to fully understand the images, as well as when looking at it from the physiological point of view. This tiny structure not only can be affected by its own pathology, but often participates in adjacent disorders either indirectly or directly, giving passage to fluids, organs or other elements through openings either congenital (i.e., hernias) and acquired (i.e., trauma).

Different lesions may be located in contact, above or under the diaphragm, and somehow cause modifications of its shape: effusions, masses, abscesses, large bullae and emphysema, etc., either unilaterally or bilaterally.

A particular question that often arises on the chest film is: where is the diaphragm? Ultrasound and especially Computed Tomography are very helpful in answering this question. Several key signs and a few tips to give the answer to this question will be discussed.

Learning Objectives:

1. To familiarize the audience with the anatomy of pleura and diaphragm, in particular with reference to the structures that may simulate abnormalities.
2. To illustrate how anatomy can condition appearance of some diseases and how it is modified by the diseases.
3. To discuss selected clinical cases to enhance the recognition of specific entities.

A-306 ♀

B. Mediastinal disease

K. Malagari; Athens/GR

Imaging examinations of mediastinal space-occupying lesions aim to increase recognition of the abnormality, exact localization within the mediastinum, demonstration of the relationships with surrounding anatomic structures, and texture analysis based on CT and MR imaging data. The localization approach comprises the traditional diagnostic differential based on a list of common anterior, middle and posterior mediastinal masses. However, cross-sectional imaging today definitely offers a more detailed analysis that, if combined with epidemiologic characteristics such as age-related incidence and density-texture information, may narrow the differential diagnosis considerably. Density information leading to specific diagnosis includes recognition of cystic density or fat, while calcification patterns often overlap. Characterization of cystic lesions may be difficult if the lesion contains nonserous fluid since this may present high attenuation at CT, and they may be mistaken for solid lesions, especially when intravenous contrast material cannot be administered. MR imaging can be useful in showing the cystic nature of these masses because these cysts continue to have characteristically high signal intensity on T2-weighted sequences. Fat-containing lesions include benign lipomas, diaphragmatic hernias, fat-containing mesenchymal tumors, teratomas, thymolipomas, and mediastinal lipomatosis.

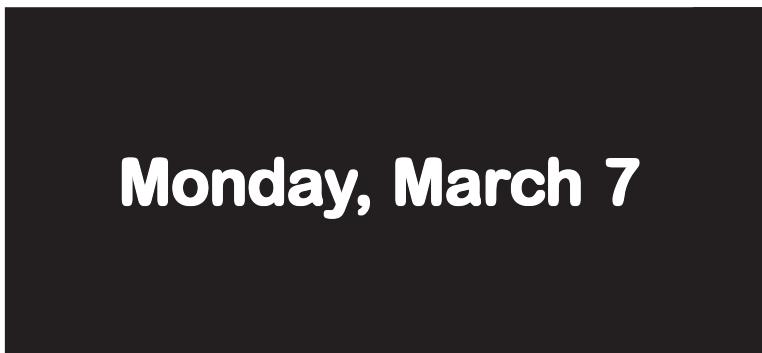

The borders of the lesion may suggest its nature, and signs of infiltration may suggest malignancy, unless inflammation or adjacent lung atelectasis coexist.

Learning Objectives:

1. To illustrate the anatomical mediastinal compartments as seen on plain films, CT and MR imaging, and discuss the concept and limitations.
2. To describe the anatomy, as well as the imaging findings of mediastinal lymph node enlargement.

3. To discuss imaging findings and differential diagnosis of space occupying lesions in the mediastinal compartments.
4. To familiarize with imaging findings of mediastinal neoplasms, pseudotumors and infectious processes of the mediastinum.
5. To promote an elaborate use of imaging modalities and interventional procedures in the diagnosis and treatment of mediastinal disease.

Craniocerebral and spinal trauma

Moderator:

P. Brennan; Dublin/IE

A-307

A. Craniocerebral trauma (1): General principles and maxillofacial trauma

B.F. Schuknecht; Zürich/CH

The sequelae of trauma to the skull and maxillofacial skeleton depends on a dynamic factor consisting of the nature of the force (energy, impact area) and a static factor which is determined by the anatomic disposition of the bone involved. A small impact area results in localized direct fractures such as a depressed skull fracture or deformation fractures of the midface. A force that is transmitted over a larger area of bone results in indirect fractures or "burst" fractures which are common at the skull base, the petrous bone, or involve the mandibular condyles bilaterally. Multirow spiral CT has increasingly replaced conventional images to depict the presence, location and deformity caused by fractures and - more importantly- reveals intracranial involvement in skull trauma. Cranial nerve and vascular complications related to osseous compromise are delineated by CT as well but may require MR to be adequately assessed. The classification of trauma is accomplished by multiplanar CT images and in case of deformity by 3D surface reconstructions. Classification of midface fractures distinguishes central (Le Fort I, II, naso-ethmoid fractures), lateral (trimolar) or combined centro-lateral (Le Fort III) fractures. Mandibular fractures are subdivided into those that affect the mandibula proper, the alveolar and condylar processes. Lateral skull base (petrous bone) fractures consist of longitudinal and transverse fractures, central skull base fractures are described as transverse and oblique fractures. While classifications in the past primarily reflected mechanism, CT and/or MR have redirected the focus on predominantly therapeutic implications and recognition of complications typical for a specific fracture type.

Learning Objectives:

1. To comprehend the two general principle pathogenic mechanisms in crano-facial trauma.
2. To learn the diagnostic procedure in isolated mandibular and midface fractures and combined cranio-facial and skull base trauma.
3. To become familiar with the classification of mandibular and midface fractures.
4. To become familiar with the classification of lateral and central skull base fractures.
5. To learn typical early and late complications in midface and skull base trauma and the principles of their diagnostic investigation.

A-308

B. Craniocerebral trauma (2): Intra- and extra-axial lesions, secondary lesions

P.M. Parizel; Antwerp/BE

Accurate radiographic diagnosis is a cornerstone in the clinical management and outcome prediction of the head-injured patient. New technological advances, such as multidetector CT scanning and diffusion-weighted MR imaging have influenced imaging strategies. In this article, we review the impact of these developments on the neuroradiological diagnosis of acute head injury. In the acute phase, multidetector CT has supplanted plain X-ray films of the skull as the initial imaging study of choice. MR imaging, including fluid attenuated inversion recovery, gradient echo T2* and diffusion-weighted sequences, is useful in determining the severity of acute brain tissue injury and may help to predict outcome. The role of MR imaging in showing diffuse axonal injuries is emphasized. We review the different patterns of primary and secondary extra- and intra-axial traumatic brain lesions, and integrate new insights. Assessment of intracranial hypertension and cerebral herniation are of major clinical importance in patient management. We discuss the issue of pediatric brain trauma, and stress the importance of MR imaging in non-accidental injury. In summary, new developments in imaging technology have advanced our understanding of the pathophysiology of brain trauma, and contributed towards improving the survival of patients with craniocerebral injuries.

Learning Objectives:

1. To document the impact of new imaging technologies on the management and outcome prediction of head-injured patients.

2. To demonstrate the growing role of MR imaging (including FLAIR, gradient echo T2*, and diffusion-weighted sequences) in acute and subacute craniocerebral trauma.
3. To discuss radiological manifestations of primary and secondary traumatic brain lesions, and integrate concepts regarding the pathophysiology of brain trauma.
4. To provide an overview of the most common extra- and intra-axial traumatic brain lesions.

A-309

C. Spine trauma

J.W. Van Goethem; Antwerp/BE

Because it may cause paralysis, injury to the spine is one of the most feared traumas, and spinal cord injury is a major cause of disability. Although the number of individuals sustaining paralysis is far less than those with moderate or severe brain injury, the socio-economic costs are significant.

Little controversy exists regarding the need for accurate and emergent imaging assessment of the traumatized spine in order to evaluate spinal stability and integrity of neural elements. Because clinicians fear missing occult spine injuries, they obtain radiographs for nearly all patients who present with blunt trauma. We are influenced on one side by fear of litigation and the possible devastating medical, psychological and financial consequences of cervical spine injury, and on the other side by pressure to reduce health care costs. Several criteria can be very useful in identifying patients who have an extremely low probability of injury and who consequently have no need for imaging. MDCT is the preferred primary imaging modality in blunt spinal trauma patients who do need imaging. Not only is CT more accurate in diagnosing spinal injury, it also reduces imaging time and patient manipulation. Evidence-based research has established that MDCT improves patient outcome and saves money in comparison to plain film.

The remainder of the text discusses the use, advantages and disadvantages of the different imaging techniques used in spinal trauma patients and the criteria used in selecting patients that do not need imaging. Finally an overview of different types of spinal injuries is presented.

Learning Objectives:

1. To learn the advantages, disadvantages and indications of different imaging modalities in spinal trauma and to be able to choose the right imaging algorithm for a particular patient.
2. To become familiar with the different types of lesions in spinal trauma.
3. To understand the pathophysiology of whiplash lesions and to know what to expect in imaging whiplash-injured patients.
4. To become familiar with traumatic spinal cord lesions.

RC 1310

Shoulder joint

Moderator:

D. Weishaupt; Zürich/CH

A-310

A. Acute and chronic shoulder injuries: US and MR imaging

F. Kainberger, C. Krestan; Vienna/AT

The main anatomic structures involved in injuries of the glenohumeral joint are the rotator cuff, the labrocapsular complex and the surrounding bones. In the acromio-clavicular joint the fibrous structures may be disrupted.

Indications: Ultrasound (US) is useful for imaging lesions of the rotator cuff but is of limited diagnostic impact in case of other traumatic disorders. MR imaging is sensitive in displaying abnormalities due to instability and in detecting osseous lesions.

Investigation: US should be performed with paracoronal and parasagittal scans and should include a dynamic investigation under external and internal rotation. MR imaging is performed in paracoronal, parasagittal, and axial slice direction with T2-weighted fat-suppressed, T1-weighted, and gradient-echo sequences. MR arthrography is still regarded as gold-standard for the detection of labrocapsular lesions. Some institutions use additional ABER-position of the elevated arm to detect certain labral abnormalities. For the AC-joint, images with a high-resolution surface coil are valuable to detect intrinsic abnormalities.

Interpretation: Partial and full-thickness tendon ruptures should be differentiated

Postgraduate Educational Programme

from other causes that lead to edema (calcifying tendinitis, Parsonage-Turner syndrome). SLAP lesions may occur in various forms depending on anatomic variants. Osseous edema is indicative of bone bruises and fractures and should be differentiated from arthritis. AC joint disruptions are often associated with ruptures of the coraco-clavicular ligaments.

Learning Objectives:

1. To understand and appreciate the indications for performing US and MR imaging with view on the diagnostic impact of each of them.
2. To know the techniques of investigation and standards of documentation with focus on slice orientation and anatomic reference structures.
3. To recognize typical appearances and pitfalls in the diagnosis of lesions of the rotator cuff, of abnormalities due to instability, and of arthritis with focus on sports injuries.

A-311

B. Soft tissue mass in the shoulder region: US and MR imaging

P.W.P. Bearcroft; Cambridge/UK

The finding of a mass related to the shoulder girdle is a common clinical entity with a wide differential diagnosis. This presentation will start by identifying how the most common causes for a soft tissue mass depends on the patient's age. Conditions will include benign and malignant soft tissue masses, bone lesions, synovial conditions, arthritis, bursitis and infection with special emphasis on conditions specifically found in relation to the shoulder girdle such as elastofibroma dorsi.

An imaging strategy for a soft tissue mass will then be discussed with particular reference to MR imaging and ultrasound including the strengths and weaknesses of each technique. Finally an approach to imaging-guided percutaneous biopsy of masses in this region will be considered, including a discussion of when such masses are best left alone.

Learning Objectives:

1. To understand and recognise the various conditions that can present with a mass in the shoulder region.
2. To know the strengths and weaknesses of the various imaging modalities.
3. To appreciate when to perform an image-guided biopsy, and when not to.

A-312

C. Postoperative shoulder US and MR imaging

C. Faletti; Turin/IT

The first thing is to know both the kind of surgery performed and the symptomatology of the patient, bearing in mind that most common pitfalls are false positive and false negative.

Therefore, the evaluation carried out by means of imaging techniques varies along with the pathology and surgery.

In the post-operative shoulder operated for instability, an incomplete resolution of the problem must be studied by plain X-ray, so as to be able to study the gleno-humeral articular relationship and the correct position of the different devices. Capsular detachment or glenoid labrum avulsion after surgical reinsertion must be studied by CT-arthrography or MR-arthrography in order to determine precisely the site and the entity of the new lesions.

In impingement syndrome, the post operative imaging study is much more complicated due to the difficulty in pin-pointing the relationship between the symptomatology and the imaging finding.

Plain X-ray examination is useful to study the bone morphology and to demonstrate the atrophic alteration or the cortical discontinuity due to an undesirable post-surgical phlogistic reaction. US examination is also useful to show intra-articular fluid and offers some basic elements to diagnose the presence of post-surgical rotator cuff tendon pathology, such as a new tear or degenerative involution.

To study the various levels in which the different articular components are involved a more panoramic picture may be obtained by using MR imaging and MR-arthrography: Bone edema, muscle atrophy, tendon degeneration, etc.

Learning Objectives:

1. To understand the proper use of the various techniques (US, MRI, arthroMRI) in the study of the post-operative shoulder, taking into account the different imaging based on the surgery.
2. To offer protocols to be used based on a determined pathology which led to surgery.
3. To identify the possible pitfalls due to the specific imaging that may be observed in post-surgical examination of the rotator cuff and gleno-humeral complex.

MR imaging of the small intestine

Moderator:

N. Gourtsoyiannis; Iraklion/GR

A-313

MR imaging of the small intestine (Introduction)

N. Gourtsoyiannis; Iraklion/GR

Recent advances in gradient technology and novel ultrafast pulse sequences made it possible to assess small intestinal diseases with MR imaging. Various pulse sequences, intraluminal contrast agents and administration techniques have been proposed. Since adequate luminal distention is considered as a major prerequisite for accurate diagnosis of even subtle intestinal lesions, MR enteroclysis was developed as a novel diagnostic method that combines the advantages of conventional enteroclysis (CE) with those of MR imaging. Clinical applications of MR imaging in the small intestine include assessment of Crohn's disease in adult and pediatric population, tumors, ischemia and obstruction. Initial results demonstrate the clinical impact of MR imaging of the small bowel and its potential limitations when applied in a clinical setting.

Learning Objectives:

1. To understand hardware and software requirements for MR imaging of the small intestine, to present an overview of the available oral contrast agents and to discuss tailored MR imaging examination protocols for specific indications in the small intestine.
2. To present clinical results of MR enteroclysis in patients with Crohn's disease, as compared with conventional enteroclysis.
3. To analyze imaging findings and clinical results of small intestinal disorders other than Crohn's disease.
4. To present imaging findings and clinical results of MR imaging applications in pediatric small intestinal diseases.
5. To analyze current limitations of different MR imaging approaches and present its future prospects in intestinal diseases.

A-314

Functional studies

D.J. Lomas; Cambridge/UK

Static imaging sequences: Modern MR imaging systems have several fast imaging sequences that allow imaging of the small bowel with either subsecond or breath-hold temporal resolution thereby reducing motion related artifacts. T1w imaging with gadolinium enhancement can delineate active inflammation in Crohn's disease but often requires anti-peristaltic agents to completely avoid motion artifacts. T2w imaging has also proven valuable in demonstrating wall thickening, but may suffer from intra-luminal motion artifacts with thin section images. Balanced T2/T1w imaging allows good delineation of wall and lumen as well as adjacent mesenteric vessels and nodes owing to the intrinsic chemical shift artifact but may suffer distortions at gas-tissue interfaces. Combining these sequences provides the ability to discriminate between artifacts and definite pathological lesions.

Interactive imaging & fluoroscopy: Currently MR systems do not have appropriate fluoroscopic capabilities and do not allow easy change of body position during an examination, unlike conventional X-ray exams. Prototype systems for interventional use may bring the required capability to allow interactive selection of contrast, imaging plane and fast switching of image acquisition type - analogous to a conventional X-ray study which combines fluoroscopy and "spot films". **Contrast media:** Intravenous gadolinium media have been used primarily with fat suppressed T1w imaging to demonstrate above normal enhancement of inflamed bowel wall. Intra-luminal contrast agents are predominantly water based with methyl cellulose widely used for nasojejunal tube studies. Orally based studies have used a wide range of agents to try and retain fluid within the lumen by osmotic or other means.

Learning Objectives:

1. To learn which imaging sequences are appropriate for imaging the small bowel, their advantages and related artifacts.
2. To learn how interactive MR fluoroscopy can be achieved and how this may be applied to small bowel examinations.
3. To understand the principles, advantages and disadvantages of the currently used intra-luminal contrast media.

Postgraduate Educational Programme

A-315

Clinical results in Crohn's disease

N. Papanikolaou; Iraklion/GR

MR enteroclysis is an emerging technique for SB imaging combining the advantages of conventional enteroclysis (CE) with those of cross-sectional imaging. MRE is equal to conventional enteroclysis in detecting, localizing and estimating the length of involved small bowel segments. Early lesions such as thickening and distortion of the valvulae conniventes and superficial type ulcers are clearly demonstrated on CE but they are not consistently depicted by MRE, due to its inadequate spatial resolution. The valvulae conniventes are shown in their best advantage and distortion of the mucosal folds are easily detected by MRE. The characteristic discrete longitudinal or transverse ulcers of Crohn's disease can be demonstrated on MRE, provided there is satisfactory distension and opacification of the bowel. Cobblestoning is caused mostly by a combination longitudinal and transverse ulceration and it is easily shown by MRE. Bowel wall thickening is clearly shown by all MRE sequences. Bowel wall thickness and length of small bowel involvement can be measured on MRE images. Narrowing of the lumen and associated prestenotic dilatation are easily recognized on MRE images by all sequences. Exoenteric manifestations of the disease are demonstrated in detail on true FISP images due to the high contrast generated from the bright mesenteric fat. Additionally, complications may be more accurately diagnosed on 3D FLASH images with fat saturation by the characteristic pattern of enhancement after gadolinium administration. The latter sequence may disclose disease activity by contrast uptake in the thickened SB wall and by mesenteric lymph nodes enhancement.

Learning Objectives:

1. To present a comprehensive MR enteroclysis imaging protocol.
2. To present clinical results of MR enteroclysis in patients with Crohn's disease, as compared with conventional enteroclysis.
3. To analyze MR enteroclysis current limitations and its future prospects in Crohn's disease.

A-316

Clinical results in non-inflammatory small intestinal disorders

H.-W. Umschaden; Wolfsberg/AT

The detection of subtle small-bowel lesions on MR imaging requires adequate distension, but there are many diseases that can be detected without distension, such as acute diseases associated with bowel wall edema, high grade small-bowel obstruction and diseases with pronounced bowel wall thickening, such as tumors or long standing Crohn's disease.

Recent technical developments facilitate MR imaging of acute diseases of the small bowel even in severely ill patients. The HASTE sequence provides adequate image quality in almost all patients and excellently demonstrates edema which is often associated with acute intestinal disorders, such as acute infectious or subacute ischemic diseases. Emboli in the superior mesenteric artery are more accurately depicted with MDCT due to the superior spatial resolution.

The demonstration of high-grade small bowel obstruction is easy with the HASTE sequence, since the loops are fluid filled and distended. The real time true FISP sequence allows functional imaging of the bowel loops proximal and distal to the obstruction and therefore a more accurate assessment of the degree of obstruction is possible.

The excellent soft tissue contrast of MR imaging is helpful in differentiating small-bowel diseases. Respiratory triggered T2-weighted TSE sequences provide more information of the bowel wall than other sequences and are therefore useful to differentiate between small-bowel diseases. In non-tumorous diseases the thickened bowel wall often shows a target pattern with high SI in the bowel wall in acute diseases and intermediate SI in chronic (Crohn's) diseases. Tumors produce asymmetric bowel wall thickening with homogeneous SI in T2.

Learning Objectives:

1. To comprehend the indications of MR imaging versus MR enteroclysis for small-bowel diseases.
2. To understand the advantages and limitations of the available sequences for small-bowel MR imaging.
3. To learn to use the superior soft tissue contrast of MR imaging for more accurate diagnosis of small-bowel diseases.

A-317

Clinical results in pediatric disorders

A. Laghi; Rome/IT

MR of the small bowel in paediatric patients requires intestinal distension, patient cooperation and the availability of fast imaging sequences. One of the major goals

of a paediatric examination is to be as minimally invasive as possible. For this reason, intestinal distension should be obtained using oral contrast agent trying to avoid naso-jejunal intubation. In the choice of the adequate oral contrast medium organoleptic properties, like taste and flavour, must be taken into consideration in order to improve patient compliance. Patients should be able to hold their breath for at least 20 sec; for this reason the examination is difficult in patients younger than six years.

The major clinical indication is represented by the work-up of children with suspected IBD. In paediatric patients the availability of a non-invasive tests for the identification of ileal inflammation is very useful in distinguishing between Crohn's disease and other gut inflammation and may represent a crucial tool in the diagnostic approach, patient selection for ileocolonoscopy and assessment of therapy response. A sensitivity of 85% and specificity of 100% for the identification of terminal ileum flogosis have been recently reported.

Another clinical indication is mainly represented by the work-up of patients with celiac disease.

The major drawback of MR imaging of the small intestine is represented by a 5% of non-diagnostic examinations due to low patient compliance and cooperation. This problem should partially be carried out from a specific preparation of both MR units suite and operator training for a better children hosting.

Learning Objectives:

1. To understand hardware and software requirements for MR imaging of the small intestine, to present an overview of the available oral contrast agents and to discuss tailored MR imaging examination protocols for specific indications in the small intestine.
2. To present clinical results of MR enteroclysis in patients with Crohn's disease, as compared with conventional enteroclysis.
3. To analyze imaging findings and clinical results of small intestinal disorders other than Crohn's disease.
4. To present imaging findings and clinical results of MR imaging applications in pediatric small intestinal diseases.
5. To analyze current limitations of different MR imaging approaches and present its future prospects in intestinal diseases.

08:30 - 10:00

RC 1302

Digital mammography

Moderator:

R.C. Otto; Baden/CH

A-318

A. Technical aspects and future trends

R. Salvador; Barcelona/ES

All the aspects concerning the state of the art in full field digital mammography are reviewed, and presented, as well as the forthcoming changes and related techniques developed in the last years.

First of all, the basic physical aspects are reviewed to know how the different systems and devices work to obtain the image. How those images obtained, in so different ways, can be compared objectively is another issue. The technical differences between FFDM and SFM are also considered. Advantages and disadvantages, image management and new items appeared related to digital imaging, different displays and management of digital imaging in monitors. Resolution requirements of every component of the systems, etc..

The forthcoming technologies applied to FFDM are also reviewed. PACS, filmless diagnosis and the new technologies CAD, breast tomosynthesis, 3D imaging, telerradiology, digital subtraction mammography, dual energy mammography, etc. and all the new techniques on digital imaging are successively overviewed. Finally some recommendations when transition to digital has been decided for a big department or a small center. A final indication for QA aspects is also described.

Learning Objectives:

1. To present the different digital mammography technologies.
2. To describe the basics to manage (reading, storage, print) digital images.
3. To bear in mind recommendations while moving from SFM to FFDM.
4. To describe key-points for comparison of digital systems.
5. To report future research trends.

Postgraduate Educational Programme

A-319

B. Logistics and workflow
F. Diekmann; Berlin/DE

Digital mammography, and in particular "direct" digital mammography, may change the procedure and workflow in performing mammographies in many situations besides screening (e.g. in diagnostic workup). This is primarily attributable to the faster availability of the images without the necessity for film development and to the high dynamic range and good contrast resolution of digital mammography. Examples will be presented to illustrate the procedural changes associated with digital mammography in different situations and it will be shown how potential future applications can be integrated into the workflow. Special focus will be held to:

- a) Wire localization procedure - temporal gain, changed workflow
- b) Changed procedures using digital mammography:
- c) Additional views: Low-dose tangential views, low-dose galactography
- d) Workflow with CAD: CAD applications for assessment, software enhancement algorithms
- e) Contrast-enhanced mammography, automated ultrasound

Learning Objectives:

1. To understand the importance of viewing software for workflow with digital mammography.
2. To learn about the impact of digital mammography on workflow in special assessment procedures.
3. To learn about integration of different CAD systems for improvement of workflow in digital mammography.
4. To discuss logistics of assessment with advanced applications in digital mammography.
5. To discuss workflow with future applications like contrast medium mammography.

A-320

C. Screening with digital mammography
P. Skaane; Oslo/NO

Full field digital mammography (FFDM) has potential benefits in future breast cancer screening programs, including: Simplified archival, retrieval and transmission of images; elimination of technical failures; increased diagnostic accuracy especially in women with dense parenchyma; implementation of CAD; telemammography; and screening program reorganization. The true flexibility and the true benefit of FFDM are realized primarily in soft-copy reading.

Factors influencing diagnostic accuracy of FFDM with soft-copy reading include spatial resolution, reading environment, comparison with hardcopies, display system, reading protocol and efficient work station, learning curve effect (training) and CAD to reduce the challenge of interobserver variation.

Results from three large-scale comparisons of screen-film mammography (SFM) and FFDM with soft-copy reading in asymptomatic women ("screening") are so far available. The two earliest studies showed a slightly lower cancer detection rate for SFM although the difference between the two modalities was not statistically significant. The third study showed a higher cancer detection rate for FFDM approaching statistical significance for the age group 50-69 years. The first study revealed a lower recall rate on FFDM but the two other studies showed a higher recall rate for FFDM.

Learning Objectives:

1. To understand the challenge of soft-copy reading in a screening program.
2. To discuss aspects of false negative interpretations in soft-copy reading.
3. To discuss the interobserver variation of SFM and FFDM.
4. To discuss the use of FFDM and CAD within screening programmes.

08:30 - 10:00

Room E2

Abdominal and Gastrointestinal

RC 1301

Imaging of the pancreas: Key questions

Moderator:
L. Lincender; Sarajevo/BA

A-321

A. The choice: US/EUS, CT, MR imaging
D. Vanbeckevoort; Leuven/BE

The diagnostic flowchart in patients with suspected pancreatic disorders depends on many factors such as local expertise, interest and availability of equipment.

Most commonly, transabdominal ultrasound (US) is the first imaging technique. In some patients this technique may also be the final examination.

The addition of colour and pulsed Doppler sonography has contributed to assessing tumour involvement of vascular structures such as the portal and mesenteric system.

However, a sonographic diagnosis of suspected pancreatic disease depends on patient-related factors and is not always straightforward.

Endoscopic ultrasound (EUS) eliminates the problem of overlying bowel gas and allows for focussed high-resolution imaging. This technique is well suited to detect vascular invasion and EUS-guided fine-needle aspiration biopsy can further increase the diagnostic accuracy in pancreatic cancer.

When compared to US the performance of computed tomography (CT) is less operator and patient dependent. The value of helical CT in the management of acute pancreatitis and pre-operative staging of pancreatic neoplasms is well established. Moreover, multislice helical CT using narrow collimation and thin slices, provides excellent spatial resolution and three-dimensional reconstructions showing all relevant anatomical information.

Due to the introduction of (ultra-)fast MR sequences and the development of new, tissue specific contrast agents, magnetic resonance imaging (MRI) may currently be as accurate as spiral CT for depicting inflammatory and neoplastic pancreatic disease. Moreover MRI has the advantage of allowing simultaneous investigation of the pancreatic duct, pancreatic parenchyma and peripancreatic vessels ("all-in-one"). In other words MRI can provide all information required to differentiate resectable from unresectable tumours.

Learning Objectives:

1. To get an update on basic imaging techniques.
2. To enable someone to choose between different imaging techniques.
3. To learn to set up a logical approach of pancreatic disease (when is US enough; and if not, should we go to EUS, CT or MRI?)

A-322

B. What lesions are difficult at CT?
R.W. Prokesch; Vienna/AT

Detection and staging of pancreatic tumors remains a challenge for radiologists. Considering the poor prognosis of pancreatic cancer, accurate preoperative staging is the key to a possibly curative surgical treatment. Contrast-enhanced helical CT has been the most commonly used for evaluation of pancreatic cancer in many institutions, although it suffers from many limitations. With the fast pace of advances in multidetector CT (MDCT), and the implementation of multidetector-row scanners, improvements in spatial resolution in the z-axis with near isotropic imaging provide exquisite multiplanar reconstructions of pancreatic anatomy.

Learning Objectives:

1. To describe the characteristic features of pancreatic tumours.
2. To present imaging findings useful in the identification of subtle pancreatic cancers.
3. To supply CT/MR criteria which help to differentiate adenocarcinoma of the pancreas from chronic pancreatitis.

A-323

C. Uncommon pancreatic tumors
T.K. Helmerger; Munich/DE

Dependent on the three main cell lineages, pancreatic tumors may arise from the duct cells, the acinar cells or the endocrine cells. The "classic" ductal adenocarcinoma of the pancreas accounts for about 80% of all pancreatic tumors, important variants as mucinous noncystic carcinomas (1-3%), adenosquamous carcinomas (3-4%) and undifferentiated (anaplastic) carcinomas (2-7%) add another 10% to the ductal tumors. The latter ones together with endocrine tumors (2%), mucinous cystic tumors (2%), intraductal papillary-mucinous tumors (1%), serous cystadenomas (1%), acinar cell carcinomas (1%), solid-pseudopapillary tumors (1%), pancreaticoblastoma (< 0.5%) and other rare entities represent the "uncommon" pancreatic tumors.

Some of these uncommon tumors may mimic the clinical findings and appearance in imaging of ductal adenocarcinomas. Nevertheless, the knowledge of specific imaging features in tailored CT and MR imaging studies may help to differentiate uncommon pancreatic tumors from the classic ductal carcinomas. This can be especially crucial since some of these tumors hold a significantly better prognosis in comparison to the generally dismal prognosis of ductal adenocarcinomas of the pancreas, while other rare tumors do not need even therapy at all.

Learning Objectives:

1. To become aware of the variety of uncommon pancreatic tumors.
2. To identify the prognostic implications of uncommon pancreatic tumors.

Postgraduate Educational Programme

3. To identify clinical and imaging features, which distinguish between uncommon tumors and classic adenocarcinomas.

Molecular Imaging and Contrast Media

RC 1306

Molecular imaging

Moderator:

O. Clément; Paris/FR

A-324

A. Molecular imaging with PET

G.K. von Schulthess; Zürich/CH

PET radiopharmaceuticals are by several orders of magnitude (10^5 - 10^8) more sensitive probes than contrast agents used in MR and CT. As a result, many radioactively labelled probes of molecular biological processes can be injected into a patient, which would be toxic when injected at doses required to produce contrast alterations in MR or CT. Consequently, PET together with conventional Nuclear Medicine methods currently represent the only forms of clinical molecular imaging.

The most frequent clinical application of PET is the use of FDG, a glucose analogue, which is an excellent probe to depict tumor glucose uptake and metabolism. Imaging this property of tissues has proven to provide an excellent tumor staging and therapy control modality, by far superior to anatomic imaging. Other molecular probes are in the pre-clinical testing phase, such as F-choline, F-thymidine, and F-tyrosine related compounds, which label cell membrane synthesis, cellular proliferation and amino acid uptake and metabolism as well as hypoxia markers. Many other PET-probes are evaluated in a research setting.

As many of the compounds show little anatomic information, fusion of images with an anatomic reference frame is becoming increasingly important. This is the reason, why PET-CT is currently the fastest growing imaging modality in the western hemisphere.

Learning Objectives:

1. To understand the essential advantages of PET over other imaging modalities.
2. To become familiar with the clinical and research potential of PET imaging.
3. To understand the advantages of PET-CT over PET imaging alone.

A-325

B. Cell targeting and cell tracking with MR imaging

H.E. Daldrup-Link; San Francisco, CA/US

New stem cell based therapies require to assess cell homing and engraftment quantitatively and qualitatively. MR imaging is well suited to depict and track transplanted stem cells in vivo, if the cells are labelled with MR contrast agents. Basic principles, capabilities and limitations of various labelling techniques will be presented.

Virtually any cell type can be labelled with MR contrast agents. Labelling techniques comprise simple incubation, receptor mediated uptake, transfection and electroporation techniques. Cells can be labelled with positive or negative MR contrast agents and can be subsequently depicted with clinical MR scanners. Iron oxide contrast agents are generally better suited than gadolinium or manganese contrast agents and SPIOs are better suited than USPIOs. However, each labelling procedure has to be tailored to the investigated cell type and target organ.

In vivo applications comprise MR based cell tracking studies of bone marrow transplantation and new cell based therapies, such as homing of mesenchymal stem cells in injured myocardium, homing and migration of neurologic stem cells in impaired brain tissue and accumulations of transplanted natural killer cells in tumors. In addition, labelled leukocytes may be used diagnostically to detect and characterize inflammation.

In conclusion, MR contrast agents can be used for labelling and in vivo tracking of various cell types with clinical MR scanners. The ability to provide in vivo cell tracking with non-invasive imaging techniques may improve our understanding of how stem cells mediate recovery of injured organs and may be ultimately applied clinically for safety assessments of transplantation procedures.

Learning Objectives:

1. To understand advantages and disadvantages of various currently available cell labeling techniques with MR contrast agents.

2. To be able to apply optimized and dedicated protocols for cell labeling purposes.
3. To get an overview of potential experimental and clinical in vivo applications.

A-326

C. Optical imaging

P. Wunderbaldinger; Vienna/AT

Molecular imaging has become one of the most exiting fields of research in radiology. In order to image on a cellular and even subcellular level new imaging techniques such as optical imaging have been developed. Optical imaging relies on either endogenous tissue contrast such as absorption and scattering (transillumination imaging), autofluorescence (spectroscopic techniques), reflectance (diffuse tomography), bioluminescence (luciferase imaging) or on optical contrast agents (fluorochromes, dye). These agents usually emit in specific bandwidths and can be used for targeted imaging by attaching them to peptides (e.g. VIP, Somatostatin), specific ligands (e.g. folate receptor), macromolecules (e.g. Transferrin). The main disadvantage of this approach is the direct dependence on receptor/binding affinity and a low signal-to-background ratio.

More promising is the use of activatable optical probes that are inactive in their native state (quenched) and following enzymatic activation start to strongly fluorescence in the near infrared light spectrum (basically no autofluorescence). These probes can be engineered to target specific enzymes (e.g. MMP-II, Cathepsin) and, thus, be used for specific tumor detection and differentiation, therapy monitoring, lymph node and plaque imaging, gene expression/therapy monitoring, etc. With the development of new imaging devices such as fluorescence mediated tomography allowing a combined optical and MR or CT imaging, endoscopic probes and hand held scanners initial problems such as low tissue penetration and poor anatomical resolution have been solved.

Based on recent observations optical imaging may soon be ready for clinical use, such as tumor detection/screening, intraoperative biopsy guidance, lymph node differentiation and therapy monitoring.

Learning Objectives:

1. To understand the basic principles of optical imaging.
2. To comprehend the different optical imaging strategies and applications.
3. To learn about different optical contrast agents/probes.
4. To hear about potential clinical applications of these new imaging techniques.

MR spectroscopy of the brain in clinical practice

Moderator:

N. Sener; Izmir/TR

A-327

A. Technique and protocols

E.R. Danielsen; Copenhagen/DK

Background: ^1H MRS is becoming an increasingly automated procedure, and will often add information to a negative or non-conclusive MR imaging study. Hypoxic, traumatic, toxic, or hypoglycaemic brain injuries, metabolic diseases, neurodegenerative diseases, or systemic diseases such as hepatic encephalopathy are typical pathologies with diffuse brain abnormalities calling for MRS. In focal brain diseases MRS should be considered in, abscess versus cystic necrotic tumor, differential diagnosis of lesions in HIV+ patients, recurrent tumor versus necrosis, tumor classification, guide for tumor biopsies, and lesions of unknown etiology.

Procedure Details: The concentrations of the metabolites, which MRS can detect in the human brain, are typically between 1 mM and 20 mM. N-acetylaspartate, total creatine, total choline, myo-inositol, glutamate, glutamine, lactate, glucose, and lipid are the most prominent detectable metabolites. It is possible to quantify the metabolites and obtain coefficient of variance between 5% and 18%, this however requires attention to methodological detail. It is crucial to know how to obtain good S/N and high resolution. Positioning and size of the selected volume, shimming, TE and TR, and even minor patient movement become important factors.

Conclusion: High quality and precise MRS results require a basic understanding of underlying methods including spatial selection methods, water suppression, shimming and how to acquire high S/N spectra. The rewards are low

Postgraduate Educational Programme

coefficient of variance, artefact-free spectra, and hereby the possibility to provide data that influence clinical decisions making for individual patients.

Learning Objectives:

1. To learn about choices of measurement protocols, and how they influence the result.
2. To understand procedures performed (automatically and manually) prior to acquisition.
3. To learn about single volume of interest versus multiple volume methods.
4. To learn about the MR spectrum, MRS visible metabolites and post processing methods.
5. To learn about normal values, reproducibility and how certain conditions unrelated to the clinical question may influence the measurement.
6. To get a brief recipe of how to use MRS to answer clinical questions.

A-328 ♀

B. Clinical applications of MRS: Focal lesions

I.M. Björkman-Burtscher; Lund/SE

MR spectroscopy allows the examination of tissue biochemistry, which adds to the diagnostic information obtained with other radiological modalities. As MRS techniques have become more user friendly and reliable, clinical *in vivo* MRS applications are increasing, more metabolites can be included in data analysis, and confidence of interpretation increases.

When investigating patients with focal brain lesions, it is advantageous to use single volume short TE methods combined with multiple volume methods adding spatial information. MRS can optimize the reliability of diagnostics and prognostics in focal brain lesions by depiction of subtle differences in complex metabolite profiles obtained by short TE studies and spatial correlation of MRS abnormalities to MR imaging features including normal appearing tissue.

This presentation will focus on differential diagnosis, spectral features and diagnostic pitfalls in brain disorders presenting with focal lesions: tumours and tumour like masses - including classification, grading and therapy response -, infectious and inflammatory diseases, and focal hypoxic and traumatic injuries.

Learning Objectives:

1. To learn about basic information on metabolites relevant for the interpretation of proton MR spectra in focal brain lesions.
2. To understand the typical spectral features of focal brain lesions.
3. To get some clues for differential diagnosis.
4. To understand the necessity to appreciate MRS as a complement to MR imaging and not a substitute for MR imaging for differential diagnosis.

A-329

C. Clinical applications of MRS: Diffuse lesions

P.J.W. Pouwels; Amsterdam/NL

Knowledge of normal regional and developmental metabolite patterns is mandatory, especially for MR examinations of a pediatric population with childhood white matter disorders. This broad field includes mitochondrial disorders and leukodystrophies, such as hypomyelinating, demyelinating, and cavitating disorders. These diseases are sometimes due to enzyme defects causing absence or accumulation of metabolites. First of all, it has to be ascertained that uncommon resonances are real and not due to artefacts. But when the presence or absence of those metabolites is recognized in the spectrum, MRS can be diagnostically specific. In most diseases however, the spectrum may only indicate processes which occur in many different diseases, such as neuronal loss, demyelination, or gliosis. Nevertheless, there are many differences between the leukodystrophies with regard to the severity, the location and the extent of spectroscopic abnormalities. And the spectra often also change during progression of the disease. Of course, conventional MR imaging is indispensable in addition to MRS for correct diagnosis of known leukodystrophies, and to recognize common patterns in as yet unspecified white matter disorders. Furthermore, other quantitative MR techniques, such as diffusion weighted imaging (yielding the apparent diffusion coefficient and fractional anisotropy), and magnetization transfer imaging (yielding the magnetization transfer ratio) add valuable information. In combination with MRS these techniques may help understand the pathology of white matter disorders.

Learning Objectives:

1. To understand normal regional and developmental metabolite patterns.
2. To understand spectral abnormalities in childhood inborn errors of metabolism, leading to white matter disorders.
3. To distinguish uncommon resonances due to accumulation of metabolites from artefacts.
4. To learn about the evolution of a spectrum after ischemia.

5. To compare MRS with other quantitative MR techniques for following disease progression.

Multislice CT of the urinary tract

Moderator:

P. Pavlica; Bologna/IT

A-330

A. Multislice CT of urothelial tumors

N.C. Cowan; Oxford/UK

Multislice computed tomography (CT) allows fast acquisition of thin slices for large body volumes. Single breath-hold acquisition & faster table speeds reduce movement artefact. Thinner slices allow reduction in pixel size with improvement in spatial resolution. By adjustment of image matrix, reconstructed FOV and pixel size, isotropic voxels may be reconstructed providing the opportunity for 3D imaging techniques to be applied to multislice CT urography (CTU).

The principle indication for CTU is the detection of urothelial tumours, which present most commonly with haematuria or more rarely with unexplained hydronephrosis. Correct timing of the acquired series is critical and is best between 10-15 minutes post-injection of contrast medium. 2-series acquisition is possible using a split-bolus technique for administration of contrast medium. The effective dose for 2-series CTU is ~11.5 mSv compared with 2.5 mSv for intravenous urography (IVU). For CTU the risk of fatal cancer induction is calculated as 1 in 1,400 and for IVU 17,600. It is important to restrict CTU for appropriate population groups at high risk for cancer.

CTU signs for urothelial tumours are of a papillary or polypoid mass sometimes with invasion of adjacent structures.

Circumferential wall thickening is a lesser-known CT sign. CTU visualizes the entire urinary tract, which is an advantage for the detection of urothelial cancer, a multifocal process. Small tumours may be identified throughout the entire upper urinary tract and also within the bladder. Wide windowing is essential.

CTU compares favourably with other imaging modalities for the detection of urothelial cancer.

Learning Objectives:

1. To optimize the use of multislice CT (MSCT) for the investigation of urothelial tumors.
2. To review the radiological signs of urothelial tumors using MSCT.
3. To illustrate the diagnostic pitfalls of using MSCT for the investigation of urothelial tumors.
4. To compare the use of MSCT for investigation of urothelial tumors with other imaging modalities.

A-331

B. Multislice CT of renal cancer

U.G. Müller-Lisse; Munich/DE

Multislice computed tomography (MDCT) has widely increased the range of helical CT scanning, the speed of data acquisition, and the spatial resolution of image data along the z-axis (long axis of body). Current MDCT scanners allow for breath-hold scanning of the abdomen and pelvis or of the chest without motion-artifact. MDCT of the kidneys and urinary tract allows for multiplanar image reconstruction with meaningful interpretation and demonstration of the precise location, size, and extent of renal lesions in imaging planes that are other than axial. Postprocessing tools provide 2D- and 3D-impressions of renal lesions in relation to renal parenchyma, extrarenal fat, renal sinus, pyelocalyceal system, ureter, blood vessels, and surrounding organs. Nephron-sparing surgery is most feasible in small (T1a, TNM 2002 classification) renal cancers that do not extend into or immediately abut hilar or pyelocalyceal structures. High temporal resolution (now down to 0.33 s/rotation) of MDCT scans distinguishes arterial, corticomedullary, nephrographic (renal parenchymal), and excretory (urographic) phases of passage of intravenous contrast media through the kidneys. Limitation of radiation exposure requires tailoring of MDCT protocols to specific clinical needs. Detection, localization, and local (T-) staging of renal cancer by MDCT demonstrate 80-95% accuracy. Current MDCT and MR imaging techniques perform equally well in the staging of renal cancer.

Postgraduate Educational Programme

Learning Objectives:

1. To learn about advantages and disadvantages of different examination protocols in MSCT of renal cancer, particularly image information versus radiation exposure.
2. To learn about the influence of MSCT information on uro-surgical decision making, particularly in small renal tumors.
3. To learn about the diagnostic value of MSCT in view of other imaging techniques in the evaluation of renal cancer.

A-332

C. Multislice CT in trauma of urinary tract

M. Hellström; Gothenburg/SE

Injuries of the kidney by blunt or penetrating trauma include renal contusion, parenchymal laceration, fracture, "shattered kidney", subcapsular haematoma and injuries to the renal pedicle, including renal artery avulsion, laceration or occlusion, or renal vein thrombosis. Depending on the extent of injury, perirenal and pararenal haematoma and, if the collecting system or ureter has been injured, urinoma may ensue. The urinary bladder may suffer intra- or extraperitoneal rupture due to blunt or penetrating or trauma, sometimes due to pelvic fractures. Multislice CT (MSCT) of the kidney is superior to ultrasonography, urography, conventional and single slice CT due to its fast image acquisition, reducing motion artefacts and allowing imaging in several phases, and the availability of multiplanar reformats, which are very helpful in visualising the full extent of injury. MSCT in suspected injury of the urinary system should include the entire abdomen and pelvis, in order to detect injuries of other organs, and to reveal the full extent of haematomas and urinomas, which may otherwise be underestimated. MSCT in the corticomedullary phase allows detection of renal vessel injuries, active bleeding and defective parenchymal perfusion. Renal parenchymal injuries and non-perfused areas are also well depicted during the nephrographic phase. Delayed imaging, 8-15 minutes after contrast administration, is necessary to reveal the full extent of contrast leakage from rupture of the collecting system, ureter or bladder. Bladder rupture may require scanning after contrast filling via bladder catheter, but only after urethral injury has been ruled out, if necessary by a retrograde urethrogram.

Learning Objectives:

1. To provide an understanding of the mechanisms and types of traumatic injuries of the kidneys and urinary tract.
2. To provide an understanding on the role of MSCT, as related to other imaging modalities, in the work-up and follow-up of traumatic injuries of the kidneys and urinary tract.
3. To provide an understanding of the diagnostic appearances, as well as diagnostic pitfalls, of traumatic injuries of the kidney and urinary tract at MSCT.
4. To provide an understanding of the technical performance, role of contrast medium administration, role of post-processing and technical limitations of MSCT in diagnosing traumatic injuries of the kidney and urinary tract at MSCT.

Percutaneous tumor ablation

Moderator:

M. Sato; Wakayama/JP

A-333

A. Liver

P.L. Pereira; Tübingen/DE

As an alternative to liver surgery, percutaneous thermotherapy has gained increasing importance within recent years. Different modalities of energy deposition have been developed: RF ablation has proven superior to other modalities as a cost-effective, efficient and safe treatment alternative. Current commercially available ablation electrodes include monopolar, bipolar, and multipolar devices. The shapes of these needles allow *in vivo* a nearly spherical ablation zone of up to 4 cm in diameter. Patients can be treated on either an outpatient or inpatient basis. The RF needle is placed into the lesion under US, CT or MR guidance. Exact navigation of the applicator into the tumour, and monitoring of the procedure are crucial factors for complete tumour coagulation. Targeting of applicator position and a near on-line monitoring of the ablation procedure are much facilitated since the introduction of MR-compatible RF-ablation devic-

es. Complications after RF ablation are infrequent (< 2%). For long term follow-up MR imaging of the liver every three months for one year, and every six months thereafter has been recommended by the Expert German Group for Radiofrequency Ablation (EGRA/AGIR/DRG). Results of multiple clinical series appeared to be very promising showing 52-98% complete ablation rates. The major determinate of success is initial tumor size, cut-off value seems to be 3.5 cm for colorectal metastases and 5 cm for encapsulated hepatocellular carcinomas. RF ablation may be favourably combined with chemotherapy or embolisation. If recurrence occurs at the ablation site, or new tumors occur outside of the treated area, additional treatments with RF ablation are potentially possible.

Learning Objectives:

1. To understand indication for RFA of the liver.
2. To know the mechanism of radiofrequency ablations for liver tumor.
3. To know different equipment and techniques.
4. To understand the results and follow-up.

A-334

B. Kidney

P.R. Mueller; Boston, MA/US

Increasingly, RCC's are detected as small incidental findings on cross-sectional imaging studies. Coupled with an aging population, the result is an increasing number of elderly people and/or people with comorbid conditions with small RCC. This population has been the impetus for development of minimally invasive percutaneous techniques to treat RCC. Because of the recent introductions of the techniques and the lack of large cohorts of patients with the gold standard 5-year survival data, ablative techniques for treatment of RCC have generally been limited to patients with one or more of the following conditions: solitary kidney, limited renal function such that surgical resection would result in dialysis, comorbid conditions rendering the patient a poor operative candidate, predisposition to multiple multifocal RCC's such as in von Hippel Lindau disease, and advanced age such that life expectancy is less than 10 years. The likelihood of achieving complete coagulation necrosis is influenced by tumor size and location. Tumors 3 cm or smaller can generally all be ablated successfully regardless of location, with a rare RCC requiring a second ablation session for complete treatment. Tumors 3-5 cm can be ablated completely, but up to 30% of these may require a second ablation session. Major complications are rare. Hemorrhage is the most common reported complication. Hemorrhage is the most common reported complication. Our experience with our 100 patients will be presented.

Learning Objectives:

1. To understand the "rationnel" for radiofrequency ablation of renal masses.
2. To know the indication for RFA of renal masses.
3. To understand the role of imaging.
4. To know the results of RFA.

A-335

C. Lung

R. Lencioni; Pisa/IT

Lung cancer is a leading cause of cancer death. Non-small cell lung cancer (NSCLC) comprises approximately 80% of primary malignant lung tumors. Lungs are also the second most frequent site of metastatic disease. Surgical resection is the treatment of choice for early-stage NSCLC and oligometastases from colorectal cancer. Unfortunately, because of the high prevalence of chronic respiratory disorders and atherosclerotic vascular disease, only 30% of patients with NSCLC are clinically operable. On the other hand, the high risk of recurrence and the need to remove functioning lung tissue along with the lesions limit the indications for surgery in patients with colorectal metastases. Image-guided radiofrequency ablation (RFA) is a minimally invasive technique used to treat solid tumors. Because of its ability to produce large volumes of coagulation necrosis in a controlled fashion, this technique has gained acceptance as viable therapeutic option for unresectable liver malignancies. Recently, investigation has been focused on the use of RFA for the treatment of lung tumors. Pilot clinical trials have shown that this technique can achieve effective and reproducible tumor destruction with acceptable morbidity and have suggested that it could represent a viable alternative or complementary treatment method for selected patients with NSCLC or lung metastases who are not candidates for surgical resection. However, further investigation in larger patient cohorts and longer follow-up will be needed to confirm these promising results and to establish the role of RFA in the clinical management of nonsurgical patients with lung malignancies.

Learning Objectives:

1. To discuss the rationale of percutaneous tumor ablation in the treatment of primary and secondary lung malignancies.

Postgraduate Educational Programme

2. To review the results of experimental animal studies.
3. To describe indications and contraindications, technical issues, results and complications emerged from clinical trials.
4. To have a good understanding of the current role of percutaneous tumor ablation in the multidisciplinary management of lung tumors and be aware of the different technical approaches by the end of the presentation.

Teleradiology: Threat or opportunity?

Moderator:

B. Silberman; Paris/FR

A-336

Teleradiology professional issues: A new radiological service

P.M.T. Pattynama; Rotterdam/NL

Teleradiology allows one to read and report radiology images at a site distant from where the examinations have been performed. Its advantages are that it provides flexibility to a radiology practice allowing for temporary shortages in manpower, it brings radiology services to remote areas and it provides easy access to outside expert opinion to raise quality of care.

In teleradiology, a division is made between the various roles of the radiologist: on the one hand, his role on-site is as a consultant to his fellow clinicians with a critical importance in clinical management, and as the person who is responsible and accountable for the quality of the in-hospital radiology service. On the other hand, he has a role as the provider of a written radiology report.

Potential problems may arise because of this role separation. Reports made at a distance in relative clinical isolation may lack clinical relevance. Legal issues remain: who is responsible for errors in reporting? Will defensive reporting abound? There is also the financial issue. Conventionally, the radiologists' fee has been based on the written report as the unit of work output. This makes sense when all reporting is done on-site. But when radiology reports will be made at a distant site, this computation will not be valid anymore because the "clinical" part of the radiologist work will then not be accounted for. In this presentation, it is argued that the "clinical services" and "report writing" parts of the radiologist's work should be separately reimbursed.

Learning Objectives:

1. To discuss the separate roles of the radiologist as a clinician, the "imaging consultant" versus the provider of the radiology report.
2. To review advantages and disadvantages of teleradiology.
3. To discuss the potential impact of teleradiology on the radiology profession.

A-337

International consensus standards for clinical teleradiology

L. Lau; Brunswick, VIC/AU

Good quality clinical radiology may be defined as the timely access to an efficient, effective and integrated delivery of clinically appropriate and accurately interpreted, good quality imaging studies in a safe, service-orientated and sustainable practice environment. Teleradiology offers a new opportunity of service delivery to a range of clinical scenarios. However, when employing this 'new modality', we need to consider other important factors which may influence quality in addition to those related to the transmission and reporting of images.

The ACR, EAR and RCR have prepared position papers on the appropriate practice of teleradiology. The RANZCR is developing a teleradiology consensus statement. However, the practice of teleradiology is not constrained by national boundaries. To ensure consistency, minimum quality and safety, it is desirable to have an international set of practice standards/guidelines in this emerging field. These standards should cover the various aspects of good quality clinical radiology and not simply focus on the technical issues alone. It is important for our profession to lead proactively rather than to have this imposed upon us by third parties.

The International Radiology Quality Network (IRQN) is a network of national and international organisations. Its objective is to promote quality in radiology through collaboration, experience sharing and mutual assistance. One of its long term tasks is the development of a set of international accreditation standards in radiology. The IRQN is ideally placed to facilitate the radiology profession towards the drafting of a set of international practice standards/guidelines in clinical teleradiology.

Learning Objectives:

1. To learn the role and impact of teleradiology in the practice of good quality clinical radiology.
2. To learn why it is important and desirable to adopt an international set of clinical teleradiology standards and practice guidelines.
3. To learn the role of the International Radiology Quality Network (IRQN) in facilitating this development by proactively working with the profession and employing a consensus approach.

A-338

Report of the ACR task force: Legal aspect, US professional last guidelines and international issues

J.P. Borgstede; Colorado Springs, CO/US

Teleradiology is a valuable tool in providing access to timely, quality radiological interpretations. Today, teleradiology has facilitated a unique role in delivering quality interpretations to hospital emergency rooms and other health facilities that did not have access to a radiologist's contemporaneous interpretation in the past. While teleradiology has led to an improved level of care in the United States, the potential use of this technology abroad raises some significant potential challenges to the assurance of high-quality patient care in the future.

The American College of Radiology (ACR) Board of Chancellors, convened a Task Force on International Teleradiology to study legal, regulatory, reimbursement, insurance, quality assurance and other issues associated with this new and emerging practice. The ability of teleradiology to transmit images electronically from one location to another, outside the borders of the United States, has made this a prominent issue for the profession and the College.

Results of the task force include the following principles: international teleradiology must not reduce quality of patient care, it must be consistent with the ACR technical standard for teleradiology, appropriate licensure and medical liability insurance must be maintained, appropriate credentialing and medical staff privileging must be maintained, independent image interpretation is required by the physician signing their report as his/her own interpretation and signing reports as one's own without reviewing the images (ghosting of reports) is unethical. Regular participation in quality assurance, availability for emergency consultations, and assurance of privacy protection were also requirements of international teleradiology recommended by the task force.

Learning Objectives:

1. To understand the background resulting in the ACR task force on international teleradiology.
2. To understand the results of the ACR task force on international teleradiology.
3. To obtain a perspective on the future of international teleradiology.

A-339

First attempt for a European guidelines for the use of teleradiology

B. Silberman; Paris/FR

The daily practise of Radiology and the benefits to patients has significantly altered with advances in science and new technics in the last 25 years. Some examples include vascular imaging, ultrasound, CT, MR imaging and digital radiography.

Teleradiology is the latest development and has to be included in the new daily radiological service for patients.

In many countries around the world and within Europe, teleradiology is already an established service.

But many threatening questions are arising about the use of teleradiology without the real involvement and responsibility of local and accredited radiologists in order to assure a good quality clinical radiological service to patients.

ACR, Italian radiological society and RCR has already published documents or guidelines.

EAR Professional Organisation Committee and UEMS radiological section worked together closely in order to present guidelines for the good use of teleradiology in Europe. This work is to be formalised through EU official professional association, as it is for the UEMS training Charter.

Learning Objectives:

1. To understand the benefits of radiology and quality standards for the delivery of a quality clinical radiological service to patients.
2. To know potential pitfalls especially if teleradiology to become a general method of national and international radiological service delivery.
3. To discuss what should be European radiological guidelines for a good clinical use of teleradiology.

Neonatal problems

Moderator:

M. Clauzon; Vandoeuvre/FR

A-340

A. Investigation of ano-rectal anomalies

M. Hiorns; London/UK

The term "ano-rectal anomalies" is often used synonymously with "imperforate anus" but more accurately encompasses a wide range of abnormalities including ectopic anus, imperforate anus, rectal atresia, and anal and rectal stenosis. The spectrum of anomalies is in part due to the complexity of the embryological development of the anorectal segment of the hind gut. Several classifications have historically been used to delineate these anomalies but the most simple distinction is into high and low malformations (depending on whether the rectum ends above or below the puborectalis sling), this having implications for both prognosis and treatment.

Presentation is either antenatal or at the immediate post natal check (absent anus). Occasionally presentation may be delayed until the infant has failed to pass meconium, or meconium is passed in the urine, or the infant becomes obstructed. If the lesion is unequivocally low it is usually managed by anoplasty or dilatation but most commonly a diverting colostomy is fashioned soon after birth with other imaging investigations being delayed.

Before definitive surgery a loopogram and cystogram are routinely performed to evaluate communications between the end of the hindgut and the genitourinary tract (a "fistula"). The range of findings will be illustrated. More accurate assessment of the position of the puborectalis sling can be made using MR imaging if required.

Due to the high association (up to 90%) with other abnormalities (part of the VACTERL syndrome) other imaging would normally include renal ultrasound and spinal ultrasound in the first few weeks of life.

Learning Objectives:

1. To understand the normal anatomy and normal development of the lower gastrointestinal tract.
2. To understand the range of anomalies of the lower GI tract.
3. To understand the range of investigation available and their applications.

A-341

B. Broncho-pulmonary foregut malformations: Antenatal and postnatal imaging

S. Puig; Vienna/AT

The foregut (FG) is defined as the anterior part of the alimentary tract leading from the mouth to the entrance of the bile duct. The human lung is a derivative of the primitive foregut and appears by 3 weeks of gestation as an enlargement of the caudal end of the laryngotracheal sulcus of the foregut. Further development of the pulmonary parenchyma includes 4 steps.

Structural and functional defects in lung development may lead to a number of abnormalities including bronchopulmonary foregut malformations (BPFM).

Routine US screening enables the visualization of fetal intrapulmonary malformations. Prenatal MR imaging, especially with ultra-fast sequences, is an important adjunct helping to differentiate different masses and/or to evaluate large or atypical masses. This is particularly useful for the planning of in-utero interventional procedures, delivery, and immediate postnatal surgery.

Prenatal US-examinations have been systematically performed for more than 30 years.

Prenatal MR imaging was introduced in 1983. Since the early 1990s single-shot rapid acquisition with refocused echos are available. This high quality fast T2-technique leads to freezing of fetal motion.

After birth, chest radiography is the primary image tool. For further evaluation, high spatial resolution of contrast enhanced multi-detector CT (MDCT) is recommended to visualize small anatomical structures to either confirm the diagnosis or to demonstrate the exact anatomy for the surgeon. Using low-dose protocols and dose modulation software in combination with multiplanar reformats lead to excellent image quality at low radiation exposure. Using new tube current modulation software, dose reductions of up to 90% were possible.

Learning Objectives:

1. To understand normal embryological development and possible developmental abnormalities, which lead to foregut malformations.
2. To describe the prenatal evaluation of foregut malformation using US and MR imaging.
3. To describe the postnatal clinical findings.
4. To describe the postnatal imaging features using radiography, US, MR imaging, and multidetector CT with special consideration of low-dose CT protocols.

A-342

C. Investigation of the dilated urinary tract

M. Riccabona; Graz/AUT

Aim: To present the common conditions and theories of paediatric UT dilation, to discuss the various imaging modalities, their potential and their importance, and to finally suggest modern imaging algorithms for typical clinical presentations and queries.

Background: We learned that dilatation itself is not a disease and does not equal obstruction; only a threat to the kidney has to be focused both clinically and by imaging. The advanced capabilities of modern imaging displays even physiologically fluid filled collecting systems, creating confusing terms such as "low degree hydronephrosis". Many conditions have to be considered: non-obstructive dilatation, megacalicosis, collecting system laxity, UPJO, MU, gross VUR, or dilatation due to tumors, clots, fungus balls and stones. The task of imaging is to depict those that may deteriorate prior to causing irreversible damage.

Imaging: Depending on the underlying condition, the presentation and age, and the availability of imaging facilities such as VCUG, US, scintigraphy, and MR imaging (with decreasing importance of IVU and CT) different imaging algorithms are used. Reliable assessment of obstruction is essential for therapy decisions - improper assessment may either lead to a diagnostic overkill or may cause permanent damage. In spite of the improved anatomical and functional assessment by modern imaging there still is no method that provides a reliable *a priori* pro futuro assessment; currently obstruction is defined by declining function, deteriorating drainage, increasing dilatation, or by indirect signs.

Conclusion: Advanced techniques have improved comprehensive imaging of the dilated UT. However, at present this is complimentary to the established "gold standard"; with only some variations of current imaging concepts.

Learning Objectives:

1. To know the common causes with its clinical implication for pediatric urinary tract dilatation and to understand their origin, pathophysiology, and future risks.
2. To refresh the knowledge on standard imaging techniques applied for investigating urinary tract dilatation, and to learn about the potential of modern imaging using modern US, scintigraphy and MRU.
3. To suggest updated imaging algorithms for the most common and typical clinical queries trying to avoid a diagnostic overkill without the risk to easily miss significant aspects that may influence therapy decisions or prognosis, based on established procedures and yet trying to include modern approaches.

A. Recruitment and retention of radiographic staff

T. O'Connor; Galway/IE

Recruitment and retention of radiographers in the Republic of Ireland has become a major issue of importance since 2001. In 2001 the normal recruitment practices were not able to sustain the level of radiography staffing required to meet service demand. The various factors that led to this situation were diverse and the impact on the remaining staff and service delivery only became obvious once the effect had reached a critical mass. Delays in making changes to the way the service was delivered meant that the staff who continued to work in the system ended up working under extreme pressure in an effort to ensure service

Postgraduate Educational Programme

delivery was not reduced. This became a factor in terms of retention of radiographers in an increasingly competitive employment market. The impact on service delivery took several different forms ranging from delays in opening new services, rotating service closures and reducing worklists on a daily basis. To address the issues a concerted overseas recruitment drive took place. A range of new recruitment methods were used by different organisations. Efforts were made to reduce delays in getting new staff on board. The ability to offer incentives to prospective employees was explored and implemented to varying degrees. The lessons of the recruitment and staffing issues from 2001 are still being learnt. Retention and incentivisation, both monetary and non-monetary, remain key to maintaining stable staff levels while in tandem reducing any delays in recruitment to ensure impact on service delivery is minimised.

Learning Objectives:

1. To understand why there is a staffing/recruitment issue, using the Irish experience.
2. To appreciate the effect of the problem on delivery of services to patients.
3. To identify different means of recruiting radiographers.
4. To identify delays in the recruitment process.
5. To learn what needs to be done to retain existing staff as well as new recruits.

A-344

B. HENRE (Higher Education Network for Radiography in Europe):

Education

A. Kettunen; Oulu/FI

The Higher Education Network for Radiography in Europe Sub Group 1 has performed an Educational Institute survey to ascertain Nature of Radiography Education across EU. The survey asks the level of education award on completion of programme, staff educational and working arrangements with clinical practice, course content, degree of multidisciplinary working, credit ratings and details about the modular system. In addition to ascertain the nature of radiographer education across the EU the survey aims to appreciate the differing capabilities of newly qualified radiographers and attempts to learn, through a competences tuning process aligned with the Bologna employment of radiographers educated in a non-host country. To date 14 countries have responded to the survey. A wide range of study options, hourage requirements/ECTS use and teaching delivery approaches have been identified. Commonalities exist amongst some countries with respect to the major comparison is the belief that a large clinical experimental component is necessary in all programmes. In conclusion it is evident that some differences need to be addressed to ensure free movement of personnel across the EU as there are national differences to the functionality of the post of radiographer. Harmonising should be done to reach an optimal level in all EU countries.

Learning Objectives:

1. To understand the nature of radiographer education across the EU.
2. To appreciate the differing capabilities of radiographers who have just qualified across the EU.
3. To learn about what further education may be necessary to employ radiographers educated in another country.

A-345

B. HENRE (Higher Education Network for Radiography in Europe):

Learning methods

J.J.M. Peeters; Eindhoven/NL

Background: Subgroup 2 of the HENRE project (3rd year) is dealing with the outcomes of a questionnaire concerning learning and teaching methods used in Radiography education in the EU. The questionnaire was developed and piloted in Austria in November 2003. Partners in the subgroup then revised it.

Findings: Analysis of the outcomes. One of the items is teaching and learning methods: subject learning - teacher centred versus Problem Based Learning (PBL), student centred learning. There are a variety of teaching and learning methods in use throughout Europe. PBL is not widely used. Furthermore the use of VLE tended to be a useful supporting technique and was being provided in a minority of the European countries. The technique enables institutions to provide education with a different didactical approach including flexibility of location. Side effect: the RLOs were developed in relation to student centred education.

Conclusion: Many countries are seeking alternatives to the teacher centred approach. Subgroup 2 has developed several RLOs being forwarded to all the participating countries. RLOs provide education, which is time-independent and interactive.

Learning Objectives:

1. To meet the similarities and differences in radiology education between the European partners development of Reusable Learning Objects (RLO) in the EU.
2. To describe the benefits of RLO in a European setting exploration and application of Virtual Learning Environment (VLE) in higher education in the EU.
3. To understand VLEs and the implementation in higher education.

A-346

B. HENRE (Higher Education Network for Radiography in Europe):

Continuous professional development (CPD)

G. Marshall; Lancaster/UK

Method: Members of the CPD subgroup of the Higher Education Network for Radiography in Europe devised a questionnaire to sample the CPD needs of radiographers in their countries. 437 questionnaires were distributed and 307 returned (70%).

Results: 92% of radiographers believed CPD was important or very important. Of those believing CPD was not important 83% had 11 or more years experience. 8% of radiographers were not prepared to spend any time on CPD, 44% 1-5 hours, 33% 6-10 hours and 15% 10 hours or more monthly. The majority 66% would prefer a combination of internet and paper based materials. 62% of radiographers would only use learning materials in their first language, with 38% being prepared to use other languages, the majority preferring English. 73% had facilities to use materials through the internet. The favored areas for CPD provision were CT 11%, MR imaging 10%, digital imaging 8% and image interpretation by 5%.

Conclusion: Most radiographers believe CPD is important, with 1-5 hours monthly being the preferred amount. A mix of paper and internet based materials in their own language would be most popular. Cross sectional imaging was the most popular area for CPD training although training in digital imaging and image interpretation were also required.

Learning Objectives:

1. To analyse the results of a questionnaire study (distributed in six languages) re. CPD requirements of radiographers.
2. To evaluate the implications of the findings.
3. To identify how CPD requirements can optimally be addressed.

Quality control and dose reduction in digital radiology

Moderator:

G. Marchal; Leuven/BE

A-347

A. Principles of flat panel X-ray detectors and photostimulable plates

B. Geiger; Forchheim/DE

In contrast to inherently digital techniques, such as CT or MR imaging modalities, all digital projection radiography techniques result from the continuous development of conventional (i.e. analogue) techniques. There is a variety of different applications for digital techniques in the field of radiology, and each application has specific requirements for the X-ray equipment.

It is characteristic for any digital-radiography device that the X-ray detection stage, the final storage, and the means for displaying the image are physically separate components. This is of importance for a definitive understanding of the differences between analogue and digital-radiography systems for the practical application as well as for quality control.

From that perspective the principles of the most popular technological solutions for radiography applications (photostimulable plates, electro-direct flat panel detectors, opto-direct flat panel detectors) are discussed. The principles of X-ray detection and signal processing will be shown on a physical level as well as its impact on practical applications.

Learning Objectives:

1. To understand the basics of X-ray detection: What happens in the scintillators, what is the captured "signal" and which processes of signal deterioration exist (noise, flare etc.).

Postgraduate Educational Programme

2. To learn the principles of available technological solutions (photostimulable plates, electro-direct flat panel detectors and opto-direct flat panel detectors).
3. To understand the differences in physical imaging performance. Practical considerations with respect to application fields will also be discussed.

A-348

B. Managing patient dose in digital radiology

E. Vano; Madrid/ES

The International Commission on Radiological Protection (ICRP) has approved in 2003, the document on "Managing patient dose in digital radiology", published in 2004. The ICRP report is structured in four chapters and three appendices. Diagnostic information provided by modern digital detectors can be equal or superior to conventional film-screen systems, with comparable patient doses but with digital systems, an overexposure can occur without an adverse impact on image quality. Overexposure may not be recognised by the radiologist or radiographer. A tendency to increase doses can occur. The ICRP document summarizes actions that can influence image quality and patient doses and includes an assessment of the impact of each action. The document includes eight formal recommendations dealing with: 1) Training aspects; 2) review of diagnostic reference levels; 3) patient dose audits; 4) availability of the original image data to the user; 5) optimisation when new digital systems or new post-processing software are introduced; 6) procedures for quality control; 7) justification criteria; 8) role of the industry promoting tools to know and control the exposure parameters. It is expected that the ICRP report helps to profit the benefits of this important technological advance in medical imaging with the best management of radiation doses to the patients. It is also expected to promote training actions before the digital techniques are introduced in radiology departments and to foster the industry to offer enough technical and dosimetric information to radiologists, radiographers and medical physicists to help in the optimisation of the imaging.

Learning Objectives:

1. To realize that the International Commission on Radiological Protection (ICRP) has published recommendations on patient dose management in digital radiology.
2. To introduce the key points of the ICRP document specially those related with aspects influencing patient dose and image quality.
3. To highlight the role of the radiology industry to help in the protection of the patient for the new digital technologies.

A-349

C. Quality assurance in digital radiology: How we do it

H.-P. Busch, C. Schilz; Trier/DE

Background: The aim of all imaging methods is to answer the diagnostic question with sufficient quality and certainty. Decoupling of image acquisition, image processing and image documentation leads to new possibilities and risks for digital radiography. For digital imaging methods a suitable choice of parameters can lead to advantages in diagnostic information. An unsuitable choice can lead to harmful effect down to wrong diagnose.

Procedure Details: The aim of image quality optimisation should be to reach the necessary quality with the lowest possible dose. The following concept shows the strategy for optimization and quality assurance in the digital radiography.

1. Optimisation

Optimal post processing is not independent from the dose range. Therefore the necessity exists to optimise the quality depending on clinical criteria.

2. Objectivation

A strategy for quality management can be performed for each kind of examination in different reference centres. Afterwards the result will be objectivated by phantom exposures.

3. Standardisation

The range of results, which corresponds to a sufficient image quality, will be defined by these reference centres. For an unknown equipment image quality can determined by evaluation of similar phantom exposures.

Conclusion: Dose and quality management means, that in a broad range the dose and image quality can be optimized and adapted to the clinical questions. For the future optimisation, objectivation and standardisation will be necessary in the framework of European quality assurance program.

Learning Objectives:

1. To discuss European guidelines for quality assurance.
2. To explain new aspects for quality assurance especially for digital radiography.
3. To fit the concept of quality assurance into the new strategy of dose and quality management.

4. To describe experience and test phantoms for routine use. (Which parameters are controlled in detail? What are objective quality criteria for digital images?).
5. To give examples of optimisation of image quality.

Paranasal sinuses

T.J. Vogl, M. Mack; Frankfurt a. Main/DE

With the advent of modern therapeutic procedures such as functional sinus surgery (FSS), cross-sectional imaging modalities have assumed major importance in diagnosis as well as treatment planning, especially in patients with chronic inflammatory diseases such as maxillary, ethmoid and frontal sinusitis. Today treatment planning is done with a CT examination, which affords maximum spatial resolution for defining key bony structures and aerated spaces. Several pathologic entities including inflammatory processes and benign or malignant tumors lead to the unspecific symptom of nasal obstruction. In general, disturbances of the epithelium in acute and chronic sinusitis lead to mucus retention and possible superinfection. In problem cases such as chronic inflammation or complete paranasal sinus obstruction, MR imaging makes an excellent adjunct for differentiating inflammatory and neoplastic processes. The understanding of normal anatomy, anatomical variations and physiology within the nasal cavity, the paranasal sinuses and its adjacent structures is a prerequisite for the radiological diagnosis of sinus disease. It will help to determine the location and nature of the ostomeatal obstruction in sinusitis and is necessary for accurate tumor staging in the paranasal region. The role of different imaging techniques will be discussed.

Learning Objectives:

1. To learn the normal anatomy and anatomical variations of the paranasal sinuses.
2. To understand the state of the art imaging technique in the paranasal region.
3. To review the most common imaging findings in patients with nasal obstruction.
4. To review typical radiologic features of benign and malignant tumors.
5. To recognize CT and MR appearance of chronic sinusitis. The typical imaging appearance of mucocele, sinonasal polyposis, and post-surgical infection will be presented.

Imaging of prostate cancer: Present and future

Moderator:

J.O. Barentsz; Nijmegen/NL

A-351

Imaging of prostate cancer: Present and future (Introduction)

J.O. Barentsz; Nijmegen/NL

This course will present the clinical role of current and new imaging techniques, such as US and MR imaging. The focus will be on how to apply these techniques and how they may influence therapy decisions. This will be presented by an expert team, including a clinician, an ultrasonographer and a MR specialist.

Learning Objectives:

1. To understand the clinical questions in patients with prostate cancer.
2. To show the role of US and MR imaging in this respect.
3. To learn how to use these techniques.

Postgraduate Educational Programme

A-352

Clinical questions

F. Witjes; Nijmegen/NL

Currently screening for carcinoma of the prostate is done with PSA pre-screening. In case with an elevated PSA, biopsies are performed, but only 20-25% of patients with a PSA between 3.0 and 10.0 actually have prostate cancer. To improve this detection rate, sometimes up to 20 biopsies per session are taken.

Question 1: Can imaging techniques improve the sensitivity of detection, and the accuracy of the biopsies without increasing the number of biopsies?

A substantial proportion of patients receive local treatment advice based on local staging done with imaging and Digital Rectal Examination. However, currently T2 tumours are understaged in 30-40% (dubious indication for surgery, screening could have been considered) and overstaged in 10% (curative option was withheld).

Question 2: Can imaging determine the T-stage?

Radiotherapy is very dependent on imaging to prevent damage outside the prostate. Future planning for an additional (salvage) boost on the (recurrent) tumour is also dependent upon imaging.

Question 3: Can imaging detect tumour (recurrence) within the prostate?

Recent reports indicate that extended lymph node dissection (LND) could cure 10-15% of N+ patients. Presence and localisation of abnormal nodes can guide a palliative approach with fine needle aspiration, preventing unnecessary surgery, or an extended LND, in patients that might profit from aggressive therapy.

Question 4: Can imaging detect nodes?

Learning Objectives:

1. To understand the therapeutic consequences of local staging of prostate cancer.
2. To understand the potential consequences of localisation of the tumour within a prostate cancer.
3. To understand the importance of imaging in recurrent prostate cancer after local treatment with curative intent (recurrence).
4. To understand the clinical consequences of proper lymph node imaging and localisation.

A-353

Ultrasound

F. Frauscher; Innsbruck/AT

The value of ultrasound in the diagnostic evaluation of prostate cancer has increased in importance in the past decade. This is mainly due to the increasing incidence of prostate cancer, the most common malignancy in men. Conventional grey-scale ultrasound has been extensively investigated, but this technique has shown a low sensitivity and specificity for prostate cancer detection. The additional use of color Doppler imaging has been shown to improve the positive predictive value only. With the introduction of ultrasound contrast agents, the role of ultrasound in prostate cancer detection has dramatically changed. Advances in ultrasound techniques were introduced to further increase the role of ultrasound contrast agents. These techniques use the interaction of the contrast agent with the transmitted ultrasound waves, and are very sensitive for the detection of microbubbles. Contrast-enhanced ultrasound investigations of blood flow within the prostate have shown that contrast-enhanced ultrasound adds important information to the conventional ultrasound technique. Early results from studies evaluating contrast-enhanced ultrasound suggest the use of ultrasound contrast agents to enhance ultrasound imaging of the prostate is feasible. Recently elastography (strain imaging), a technique which enables the visualisation of displacements between ultrasonic image-pairs under compression, has been shown to be of potential use for the detection of prostate cancer. Therefore the application of contrast-enhanced ultrasound and elastography for the detection and clinical staging of prostate cancer is promising. However, future clinical trials will be needed to ensure that the promise these new ultrasound techniques of the prostate have demonstrated evolves into clinical application.

Learning Objectives:

1. To demonstrate current new developments of ultrasound in prostate cancer.
2. To demonstrate the clinical relevance of these new techniques.
3. To demonstrate future prospects.

A-354

MR imaging

J.O. Barentsz; Nijmegen/NL

This paper describes the local staging performance and localization of prostate cancer in magnetic resonance (MR) imaging. Both a literature review and our

own results are presented. Additionally, potential ways to improve local staging performance and localization with MR imaging will be described. Various staging methods, including digital rectal examination, prostate specific antigen level (PSA), Gleason score, transrectal ultrasound and MR imaging are discussed.

Also new developments of MR in evaluating prostate cancer and its subsequent clinical role will be shown. The use of USPIO in detecting lymph node metastases in small (5 mm) nodes will be discussed. The role of endorectal coil MR imaging, dynamic MR imaging and MR-spectroscopy will be illustrated. Fusion of CT with functional MR images, allowing more precise radiotherapy will be shown. Finally advantages of 3 T endorectal coil MR imaging, being high spatial, spectral and dynamic resolution are presented.

Learning Objectives:

1. To show how state-of-the art MR imaging should be performed.
2. To present the clinical relevance of MR imaging.
3. To show new developments.

Diagnostic workstations: The new super-assistants of the radiologist and surgeon

Moderator:

B.M. ter Haar Romeny; Eindhoven/NL

A-355

Diagnostic workstations: The new super-assistants of the radiologist and surgeon (Introduction)

B.M. ter Haar Romeny; Eindhoven/NL

In the medical sciences image acquisition and image interpretation play a crucial role. 80% of all diagnoses and surgery planning are based primarily on images. Many modalities exist, and new imaging techniques continue to appear, such as the recent molecular imaging techniques. Every major vendor has a gamut of workstation applications in its product range. 3D visualization, MIP and cine-view are currently the most frequently used modes, but there is much more to come into the daily routine, with great benefits for sensitivity and specificity, and serious reduction of workload.

The conventional visual interpretation of these images however is hampered by significant variations between the interpreters, and within one and the same interpreter. On the other hand, a semi-quantitative approach with manual contour tracing of the object of interest requires much concentration and time of the user, and also leads to significant observer variations.

In addition, the modern MR imaging and multi-slice CT scanners provide enormous amounts of 3D data to the extend, that software solutions on high speed workstations are required to visualize and present all the data to the medical specialist in a convenient manner.

The medical image processing developments are directed at the automated recognition (or segmentation) and subsequent measurement (i.e. quantification) of structures in medical images to support the clinical decision making processes for both diagnosis and therapy and the clinical research. Modern research and development in image processing attempt to include knowledge about the structures to be detected as much as possible in the segmentation process, in order to minimize the user interactions, to increase the accuracy, and optimize the degree of automation. To be able to apply this kind of techniques in clinical practice, requires extensive validation studies.

Three world renowned experts will highlight in this special educational session the developments in workstation applications, richly illustrated with examples.

Learning Objectives:

1. To have a good overview of the state-of-the-art in modern medical workstation applications.
2. To learn about modern applications of diagnostic workstations, for surgery, cardiology and computer aided diagnosis.

A-356

Workstations for computer aided diagnosis and surgery planning

H.-O. Peitgen; Bremen/DE

In this tutorial we will discuss new software assistants for the radiological work towards surgery planning in oncological and living-donor-liver surgery. For oncological surgery the issue at hand is to detect and quantify the lesions and evaluate

Postgraduate Educational Programme

ate the risks of, for example, a compromised liver function after resection. To that end the assistant permits the user to choose variable safety margins and determines the parenchyma at risk from the point of view of compromised branches of the hepatic vascular systems. Finally, the assistant supports the choice of optimal resection proposals.

For living-donor-liver transplantation the issue at hand is to quantify the risks when a graft or remnant lobe has critical volume; determine, quantify and visualize the risks when grafts or remnant lobes are left with compromised territories; and to determine the appropriate cutting lines interactively and associate these with resulting risks.

Software assistants that support analogous issues in oncological brain surgery (compromised axonal fibers) and lung surgery (compromised subsegments) will also be presented.

MeVis - Center for Medical Diagnostic Systems and Visualization at the University of Bremen - has established a new research and prototyping platform - MeVisLab (www.mevislab.de) - for medical image processing and visualization. Several software assistants have been developed for CAD problems such as for example diagnosis and therapy monitoring of neurological diseases; detection and quantification of stenoses; bone removal in CTA data; diagnosis of contrast enhanced dynamic MRT data - in particular for breast MR imaging - and therapy monitoring for tumors.

Learning Objectives:

1. To comprehend compromised liver function based on CT imaging in liver tumor surgery and living-donor-liver surgery.
2. To understand the radiological role of new preoperative planning tasks for oncological liver surgery, living-donor-liver transplantation, interventional ablation procedures.
3. To become familiar with new risk assessment strategies in the radiological work up for liver surgery and intervention planning.

A-357

Computer-aided quantitation and diagnosis in cardiovascular applications

J.H.C. Reiber; Leiden/NL

In all aspects of cardiovascular medicine, from the daily clinical decision making processes, to therapeutic interventions and the clinical research, imaging plays a dominant role, which will only increase and expand in the coming years. In addition, all existing imaging modalities are used from conventional X-ray imaging during catheterization procedures to multi-slice tomography (MSCT), echocardiography including intravascular ultrasound, nuclear cardiology with SPECT and PET, and magnetic resonance imaging (MRI). Applications include both organ (left and right heart chambers and atria) and vessel (coronary and peripheral vessels) imaging, as well as fusion approaches between the different modalities, such as PET and MSCT or MRI.

There is a continuous need for automated analysis of such data sets with minimal user interactions, and small systematic and random errors, to support the interventions, as well as to properly describe the baseline and follow-up situations, and the associated changes. This field is denoted computer-aided quantitation and diagnosis. Modern cardiovascular workstations should be able to acquire data sets from the equipment of different vendors from local and hospital-wide networks (PACS systems), display the data in an intuitive manner to the user, allow the quantitation of the data, provide appropriate and customized reporting, and be able to transfer the derived data to databases for subsequent statistical analyses.

In this presentation a number of widely used quantitation approaches will be described, such as the assessment of the severity of narrowings in coronary and peripheral vessels by conventional X-ray and MSCT, of wall motion, thickening/thinning and perfusion of the myocardial muscle by MRI and MSCT, of flow measurements in vessels by MRI, etc. Research towards the fully automated analysis of the 3D data sets have made clear that statistical models of the organs to be detected are required; these have been shown to be very promising and effective. It has also become clear that combinations of various segmentation techniques are often required to approach the (fully)-automated analysis in routine practice with widely varying imaging qualities. Finally, extensive validation studies are always necessary before such quantitation techniques can be used in clinical practice.

Learning Objectives:

1. To become familiar with the developments in the field of computer-aided quantitation and diagnosis in cardiovascular imaging.
2. To understand its possible implications in the daily workflow and in clinical research.
3. To understand the advantages and limitations of the computer-aided quantitation and diagnostic approaches.

A-358

Workstations for image guided interventions

P. Suetens; Leuven/BE

In 1947 the first image-guided intervention was applied to a human brain. At that time X-ray and ultrasonic images were the only imaging modalities. A stereotactic frame fixed to the patient's head was used to geometrically register the images and planning data with the surgical instruments. The introduction of computers and 3D imaging modalities boosted the use of stereotactic neurosurgery. Whereas in its early days (1950-1970) stereotactic interventions were primarily used to treat functional disorders, such as certain persistent pain syndromes, in the 1970s many tumors and other pathologies could be identified everywhere in the brain. In the past two decades, neurosurgical procedures have continuously been augmented and improved with new technical possibilities, such as frameless systems, multimodal image fusion (CT, MR imaging, MRA, PET), true 3D visualization, and navigation systems.

The technical improvements opened the way to new applications outside neurosurgery. This is for example the case in orthopaedics, traumatology, maxillofacial surgery and dentistry, where the same technology can be applied to rigid bony structures. Unlike in brain surgery, complex cutting planes require that more attention is given to 3D visualization and corresponding user interfaces. On the other hand, the (mathematically) complex shape of the bony structures gives the opportunity to use synthetic templates and personalized equipment and prostheses without the need for a navigation system. An overwhelming number of products and services is currently being offered by several companies for a diversity of applications, such as personalized dental implants and prostheses with immediate function, distraction osteogenesis and orthognathic maxillofacial surgery with soft tissue simulation, and knee replacement surgery with kinematic analysis for an optimally balanced leg alignment.

While surgery planning is mostly performed on pre-operative images, intra-operative imaging is not new. Examples are laparoscopy, endoscopy, angiography for vascular repermeabilization, fluoroscopy for osteosynthesis in traumatology, and ultrasound imaging for biopsies and for abscess drain. Computer-based interventional imaging, however, such as CT for stereotactic craniotomy and MR imaging for thermotherapy are more recent but already proved their relevance. Intra-operative imaging is particularly useful in case of expected tissue deformation between pre-operative imaging and surgery, which is the case for most interventions on soft tissue.

Besides for diagnosis, intra-operative imaging can also be useful for the registration of pre-operative images and planning data with the surgical instruments. Examples are the automatic fusion of pre-operative CT images with intra-operatively acquired fluoroscopic images for percutaneous localization of the spine, or with 2D portal images for accurate positioning of the prostate prior to radiotherapy. After registration, the intra-operative images can also be visualized together with the pre-operative images, planning data, and tracked instruments into a single integrated image, known as augmented reality.

It can be expected that interventional imaging will become increasingly important in the future.

Learning Objectives:

1. To become familiar with the opportunities of medical imaging for therapy and surgery.
2. To learn the principles underlying the techniques of image guided interventions.
3. To comprehend the capabilities and technical limitations of image guided therapy and surgery.

Pulmonary circulation: From old to new imaging modalities

L. Bonomo; Rome/IT

The lung is the only organ where vessels (arteries and veins) are visualized without contrast administration.

Since the advent of spiral CT and MR the chest radiograph has been the only non-invasive imaging modality for evaluating the pulmonary vessels.

The gravitational distribution of pulmonary blood flow, a fundamental observation made in 1927 by Bjure and Laurell, represented and still represents the fundamentals of functional radiology.

Computed tomography and magnetic resonance, thanks to angiographic and functional techniques, have increased the potentials of non-invasive imaging of the pulmonary vessels.

Rapid technical developments of CT and MR allow the radiologist to achieve a qualitative morphologic and quantitative functional evaluation of pulmonary perfusion so that the role of angiography and V/Q scintigraphy can be significantly reduced.

Learning Objectives:

1. To get familiar with the different imaging modalities available for evaluating the pulmonary circulation.
2. To learn about the different roles of chest radiography, CTA, MRA in the diagnosis of pulmonary vascular diseases.

A-360

"Oriental Pearls" in oncology imaging: Imaging-pathologic correlation of early cancer in gastrointestinal tracts (Introduction)

T. Ishigaki; Nagoya/JP

The number of cancer deaths in 2002 in Japan was 304,286, and the death rate per 100,000 was 241.5, accounting for 31.0% of the total number of deaths. Lung cancer is the most common, accounting for 22.0% of all cancer deaths for males, followed by stomach cancer with 17.8% and hepatic cancer with 13.0%, while stomach cancer is the most common for females with 14.8%, followed by lung cancer with 12.7% and colon cancer with 10.1%. The number of deaths from cancer of pancreas and biliary tract is also increasing. Stomach cancer and uterine cervix cancer which used to be major causes of death among the Japanese now show decreasing trends, indicating that the advance of medical technologies such as early detection and early treatment is also a relevant factor. In this session imaging-pathologic correlation of early cancer in upper abdominal organs is presented and efficacy of imaging modalities including CT and MR imaging is discussed. Four Japanese diagnostic radiologists will present excellent papers: Early gastric and colonic cancers, early hepatic carcinoma, early-stage pancreatic cancer and early cancer of the biliary tract. It is sure that remarkable progress of the diagnostic imaging of an early cancer can be introduced.

Learning Objectives:

1. To learn "What is early cancer?"
2. To learn the correlation between pathology and diagnostic imaging in early cancer of gastrointestinal organs.
3. To understand the role of CT, MR imaging, and other diagnostic imaging modalities for the detection and diagnosis of the gastrointestinal organs.

A-361

Early gastric and colonic cancers

Y. Imai; Isehara/JP

Though the mortality from gastric cancer has slightly decreased recently in Japan, the incidence of gastric cancer is still high. While the morbidity of colorectal cancer is increasing year by year, because of the change in eating habits to western style.

Cancer detection in the gastrointestinal tract is mainly performed by double contrast radiography (DCR) and optical endoscopy. Recently, virtual endoscopy (VE) from the data of multi-slice CT has also been utilized. In Japan, the key point for the reliable modality in cancer detection is how to pick up the superficial depressed cancer of the stomach and superficial type cancer of the colon. Recently developed multi-slice CT can evaluate such a superficial type tumor, which is even difficult to diagnose by optical endoscope.

Accuracy of the tumor staging in early gastric and colorectal cancers by DCR is more than 90%, however lower percentages are achieved in advanced staged tumor. MR imaging using an endorectal coil provides a more accurate preoperative assessment of tumor staging for rectal cancers. Intramural tumor invasion confined to the intestinal wall was best evaluated on T2-weighted images. In 45 out of 55 cases (81.8%) of rectal cancers including in both early and advanced stage, MR imaging led to the correct diagnoses on the extent of tumor infiltration. MR imaging findings correlated well with the pathological in terms of macroscopic growth pattern, depth of mural invasion and other histological features. Computer aided diagnosis (CAD) using the volume data of multi-slice CT for the detection of gastric and colorectal cancers will develop in near future.

Learning Objectives:

1. To comprehend the role of DCR, VE and MR imaging for the diagnosis of the early gastric and colorectal cancers.
2. To understand the clinical significance of superficial type cancer in the stomach and colon in Japan.
3. To learn the radiological findings of the superficial type early gastric and colorectal cancers obtained by DCR and VE.
4. To understand MR imaging findings of normal layering structure of the intestinal wall and the diagnosis of tumor staging.

A-362

Early hepatocellular carcinoma: Imaging of multi-step hepatocarcinogenesis

O. Matsui; Kanazawa/JP

In Japan, around 31 deaths/100,000/year due to hepatocellular carcinoma (HCC) are seen and around 95% of them are due to hepatitis C (80%) or B (15%) virus infection. By periodic imaging of high-risk patients it has become possible to detect small, early stage HCC. In addition, multi-step development of HCC from adenomatous hyperplasia (AH, low-grade dysplastic nodule), atypical AH (high-grade dysplastic nodule), early HCC (highly well-differentiated HCC), well-differentiated HCC, to HCC with ED.II or above (classical HCC) has been clarified.

The pathologic and imaging features of early HCC are a small nodule with indistinct margins, occasional fatty metamorphosis, arterial hypovascularity, internal portal tracts or portal flow and isointensity on T2-weighted images. However, because of the histological continuity among these nodules, the precise imaging diagnosis of early HCC is often difficult. Therefore, understanding the sequential changes of imaging features during hepatocarcinogenesis is important.

In the course of hepatocarcinogenesis, both arterial and portal supply decrease first due to decreased portal tracts (borderline lesion), then arterial supply returns to the equivalent of the surrounding liver due to newly formed abnormal arteries (early HCC), while the portal supply continues decreasing, and finally the portal supply vanishes and only arterial blood supplies the lesion (classical HCC). Signal intensity on T2-weighted images also shows sequential changes from hypointensity (borderline lesion), isointensity (early HCC) through to hyperintensity (classical HCC).

Because there was intense correlation between the imaging features and prognosis of the nodules, it has become possible to estimate the grade of malignancy of the nodules by imaging.

Learning Objectives:

1. To understand the screening system of small early-stage HCC.
2. To understand the concept of multi-step human hepatocarcinogenesis
3. To know the sequential changes of pathological and imaging features during multi-step hepatocarcinogenesis.
4. To understand the imaging features and their pathological background of early HCC.

Early-stage pancreatic cancer

H. Mori; Oita/JP

During the past decades, the incidence of pancreatic cancers has increased in Japan, and it has become the 5th most common cause of death from cancer. About 18,000 new patients have been found every year. Only 10% to 15% of patients have resectable disease with negative surgical margin and postoperative median survival of 12 to 18 months was unfavorably short. The early-stage cancers may be defined as the margin-negative tumors when they underwent pancreatic resection. This means tumors with invasion to extrapancreatic nerve plexuses, to roots of peripancreatic mesenteries, and to the superior mesenteric-portal venous axis are excluded. The modern role of pancreatic imaging is to evaluate these criteria of local invasiveness as well as metastases to discourage unnecessary surgery. For the assessment of peripancreatic veins, contrast-enhanced CT including multiplanar images on multidetector CT is essential rather than angiography. Observation of peripancreatic veins such as the inferior pancreatic vein leads to diagnosis of cancerous involvement of extrapancreatic nerve plexuses and peripancreatic mesenteries. Differentiation from mass-like chronic pancreatitis or focal-appearing autoimmune pancreatitis became important because a fairly large number of pancreatic resections had been undertaken for these non-malignant diseases. There may be some characteristic contrast enhancement patterns over the time of pancreatic cancer and benign fibrosis that are recognizable on multiphasic CT, which are influenced by microvessel density and fibrosis. For future perspectives, the establishment of screening system such as fecal DNA analysis, clinical installment of new serum tumor marker, and image-guided pancreatic biopsy with p53/Ki-ras staining are essential for detection of the early-stage pancreatic cancer.

Learning Objectives:

1. To comprehend the role of CT including multidetector CT, and MR imaging for the diagnosis of the early-stage pancreatic cancers.
2. To learn the radiological findings of the early-stage pancreatic cancers obtained by CT.
3. To learn CT finding of invasion of pancreatic cancer to the extrapancreatic neural plexuses, roots of small bowel mesentery/ transverse mesocolon.
4. To learn normal anatomy of peri-pancreatic veins, peripancreatic lymphatic drainage pathways to understand the tumor staging.
5. To learn differential diagnosis between pancreatic cancer and focal pancreatic fibrosis or pancreatitis on multiphasic CT or MR imaging study.
6. To understand the recent development of gene/DNA level researches about tumor aggressiveness of pancreatic cancer and possibility of their clinical installment.

A-364

Early cancer in biliary tract

S. Hirohashi; Nara/JP

The early detection of gallbladder or bile duct carcinoma is considered to be difficult because it seldom shows any symptoms except for carcinoma of the papilla Vater. Although various kinds of non-invasive therapy have recently been developed for other carcinomas, complete resection as the classical surgical treatment is the only curative treatment available, and there is no effective evidence-based non-invasive therapy like radiotherapy or chemotherapy for gall bladder or bile duct carcinoma. However, a good prognosis can be expected if complete resection can be carried out, making early detection of these carcinomas by imaging diagnosis mandatory. In Japan, abdominal ultrasonography has become routine in medical checkup screening, and consequently early carcinoma, especially adenocarcinoma in adenoma, is being picked up increasingly frequently. In this lecture, I will talk about the pathology and tips on imaging diagnosis for three major early carcinomas (gall bladder carcinoma, bile duct carcinoma, and carcinoma of the papilla Vater) by various imaging modalities focusing on the practical radiological aspects.

Learning Objectives:

1. To understand the clinical significance of superficial type cancer in the gall-bladder and bile duct carcinoma in Japan.
2. To learn the EUS or IDUS findings of normal layering structure of the gall-bladder and bile duct wall and the diagnosis of tumor staging.
3. To understand the imaging features and their pathological background of early gallbladder and bile duct carcinoma.
4. To comprehend the role of EUS, IDUS and other imaging modalities for the diagnosis of early gallbladder and bile duct carcinoma.

Cervical spine trauma

D.J. Wilson¹, C. van Kuijk²; ¹Oxford/UK, ²Nijmegen/NL

Cervical spine fractures are common and account for 65% of spinal fractures and occur in 3% of major trauma victims. The increased availability of fast helical CT and MR imaging have changed the sensitivity, accuracy and precision of imaging and now should be routine tools.

The role of screening is to detect or exclude both fractures of bone and ligament/disc injury that would lead to instability.

Different approaches to fracture detection using plain films, CT and MR imaging will be discussed covering the pitfalls, strengths and weaknesses of each protocol. Severe cord damage may be present with normal plain films and CT examinations. Most teams will await recovery of consciousness and reduction of pain before attempting to study for instability.

Whiplash injuries may show little on imaging despite the severity and chronicity of the symptoms.

MR is the primary technique in determining the nature of cord and neurological damage.

Fracture patterns include:

- Compression fractures
- Burst fractures
- Combined transverse and ligamentous fractures (Chance)
- Spinous process avulsion fractures (Clay Shoveler's)
- Odontoid peg fractures.
- Lateral mass dislocation due to C1 axial loading fractures (Jefferson)
- Facet fractures and dislocations.
- Avulsion fragments.

Imaging will have a role in planning treatment. CT is the best technique for most cases but MR will have a vital role when there is suspicion of cord damage.

Learning Objectives:

1. To recognise the need for screening for cervical spine injury.
2. To understand the role of imaging in the screening process.
3. To appreciate the benefits and limitation of plain films.
4. To be aware of the value of CT and MR imaging in screening for injury.
5. To recognise fracture and injury patterns.
6. To understand how imaging influences management and treatment.
7. To understand the pitfalls of imaging interpretation.

A. Degenerative disorders of the spine

M. Gallucci; L'Aquila/IT

The widespread prevalence of patients with back and neck pain makes the spine one of the most frequently radiologically investigated areas, having a significant impact on health care costs. Some authors estimate that up to 80% of all adults have low-back pain at some time in their lives and that a herniated nucleus pulposus is the cause of only a small percentage of these cases.

Pathology and imaging of degenerative spine disease will be discussed starting from normal age-related changes of the intervertebral disc and vertebral body. Interventional radiology also offers several possibilities in therapy, with percentage success rate ranging from 65 to 75%. Minimally invasive procedures such as CT or fluoroscopy-guided radiofrequency discoplasty, O₂-O₃ or corticosteroid in-

Postgraduate Educational Programme

tradiscal and periganglionic injection will be specially discussed. Differential diagnosis from other forms of back pain is also mandatory in order to discriminate further forms susceptible to interventional therapy, like facet syndromes treatable by peri-facet steroid injection, synovial cysts, by evacuation and steroid injection, sacro-ileitis, by intra-articular steroid injection.

The interventional approach can be also successfully widely proposed in cases of osteoporotic (or tumoral) vertebral fractures and vertebroplasty is a progressively growing therapeutic challenge.

Learning Objectives:

1. To understand pathophysiology and classification of normal aging and degenerative diseases of the spine.
2. To become familiar with diagnostic radiology main indications and techniques.
3. To discuss the usefulness of dynamic conventional exams and axial loaded dynamic MR and CT studies.
4. To introduce to interventional radiology in the management of disk and vertebral diseases.

A-367

B. Tumors of the spinal canal

D. Balériaux¹, J. Brotchi¹, I. Salmon¹, W. Fang²; ¹Brussels/BE, ²Shanghai/CN

Early diagnosis plays an important role in the management of tumors of the spinal canal and affects the prognosis and final outcome of the patient. Tumours involving the spinal canal are mostly epidural malignant lesions, predominantly metastases. Intracanalar extramedullary tumors are on the contrary mostly benign and consist of meningiomas and schwannomas. Their prognosis is excellent. Intramedullary tumors are rarer but should be diagnosed early as their prognosis depends largely not only on histology but also tumour size. MR imaging has definitely become the imaging modality of choice for the investigation of the content of the spinal canal. 3D CT on the contrary is the optimal modality for evaluating the bony components of the spine.

Spinal cord tumours occur at any age but are commonly seen in children and young adults. Clinical presentation of spinal cord tumours is poorly specific, with pain surprisingly being the most common and frequently the first symptom. According to tumour localisation, sensory and motor deficits, urinary and sexual disturbances occur, the latter developing usually late in the course of the disease. Astrocytoma, ependymoma and hemangioblastoma account for more than 75% of the lesions: the radiologist may play a key role in trying to differentiate these lesions as surgical approach and final prognosis are different. The differential diagnosis includes uncommon tumours (cavernoma, ganglioglioma, oligoastrocytoma, metastases) as well as inflammatory/infectious mass lesions that do not necessarily require surgery.

Learning Objectives:

1. To be able to perform optimal imaging procedures to diagnose rapidly and efficiently tumors of the spinal canal.
2. To make a differential diagnosis between extracanalar lesions versus intracanalar extradural and intracanalar intramedullary tumors.
3. To become familiar with the differential diagnosis of intramedullary space occupying lesions.

A-368

C. Infectious disease of the spine

E.T. Tali; Ankara/TR

Spinal infection is a significant cause of morbidity and mortality and has an increasing prevalence amongst the general population. Definitive diagnosis based solely on clinical grounds is usually not possible and radiological imaging is used in almost all patients. Spinal infections can be categorized into three groups according to the involved compartment:

1. Extradural infections (osseous spine, epidural space, facet joints, and paraspinal soft tissues)
2. Intradural extramedullary infections
3. Intramedullary infections

Spinal infections are pyogenic, granulomatous, parasitic, viral and, fungal in origin. The incidence is largely dependent on the involved compartment and immunological status of the patient. Epidural and intradural extramedullary infections are most often pyogenic, whereas intramedullary infections are usually caused by viral agents. Infections of each compartment have distinct imaging findings and differentiation can be made by the use of these characteristic imaging patterns. MR imaging has become the modality of choice with its higher sensitivity for the intradural infections than plain X-rays and CT. Contrast administration is essential for the diagnosis. Contrast administration increases the sensitivity but does not affect the specificity and is also useful for the treatment monitoring. Mass-like lesions are seen for epidural infections while different patterns of me-

ningeal contrast enhancement are characteristic for meningitis-arachnoiditis. Fusiform enlargement of the spinal cord with signal change on T1- and T2WI, with/without contrast enhancement is the usual imaging findings of the myelitis. Neoplasms, nonbacterial granulomatous diseases and acute ischemic cord lesions should be considered in the differential diagnosis.

Learning Objectives:

1. To learn briefly about the classification, prevalence, etiology and clinical features of spinal infections.
2. To become familiar with the algorithm and the latest imaging techniques.
3. To learn the basic imaging findings and also imaging hints and tips of epidural, intradural and intramedullary spinal infections.
4. To discuss the imaging findings of different causative agents.
5. To get an overview of differential diagnosis.
6. To get an idea of the latest researches on the spinal infections.

Pulmonary hypertension:

All that the radiologist needs to know

Moderator:

D. Musset; Clamart/FR

A-369

Pulmonary hypertension: All that the radiologist needs to know (Introduction)

D. Musset; Clamart/FR

During the world symposium on PPH in Evian in 1998, a group of specialized physicians was selected by the WHA to make a more physiopathological classification of PPH than the preceding ones. My colleague, Prof. Gerald Simonneau, will explain to you this new classification which was revisited and simplified in 2003.

Among the different diseases included, major knowledges and improvements were done during the past few years for the diagnosis and treatment of two types of vascular entities.

Prof. Martine Rémy-Jardin will focus his talk on chronic thrombo-embolic disease and demonstrate the role of imaging methods for the diagnosis and pre operative staging of this disease.

Dr. Arnaud Resten on the sporadic unexplained PH. He will try to show you the difference of this last presentation with other clinically similar diseases which are the veno occlusive disease and the capillary hemangiomatosis because of the therapeutic implications.

Learning Objectives:

1. To learn the new classification of PPH from the WHO.
2. To understand the clinical presentations of the different types of this disease.
3. To comprehend the indications of imaging methods for the diagnosis and pre operative staging of the chronic thrombo-embolic disease.
4. To become familiar with the different radiological presentations of primary pulmonary hypertension and their consequences on prognosis and treatment of this entity.

A-370

Pulmonary hypertension: Classification, clinical data

G. Simonneau; Clamart/FR

In 1998, during the Second World Meeting on pulmonary hypertension held in Evian, a clinical classification of PH was proposed. The aim of the Evian classification was to individualize different categories sharing similarities in pathophysiological mechanisms, clinical presentation and therapeutical options. The Evian classification is now well accepted and widely used in clinical practice especially in specialized centers. In addition, this classification has been used by the Food and Drug Administration and European Agency for Drug Evaluation for the labeling of newly approved drugs in pulmonary hypertension. In 2003, during the Third World Symposium on PH held in Venice, it was decided to maintain the general architecture and philosophy of the Evian classification. However, some modifications have been proposed, mainly: To abandon the term "primary pulmonary hypertension" and to replace it with "idiopathic pulmonary hypertension", to reclassify pulmonary veno-occlusive disease and pulmonary capillary hemangiomatosis, to update risk factors and associated conditions for PAH, and to pro-

Postgraduate Educational Programme

pose some guidelines in order to improve the classification of congenital systemic-to-pulmonary shunts.

Learning Objectives:

To update and learn on clinical classification of pulmonary hypertension.

A-371

Chronic thromboembolic disease

M. Rémy-Jardin, J. Rémy; Lille/FR

Among the various causes of pulmonary hypertension, the recognition of chronic thromboembolic obstruction of pulmonary arteries resulting in pulmonary hypertension is important since this condition is potentially curable by pulmonary endarterectomy. Several mechanisms are postulated to be responsible for the development of chronic pulmonary hypertension including the recurrence of acute embolic events, the incomplete resolution of treated thrombi leading to variable degrees of residual vascular obstruction as well as *in situ* thrombus propagation into pulmonary branch vessels. Clinically, the disease manifestation is similar to that of primary, idiopathic pulmonary hypertension, a condition associated with a disappointing management despite advances in pharmacotherapy and transplantation. Although the CT diagnosis of chronic thromboembolic disease relies on precise vascular features, the distinction between thromboembolic pulmonary hypertension and primary pulmonary hypertension may be sometimes difficult as *in situ* pulmonary artery thrombosis in patients with primary pulmonary hypertension may mimic occlusions of pulmonary arteries caused by thrombotic material of embolic origin. The purpose of this presentation is to review the most characteristic features of chronic thromboembolic disease as well as newly recognized abnormalities at the level of vessels and lung parenchyma. Updated CT angiographic protocols will also be reviewed in order to emphasize the current trends in dose reduction and optimization of administration of contrast medium in this subset of patients.

Learning Objectives:

1. To describe and illustrate the transition between acute and chronic pulmonary embolism.
2. To review the characteristic CT features of chronic thromboembolic disease.
3. To discuss recent advances in multislice CT technology and their application in routine clinical practice when evaluating patients suspected of having thromboembolic pulmonary hypertension.

A-372

Primary pulmonary hypertension

A. Resten; Clamart/FR

Pulmonary hypertension (PHT) is defined as a mean pulmonary artery pressure above 25 mmHg at rest with a normal pulmonary artery wedge pressure (< 12 mmHg) measured by right heart catheterization. Primary pulmonary hypertension (PPH) is an idiopathic condition at the precapillary level that occurs in the absence of an embolic source or any other identifiable cause such as cardiac shunt, toxic insult or interstitial lung disease. It is a rare condition, with an estimated prevalence of 1-2 per million people. The natural history of PPH is usually progressive and fatal. Pulmonary arterial hypertension with associated conditions can be brought closer. Pathologic confirmation is rarely required and diagnosis is most often posed on the conjunction of an evocative clinical presentation, hemodynamic data and complementary examinations, intended to eliminate the great "causes" of pulmonary hypertension.

Imaging can show nonspecific aspects of pulmonary arterial hypertension, but its main interest is to eliminate secondary causes of hypertension. It is particularly helpful to eliminate a pulmonary venoocclusive disease (PVOD), contraindicating the medical treatment of PPH by prostacyclin, harmful and occasionally fatal in PVOD.

So, in a first part of this presentation, we will review imaging findings of PPH and pulmonary arterial hypertension with associated conditions, dominated by enlargement of pulmonary arteries. In a second part, we will review imaging findings of PVOD and particularly thin-slices CT findings, dominated by ground glass opacity, septal lines and adenopathy.

Learning Objectives:

1. To understand the role of imaging, and particularly CT in the management of primary pulmonary hypertension.
2. To become familiar with radiological findings of primary pulmonary hypertension.
3. To learn the principles underlying the techniques used by radiologists in the management of primary pulmonary hypertension.

Room E1

Breast

RC 1602

Radiopathological correlation

Moderator:

I.M. Ramos; Porto/PT

A-373

A. Tumoral growth

T. Tot; Falun/SE

Most pathologic processes in the breast originate in the terminal ductal-lobular units (TDLUs) of one sick lobe. The affected TDLUs are distended, distorted or destroyed by accumulation of fluid, mucin, cancer cells, necrotic debris or calcium in the lumina or by accumulation of collagen, glycoproteins or stromal cells in the intralobular stroma. All these processes lead to a considerable enlargement of the TDLUs. In neoplasia, the largest diameter of the largest invasive focus is considered to be the *tumor size*. If the pathologic process involves a single or a few neighboring TDLUs, a *unifocal* lesion develops. If the process simultaneously involves distant TDLUs, leaving uninvolved TDLU-s in between, a multiple (*multifocal*) lesion develops. Lesions developing from a large number of simultaneously involved TDLUs may exhibit a *diffuse* growth pattern, often losing their lobulocentricity in an advanced stadium. The entire area of the present invasive and *in situ* tumor foci is referred to as the *extent of the disease*. Within this area, a considerable *intratumoral and intertumoral heterogeneity* is often observed. All these morphological parameters are dynamically changing over time: The size increases, an initially multifocal lesion may become unifocal by coalescence of the tumor foci or an initially unifocal lesion may become multifocal as new independent foci develop. This *progression* is related to the age of the patient and to the histological type and grade of the tumor. The progression may also be altered by *dedifferentiation* of the tumors during their growth as well as by effective medical interventions.

Learning Objectives:

1. To discuss the different growths of breast tumors.
2. To discuss the tumoral growth timing (enhance problems linked to litigation) and its correlation to imaging (enhance mammography and ultrasound).

A-374

B. Size and vascularity

J. Teubner; Mannheim/DE

The tumor size is recorded as one of multiple prognostic data of breast carcinoma. Gold standard is the measurement on the excised specimen and that obtained on histological preparation. The invasive part, accompanying intraductal components, multifocal satellites and multicentric growth have to be documented, if present.

The nearest distance of tumorous spread towards the excision margin may be important in determining the risk of recurrence. Preoperative imaging is therefore essential for the surgeon's choice on an optimal pathway of excision. In this field mammography, ultrasound and magnetic resonance have specific strengths and limitations in cancer visualization. Since the methods provide complementary tissue information, a multimodal approach will give best results, even though in many cases one method alone presents already all diagnostic information which will not be gained by the others. Parameters affecting the diagnostic value are: Tumor size, histomorphological entity, macroscopic growth pattern, vascularity, presence of microcalcifications and tissue composition of the surrounding tissue. Major imaging differences become apparent in the evaluation of tiny tumors and the estimation of potentially extensive intraductal component in invasive (EIC) or *in situ* carcinoma (DCIS). Postoperative specimen sonography and/or thin sectioning with consecutive specimen radiography are helpful tools in the interdisciplinary approach on the evaluation of the "real" tumor size. Both methods invaluable assist the pathologist in the assessment of the specimen's margins.

Vessel density, permeability and perfusion characteristics differ from benign to malignant lesions. With upcoming contrast agents further tumor characteristics may be evaluated by Doppler sonography and contrast-enhanced MR imaging.

Learning Objectives:

1. To discuss which is the real size of breast cancer, including multifocality and multicentricity.
2. To discuss the potential of the imaging methods in assessing the "useful" tumoral size.
3. To discuss the vascularity of breast cancer as assessed by non radiological and imaging methods.

Postgraduate Educational Programme

A-375

C. Nodal invasion
G. Rizzatto; Gorizia/IT

The principal route whereby most carcinomas migrate to distant tissues, is via the lymphatics. Therefore nodal invasion is a very important determinant in breast staging.

This evaluation is mostly based on the sentinel node (SLN) concept: The efferent lymphatic channel draining a primary tumor leads directly to the first SLN in the regional lymphatic basin.

To better detect the SLN the use of a radiolabeled colloid at preoperative lymphoscintigraphy and intraoperative detection with gamma-ray detection probe have been incorporated into the traditional blue dye protocol. Actually this is the gold standard with a technical success rate of 88%, sensitivity of 93% and accuracy of 97%.

Based on these excellent results many centers perform the axillary dissection only if sentinel nodes are not found or if positive nodes are found at physical examination.

Incorporating ultrasound in the preoperative evaluation of nodal chains may avoid SLN procedure in over 20% clinically node-negative patients. Contrast agents allow perfusion studies that increase the sensitivity for small nodal metastases and allow useful monitoring in locally advanced breast cancers.

Recent studies show interesting potentials also for PET and MR lymphography. In the near future nodal staging will include also molecular imaging with optical and near-infrared probes.

Learning Objectives:

1. To discuss the pathways of nodal invasion.
2. To discuss the potential of the imaging methods in assessing nodal invasion.
3. To propose a cost-effective flow chart.

Thoracic manifestations of extra-thoracic disease

Moderator:
L. Bonomo; Rome/IT

A-376

A. Lung nodules in patients with extra-thoracic neoplasia
S.R. Desai; London/UK

In patients with a known primary extrathoracic malignancy, staging investigations will commonly include an examination of the chest. Whilst most patients will be referred for a plain chest radiograph, there is a limit to the size (typically around 1 cm diameter) of pulmonary nodules detectable by conventional radiography. Because the contrast resolution of computed tomography (CT) is higher and there is no anatomical superimposition, small intrapulmonary nodules will frequently be identified; this is particularly true since the advent of spiral and now, multidetector-row CT machines. However, determining the significance of focal intrapulmonary nodules, in patients with a known malignancy, remains a vexing problem for the radiologist and clinician. The significance of imaging findings (specifically at CT) in patients with underlying malignancy will be discussed. The relevance of multiplicity, size of pulmonary nodules, the presence/absence of an underlying malignancy and the smoking history will be reviewed.

Learning Objectives:

1. To understand the capabilities and limitations of imaging studies in the detection of focal pulmonary lesions.
2. To determine the significance of intrapulmonary nodules in patients with underlying extrathoracic malignancy.
3. To appreciate the potential importance of the multiplicity and size of pulmonary nodules in patients with known extrathoracic malignancy.

A-377

B. Collagen vascular disease
T. Franquet; Barcelona/ES

The connective tissue diseases are a heterogeneous group of immunologically mediated disorders in which the lungs are an important target organ due to their abundant connective tissue. The most common form of diffuse pulmonary lung disease in patients with collagen vascular disorders is a chronic pulmonary fibro-

sis indistinguishable from other causes of usual interstitial pneumonia (UIP). Rarely, the chronic pulmonary fibrosis may precede the extrapulmonary manifestations of the disease. Other complications of the connective tissue diseases include esophageal dysfunction leading to recurrent aspiration and secondary infection (in scleroderma and mixed connective tissue disease), respiratory muscle weakness contributing to atelectasis and secondary infection (in systemic lupus erythematosus, polymyositis) and drug-induced lung disease (methotrexate and gold treatment in rheumatoid arthritis). Because the pathology of chronic interstitial pneumonia takes a limited number of forms, there are also a limited number of radiographic manifestations. Although of limited value in detecting early stages of disease, conventional chest radiography still remains an invaluable aid in documenting the presence of ILD. Currently, high resolution computed tomography (HRCT) is the imaging method of choice in evaluating patients with ILD.

Learning Objectives:

1. To summarize the HRCT features in collagen vascular diseases.
2. To describe some complications associated with collagen vascular diseases.
3. To learn key points in distinguishing collagen vascular disease from other infiltrative lung diseases.

A-378 ♀

C. Multisystem vasculitides
K. Malagari; Athens/GR

Multisystem vasculitides are a group of diseases characterised by chronic inflammation of the vessel walls. Clinical and immunological overlaps are very common, while the aetiology is unknown (primary). The dominant classification system today of primary non-infectious systemic vasculitides is based on the 1994 Chapel Hill International Consensus Conference, classifying vasculitides according to vessel size predominantly involved into: large-vessel vasculitis (Giant cell arteritis, Takayasu arteritis), medium-sized vessel vasculitis (polyarteritis nodosa, Kawasaki's disease), and small-vessel vasculitis. The latter group is further subclassified according to ANCA positivity into: microscopic polyangiitis arteritis, Wegener's granulomatosis, Churg Strauss syndrome (ANCA positive) and ANCA negative group including, Henoch Schonlein purpura, cryoglobulinemia and cutaneous leucoclastic angiitis.

Despite the considerable overlap, small vessel vasculitides are more often manifested by alveolar hemorrhage associated with increased permeability of the small lung vessels, while moving to larger vessel involvement, manifestations are associated with weakening and inflammation of the vessel walls forming aneurysms, stenosis, occlusion and infarcts.

HRCT features, criteria to establish the diagnosis and differential diagnosis will be discussed.

Learning Objectives:

1. To discuss about anatomic features of pulmonary microcirculation and differentiate between occlusive and inflammatory vasculopathies.
2. To review HRCT, and histologic features of entities in which pulmonary vasculitis is the central pathologic process including Wegener's granulomatosis, Churg-Strauss syndrome, and pulmonary capillaritis.
3. To describe HRCT manifestations of pulmonary involvement in other systemic vasculitides: Giant cell arteritis, Takayasu's arteritis and Behcet's disease.
4. To discuss the differential diagnosis of pulmonary haemorrhage, and anti-glomerular basement membrane disease.

Inflammatory joint disease

Moderator:
V. Jevtic; Ljubljana/SI

A-379

A. Plain film analysis
M. Cobby; Bristol/UK

Imaging studies may be performed in patients with suspected or definite arthritis to:

- determine the presence of an arthritis
- establish a diagnosis
- determine the extent of disease

Postgraduate Educational Programme

- assess disease activity
- evaluate progression
- select patients for surgery
- determine the type of surgical procedure

This talk will concentrate on the radiological differential diagnosis of an inflammatory arthritis. This is achieved most effectively by:

- determining what tissue within a joint is primarily affected
- identifying which joints are involved

For a radiological analysis there are essentially three sites of involvement within a joint that can be differentiated:

- the "bare" area, where synovium directly contacts bone
- hyaline cartilage and the immediate subchondral bone
- the enthesis

Once the principal site of involvement has been determined a series of further questions need to be asked:

- A. Synovial disease. Symmetrical or asymmetrical soft tissue swelling? Erosions: Well-defined, ill-defined, proliferative or non-proliferative?
- B. Cartilage disease. Loss of cartilage, thickening of cartilage or calcification of cartilage? Secondary bone changes?
- C. Enthesal disease. Non-erosive or erosive? Symmetrical or asymmetrical involvement?

Using this combination of binary analysis in conjunction with the distribution of joint involvement a specific diagnosis or short differential diagnosis of an arthritis can usually be made.

Learning Objectives:

1. To provide an overview of the radiographic features of the various inflammatory arthropathies.
2. To show how the changes within an individual joint enable the various arthropathies to be differentiated.

A-380

B. What's new in sero negative joint disease?

A.G. Jurik; Arhus/DK

The group of seronegative spondylarthropathies (SpA) encompasses ankylosing spondylitis, psoriatic, reactive, enteropathic, pustulotic and unclassifiable arthropathy. The prevalence of SpA is similar to that of rheumatoid arthritis, but they have not gained the same attention regarding imaging. The promising effect of new therapies, especially biological therapy, has made the need for accurate diagnosis and disease monitoring obvious.

The sacroiliac joints (SIJs) are involved in most forms of SpA, and an accurate diagnosis of sacro-ilitis is therefore important. MR imaging has proven valuable with regard to this, having a high sensitivity and specificity. However, the performance and interpretation of MR imaging of the SIJs demands knowledge about the normal joint anatomy and optimal technique. With such knowledge, it is possible to gain greater benefit from MR imaging. It can demonstrate both joint destruction and signs of disease activity, and is able to detect inflammatory SIJ pathology before it has resulted in osseous destruction visible at radiography and CT. Furthermore, MR imaging may be of help in differentiating between the different forms of SpA early in the disease, and provides the potential for monitoring disease severity during therapy. MR imaging can also be valuable with regard to the detection of early spinal lesions, in addition to evaluation of disco-vertebral or other lesions later in the disease. In the case of clinical signs indicating spinal cord compression, cross sectional imaging is always needed.

Learning Objectives:

1. To understand and recognise the features of normal sacroiliac joints (SIJ) at MR imaging and technical aspects.
2. To know the differentiation between SIJ involvement in the different forms of SpA.
3. To suggest a system for MR imaging grading of SIJ involvement to be used for monitoring disease.
4. To know the imaging features of spinal involvement in the different forms of SpA with emphasis on MR imaging.

A-381

C. What's new in rheumatoid arthritis?

P.J. O'Connor; Leeds/UK

MR imaging and ultrasound have an increasingly prominent role in the assessment of articular disease. Rheumatoid arthritis (RA) is a chronic inflammatory polyarthritis characterised by synovitis and joint destruction, particularly of the small joints. Studies have shown progression of joint destruction despite suppression of synovitis. Other studies indicate that despite no change in clinical

synovitis measures, certain therapies retard bone damage. More recently it has been demonstrated that the suppression of disease activity will slow or even halt progression of bone damage although there was poor correlation between clinical response and radiological change in these studies. Such clinical and radiographic observations, where synovitis and bone damage are seemingly independent processes, have been supported by experimental models of RA where joint damage may be uncoupled from synovitis. However, all studies have used either indirect or insensitive measures of synovitis and bone damage or have imaged complex joints such as the wrist which makes interpretation of any imaging findings difficult. An understanding of the inter-relationship between synovitis and bony damage is critical for the optimal management of patients, especially in determining a logical approach for drug treatment, and provides the model for all disease where chronic inflammation is a prominent feature.

This lecture focuses on the use of MR imaging and ultrasound in the assessment of rheumatoid disease with specific emphasis on the detection and potential impact of diagnosing sub-clinical synovitis, pre-radiographic erosion and complications. A list of relevant references will be provided.

Learning Objectives:

1. To appreciate the relationships between imaging abnormalities and the rheumatoid arthritis disease process.
2. To understand the diagnostic and therapeutic impact of imaging in the rheumatoid arthritis patient.
3. To understand potential pitfalls in employing new imaging modalities in inflammatory arthritis.
4. To be aware of the relevant literature regarding the use of MR and ultrasound in rheumatoid arthritis.

Imaging of skull base tumors: A practical approach for your daily practice

Moderator:

H.B. Eggesbø; Oslo/NO

A-382

A. Anterior skull base

R. Maroldi; Brescia/IT

Assessment of anterior cranial fossa floor neoplastic invasion has a great impact on surgical planning. Bone destruction of the skull base and dura mater invasion are key information provided by imaging techniques. CT shows bone destruction better, whereas MR is more precise in *grading* dural invasion, which implies a worse prognosis. A proper assessment requires the careful analysis of the signal intensities that compose a "sandwich" of signals corresponding to the bony floor of anterior cranial fossa, the overlying dura mater, and the CSF. On enhanced sagittal and coronal SE T1, when a sinonasal neoplasm abuts the cribriform plate interface, without interrupting its hypointense signal, the lesion should be considered limited to the ethmoid/nasal fossa. Replacement of the hypointense signal by tumor implies bone penetration. In this case, a thickened enhancing dura mater usually borders the neoplasm. If uninterrupted, the neoplasm may be graded as intracranial-extradural. Conversely, focal or more extensive replacement of enhanced thickened dura mater by tumor signal indicate intracranial-intradural invasion. Cerebral invasion is suspected in the presence of edema. Resectability of tumors invading the brain does not depend only upon the assessment by imaging of the depth of tumor extent into the brain or on the detection of bilateral brain invasion. It requires a thorough evaluation of several other issues, the most important being the histotype and patient's performance status. Patients with limited brain invasion treated by craniofacial resection are reported to have a non-significant decrease in survival compared to those with dural invasion only.

Learning Objectives:

1. To become familiar with the CT and MR techniques and how to use them in patients with suspected anterior skull base tumors.
2. To know the basic anatomy of the anterior skull base and to be able to identify anatomic variants.
3. To know the characteristic aspect of a variety of anterior skull base tumors and be able to provide a differential diagnosis.
4. To be able to recognize characteristic patterns of tumor spread.
5. To be aware of the therapeutic implications.

Postgraduate Educational Programme

A-383

B. Central skull base

S. Köslin; Halle a.d. Saale/DE

Anatomy: The primary component of the central skull base (CSB) is the sphenoid bone (basisphenoid, greater and lesser wing) with its sinus. A smaller contribution comes from the clivus. Apertures (superior orbital fissure; foramen ovale, rotundum etc.) and adjacent structures as the pterygopalatine fossa and the cavernous sinus are integral parts of the CSB. A key point is the knowledge of cross-ways between the extracranial and intracranial spaces.

Imaging technique: Both CT and MR imaging are often needed to study CSB lesions exactly. In CT examinations, the following general guidelines are recommended: slice thickness ≤ 3 mm; axial and coronal planes (as reformations in multi-detector CT); bone algorithms. A routine MR imaging examination of this area should include axial, coronal and sagittal images such as T1-weighted and T2-weighted sequences with a slice thickness between 3 to 5 mm. Intravenous contrast medium is used to evaluate the cavernous sinus and potential tumours. Contrast enhanced T1-weighted images are helpful in the demonstration of perineural spread. Nowadays angiography is mostly performed in combination with interventions.

Diseases of the skull base: Diseases of the skull base can be divided into intrinsic lesions and lesions affecting the skull base from adjacent spaces. The latter one will only be mentioned. In intrinsic lesions, the volume of the lesion is centred in the skull base. These lesions are rare. Normal variants, congenital, inflammatory, traumatic lesions, tumours and tumour like lesions will be demonstrated on typical examples. The diagnostic possibilities and their influence on the therapeutic strategy are discussed.

Learning Objectives:

1. To know the basic anatomy of the central skull base.
2. To become familiar with CT and MR imaging protocols in imaging of the central skull base.
3. To be able to recognize common central skull base lesions and be able to provide a differential diagnosis.
4. To be able to depict characteristic patterns of spread and the relationship of lesions to important anatomic structures.
5. To be aware of the therapeutic implications of imaging findings.

A-384

C. Temporal bone

F. Veillon; Strasbourg/FR

MR imaging and CT are both necessary for evaluating temporal bone tumors. Injection of contrast medium is performed in most of the cases: Primitive cholesteatoma and cholesterol granuloma never enhance.

The following will be considered; in the external auditory meatus (EAM): Polyps, granulomatosis, carcinoma; in the middle ear (ME): Glomus tumors, neuroma of the VII and VIIIth nerves, granulomatosis, extension of lesions from the EAM, jugular foramen (JF) and apex; in the inner ear (IE): Papillary tumors of the endolymphatic sac, extension of lesions from the ME, JF and apex. Primitive cholesteatoma (PC) are found in the EAM, ME, IE.

Other lesions in the skull base are; in the jugular foramen: Jugular glomus tumor (JGT), meningioma, mixed nerve neuroma; in the apex: Cholesterol granuloma, PC, vascular dysplasia, chondrosarcoma (CS), neuromas of the V and VIII cranial nerves, mixed nerve neuromas, meningiomas, extension of carcinoma from the adjacent pharynx and lateral pharyngeal space, sphenoidal sinus, pituitary gland adenoma, JGT. Bony temporal bone lesions include: Osteoma (EAM), chondrosarcoma (apex), giant cell tumors (apex), myeloma (apex), osteoblastoma (mastoid), fibrous dysplasia, Pagets. Finally metastases can occur from the following primaries: Oropharynx, breast, prostate, lung.

In most of the cases the etiologic diagnosis is possible.

Learning Objectives:

1. To learn the imaging techniques needed to detect tumors of the temporal bone.
2. To be able to recognize the most common temporal bone tumors and be able to differentiate them from non-tumorous pathology.
3. To be able to assess characteristic patterns of tumor spread and involvement of important anatomic structures located in immediate vicinity of the temporal bone.
4. To be aware of the therapeutic implications of imaging findings.
5. To learn how to report the imaging findings to the clinical colleagues.

Percutaneous access to the abdomen

Moderator:

I. Rozanes; Istanbul/TR

A-385

A. Biliary drainage

A. Adam; London/UK

Percutaneous biliary drainage has a high success rate and is preferable to endoscopic drainage in the case of hilar malignant strictures. Endoprostheses should be used in virtually all patients, in order to avoid the physical and psychological complications associated with external catheters. Self-expandable metallic biliary endoprostheses combine the advantages of a small track through the liver and a large lumen, which is less likely to become occluded by encrusted bile. Their insertion is less painful than that of plastic stents. The usual cause of obstruction is growth of tumor above or below the stent or through the stainless steel mesh, which forms the wall of the endoprosthesis. A very effective way of dealing with this problem is the insertion of a second stent overlapping with the first. Cost effectiveness analyses have shown that the cost of treatment is lower when using Wallstents than when using plastic endoprostheses, because of the lower rate of re-intervention. Benign biliary strictures should be treated with balloon dilatation, which often has to be repeated. Pigment stones often co-exist with benign strictures. They are best cleared with occlusion balloons or saline irrigation. Metallic stents should be used only as a last resort as they often become occluded by epithelial hyperplasia. Roux loops secured to the parietal peritoneum provide convenient access to the biliary tree in patients undergoing hepaticojejunostomy.

Learning Objectives:

1. To learn the indications for percutaneous biliary interventions.
2. To learn the principles of the main percutaneous radiological techniques used in the management of benign and malignant biliary strictures.
3. To understand the technical possibilities and limitations of biliary interventions.

A-386

B. Abscesses drainage

M. Bezzi; Rome/IT

Over the last 20 years, percutaneous abscess drainage (PAD) has evolved from revolutionary to routine, replacing surgical drainage in all but the most inaccessible cases. Even septated and viscous collections may be successfully treated, particularly with the use of lytic agents; however, the simpler the abscess, the more likely PAD will be rapidly successful. Pre-procedural work-up include evaluation of clinical conditions and imaging studies to make sure that percutaneous drainage is indicated and feasible. After consultation, further imaging may be indicated to differentiate abscess from other lesions or to assess the best approach. In our Institution US guidance is used in 80-85% of cases, while CT guidance is preferred in cases where US does not guarantee a safe access. Transperitoneal and extraperitoneal approaches as well as approaches through solid organs and abdominal viscera will be discussed. Post-procedural care include rounds every 2 days and sinograms every 3-4 days. Catheter removal should be performed after a sinogram has established abscess resolution. Strategies to enhance success will be discussed and consist of careful planning of best drainage site (most dependant portion, larger loculations, etc.), use of multiple catheters in complex conditions, use of fibrinolytic agents, mechanical removal of necrotic tissues from pancreatic collections, and establishment of permanent internal drainage in selected cases. Success rate is higher than 80-90%. Significant complications are rare and include bleeding and fistula formation with other viscera. The greatest complication risk for all catheter placement procedures remains catheter dislodgment and catheter occlusion due to poor post-PDA care.

Learning Objectives:

1. To understand the percutaneous approaches and imaging guidance techniques used in abscess drainage.
2. To discuss the follow-up strategies and the post-procedural care.
3. To critically analyze the results and the reason of an unsuccessful outcomes.

Postgraduate Educational Programme

C. Interventions in the renal pelvis and ureter

C. Allen; London/UK

Percutaneous renal tract interventions are carried out for a wide variety of indications, the most common being stone removal, relief of obstruction, tumour treatment and following trauma.

Successful and safe percutaneous access to the renal tract requires an appreciation of renal anatomy. Renal tract imaging using ultrasound and/or IVU [intravenous urogram] is acceptable for simple renal access but new MDCT [multidetector computed tomography] and MR [magnetic resonance] techniques are becoming necessary in order to plan complex interventions. The interventional anatomy of the kidney will be discussed along with the imaging features.

Simple access for temporary drainage of the renal tract will be briefly described followed by the indications and techniques for more complex access. This will include calyx selection and track dilatation using ultrasound and fluoroscopic guidance. Examples of renal access will be illustrated using cases of complex stone removal. The complications of such access and their treatment will be discussed.

Techniques of ureteric access will be described including access via conduits and the rendezvous procedure. Indications for and the technique of temporary and permanent stenting will be discussed. Cases illustrating ureteric interventions including the treatment of fistulas will be shown.

This lecture will review percutaneous intervention in the kidney and ureter. The important role of renal anatomy will be highlighted and various access techniques will be discussed including their limitations and complications. Each type of intervention will be illustrated using case presentations.

Learning Objectives:

1. To discuss the indications for complex percutaneous intervention of the kidney and ureter.
2. To describe the benefits of preoperative 3D imaging.
3. To describe the variety of techniques available.
4. To describe outcomes and complications.

Vascular

WS 1615

Imaging of atherosclerotic plaques

Moderator:

K.Y.J.A.M. Ho; Groningen/NL

A-388

A. CT and EBT for coronary plaque detection

F. Cademartiri; Rotterdam/NL

Electron beam tomography (EBCT) first and multislice computed tomography later (MSCT) have emerged as non-invasive diagnostic modalities that can quantify coronary calcium. The role of coronary calcium is well known, and in particular its association with cardiovascular risk and coronary plaque burden.

The most recent generations of MSCT scanners, able to scan 16 and up to 64 slices per rotation with high temporal and spatial resolution, allow non-invasive assessment of coronary plaques. This development creates an alternative to traditional plaque imaging modalities for in-vivo evaluation (e.g. intra-coronary ultrasound: ICUS).

MSCT has shown the ability to display, quantify, and characterize the various components of atherosclerotic plaque. Eventually, this could become the approach for the identification of vulnerable plaques.

A particular advantage of MSCT over ICUS is also related to its ability to visualise the entire coronary tree and its plaque (calcific and non-calcific) burden. This last concept could enter clinical practice as a predictor of outcome in several conditions.

In this scenario, though, several issues and limitations remain. The most important limitations are the ones that impair the successful completion of a MSCT coronary angiography (e.g. high and irregular heart rates). Additional limitations can be addressed regarding the radiation dose. In fact, thinking about extensive investigations of a population at high risk, for the purpose of plaque imaging the radiation dose currently necessary to obtain the information seems quite high.

Learning Objectives:

1. To understand the features of EBT and spiral CT images relevant for atherosclerotic plaque imaging.

2. To learn how to look and classify atherosclerotic plaques with EBT and CT.
3. To understand the potential use of EBT/CT based plaque imaging in clinical research.
4. To recognize the pitfalls of both techniques affecting plaque detection and characterization.

A-389

B. MR imaging of the vessel wall

R.H. Mohiaddin; London/UK

Cardiovascular disease is an important cause of worldwide mortality, accounting for almost 17 million deaths annually, predominantly through coronary and carotid artery disease. Cardiovascular magnetic resonance (CMR) provides quantitative assessment of plaque burden in a noninvasive manner. In addition, it provides tomographic assessment with consistent localization which enables identification of arterial remodeling over time. In this process, the external border of the artery expands and thickens well before luminal encroachment occurs, allowing tomographic vessel wall imaging to identify early atherosclerosis well before conventional luminal angiography. The main task of this talk is to introduce CMR as a non invasive tool for assessment of atheromatous vascular disease, describe the technical requirements for performing such studies including image resolution, sequence design and receiver coils, review common current applications and discuss advantages and limitations.

Learning Objectives:

1. To introduce MR imaging as an emerging non-invasive tool for vascular wall imaging.
2. To give an overview of the basic technical requirement and the MR imaging techniques commonly used for wall imaging.
3. To discuss advantages and limitations.
4. To review the current status for the main applications.

A-390

C. Molecular imaging of vulnerable plaques

I. Carrió; Barcelona/ES

Understanding of the biology of atherosclerotic plaques has led to the concept of plaque vulnerability. Such vulnerable plaques usually do not cause high-grade stenosis, they have a large lipid core and a thin fibrous cap that is often infiltrated by inflammatory cells. Rupture at the site of a vulnerable atherosclerotic plaque is the most frequent cause of acute coronary syndromes. Radionuclide imaging of vulnerable plaques is focused on targeting either the lipid cores, the macrophage infiltration or the proliferating smooth muscle cells. In vivo visualization of vulnerable plaques is feasible by SPECT and PET/CT.

Several components of the lipid pool have been radiolabelled for imaging of atherosclerotic plaques, including low-density lipoproteins, cholestry ester and apolipoprotein B, radiolabelled porphyrins, and antibody MDA2, which only recognizes oxidized LDL. Accumulation of radiolabelled porphyrins has also been demonstrated in the esterified cholesterol deposits.

Another important strategy for the imaging of vulnerable plaques is based on targeting of macrophages. Expression of scavenger receptors on plaque macrophages results in unlimited ingestion of modified LDL cholesterol. In addition, chemoattractant receptors and activation-dependent receptors are upregulated during diapedesis of monocytes. Iodinated monocyte chemotactic peptide MCP-1 has been used to evaluate the intensity of macrophage infiltration in experimental atherosclerotic lesions. Activation-dependent receptors such as Mac-1 may be targeted by radiolabelled LFA or ICAM or VCAM, and matrix metalloproteinase release can be targeted with radiolabelled inhibitors of metalloproteinases. Predicting outcome by plaque characterization should offer a new paradigm for the management of coronary artery disease.

Learning Objectives:

1. To understand the molecular targets in the atherosclerotic plaques.
2. To learn the different ligands for targeted imaging of atherosclerotic plaques.
3. To understand the potential role of PET and SPECT in imaging vulnerable plaques.
4. To review the current status of nuclear imaging of vulnerable atherosclerotic plaques.

A-391

A. Abdominal distension in the neonate

T. Berrocal; Madrid/ES

Radiological investigation is one of the most important sources of information in the evaluation of abdominal distension in the neonate, but the need for these examinations should be carefully weighed in order to avoid inconveniencing the patient, unnecessary exposure to radiation or delaying surgical correction. This lecture will present a general approach to neonatal abdominal distension and will discuss the most common specific causes, the indications as well as the diagnostic value of the commonly used modalities, giving some suggestions for an efficient imaging algorithm.

Intestinal obstruction is the most important cause of abdominal distension in the newborn period. The role of imaging may vary from helping to establish a diagnosis, to the evaluation of associated abnormalities, to surgical planning, or to therapy for some conditions like meconium ileus or meconium plug syndrome. Plain abdominal radiographs and sonography frequently can answer the most clinically important questions; however, in certain conditions contrast enema is mandatory. Only rarely is CT or MR imaging indicated.

Ultrasound is the best imaging modality to assess urinary tract dilatation causing abdominal distension, the result of this study guiding the selection of subsequent imaging modalities. Ultrasound is also suited to the screening of solid or cystic masses and organomegalias. CT and MR imaging are unsuitable techniques for general screening but they provide superb anatomic detail and add diagnostic specificity in the evaluation of complex anomalies and to plan surgery.

Learning Objectives:

1. To understand normal and abnormal gas distribution patterns in the neonatal gastrointestinal tract.
2. To discuss the embryological and pathological basis of conditions that cause abdominal distension in the neonate.
3. To describe the clinical manifestations and imaging features of selected abnormalities causing abdominal distension in the neonate and their differential diagnoses.
4. To describe the imaging appearance and to understand the merits and pitfalls of each imaging modality.

A-392

B. Imaging in neonatal distress

B. Smevik; Oslo/NO

Neonatal distress may be caused by a variety of different conditions related to the lungs, the heart, the diaphragm or the chest wall. Imaging procedures play an important role in diagnosing and monitoring respiratory distress, and although chest radiography is the most important diagnostic tool, sometimes additional imaging modalities like computed tomography, angiography, ultrasonography and magnetic resonance imaging may be needed. An overview of conditions causing neonatal distress will be given. Diseases typical of premature babies like idiopathic respiratory distress syndrome and conditions related to air leak, like pneumothorax and pneumomediastinum are explained. An open ductus arteriosus and persistent foetal circulation may be important factors in neonatal distress. Meconium aspiration, neonatal upper airway obstruction and pleural and pericardial effusions will be discussed. A special focus on the placement of the different tubes, catheters and drains needed for treatment is included. Chest wall abnormalities, abnormalities in lung development and in the diaphragm as well as important lung- and heart malformations responsible for neonatal distress are also presented. Imaging characteristics of the initial presentation as well as during and after treatment will be shown.

Learning Objectives:

1. To recognise the characteristic radiological presentations of the most important conditions resulting in neonatal distress.
2. To become familiar with the different types of air leak in the newborn.
3. To understand the influence of congenital heart disease on neonatal distress, and to comprehend the role of the adaption of the pulmonary circulation at birth.

A-393

C. The asphyxiated newborn: Role of new MR imaging techniques

E. Whithy; Sheffield/UK

Despite improvements in obstetric and paediatric practice and a major decline in neonatal death rate, neonatal asphyxia remains a significant problem.

Hypoxia/ischaemia is a significant cause of neurological damage arising in the pre and perinatal periods. Term infants with hypoxia/ischaemic brain injury have a better prognosis than the preterm infant. The pattern of brain damage depends on the maturity of the brain at the time of the insult, the severity of the insult and the duration of the damaging event. Selective vulnerability occurs in different parts of the brain depending on the gestational age.

MR imaging techniques allow accurate detection of the site of the lesion and pattern of damage. This is not only important for timing for the medico-legal environment but also for the understanding of the different aetiologies and future interventions.

Large prospective studies with consecutive scans and post-mortem data if appropriate will allow assessment of the newer novel MR techniques. Close collaboration of clinicians and radiologists is essential to obtain an accurate clinical history and examination findings to ensure any patterns of damage are appropriately attributed to the suspected aetiology.

Learning Objectives:

1. To clarify important issues about the timing of the MR examinations.
2. To understand that the clinical history helps predict the pattern of injury.
3. To understand the evolution of lesions with time.
4. To establish the optimum sequence and plane for identifying the recognised patterns of lesion.
5. To identify the clinical sequelae of each pattern of lesion.
6. To establish the role of newer techniques such as FLAIR, diffusion and perfusion weighted imaging in the examination of the asphyxiated neonate.
7. To discuss the effect of future developments on the choice of imaging sequences and their timing on lesion evolution and clinical outcome.

A. CT multitrauma protocol

P. Beyer-Jørgensen, A. Hartvig Sode; Odense/DK

Working at a hospital which is a trauma center, means that the staff involved in the trauma situation is able to work close together, and every one is aware of their function in the team. We are going to describe the admission of the traumatised patient, and follow the patient from emergency to the CT trauma scan. Within the last three years we have CT scanned traumatised patients with a new scan technique, where the patient is positioned in a trauma pillow, which is specially designed for the scanning of the traumatised patient. This meant a new way of thinking, and a new protocol for the scan procedure.

We will show the new protocol, and go over the detail of our results.

The new protocol is clearly time reducing and gives information of the traumatised patient from the top of the head to bottom of the pelvis. This information is gathered without changing the position of the patient.

As an additional bonus to the trauma scan, we visualize the vessels of the neck, because we scan with I.V. contrast in this area.

We will show scans made with this protocol, and go through our intentions behind the admission of the I.V. contrast, considering the patients condition.

Learning Objectives:

1. Admission of the traumatised patient
 - 1.1. To understand the A-B-C-D-E principle.
 - 1.2. To identify the importance of the trauma coordinator.
 - 1.3. To identify the importance of the golden hour.
2. A new scan technique on a multislice CT scanner.
 - 2.1. To identify the pro and cons in development of the trauma pillow.
 - 2.2. To see the challenge in development of a new protocol for the trauma patient.

Postgraduate Educational Programme

- 2.3. To understand the i.v. contrast administration for this protocol.
- 2.4. To identify the parameters which give less quality for CT examination.
- 2.5. To learn the benefits of the protocol for the patient and the staff.
3. The challenges for the future.

A-395

B. Multislice CT: Introduction and application

A. Riemer; Neuss/DE

Because the parallel acquisition of up to 64 slices per rotation and a rotation speed of 400 msec per rotation, the multislice-CT is up to 128-times faster than a standard one-second-single-slice-CT-scanner. This high scan speed enables the scanning of large volumes with thin slices in one breath hold and gives multislice-CT the capability to acquire 3D-volumes in isotropic voxel geometry. This means that we can reformat the scanned volume in every plane without loosing spatial resolution. The high scan speed and the excellent spatial resolution of multislice-CT makes new diagnostic and functional applications possible. Multislice-CT enables us to adapt the scan-strategy and protocol to every patient very precisely and the combination of high speed isotropic scanning and a powerful bolus-tracking-software enables independent from the cycle time of the patient a very precise contrast timing.

In comparison with a single-slice-CT the multislice-CT has less limitations in scanning. So it could be very tempting to scan more than necessary and increase the X-ray dose. It is very important to use the scanner very conscientious. On principle the correct application of a multislice-CT in combination with optimised scan-protocols, quantum denoising filters and a software for X-ray modulation the patient dose can be extremely reduced.

Learning Objectives:

1. To understand the basic of multislice technologie (detector technology, fan-beam/conebeam, reconstruction algorithm, isotropic voxel geometrie, patient dose in multislice CT).
2. To learn new diagnostic and interventional applications (diagnostical advantages of isotropic imaging, cardiac applications, multislice angio applications, new concepts in trauma diagnostic).
3. To handle image data.

Justification and optimization of multislice CT (MSCT) examinations

Moderator:
W. Bautz; Erlangen/DE

A-396

A. Justification of MSCT examinations

J. Geleijns, J.L. Bloem, J. Kievit, A. Spilt; Leiden/NL

The potential benefit of multislice CT (MSCT) depends on the appropriate selection of patients. Benefits based on accurate detection or exclusion of disease are appropriate treatment decisions such as starting, continuing, discontinuing or even withholding specific treatment, or additional diagnostic procedures. Decisions on proper indications for MSCT are even more relevant considering the radiation risk factor. Because the accuracy of diagnostic tests is not perfect, the second type of risk is an erroneous treatment decision based on an erroneous test result. The third type of risk is direct complication of the test itself, for MSCT these are predominantly adverse effects related to contrast agents. The balance between benefits and risks of MSCT should be in favour of the benefits. Justification of MSCT deserves special attention since recent technical progress caused an increase of the number of MSCT examinations and an expansion of the clinical indications for MSCT. Differences between the volumes of imaging tests, including MSCT, in European countries is large. This reflects differences in mortality attributable to diagnostic X-ray imaging and demonstrates that there is ample room for improving appropriate use of imaging, including MSCT. Appropriateness criteria such as those published by the American College of Radiologists and the UK Royal College of Radiologists serve as guidelines for the physician. Decision trees can be used to describe optimal patient flow through the diagnostic process. To resolve remaining problems further research, including meta-analysis and prospective studies, is required.

Learning Objectives:

1. To present justification of MSCT examinations in the context of radiation protection.
2. To present justification of MSCT examinations in the context of medical decision theory.
3. To learn about the practical clinical implementation of justification of MSCT examinations.

A-397

B. MSCT: Balancing image quality and dose

W.A. Kalender; Erlangen/DE

As an introduction the technical basis of MSCT will be reviewed briefly. The most important component is the detector which typically allows simultaneous scanning of 4 to 64 slices in today's MSCT scanners. In general, the geometric efficiency decreases and the collimation efficiency may increase as the detector pixel pitch becomes finer and the number of detector rows increases. The respective aspects are illustrated and discussed in detail. The X-ray source, the inherent and added filtration, the reconstruction algorithms can also influence dose efficiency; the respective factors will be reviewed.

Patient dose levels in MSCT can be assessed quite accurately today based on tabulations or based on scanner- and patient-specific calculations. Typical values range between 1 to 20 mSv per examination. The parameters which affect patient dose are above all the scan volume, the chosen X-ray parameter settings and, to some degree, the reconstruction algorithm. It is important to scan with parameters which allow maximum resolution, but to consider reconstructions with lower spatial resolution to limit pixel noise. The respective dependencies of spatial resolution and image noise will be explained and demonstrated interactively. Low-contrast detectability and soft tissue differentiation, the prime objectives in most CT examinations, are affected by image noise and contrast characteristics. The influence of the spectrum on contrast and on low-contrast detectability will be explained and demonstrated.

Learning Objectives:

1. To understand the technical basics of MSCT.
2. To know the patient dose levels and parameters affecting dose.
3. To understand the influence of dose on low-contrast detectability.

A-398

C. Optimization of pediatric MSCT examinations

S. Puig; Vienna/AT

The introduction of MSCT in 1998 was a breakthrough in CT technology. Recently, new 64-slice-CT scanners were introduced. However, a major disadvantage of MSCT scanning is the high radiation. Using unfavourable scanning parameters, exposure dose is substantially increased compared to single-slice scanning. A comparison of radiation exposure in multi- and single-slice CT showed that companies recommended MSCT protocols leading to a radiation dose eight times higher than with single slice CT! Furthermore, a small field of view results in a relative increase of the pixel size and so-called "noisy" images. Individual dose modulation and overlapping reconstructions provide a so-called "secondary raw-data set" which can be used for further image reconstructions. Software for tube current modulation is characterized by online monitoring of the attenuation and subsequent tuning of tube current. New software programs have been introduced, which enable tube current (mA) modulation according a predefined noise level along the z-axis. With this software called CARE Dose4D, a dose reduction of up to 66% are possible in adults and children using 16 row scanners. In a phantom study, a dose reduction of 90% was possible in neonates and small infant. Comparable mA modulation software was introduced by GE (AutomA) and by Toshiba (RealEC).

There are several programs available, which help to estimate the doses or the CTDI of different imaging protocols in different scanners, including WinDose, CTDOSE, CT-Dose, CTDosimetry or CT-Expo.

However, the most sufficient way to protect the patient from radiation exposure is to use radiation-free techniques.

Learning Objectives:

1. To learn how to develop low-dose protocols for pediatric MSCT of the chest and the abdomen.
2. To understand how image noise affects the image quality of low-dose scans.
3. To understand which impact the field of view has on image resolution.
4. To learn how to improve image quality of low-dose scans using to post processing techniques.
5. To learn how to reconstruct secondary raw data sets replacing original raw data sets which need large storage capacity in order to enable further 3D reformations.

Metastatic disease of the brain and spine

Moderator:

L. van den Hauwe; Brasschaat/BE

A-399

A. Metastases in the brain parenchyma

G. Krumina; Riga/LV

Brain metastases are the most common manifestation of somatic primary tumours. The placement of tumour emboli in the brain depends on passive supply of tumour cells via blood circulation. Brain stem, cerebellar and hemispheric metastases arise proportionally to the weight of these structures and blood circulation. Deposition of metastases occurs at the points of turbulent flow where vessel calibre changes or at arterial end points. The most common neoplasms producing brain metastases, are lung, breast, melanoma, colorectal, and urogenital cancers. Clinical presentation and therapeutic options depend on dissemination of systemic malignancy, number and localisation of brain metastases. CT and MR imaging are the mainly used imaging modalities. Contrast-enhanced (CE) MR imaging is more sensitive than CE-CT. The lesions undetected on CT are less than 1-2 cm in diameter and located near to the convex and skull base. Visualisation of additional metastases on CT could be improved by administering double to triple contrast dosage and performing scans with 1-3 hours delay. In cancers that frequently seed brain metastases, MR imaging as a primary screening method is more reasonable and cost-effective. Routine contrast dose T1-WI with mt contrast improves detection of small lesions. In contrast to CT, delayed post contrast MR imaging does not improve lesion-to-brain contrast. The recommended basic MR imaging protocol and usefulness of additional functional MR sequences are described and disputed. Primary malignant glial tumour, brain abscess, primary CNS lymphoma, inflammatory granuloma and also spontaneous parenchymal haemorrhage are differential diagnoses for solitary brain metastases. Differential diagnoses for multiple metastases include abscesses, inflammatory granulomas, lymphoma, and demyelinating disease.

Learning Objectives:

1. To review the basic concepts of metastatic disease of the brain parenchyma: incidence, theories of the spread, general locations, tumours of origin, typical clinical presentations and treatment modalities.
2. To describe CT and MR imaging algorithms for patient's evaluation with suspected parenchymal brain metastases.
3. To present typical differential diagnostic features and possible diagnostic pitfalls for solitary and multiple parenchymal brain metastases.

A-400

B. Extra-axial metastases (skull, dura, leptomeningeal) and tumor spread

R. Maroldi; Brescia/IT

Extra-axial intracranial metastases may arise through several routes. Hematogenous spread to the meninges is the most frequent. Direct extension from contiguous extra-cranial neoplasms, secondary invasion of the meninges by calvarium and skull base metastases, and migration along perineural or perivascular structures are less common. The incidence of leptomeningeal metastasis seems to increase, probably because of the increment in survival of many systemic neoplasms. Leptomeningeal invasion gives rise to tumor cell dissemination by CSF, eventually leading to neoplastic coating of brain surfaces (neoplastic meningitis). The CSF exam is the most useful non-imaging based test. Contrast-enhanced MR imaging is complementary and can be invaluable, detecting up to 50% of false-negative lumbar punctures. MR findings range from diffuse linear leptomeningeal enhancement - following the gyri and extending into the sulci - to multiple enhancing extra-axial nodules. Obstructive communicating and non-communicating hydrocephalus may occur, due to obstruction of the ventricular system or CSF resorption. Both calvarial and epidural metastases infrequently transgress the dura, which acts as a barrier against tumor spread. Radionuclide bone studies are still a valuable screening test to detect bone metastases. On CT and MR, bone metastases extending intracranially and primary dural metastases show the characteristic biconvex shape, usually associated with brain displacement away from the inner table. Although CT is better in detecting bone erosion of the skull base, MR is more sensitive in demonstrating even subtle abnormalities of the meninges, providing more detailed information about dural involvement.

Perineural and perivascular spread from head and neck neoplasms require thin-section contrast-enhanced MR.

Learning Objectives:

1. To comprehend the mechanisms of extra-axial metastases to the skull base, the dura mater and leptomeninges, skull base invasion, and neoplastic intracranial spread.
2. To become familiar with the basic anatomy of the skull base, meninges, and how to use the imaging techniques to identify neoplastic involvement.
3. To recognize characteristic aspects of leptomeningeal, dural metastases, and to be able to provide a differential diagnosis.
4. To be able to recognize perineural and perivascular spread from head and neck neoplasms.
5. To be aware of the therapeutic applications.

A-401

C. Metastatic disease of the spine

C.F. Andreula; Bari/IT

Metastases of the spine occur in the spinal cord, in the extramedullary dura, in the epidural space and in the vertebral bodies.

Imaging modalities evaluate patients with symptoms; they can also be used to screen for lesions; assessing the localisation and the compartments involved (extradural, epidural, subdural, and paraspinal) and can help suggest a therapeutic strategy.

The suggested patients for screening of metastases are:

- asymptomatic patients suspected for metastases
- the patient with neurological symptoms.

Imaging modalities are indispensable in the differential diagnosis of non tumoral lesions mimicking metastases.

Learning Objectives:

To suggest the diagnosis criteria differentiates them between metastasis and other pathologies.

08:30 - 10:00

Room B

Musculoskeletal

RC 1710

Knee joint

Moderator:

M. Zanetti; Zürich/CH

A-402

A. Soft tissue structures of the knee with US and MR imaging

E.G. McNally; Oxford/UK

Meniscal tears can be divided into two groups, those that manifest as abnormal lines breaching an articular surface and those that cause abnormalities of meniscal morphology. The commonest tear patterns are usually easy to identify, but more subtle lesions, particularly those that involve more subtle derangement of normal meniscal morphology, are sources for diagnostic error. These and other common pitfalls will be reviewed. MR imaging also plays an important role in assessing the intra-articular ligaments. The extra-articular ligaments are also easily examined by ultrasound, though as many injuries occur in combination, MR imaging reserves the dominant role. An exception is the extensor mechanism where patellar tendinopathy is a common cause of anterior knee pain and is easily assessed using ultrasound. Cystic lesions around the knee are common, the majority are extra-articular and a firm diagnosis can usually be made by their location, ultrasound or MR imaging appearances. The diagnosis of intra-articular soft-tissue masses is more problematic, but an approach to differential diagnosis will be offered.

Learning Objectives:

1. To describe the common patterns of injury to the menisci.
2. To establish a methodology for detecting the more subtle avulsion meniscal tear.
3. To describe the common ligament abnormalities and comment on their important associations and patterns of multiple ligament injury.
4. To review the abnormalities that can be found in other intra and extra-articular soft tissue structures such as Hoffas fat pad, periarticular bursae and muscles.

Postgraduate Educational Programme

A-403

B. MR-based cartilage imaging in the knee prior and after transplantation

C. Glaser; Munich/DE

The motivation for MR imaging-based assessment of articular cartilage is the increasing availability of and experience with cartilage dedicated therapies, mainly on the background of acute trauma or osteoarthritis.

Yet, cartilage MR imaging still remains challenging due to its complex composition and small spatial dimensions. High spatial resolution, good SNR/CNR and reasonable imaging times are prerequisites for an accurate MR imaging assessment of articular cartilage. Fat suppression eliminates chemical shift artefacts and improves CNR of cartilage. Using selective water excitation (WE) contributes to further reduce imaging time. T2-/PD-w FS sequences are considered to be sensitive to focal intra-cartilaginous signal alterations and show a good delineation of the cartilage surface from effusion indicating even relatively small cartilage lesions. However, assessment of such small lesions is still problematic and suffers from low accuracy.

Clinical classification systems are based on evaluation of focal lesions, of diffuse thickness reduction and of intra-cartilaginous signal intensity changes as well as erosion of the subchondral bone plate and BMEP-like signal within the underlying bone. Usually, they are derived from arthroscopic grading scales. Although still not common place, there is increasing (short term) experience with MR imaging of OATS and ACI procedures underlining surface congruity, bony healing and development of subchondral cystic lesions to be important prognostic factors for graft ongoing/loosening.

First longitudinal volumetric studies indicate an annual rate of cartilage loss of 4-6% in OA. T2 has been associated with spatial arrangement and water content and focal alterations in T2 with cartilage degeneration.

Learning Objectives:

1. To outline basic patho-anatomic considerations for MR imaging-based cartilage imaging.
2. To describe MR imaging sequences for cartilage imaging in clinical routine including artifacts.
3. To discuss the evaluation of cartilage lesions.
4. To review MR imaging of cartilage repair procedures: OATS and ACI.
5. To give an outlook on advanced MR techniques for assessing the matrix of articular cartilage.

A-404

C. Postoperative knee

V.N. Cassar-Pullicino; Oswestry/UK

This lecture will focus on the imaging of the knee following operative procedures carried out to cruciate ligaments, menisci and articular cartilage. Accurate diagnosis requires a clear understanding of the clinical symptoms and signs which will help tailor the optimal imaging methods and protocols that are required. Accurate interpretation of the post-operative status also requires a thorough working knowledge of the surgical procedures employed, including familiarity with the expected post-operative imaging appearances following surgical repair, resection, replacement or transplantation. It is also essential to understand the individual strength and weaknesses of the imaging modalities with particular reference to radiography, CT, ultrasound and MR imaging with or without contrast enhancement.

Learning Objectives:

1. To discuss the relative merits of US, CT and MR imaging in the assessment of the post-operative knee.
2. To familiarise the delegates with the expected post-operative knee appearances.
3. To describe the role of CT/MR imaging in the symptomatic knee following anterior cruciate ligament reconstruction.
4. To describe the role of MR imaging and MR arthrography in assessing residual or recurrent knee symptoms following meniscal surgery.

Fetal MR imaging

Moderator:

I.M. Björkman-Burtscher; Lund/SE

A-405

Fetal MR imaging (Introduction)

I.M. Björkman-Burtscher; Lund/SE

Although prenatal diagnosis of developmental disorders or in utero injuries is still dominated by the use of ultrasound, fetal MR imaging has been evolving continuously during the past few years. Fetal MR imaging offers the possibility to assess not only the fetus, but also intrauterine structures, such as the placenta and umbilical cord, and the uterus. The technique demands knowledge of normal fetal development, optimal techniques for fetal MR imaging studies and careful interpretation of pathologic findings. Many clinical strategies remain to be discussed, results are yet to be validated and standards have to be established. However, physicians are beginning to appreciate the capabilities of fetal MR imaging as a method to optimize the reliability of prenatal diagnostics and prognostics.

In three presentations at the cutting edge of technique and clinical application the speakers will share and discuss their experience in fetal MR imaging, offering the audience the opportunity to learn the essentials of this emerging field and allow patients to benefit from the technique even beyond major centres of prenatal care.

Learning Objectives:

1. To learn the choice of sequences/coils and specific safety issues.
2. To understand the symptomatology of MR imaging in cerebral malformation.
3. To discuss the correlation between fetal MR and postnatal imaging or neuro-fetopathology.
4. To learn the normal and pathological MR-appearance of the fetus, placenta, umbilical cord, and amniotic fluid.
5. To discuss imaging protocols of frequent clinical indications.

A-406

Technical considerations

P.A. Gowland; Nottingham/UK

The value of MR imaging in studying fetal congenital pathologies has been proved, but it also has potential applications in studying fetal development and physiology. MR imaging can be used to measure the fetal growth and has shown different patterns of brain growth compared to ultrasound in fetuses suffering fetal growth restriction. Similarly MR imaging is being used to study fetal brain development, anatomically as well as in terms of pre-myelination and myelination related changes. MR imaging can also be used to measure placental blood flow and preliminary data indicate that measures based on the intravoxel incoherent motion are able to distinguish pregnancies affected by pre-eclampsia.

Given the probable increase in fetal MR imaging over the next few years, it is important to consider the possible associated risks. Although no teratogenic effects are associated with clinical exposures to the various magnetic fields associated with MR imaging, there are some particular areas of concern. RF exposure limits are based on models of heat loss from the adult, but the fetus has reduced heat loss mechanisms. Similarly, acoustic noise exposure levels assume that an adult is wearing ear defenders. The maternal abdomen and the fluid-filled fetal ear will attenuate air borne noise, but mechanical vibrations of the bed will be coupled to the fetus through the maternal abdomen.

To enable dynamic studies for instance of cardiac function, it is necessary to monitor the fetal heart beat. At present this is generally carried out with fetal CTG, although some groups are investigating the use of ECG.

Learning Objectives:

1. To learn about novel measurements that MR imaging can provide in obstetrics.
2. To discuss technical pros and cons of MR imaging and ultrasound for quantitative assessment of fetal/placental growth/function.
3. To understand the specific safety issues relevant to fetal imaging (particularly acoustic noise, RF and 3 T).
4. To understand additional methods of monitoring the fetus within the MR environment (CTG).

Tuesday

Postgraduate Educational Programme

A-407

CNS malformations

C. Garel; Paris/FR

Background: The role held by fetal MR has grown in importance during the past few years and fetal MR plays now an essential part in major centres of antenatal diagnosis.

Procedure Details: The main advantages of MR over US are its ability to depict the surface of the brain and hence to delineate sulcation, and its higher contrast resolution which allows improved analysis of the cerebral parenchyma. Moreover, some structures (optic chiasm, olfactory bulbs, pituitary gland and stalk) can be visualised only with MR and not with US, so that some pathologies can be diagnosed only with MR. It must also be kept in mind that some *in utero* acquired cerebral abnormalities may be very difficult to differentiate from genetically determined malformations.

This talk will give a brief overview of the main fetal cerebral malformations, whose main highlights are the findings described above.

Conclusion: Cerebral malformations account for a large part of fetal anomalies and their detection constitutes a critical element of antenatal diagnosis. Fetal MR has become an indispensable adjunct to ultrasound in the diagnosis of such pathologies.

Learning Objectives:

1. To learn the symptomatology of MR imaging in cerebral malformations.
2. To understand the contribution of this technique compared to US.
3. To discuss the correlation between fetal MR and postnatal imaging or neurofetopathology for a better understanding of fetal MR images.

A-408

Body MR imaging

D. Prayer; Vienna/AT

Fetal body MR imaging is used to assess face, neck, thoracic and abdominal organs, and limbs. In addition, with any fetal indication, the placenta, umbilical cord, the amniotic fluid and the uterine wall should be examined too. T2-weighted contrast is acquired with single shot fast spin-echo (SSFSE) sequences, steady state free precession sequences or advanced gradient-echo sequences. T1-contrast, necessary to depict hemorrhage, fat, the thyroid gland, meconium and liver, can be achieved using 2D or 3D gradient-echo sequences, with or without fat suppression, or T1-weighted FLAIR sequences. Thick-slab SSFSE sequences create a 3D-like effect that is helpful with the assessment of body surface structures and limbs. Dynamic sequences allow visualization of intrinsic fetal movements, such as swallowing. In the fetal body diffusion-weighted sequences selectively display the kidneys, which may be important in assessment of suspect renal dysfunction, morphological abnormalities or oligohydramnios. Hallmarks of normal lung development are calculated volumes and T2-weighted and FLAIR hyperintensities increasing with gestational age. Bowel-development is assessed by using T2-weighted signal characteristics of fluid-filled intestines and meconium-based T1-weighted signal properties of the colon. The latter features help with the prognosis of pathologies involving both systems like congenital diaphragmatic hernias, where intrathoracic abdominal organs interfere with lung development and the amount of functional lung tissue determines postnatal survival. Complex pathological situations including intrauterine growth restriction, premature rupture of membranes and pathological umbilical cord Doppler values, underline the necessity of investigating the whole fetus and the extrafetal intrauterine structures regardless of the clinical indication.

Learning Objectives:

1. To learn the normal and pathological MR-appearance of the fetus, placenta, umbilical cord, and amniotic fluid.
2. To understand MR in intrauterine growth restriction, premature rupture of membranes, and pathological umbilical cord Doppler.
3. To discuss imaging protocols of frequent clinical indications and postnatal/postmortem controls to point out the contribution of prenatal MR imaging.

08:30 - 10:00

Room E1

Cardiac

RC 1703

Morphological and functional assessment of the heart

Moderator:
R. Fattori; Bologna/IT

A-409

A. Morphological assessment of the heart

V.E. Sinitsyn; Moscow/RU

Modern tomographic modalities like MR imaging and MSCT are more and more frequently used for morphological evaluation of the heart. Both these methods have several advantages over traditional cardiac imaging technologies, among them are large artefact-free field-of-view, high spatial and temporal resolution. Due to continuous and rapid movements of the heart, MR imaging and MSCT studies must be synchronized with the cardiac cycle.

Anatomical axes of the heart do not coincide with conventional orthogonal planes. It is important to evaluate the heart along anatomical axes and planes. Both MR imaging and MSCT give allow the possibility of creation of 3D reconstructions of heart chambers.

In the clinical setting the most common indication for MR imaging is further characterization of abnormalities discovered on echocardiography, nuclear cardiac studies or even on cardiac catheterization. It has been proven that they could be methods of choice in the following clinical situations:

- Complex congenital heart diseases
- Postoperative assessment of patients after heart surgery
- Aortic and pericardial pathology
- Arrhythmogenic dysplasia
- Hypertrophic cardiomyopathy (especially apical)
- Cardiac and paracardiac masses
- Quantification of heart chamber volumes, myocardial mass.
- Characterization of myocardium (areas of ischemia, inflammation, necrosis, scars)

Learning Objectives:

1. To discuss the principles and techniques of cardiac images.
2. To compare advantages and limitations of the different imaging modalities in the morphological assessment of the heart.
3. To describe anatomy by means of CT and MR imaging.

A-410

B. Assessment of the left heart function

N.L. Kelekis; Athens/GR

Echocardiography is currently the most commonly used modality in the assessment of LV function. It is widely available, cheap and easily combined with pharmacological stress-test. Recent advances include better delineation of endocardial border using harmonic imaging or contrast agents. There are, however, limitations, including poor acoustic windows in obese or postoperative patients, occasional difficulty in assessing postero-basal, postero-lateral and apical myocardial segments. Evaluation of global function relies on geometric assumptions, which may not be valid in several disease states such as LV remodeling post myocardial infarction or LV aneurysms.

SPECT and multidetector-row spiral CT provide objective volumetric assessment without geometrical assumptions, but both require contrast administration and exposure to ionizing radiation.

MR imaging offers objective reproducible quantitative volumetric and velocity/flow assessment, irrespective of ventricular shape and remodeling, as well as high contrast delineation of endocardial and epicardial borders. Its overall high anatomical detail permits excellent regional function evaluation, which may be boosted by quantification of 3-dimensional motion information from tagging techniques. It may also be combined with stress testing, studies of myocardial viability using delayed enhancement, and angiographic assessment of proximal coronary arteries in a comprehensive examination.

MR imaging is still expensive, with relatively limited availability, more time-consuming, needs breath-holding and effective cardiac synchronization. Latest developments, however, permit real-time cine imaging without the need of triggering with a quality superior to ultrasonography and comparable to today's state-of-the-art breath-hold cardiac-triggered SSFP cine sequences.

Postgraduate Educational Programme

Learning Objectives:

1. To compare advantages and limitations of the different imaging modalities in the functional assessment of the left ventricle.
2. To describe the method and clinical meaning of the global functional analysis.
3. To describe the method and clinical meaning of the regional functional analysis.

A-411

C. Assessment of the right heart function

M. Gutberlet, B. Spors, K. Klimes, M. Grothoff, R. Felix; Berlin/DE

The right ventricle has a complicated shape and therefore geometric assumptions can not be made for volumetric assessments like for the left ventricle. The left ventricle can be seen as an ellipsoid, so that a 2-dimensional calculation of ventricular volumes by area-length methods is possible. For the volumetric assessment of the right ventricle such easy and less time consuming methods are not available. Thus, the so called Simpson's rule, which uses a contiguous set of short axis slices covering the whole ventricle, has to be used for the volumetric assessment of the right ventricle. Hence, magnetic resonance imaging (MRI) is the optimal modality for the evaluation of right ventricular function, especially in patients in whom lifelong follow-ups are necessary, like in patients with corrected congenital heart diseases. Beside CINE-MRI with the use of steady state free precession sequences (SSFP) there are other MRI methods available to assess right ventricular function like myocardial tagging or phase velocity mapping, which will be addressed also. The different appearances of the right ventricle in patients with pressure or volume overload will be discussed.

Learning Objectives:

1. To compare advantage and limitations of the different imaging modalities in the functional assessment of the right ventricle.
2. To describe the method of functional analysis.
3. To discuss the clinical applications.

08:30 - 10:00

Abdominal and Gastrointestinal

RC 1701

CT colonography and colon cancer

Moderator:

R.A. Frost; Salisbury/UK

A-412

A. Epidemiology and evidence for screening

S.A. Taylor; Harrow/UK

The colorectum is the fourth commonest site for cancer world wide, although the incidence is second only to lung cancer in Northern Europe and North America. There has been a marked increase in incidence amongst migrants adopting a Western lifestyle, and although a clear genetic predisposition exists, over 75% of cancers develop in people with no identifiable risk factors. Most colorectal cancer arises from precursor adenomatous polyps, with the adenoma-carcinoma sequence taking around 10 years. There is however an increasing realisation that progression of disease may be accelerated in flat or depressed adenomas, which could account for up to 25% of cancers. Good evidence exists that endoscopic polypectomy can prevent colorectal cancer and a clear relationship exists between cancer stage and prognosis. Colorectal cancer thus lends itself well to population screening, being prevalent, treatable and preventable by well-established techniques. The optimum screening strategy is not yet established. Many candidate tests exist, but only faecal occult blood testing (FOBT) has been shown to be both feasible and to reduce mortality in randomised control trials. Data from large-scale trials of flexible sigmoidoscopy are currently awaited. Emerging technologies such as CT and MR imaging colonography and DNA based stool tests may play future roles. Mass screening is not without risk with cardiac morbidity secondary to laxative use or sedation, and complications related to endoscopy such as perforation and haemorrhage all well described. Cost effectiveness compares well to more established programmes such as breast screening, but is heavily reliant on frequency and initial screening age.

Learning Objectives:

1. To demonstrate an understanding of the epidemiology of colon cancer.
2. To review the rationale of screening for colorectal cancer.
3. To discuss the disadvantages of screening.

A-413

B. Performance and technique of CT colonography

A. Laghi; Rome/IT

CT colonography is a noninvasive test for the examination of the colon. The technique is extremely easy. Following the same meticulous bowel preparation as conventional colonoscopy, the colon is inflated with air or carbon dioxide using a rectal tube. No sedation is required. Dual scanning with the patient respectively in a prone and supine position is obtained. A major technical advance in the procedure is represented by the introduction of multislice CT scanners, which provide higher resolution as well as faster acquisition. Low-dose protocols also minimize radiation exposure. The acquired volumetric dataset is post-processed on dedicated workstations using commercially available software programs. Image analysis is performed using a primary 2D or 3D approach (i.e. scrolling through axial slices and multiplanar reformatted images on the workstation and using 3D endoluminal views as problem-solving support, or using 3D endoluminal view as a primary approach for lesion detection).

To date, several studies have reported a high sensitivity and specificity of CT colonography in the detection of colonic neoplasms - not only large colonic carcinomas, but also polyps. In the polyp-rich population per-patient sensitivity for polyps 10 mm or larger is around 88%, for polyps between 6 mm and 9 mm is 84% and for polyps 5 mm or smaller is 65%; specificity is around 95%. In the screening population data are more controversial, with one large study (Pichard et al) showing similar results between CT colonography and conventional colonoscopy and others (Johnson et al; Cotton et al) demonstrating poor sensitivity as well as wide interobserver variability.

Learning Objectives:

1. To discuss patient preparation.
2. To teach the technique of CT colonography.
3. To teach the interpretation of CT colonography.

A-414

C. The practical application of CT colonography

J. Stoker; Amsterdam/NL

CT-colonography (CTC) is an accurate technique for the detection of colorectal cancer and significant polyps in symptomatic patients. CTC has replaced double contrast barium enema as the primary imaging technique in symptomatic patients and is important as an adjunct in incomplete colonoscopy examinations. Most series concern CTC after extensive bowel cleansing, but more recent series have demonstrated that accurate CTC after limited bowel preparation is feasible thus resulting in reduced burden to patients. Primary two-dimensional evaluation is commonly performed, but recent studies seem to indicate the advantage of primary three-dimensional evaluation.

The role of CTC in screening is currently extensively studied. Studies on CTC with extensive bowel preparation in low prevalence populations have demonstrated that high sensitivity and specificity can be obtained in such populations. However, factors such as reader experience and evaluation technique influence the results and require further study. Reduction of the burden of CTC (primarily extensive bowel preparation) is mandatory before the technique can be implemented. Modified bowel preparation and radiation exposure reduction are feasible and large series with this CTC-modifications are mandatory in low prevalence populations. Development of accurate automated polyp detection is important for cost effective screening programs.

Learning Objectives:

1. To discuss the role of CT colonography in the screening situation.
2. To discuss the role of CT colonography in the symptomatic patient.
3. To discuss the use of CT colonography as an adjunct to conventional colonoscopy.

HRCT in diffuse lung disease

Moderator:

S. Akyar; Ankara/TR

A-415

A. Nodular pattern

S.P.G. Padley; London/UK

This component of the refresher course will focus on nodular lung disease as depicted with HRCT. Pulmonary nodules are usually in the 1 millimetre to 1 centimetre size range. The nodular pattern is a relatively common HRCT finding that is often poorly characterised on conventional chest radiography. HRCT allows accurate assessment of distribution, outline, size, density and uniformity of pulmonary nodules and allows the presence of cavitation to be determined. This presentation will illustrate the range of these characteristics and then demonstrate how appreciation of these features may be used to arrive at a meaningful differential diagnosis. Whilst the presentation will concentrate on the more commonly encountered nodular disease processes it will also include rarer causes of a nodular pattern.

Learning Objectives:

1. To describe and illustrate the nomenclature for description of different HRCT findings.
2. To present typical HRCT manifestations of different pathologic conditions.
3. To discuss the impact of HRCT on diagnostic strategies in patients with diffuse infiltrative lung disease.

A-416

B. Reticular pattern

N.J. Screaton; Cambridge/UK

A reticular pattern consists of innumerable interlacing lines resembling a net and almost invariably indicates interstitial disease. It may result from inter- and/or intra-lobular septal thickening. Interlobular septal thickening is commonly associated with peribronchovascular and intralobular interstitial thickening. The latter is identified either by intralobular fine reticular pattern or, when below the resolution of HRCT, by diffuse ground-glass opacity. Occasionally peribronchiolar or perivascular interstitial fibrosis results in centrilobular nodules as in asbestososis. Fibrotic parenchymal distortion commonly causes traction bronchiectasis.

Extensive fibrosis associated with severe distortion of normal lobular architecture causes a coarse reticular pattern or, when characterised by the presence of irregular cystic spaces, a honeycomb pattern.

Clearly visible interlobular septa almost always indicate interstitial abnormality. Although interlobular septal thickening is seen in numerous interstitial diseases, when it is the predominant finding the differential diagnosis is limited. Although the division of interlobular septal thickening into smooth, nodular or irregular can be difficult, it may aid diagnosis. Smooth septal thickening is seen in pulmonary interstitial oedema, and alveolar proteinosis, nodular septal thickening in sarcoidosis and lymphangitic spread of tumour, while irregular septal thickening results from architectural distortion by interstitial fibrosis.

Several factors assist diagnosis of a reticular pattern on HRCT. These include character of the HRCT features such as the coarseness of the pattern and the presence and nature of interlobular septal thickening. The distribution of reticulation, ancillary imaging features and clinical features are also instrumental in refining the differential diagnosis.

Learning Objectives:

1. To describe and illustrate the nomenclature for description of different HRCT findings.
2. To present typical HRCT manifestations of different pathologic conditions.
3. To discuss the impact of HRCT on diagnostic strategies in patients with diffuse infiltrative lung disease.

A-417

C. Ground glass opacities

S. Diederich; Düsseldorf/DE

Ground glass opacity is defined as infiltration of the lung parenchyma which is not dense enough to obscure pulmonary vessels. Histologically, the key feature

is the preservation of air-filled alveoli in lung parenchyma with otherwise increased soft tissue attenuation.

It may be due to increase in the volume of the interstitium, partial filling of air spaces with cells or fluid, or both.

Ground glass opacity presenting as areas of increased density in otherwise normal density lung parenchyma needs to be differentiated from the apparent increased density of normal lung parenchyma in the presence of abnormal decreased attenuation either due to air-trapping or mosaic perfusion. Observation of the width of pulmonary vessels in areas of low density is helpful in deciding whether areas of increased or decreased density are abnormal in such circumstances. HRCT in expiration may also assist in this differential diagnosis. In many diseases, ground glass opacity corresponds to areas of active disease, prompting initiation of therapy. However, as it may also represent end-stage fibrosis. Secondary signs need to be recognized which can indicate irreversible fibrosis, such as traction bronchiectasis and bronchiolectasis and parenchymal distortion.

Ground glass opacity may be found in a variety of diseases. Examples will be presented including pneumonia (e.g. pneumocystis carinii pneumonia, viral and bacterial pneumonias, fungal pneumonia), pulmonary oedema, haemorrhage, collagen vascular disease, other diffuse infiltrative lung diseases and effects of therapy. Imaging protocols to assess and quantify the presence of ground glass infiltration and facilitate the differential diagnosis will be presented.

Learning Objectives:

1. To describe and illustrate the nomenclature for description of different HRCT findings.
2. To present typical HRCT manifestations of different pathologic conditions.
3. To discuss the impact of HRCT on diagnostic strategies in patients with diffuse infiltrative lung disease.

Pediatric neuroradiology

Moderator:

K.A. Vergesslich; Basle/CH

A-418

A. Congenital lesions of the brain

N. Girard; Marseille/FR

Congenital lesions of the brain is a vast chapter including: congenital malformations, congenital infections, inborn errors of metabolism and destructive brain lesions acquired in utero.

Malformations are described following embryological timing and include neural tube defects, disorders of diverticulation (holoprosencephaly spectrum, cystic malformations of the posterior fossa), commissural agenesis, malformations of cortical development that can involve cellular multiplication, differentiation, migration and organization. Malformations also include extracerebral cysts and vascular malformations. Although brain malformations are characterized by specific anatomical features, MR imaging features can change with time along with brain maturational changes, especially in cases of malformation of cortical development, but also in midline lipomas.

The most common congenital infections are CMV and toxoplasmosis and result in brain malformations and destructive lesions of the brain. Neonatal herpes encephalitis is less frequent and highly destructive.

Inborn errors of metabolism can be encountered in utero and in neonates, the most frequent seen being mitochondrial cytopathies that rarely display basal ganglia involvement (until the first year of life) compared to older children. Some metabolic disease are also known to give brain malformations (i.e. corpus callosal agenesis in pyruvate dehydrogenase deficiency). Other metabolic disease are known to lead to brain damage similar to cerebral lesions of hypoxic-ischemic origin.

Destructive brain acquired in utero of hypoxic origin can be encountered postnatally especially in the neonatal period such as stroke and necrosis. Acute events one to several days before birth also happen leading to brain damage sometimes difficult to differentiate from cerebral damage that have taken place pernatally.

Learning Objectives:

1. Listing of the different types of congenital lesions of the brain.
2. To recognize the different types of malformation.
3. To recognize the different features of a definite malformation depending on the age at the time of neuroimaging.

Postgraduate Educational Programme

4. To recognize anatomic markers of an etiology (i.e. congenital infection and brain lesions).

A-419

B. Non-accidental head injury/child abuse

O. Flodmark; Stockholm/SE

To the radiologist, neuroradiologist in particular, physical abuse of infants and babies are of greatest interest since neuroradiology is often the only means by which the diagnosis of abuse can be suspected and subsequently proven. Small infants are most often shaken while larger infants are more often submitted to shaken/impact injury. The resulting brain damage is devastating. The infant presents with most non-specific symptoms, making the clinical diagnosis of abuse extremely difficult.

The repeated accelerations and decelerations and rotations associated with repeated shaking of a small baby will cause venous haemorrhage into the subdural space, a very important marker indicating that the baby has been shaken. Repeated instances of abuse will cause haemorrhages of different ages. The same treatment will also cause tearing injuries seen in the white/grey matter interface, often with small haemorrhages as well as retinal haemorrhages. Hypoxic/ischaemic brain injury added upon the tearing injuries aggravates brain oedema.

The finding of subdural haemorrhages, brain oedema and retinal bleeds in combination provides as close to 10% proof for child abuse as is possible.

The most important method used to diagnose abuse of infants is CT-scanning. It is an effective way of showing subdural haemorrhage and can give an indication of the age of the haemorrhage. MR imaging has a superior sensitivity in detecting collections of haemorrhage in the subdural space. It has a superior ability to demonstrate brain injury. The only, but most important weakness of MR imaging is its inability to accurately show the age of a subdural haemorrhage.

Learning Objectives:

1. To learn about the incidence of child abuse.
2. To understand how a baby or child commonly is abused.
3. To understand the mechanisms behind skull fractures and brain injury following child abuse.
4. To know how these injuries can and should be imaged.
5. To understand how to interpret the imaging findings of skull and brain injury in child abuse.
6. To discuss briefly the role of the radiologist in the legal process often following on detection of child abuse.

A-420

C. Hydrocephalus

S. Cakirer; Istanbul/TR

Hydrocephalus is a condition in which there is increase in ventricular size due to an imbalance between the production of cerebrospinal fluid (CSF) and its drainage by the arachnoid villi. The result is increased intracranial pressure.

Three major mechanisms account for the development of hydrocephalus. The first mechanism is obstruction to CSF flow, usually secondary to congenital lesions as stenosis/web of aqueductus Sylvii, inflammatory conditions such as tuberculosis, meningitis, granulomatous infiltrations, blood clot, and various tumors. Second is decreased absorption of CSF by arachnoid villi, this is seen in subarachnoid and intraventricular bleeding, inflammatory conditions, and tumoral seeding to the subarachnoid spaces. Third is the overproduction of CSF, unique to infants and young children and caused by choroid plexus papillomas and carcinomas. While congenital anomalies, infections and hemorrhagic insults are leading causes in newborns and infants, infections and tumors are more common in older age groups. Hydrocephalus may be classified on the basis of level of obstruction as communicating (extraventricular) or noncommunicating (intraventricular) hydrocephalus. The situation might be compensated or noncompensated depending on the presence of transependymal CSF migration.

All of the above will be discussed during the lecture with their corresponding neuroimaging findings, including antenatal and postnatal transcranial ultrasound, computed tomography, magnetic resonance (MR) imaging and advanced techniques such as cine MR, fetal MR studies.

Differential diagnoses for neuroimaging findings and for age groups as well as neuroimaging findings following therapeutic shunting operations with their complications will be discussed briefly as well.

Learning Objectives:

1. To learn about the etiology and pathogenesis of the pediatric hydrocephalus.
2. To identify imaging modalities used in the study of hydrocephalus.
3. To learn about the potential of new MR imaging techniques in the study of hydrocephalus.

How to investigate facial pain

Moderator:

K. Marsot-Dupuch; Le Kremlin-Bicêtre/FR

A-421

A. Neuralgia and uncommon causes

T.J. Vogl, S. Bisdas; Frankfurt a. Main/DE

Facial pain presents predominantly as unilateral pain and is caused by dental, neurological, vascular, temporomandibular, and atypical neuralgic conditions. Imaging techniques will be presented, including conventional X-ray (digital radiography), multislice computed tomography (MS-CT), and high-resolution magnetic resonance imaging (MR imaging techniques).

Imaging findings due to dental causes such as osteomyelitis and compression syndromes have to be evaluated. Temporomandibular joint disorders are evaluated by performing static and dynamic MR imaging techniques. The major cause of facial neuralgia is trigeminal neuralgia (TN). Here the evaluation has to include compression of the trigeminal nerve by vascular loops or other space-occupying lesions such as inflammatory diseases or primary and secondary tumors.

Plain radiographs and CT of the nasal cavity and paranasal sinuses are helpful for detecting sinus disease as a cause for facial pain. MR imaging is the elective method for neoplastic disease evaluation and pre-operative imaging.

In summary, clinical evaluation and other imaging techniques such as conventional X-ray, CT and MR imaging have to be used according to the clinical question and the evaluation has to follow exact topographic knowledge and detailed morphological findings of the radiological causes.

Learning Objectives:

1. To be become familiar with the causes of neuralgiform facial pain and the currently existing treatment modalities.
2. To be aware of the key anatomic structures that play a role in facial pain of neurogenic origin.
3. To be aware of the advantages and disadvantages of the imaging modalities to use and to know when to perform the most appropriate imaging technique.
4. To be able to recognize the most common causes of neuralgiform facial pain.
5. To be aware of rare diseases that may lead to facial pain.

A-422

B. Pain of dental origin

A. Gaheitner; Vienna/AT

Pain of dental origin is most frequently caused by the root canal or the periodontal ligament space. Inflammation, trauma or tumor in this region can easily spread into the surrounding soft tissue, sinus or jaw bone. Separate to this, a multitude of diseases occurring in the jaw can involve the teeth leading to pain as a first indicator of a lesion. While conventional imaging methods such as panoramic radiography and dental films are very useful in detection of these diseases, newer imaging methods as dental-CT and dental-MR have recently gained importance in diagnosing dentition-associated diseases of the mandible and maxilla. Unfortunately, most radiologists have had little experience in this area and many of the CT and MR findings remain undescribed.

This presentation will focus on the technique and usefulness of CT and MR in diagnosing pathologic conditions and complications as a cause for pain of dental origin. Furthermore the correct imaging technique and the most important error sources will be discussed. To enable a clear understanding of dental-CT and MR, clinical images and aspects will be added to facilitate the transition from the intraoperative situation to radiological presentation.

As a goal the radiologist should be aware of possible findings presenting as pain in the jaw region and should be able to communicate them to the clinician.

Learning Objectives:

1. To become familiar with the various causes of facial pain of dental origin.
2. To be aware of the advantages and disadvantages of the imaging modalities to use and know when to perform the most appropriate imaging technique.
3. To recognize the diagnostic features of the most common causes of odontogenic facial pain, such as, periapical granuloma, radicular cysts, osteomyelitis of the mandible and odontogenic tumors.

Tuesday

Postgraduate Educational Programme

A-423

C. Pain related to the temporomandibular joint and muscles of mastication

S. Robinson; Helsinki/FI

Facial pain related to the TMJ and masticator space can occur in both open and closed mouth positions and can be accompanied by a clicking noise on movement of the jaw, difficulties in opening the mouth, malocclusion, skin deviation, asymmetry of the muscles of mastication or a palpable mass.

The mandibular condyle and fossa are separated by the disk, which is attached to the upper belly of the lateral pterygoid muscle anteriorly and the elastic fibers of the bilaminar zone posteriorly.

Cortical changes are best depicted by CT; soft tissue including bone marrow is best visualized by MR imaging and OPG shows the relationship to the dentoalveolar system.

Common causes of pain are disk dislocation, osteoarthritis ("internal derangement"), rheumatoid arthritis, and trauma.

Imbalance of the muscles of mastication or masticator space tumours, as well as dysfunction of the cervical spine or sacroiliac joint are rare causes for facial pain.

Learning Objectives:

1. To become familiar with the clinical aspects of facial pain related to the TMJ and masticator space and to be aware of their therapeutic implications.
2. To know the key anatomic structures that play a role in facial pain related to the TMJ and masticator space.
3. To be aware of the advantages and disadvantages of the imaging modalities to use and to know when to perform the most appropriate imaging technique.
4. To be able to recognize the most common types of TMJ dysfunction, as well as common diseases that may affect the muscles of mastication and mandible.
5. To be aware of rare diseases that may lead to facial pain related to the TMJ and masticator space.

Venous occlusion

Moderator:

N. Batakis; Athens/GR

A-424

A. Deep venous thrombosis

H. Bjarnason; Rochester, MN/US

Learning Objectives: To describe the sequelae of deep venous thrombosis, discuss incidence, distribution and pathophysiology. The different technical aspects of venous thrombolysis and use of mechanical thrombectomy devices as well as different thrombolytic agents will also be briefly discussed. The past literature and future developments will be discussed as well.

Background: Traditionally, deep vein thrombosis has been treated with anticoagulation alone. It has been estimated that up to 65% of patients who suffer acute deep vein thrombosis will develop post-thrombotic syndrome. In addition to dependent edema and chronic leg swelling, as many as 5% will develop venous ulcers. Early spontaneous lysis of the thrombus has been found to prevent damage to the valvular elements.

Outcomes: A number of small-randomized studies have demonstrated significantly increased clot lysis in patients treated with systemic thrombolysis compared to conventional anticoagulation. This treatment has though been found to be associated with a higher risk of bleeding complications which has lead to use of catheter directed thrombolysis. Two retrospective evaluations of catheter-directed venous thrombolysis have been performed. Major bleeding complications were encountered in 5% and 11% of patients respectively but more than 50% lysis was achieved in 83% and the 1-year primary patency rate was 60%. With the use of mechanical thrombectomy in combination with thrombolytics the treatment time has been reduced from over 50 hours to 2 to 24 hours with low rate of complications.

Conclusion: Long-term outcomes still need to be evaluated and there are studies ongoing where thrombolysis is randomized to anticoagulation alone.

Learning Objectives:

1. To give an insight into sequelae of deep venous thrombosis, frequency and pathophysiology.
2. To review past literature on systemic and catheter directed thrombolysis for iliofemoral deep venous thrombosis.

3. To discuss the current methods applied for mechanical and pharmacologic thrombolysis.
4. To discuss upcoming issues related to the topic.

A-425

B. Vena cava management

C.L. Zollinger; Winterthur/CH

Vena cava obstruction is caused by malignancies in 95% of the cases and only a minority are of benign origin and most commonly the sequelae of iatrogenic interventions such as central venous lines, hemodialysis fistulas or thrombotic occlusions such as deep vein thrombosis etc. Stenting of malignant central venous obstruction has become the method of choice for these mostly severely ill patients. A significant relief of symptoms within 12-24 hours can be expected in 70-100% with this low risk procedure. Long-term palliation including secondary interventions usually lies in the range of 85% or more, however, due to tumour progression additional stents may have to be implanted. Stent procedures for benign disease of the central veins have a very high success rate with an 90-100% overall initial and 80-100% longterm clinical success. Morbidity and complication rates are extremely low. Particularly for treatment of the May-Thurner syndrome stents are the method of choice. Central venous lesions related to hemodialysis fistulas are a further indication for primary stenting to improve the often unsatisfactory result of simple balloon dilatation. However, because of the high rate of intimal hyperplasia, usually occurring after 8-12 months, a close shunt surveillance is mandatory to install early reintervention. Indications, techniques and results will be discussed for the various clinical manifestations of central venous obstruction.

Learning Objectives:

1. To understand the indications and limitations for vena cava recanalisation and stenting.
2. To be able to select the appropriate patients with vena cava obstruction.
3. To be familiar with the techniques and possible complications of vena cava stenting.
4. To have a better understanding of the importance and techniques and results of vena cava recanalisation and stenting by the end of this presentation.

A-426

C. Pulmonary embolism: Protection and treatment

T. Schmitz-Rode; Aachen/DE

Despite prophylactic anticoagulation acute massive pulmonary embolism (PE) is still a common and often life-threatening entity. Survival of patients with right ventricular dysfunction depends on rapid recanalisation of the pulmonary arterial occlusion. Percutaneous catheter treatment represents an therapeutic option. Catheter devices include standard diagnostic catheters, balloon catheters, dedicated suction catheters (Greenfield vacuum cup catheter), rotating pigtail catheter, hydrodynamic thrombectomy catheter, and high-speed rotating tip catheters. The principles employed are extraction and/or fragmentation of the embolic material. Fragmentation of central emboli and dislocation of the fragments to the periphery result in a relative gain of non-obstructed cross-sectional area. The increased total surface area of the fragments accelerates the efficacy of an accompanying thrombolysis or of spontaneous intrinsic lytic activity. In the workshop pulmonary placement and navigation of the pigtail rotation catheter will be demonstrated as well as the mechanical action for recanalisation. The indications, safety, efficacy, the influence on hemodynamic parameters, possible complications, and pitfalls will be discussed. Percutaneous inferior vena cava (IVC) filter implantation represents a mechanical prophylaxis of PE. Absolute indications are recurrent PE despite sufficient anticoagulation and occurrence of PE in patients with contraindicated anticoagulation. The most common IVC filters will be presented. Implantation can be performed via femoral or jugular access. Temporary and facultative temporary filters can be removed within a certain duration after placement. Filter complications include misplacement, IVC thrombosis, perforation, migration, filter breakage, and recurrent PE. Therefore, diligent check of the indication for IVC filter implantation is advisable.

Learning Objectives:

1. To discuss indications, contraindications, and complications of catheter therapy of PE.
2. To discuss types of catheters and techniques.
3. To discuss selective vs systemic thrombolysis of PE.
4. To discuss indications and contraindications of IVC filter placement.
5. To discuss IVC filter placement techniques, filter removal, filter complications.

Planning issues in vascular radiological intervention

Moderator:

L.K.A. Tan; Singapore/SG

A-427

A. How to set up an endovascular centre

L.A. Jacob; Basle/CH

1. **Place:** Your new interventional center must be located at a hospital. The severity of illnesses and of the possible complications dictates an immediate availability of emergency facilities.
2. **Planning:** The planning is to be embedded into the hospital's strategy and profile: Patient referral patterns, interventional, OR- and ICU-facilities and other factors must be taken into account.
3. **Players (partner, opponents):** Besides the patient, the interventional radiologist and the technicians there are other people that have to be dealt with: vascular surgeons and/or internists (aka angiologists), other medical and surgical specialties, the hospital administration, insurances, political entities etc. Assign an attractive role for all important players to make them partners.
4. **Pliancy:** Adapt your plan to the local realities. If you cannot make a partner out of a particular player, or do not have the patients in a certain segment, you have to find a way around, leave the field out, or even cancel the whole plan.
5. **Patient access:** Normally an interventional radiologist has to rely on referrals from other clinicians. Direct patient access should be sought whenever possible: interventional rounds, a parlor, an outpatient clinic are all important means.
6. **Procedure rooms:** The physical configuration and equipment is less important than the other factors mentioned. You will solve these problems together with your partners. Again, local characteristics will strongly influence your choices.
7. **Patience and perseverance:** You will need some time to find your place among the other clinicians. Hang on!

Learning Objectives:

1. To impart information needed and issues to be discussed in setting-up an endovascular centre.
2. To understand the practical issues in setting-up such a service in conjunction with vascular surgery.
3. To know what equipment is needed e.g. CT, MR, interventional suite and theatre-time.
4. To be able to discuss working models with vascular surgeons.

A-428

B. Mapping peripheral vascular disease

M.G. Cowling; Stoke-on-Trent/UK

Assessment of peripheral vascular disease depends in the first instance on careful history taking and examination. Decisions about endovascular or open surgical intervention also depend on knowledge of the precise nature and location of stenotic or occlusive arterial disease.

Palpation of peripheral pulses is known to be unreliable in determining the presence and level of arterial disease. For example, the femoral pulse may be difficult to feel because of obesity, and the popliteal artery can be very difficult to palpate, even when normal. Severity of limb ischaemia is relatively easy to assess. The most commonly used technique for assessment of severity of arterial disease is the measurement of Doppler ankle pressures to derive the ABPI. In difficult cases the value of ABPIs may be enhanced by the use of exercise testing. Other techniques, such as plethysmography, transcutaneous oximetry and isotope blood flows are also available and will be discussed.

Non-invasive assessment of the location of arterial disease is more difficult. Segmental arterial pressures have been used, but are unreliable in the assessment of aortoiliac disease in the presence of femoropopliteal disease. Duplex ultrasound is a very valuable non-invasive tool, which allows analysis of the waveform and measurement of peak systolic velocity. Use of colour flow imaging allows relatively rapid assessment of an arterial segment. Areas of concern can then be examined in more detail. In many institutions, including our own this has become the mainstay of non-invasive arterial imaging.

Learning Objectives:

1. To understand the value and use of clinical examination.
2. To understand the role of clinic based non-invasive investigations.
3. To understand the optimal use of vascular laboratory investigations.

Musculoskeletal imaging

Moderator:

E. Sorantin; Graz/AU

A-429

A. Imaging of juvenile idiopathic arthritis

K.J. Johnson; Birmingham/UK

Juvenile idiopathic arthritis (JIA) is an inflammatory disorder of childhood that may affect any joint or organ system. JIA is a relatively recent classification for childhood arthritis and is an attempt to unify a disease that was previously described as Juvenile Chronic Arthritis (JCA) in North America and Juvenile Rheumatoid Arthritis (JRA) within Europe.

The purpose of this presentation is to illustrate the imaging findings of JIA. The different subgroups of JIA will be discussed including any of their unique imaging features. The presentation will highlight the very early and subtle radiographic appearances of JIA that may enable an early diagnosis of the disorder to be made.

The chronic features and complications of the disease will also be illustrated. A review of the differential diagnoses that need to be considered in childhood arthritis will also be made.

The value of both MR imaging and ultrasound in assessing the joint will be discussed. The most appropriate MR imaging sequence selection to allow visualisation of joint structures; articular cartilage and inflamed synovium will be detailed. In particular the use of post Gadolinium fat-saturated T1 weighted sequences for the detection of inflamed synovium will be emphasised.

There have been major advances in therapeutic options in the management of JIA. It is important that the diagnosis is arrived at as early as possible so that treatment can be optimised and the child maintain as normal function and mobility as possible.

Learning Objectives:

1. To increase awareness of the disease.
2. To show the imaging features (X-ray, US, MRI) of early disease.
3. To demonstrate chronic disease changes.
4. To show complications of the disease.
5. To describe other diseases that should be considered in the differential diagnosis in pediatric joint disease.

A-430

B. An approach to the diagnosis of skeletal dysplasias

A. Offiah; London/UK

During the course of their training programme, most radiology residents are taught systematic approaches to analysing plain radiographs of e.g. bone tumours and arthritic disease. We are all familiar with the approach to interpretation of a chest radiograph. However very little is taught on the approach to diagnosing skeletal dysplasias and other constitutional disorders of bone. The result is that many radiologists feel daunted when faced with a skeletal survey of a child with a possible dysplasia. The purpose of this talk is to present delegates with a simple but systematic method of diagnosing skeletal dysplasias.

Learning Objectives:

1. To highlight the radiographs obtained as part of a routine skeletal survey.
2. To discuss circumstances in which additional radiographs may be required.
3. To outline a simple approach to interpreting skeletal surveys in possible dysplasia.
4. To demonstrate this approach using radiographs from surveys of children with various skeletal dysplasias.
5. To discuss methods in which after having identified the abnormalities, the final diagnosis may be reached.

A-431

C. Imaging of malignant tumors of the long bones in children: What to do or not to do

H. Brisse; Paris/FR

Background: Osteosarcoma and Ewing's sarcoma represent more than 90% of all primary malignant bone tumours in children. The current treatment for local-

Tuesday

Postgraduate Educational Programme

ized forms is based on neoadjuvant chemotherapy designed to treat micrometastatic disease and reduce tumour volume to facilitate the surgical procedure. Surgery must be as conservative as possible, but must ensure complete resection. The role of imaging is to precisely evaluate the degree of local extension prior to surgery and to assess the response to chemotherapy. The current treatment protocols are still based on the gold standard of histological response.

Imaging findings: MR imaging is currently the best method to evaluate local extension prior to tumour resection, especially to assess the feasibility of conservative surgery. Morphological criteria on plain films and static MR imaging are insufficiently correlated with histological response. The contribution of dynamic MR imaging, diffusion-weighted MR imaging and nuclear medicine (¹⁸FDG-PET) to monitor tumoural necrosis are described.

Conclusion: The initial pre-treatment imaging actually remains the most important assessment. The first MR examination performed before treatment and initial biopsy constitutes the reference for follow-up during treatment and for local staging. Various nonspecific morphological and signal changes are induced by pre-operative chemotherapy, and assessment of response on the basis of these changes must be interpreted cautiously. Dynamic MR imaging can be used as a complementary technique for local staging and assessment of response for inoperable forms. Quantitative models in dynamic MR imaging and ¹⁸FDG-PET are currently being developed in order to demonstrate early prognostic criteria, which could be decisive in future protocols.

Learning Objectives:

1. To learn how to perform MR examinations of a malignant tumor of the long bones in children at diagnosis, during neoadjuvant chemotherapy and before surgery.
2. To learn how to precisely evaluate the degree of local extension and help the surgeon regarding the decision of conservative surgery.
3. To learn how to assess the response to neoadjuvant chemotherapy with imaging.

A. Breast cancer and imaging

D. Scutt, A. Nandi, L. Zhang, L.B. Jack; Liverpool/UK

We have combined 2 sources of information (mammographic reports and separately held questionnaire and nurse examination data from the Liverpool Breast Cancer Risk Factor study 1977-84; current diagnostic data from the Merseyside and Cheshire Cancer Registry). The secondary analysis on this combined data will allow a) an assessment of individual risk factors associated with subsequent diagnosis of breast cancer over a 30 year period and b) the development of a multifactorial risk model. We intend to subject the data to some comparatively recent machine learning algorithms, adopted and further developed at the Department of Electrical Engineering and Electronics. We will work with the main dataset of known outcome (cancer/no cancer). This will be split into two sets. One set will be used for learning (training) that could highlight risk factors. The other set will be used for testing to confirm its predictive accuracy. Subsequently we will undertake a prospective randomised controlled trial in patients with suspicion of, or at risk from breast cancer.

Learning Objectives:

1. To give an appreciation of the role of imaging in the diagnosis of breast cancer.
2. To raise awareness of the risk factors for breast cancer - results of a 30 year Liverpool study.
3. To give an overview of Liverpool developments in breast cancer imaging using microwave technology.

A-433

B. Softcopy display of mammograms

L. Costaridou; Patras/GR

Mammography is at present the dominant technique for early detection of breast cancer. However cancer signs, such as microcalcifications and masses, have often similar density to dense tissue, due to low inherent contrast, non-linear film

response to incident radiation exposures and tissue superimposition.

Full field digital mammography systems are characterized by improved contrast resolution compared to screen/film mammography, by decoupling image acquisition from display, while providing digital images to filmless- and tele-radiology environments. Softcopy display, i.e. interpretation of mammograms from electronic displays such as CRTs, is an essential part of such systems. Issues of software functionality and speed are of major importance to softcopy display. Meeting the technical challenge of matching display spatial resolution to acquisition resolution is an on going effort, partly fulfilled by the highest end display systems, not commonly available. Thus at present, a key issue of softcopy display is the treatment (processing) of display image intensities to benefit human image interpretation, also exploited in digitized mammography. Image processing methods, termed contrast enhancement methods, are targeted to fully utilizing the acquired intensity range as well as intensity differences (edges), conveying image structure. In such methods emphasis is given to locally adaptive ones, as well as in evaluating diagnostic performance efficiency by observer and quantitative means.

Learning Objectives:

1. To illustrate the basic principles of contrast- and edge-enhancement methods.
2. To provide application examples of major state-of-the-art enhancement methods on mammograms, with emphasis on difficult cases (e.g. dense tissue).
3. To discuss performance of enhancement methods and workstation issues (e.g. digitizer, display monitor, compression algorithms).

A. Tracheobronchial stenting

T. Sabharwal; London/UK

Large-airway obstruction may be caused by intraluminal disease, stenosis, tracheobronchial collapse, or extrinsic compression. In benign strictures, surgical resection and anastomosis or various forms of tracheoplasty represent the standard approaches to the treatment of symptomatic tracheal stenosis. This method, however, is not always possible for long lesions (> 6 cm); in such cases, surgery is often debilitating, and the anastomosis can be the site of recurrent stenosis. In malignant strictures, palliative therapy is required, and a combined approach to treatment is often used, with alternative methods that include endoscopic debriement, brachytherapy, percutaneous balloon dilation, endoluminal splinting, percutaneous irradiation, and chemotherapy. Recent advances in interventional radiology techniques and materials have enabled the endoluminal use of tracheo-bronchial stents. Effective and immediate palliation of obstructive airway symptoms usually result in significant improvement in the functional status and quality of life of patients with benign and malignant airway problems. Balloon or self expanding metallic stents can be used (author prefers the latter group). Uncovered stents are deployed in the bronchus so that airway branches are not occluded and covered stents reserved when there is a fistula. In the trachea, covered or uncovered stents can be deployed. CT images are helpful to size the stents and for planning of the procedure. The stent insertion can be done under sedation and fluoroscopic guidance but in our institution we perform them using combined fluoroscopic and endoscopic guidance under general anaesthesia. The three major problems currently associated with airway stents are mucous impaction, the formation of granulation tissue, and migration.

Learning Objectives:

1. To be familiar with the principle and application of tracheo-bronchial stenting.
2. To learn the radiological technique for stent insertion and to know the different available stents.
3. To discuss the indications, contraindications and radiological placement of tracheobronchial stenting.
4. To understand potential complications and brief outline of literature review.

A-435

B. Pulmonary vascular intervention

J.E. Jackson; London/UK

Massive haemoptysis, which is perhaps best defined as bleeding into the bronchial tree at a rate that poses a threat to life, is associated with considerable mortality unless treated aggressively. Common aetiologies include bronchiectasis, active tuberculosis (TB) and colonization by aspergillus species of a pre-existing pulmonary cavity. The majority of patients are not surgical candidates because of the presence of severe bilateral pulmonary disease. The primary vascular abnormality that occurs is the development of abnormal broncho-pulmonary shunts within peri-bronchial inflammatory tissue. The bronchial arteries, and other non-bronchial systemic arteries, dilate because of the resultant increased blood flow and the small fragile vessels within the inflammatory tissue are thus exposed to systemic arterial pressure. Bronchial arterial embolization is aimed at reducing the perfusion pressure to the fragile vessels within the inflammatory tissue by occluding systemic arterial inflow. A pulmonary source of haemorrhage in chronic lung disease may occur in as many as 10% of individuals. It most commonly arises from a pseudo-aneurysm caused by erosion of a pulmonary arterial branch by adjacent lung disease and should be considered in any patient who has a further large haemoptysis shortly after a technically successful embolization of bronchial and non-bronchial systemic arteries. The immediate control of haemorrhage will be achieved in between 75% and 90% of patients by bronchial embolization but at least 20% of these individuals will rebleed within the next six months and up to 50% may have further significant haemoptysis on longer term follow-up.

Learning Objectives:

1. To learn the indications for angiography and embolization in massive haemoptysis.
2. To be familiar with the angiographic abnormalities seen in patients with haemoptysis due to chronic inflammatory lung disease and understand why they develop.
3. To understand the importance of imaging and embolizing both the bronchial and non-bronchial systemic arterial supplies to the lung.
4. To be aware of the importance of a pulmonary arterial source of haemorrhage in some patients.
5. To understand the potential complications of bronchial angiography and embolization.

A-436

C. Thermal ablation of lung tumors

T.K. Helmberger; Munich/DE

The lung is a common site for primary or secondary malignancies, whereas pulmonary metastases present a significantly higher incidence than bronchial carcinomas. While radiotherapy +/- chemotherapy can provide sufficient tumor control dependent on the underlying tumor entity, in resectable patients surgical resection is considered the only curative therapy. Recently, percutaneous, minimal-invasive interventional methods as thermal ablation by radiofrequency or laser are competing with minimal - invasive surgical resection techniques as thoracoscopical surgery. In general, thermal ablation of pulmonary tumors is comparable to thermal ablation in other soft tissue tumor entities. Nevertheless, specific technical advisements, a different spectrum of indications and contraindications as in comparison to e.g. ablation in hepatic tumors, different types of tissue reactions and complications after thermal ablation, and specific thoughts regarding the follow-up have to be considered. The limited world wide available data are indicating that thermal ablation of pulmonary tumors might be a safe and effective treatment option. However, no long term data are yet available nor comparative studies to surgical minimal-invasive treatments. Therefore, specific attention has to be paid to the implementation of pulmonary thermal ablation into an oncological therapy regimen. The task of present and future research has to define the clinical significance of pulmonary thermal ablation especially in comparison to other evolving treatment techniques.

Learning Objectives:

1. To know the technique of pulmonary thermal ablation.
2. To assess the indications and contraindication for pulmonary thermal ablation.
3. To be familiar with the potential side effects and complications in pulmonary thermal ablation.
4. To understand the role of thermal ablation within a multidisciplinary concept in pulmonary tumor treatment.

The measurement and evaluation of lumbar muscularity in lumbar degenerative kyphosis (LDK) patients: Comparison with non-LDK patients on MR imaging

C. Kang, M. Shin, J. Ryu, S. Lee, S. Kim; Seoul/KR

Purpose: To compare lumbar muscularity in lumbar degenerative kyphosis (LDK) patients and non-LDK patients.

Materials and Methods: The study comprised LDK group (54 women, aged 44-74, mean 60) and non-LDK group with low back pain (36 women, aged 45-73, mean 60). Patients with spinal fracture, tumor, infection or previous surgery were excluded. The cross-sectional area (Acs) of individual muscle (psoas, erector spinae and multifidus) and intervertebral disc was measured at L4-5 by MR imaging using 1.5 T magnetic resonance system. Lumbar muscularity was expressed by three ratios; the ratio between Acs of right psoas, erector spinae, multifidus and Acs of disc (P: disc, ES: disc, MF: disc). The degree of fat deposit in erector spinae and shape of fascia overlying erector spinae on L5-S1 were analyzed. The degree of fat deposit was estimated using four grades: normal, mild, moderate and severe. The shape of fascia overlying erector spinae was classified into one of concave, flat and convex.

Results: Lumbar muscularity was found to be significantly smaller ($p < 0.001$, t-test) in LDK (P: disc=0.39, SD 0.11; ES: disc=0.95, SD 0.33; MF: disc=0.27, SD 0.1) than non-LDK (P: disc=0.51, SD 0.11; ES: disc=1.33, SD 0.3; MF: disc=0.44, SD 0.12). The degree of fat deposit and shape of fascia overlying erector spinae were also statistically different in two groups ($p < 0.05$). LDKc showed more fat deposit in erector spinae and has a tendency of flat or concave fascia overlying erector spinae.

Conclusion: Patients with LDK have a smaller lumbar muscularity and more fat deposit in erector spinae. The flat or concave fascia overlying erector spinae is significant feature of LDK.

B-002 10:39

Degenerative changes of the intervertebral disc and facet joint of the adjacent motion segment in the pre-operative MR imaging: Can it be the predictable factor of post-operative instability after posterolateral fusion of lumbar spine?

J. Ryu, M. Shin, S. Kim, S. Lee, C. Kang; Seoul/KR

Purpose: To assess whether the degenerative changes of the intervertebral disc and facet joint of the adjacent motion segment seen in pre-operative MR imaging can be the predictable factor of post-operative instability after posterolateral fusion of lumbar spine, with comparison of post-operative MRI imaging.

Materials and Methods: We included 40 patients with pre and post-op MR imaging and divided them into two groups according to the presence of instability of adjacent motion segment. We assessed the presence of instability in the flexion-extension view, and the degeneration of the disc, facet joint change, and the size of osteophyte in the pre and postop MR imaging. We had tried to clarify the possibilities of the degenerative changes to predict future development of the adjacent motion segment instability.

Results: The sum of the increase of the grade of disc degeneration in the group of instability was a mean of 1.05/patient, and mean of 0.5/patient in the other. Those of the osteophyte were mean 0.75 and mean 0.55, each other. Facet joint fluid was developed in eight cases in the instability group, and only three in stability group. These showed the tendency of the occurrence of instability.

Conclusion: Instability in the failed back surgery syndrome could not fully explained with these degenerative changes. This suggests the possibility that other factors affects the instability in the failed back surgery syndrome, and the more subtle findings that were not included in the criteria of this study may contribute to the instability.

B-003 10:48

Steroid-induced femoral head osteonecrosis: Comparison of proximal femur marrow status at baseline MR imaging between patients who will develop and who will not develop femoral head osteonecrosis during corticosteroid-treatment

R. Gilon, F.A. Houssiau, B.C. Vande Berg, F. Lecouvet, J. Malghem; Brussels/BE

Purpose: To test the hypothesis that the development of steroid-induced femoral head osteonecrosis may be influenced by the femoral neck marrow status before treatment.

Materials and Methods: 20 consecutive untreated patients with a newly diagnosed rheumatic disease in whom a standardized GC regimen was planned were selected for this study. MR parameters obtained before the start of treatment included (a) determination of Index of marrow conversion (IMC; SI (neck)/SI (greater trochanter)*100) and proportion of surface area of femoral neck occupied by fatty marrow (on coronal T1W SE images) and (b) bulk T1 and T2 relaxation time values of femoral head and neck marrow (on a quantitative MR sequence). Presence of osteonecrosis was determined at follow-up MR imaging obtained 6 months after onset of treatment.

Results: Four patients (20%) developed femoral head osteonecrosis at follow-up MR. The mean IMC value was higher in ON-positive (83.2 ± 6.2) than ON-negative patients (75.8 ± 8.1) ($p = 0.09$). The mean percentage of fat marrow in the femoral neck was higher in ON-positive ($86.5 \pm 1.3\%$) than in ON-negative patients (31.7 ± 35) ($p = 0.0066$). Mean T1 relaxation time values of femoral neck were shorter in ON-positive (257 msec) than in ON-negative patients (307 msec) ($p = 0.0423$).

Conclusion: A high fat content in the proximal femur marrow as determined by MR imaging before CS-treatment is predictive for the development of femoral head ON in CS-treated patients.

B-004 10:57

Comparative study of post-operative and spontaneous pyogenic spondylodiscitis

A. Feydy, V. Dufour, L. Le Page, N. Belmatoug, B. Fantin, V. Vilgrain; Clichy/FR

Purpose: Post-operative spondylodiscitis are poorly characterized, partly owing to their rarity. The aim of this prospective study was to compare the clinical, biological, bacteriological and imaging features of post-operative and spontaneous spondylodiscitis.

Methods: A multidisciplinary spondylodiscitis cohort follow-up study was conducted between February 1999 and June 2003 in a 500-bed teaching hospital. All patients hospitalized in internal medicine, orthopedic and neurosurgery wards with a culture-proven diagnosis of pyogenic spondylodiscitis were included. Clinical and bacteriological data were collected. All patients underwent computed tomography and/or magnetic resonance imaging of the spine.

Results: 16 patients had spontaneous spondylodiscitis (SS) and 7 patients had post-operative spondylodiscitis (POS). Patients with POS tended to be younger (52 versus 69 y), with less frequent underlying diseases (29% versus 75%) and a more prolonged interval between symptom onset and diagnosis (16 versus 3.4 weeks) than patients with SS. Blood cultures were positive in 14% and 81% of cases in the POS and SS groups respectively, and invasive diagnostic procedures were therefore necessary in 86% of patients with POS and 19% of patients with SS ($p = 0.005$). Staphylococci were the more frequent isolates in both groups but were more frequently coagulase-negative in POS patients than in patients with SS ($p = 0.01$). Vertebral edema tended to be more frequent in POS and was located more posteriorly than in SS ($p = 0.023$).

Conclusions: POS are associated with specific clinical, microbiological and imaging features possibly related to pathophysiological characteristics. Knowledge of these characteristics should help reduce the current delay in the diagnosis of POS.

B-005 11:06

Investigation of a tightly collimated lateral view of the cervico-thoracic region as a alternative to Swimmers's view for trauma patients

D. O'Leary¹, A. O'Loughlin², ¹Dublin/IE, ²Cork/IE

Purpose: Radiographic visualisation of the lateral cervico-thoracic region is rarely easy and is the greatest cause of trauma patients being delayed in X-ray. The region is obscured by the trapezius muscle/ humeral heads depending on patient body habitus. Previous studies show non-demonstration in 26%-38% of patients.

"Swimmer's view" is commonly employed to image C7/T1; the success of which is unpredictable with high radiation dose. "Swimmer's" is contra-indicated in the presence of an unstable cervical spine fracture. CT scanning is higher dose but

Scientific Sessions

remains the gold standard. An alternative projection is proposed: a true lateral, tightly collimated projection of the cervico-thoracic region (CTL) involving no patient movement and low exposure factor settings. We compared via a prospective study the proposed CTL projection and "swimmer's" projection for diagnostic efficacy, time efficiency and patient dose reduction.

Method: Trauma patients presenting for cervical spine radiography were randomised into two groups, half imaged with "Swimmer's" and half with CTL. Entrance Surface Dose (ESD) and Thyroid Dose (TD) were recorded using thermoluminescent dosimeters.

Results: ESD for CTL was consistently below 11 mGy. ESD for "Swimmer's" ranged from 7 mGy to 320 mGy. Assessment by a team of radiologists, radiographers and emergency physicians indicated that CTL is comparable to "swimmers" in image quality and diagnostic efficacy, while the patient dose was reduced to 2% of that for "swimmers". Imaging time and number of repeats were reduced.

Conclusion: The CTL projection considerably reduces patient dose with comparable diagnostic efficacy while reducing the time spent in the X-ray department.

B-006 11:15

Multi-slice CT (MSCT) as an integral component in primary trauma resuscitation

M. Körner, K.-G. Kanz, U. Linsenmaier, K.-J. Pfeifer, W. Mutschler, M. Reiser; *Munich/DE*

Purpose: To evaluate the time needed for whole-body MSCT in the early phase of trauma resuscitation.

Methods and Materials: In a prospective series, 125 consecutive patients fulfilling criteria for major trauma were evaluated. Initial imaging is limited to abdominal sonography (FAST) and supine chest radiograms. MSCT examination is initiated as an adjunct to primary survey immediately after clearing of critical conditions (i.e. intubation, chest tube, bleeding control). It consists of cranial, thoracic and abdominal CT. All MSCT scans were evaluated for time (min) from admission to CCT completion, duration of CT examination, and MPR calculating time as well as complications from early MSCT scanning.

Results: Time from trauma room admission to completion of cranial CT scan was 21:12 min. (median, interquartile range (IQR) 18:13 - 27:52), duration of complete CT examination including planning and contrast media administration was 6:08 min. (median, IQR 4:40 - 8:27). All MPR data was calculated in 5:29 min. (median, IQR 3:26 - 8:14). By using multiple workstations, data processing, image calculation, multiplanar reconstructions (MPR), and image reading can be performed at the same time. By processing the raw data, which is acquired by scanning the thorax and abdomen with 5 mm slice thickness, reconstructions of the spine with 3 mm slice thickness can be provided. No life-threatening complication due to early phase CT scanning was observed (0/125 CI 95% 0-3).

Conclusion: Integration of MSCT in very early trauma care provides a high standard of imaging in very short time without endangering a patient.

B-007 11:24

Imaging scaphoid trauma: An international survey of hospital practice

A.M. Groves, I. Kayani, R. Syed, N. Nagabushan, P.J. Ell; *London/UK*

Purpose: The scaphoid is the most common carpal bone fracture. The fracture must be identified early, as immediate treatment is required to minimise the chances of non-union and avascular necrosis thereby avoiding disability. However the imaging and treatment of such fractures remain controversial. In order to assess the consistency and evidence base of scaphoid imaging strategies we performed a survey of hospital practice in suspected scaphoid fracture.

Materials and Methods: Trauma or imaging specialists were surveyed by email regarding the imaging strategy in their respective hospitals of patients with suspected scaphoid fracture with normal/equivocal radiographs. 30 hospitals were surveyed including 12 from Europe, 6 from North America, 3 from South America, 6 from Asia and 3 from Australia.

Results: Data was obtained from 18/30 hospitals surveyed. None of the 18 hospitals had the same scaphoid imaging strategy. Less than half had a fixed protocol. The number of views of scaphoid plain radiographs varied from 2-6. Repeat radiographs were performed in 15/18 institutions, whilst in 3/18 other imaging modalities were used without further radiography. The definitive investigation was clinical examination in 1/18, scintigraphy in 5/18, magnetic resonance imaging in 4/18, computed tomography (CT) in 3/18, both CT and scintigraphy in 1/18, both MR imaging and scintigraphy in 1/18 and no single recognised definitive investigation in 3/18.

Conclusion: Despite the importance of early diagnosis/treatment of scaphoid

fracture, there is a lack of consistency and evidence base in scaphoid trauma imaging protocols. Further research is being performed at our institution to address this.

B-008 11:33

MR imaging in thoracolumbar burst fractures

N.A. Ghanem, M. Schwarz, G. Pache, C. Müller, M. Uhl, T. Bley, M. Langer; *Freiburg/DE*

Purpose: Evaluation of the diagnostic value of MR imaging in trauma patients with thoracolumbar burst fractures.

Material and Methods: A prospective study with 71 trauma patients was performed on a 1.5 T Magnetom. The MR imaging using sagittal T1-W-SE and T2-W-TSE or TIRM sequences was performed in a time frame of 5.8 days (range 1-19) 110). The evaluation included injuries of the vertebral body, adjoining intervertebral discs, ligaments, spinal canal and cord and adjoining soft tissue.

Results: Vertebral fractures were mostly located in the thoraco-lumbar transition (70.1% from T11 to L3) as well as the affected intervertebral discs (72%, 70 discs from T11 to L4). Anterior part involvement (48 cases, 67.6%) and posterior part involvement (56 cases, 78.9%) are usual after spine trauma, double fractures (32.9%) and a retropulsion of the posterior bone fragment (40%) less frequent. A spinal canal stenosis was shown in 72 fractures, a myelon compression the myelon was seen in 21 cases (30%) and a prevertebral haematoma was detected in 19 cases (26.8%). Signal alterations appeared in 97 intervertebral discs. MR imaging detected in 60/97 cases intradiscal bleedings (61.9%), herniations in ventral position were seen in 29.9% (29 cases), in medial position 44/97 (45.4%) and 5/97 (5.2%) in dorsal position. Stripping of the anterior longitudinal ligament (ALL) was seen in 56.3%, the posterior longitudinal ligament (PLL) was stripped in 28.2%.

Conclusion: MR imaging as a non-invasive method detects fractures and associated traumatised discs and ligament injuries and is essential for surgical treatment.

B-009 11:42

Traumatic injuries of the pelvis and thoracic and lumbar spine. Does thin-slice multidetector-row CT increase diagnostic accuracy?

C. Herzog, M.G. Mack, S. Zangos, W. Schwarz, K. Eichler, L. Thomas, T.J. Vogl; *Frankfurt a. Main/DE*

Purpose: To evaluate different multidetector-row CT (MDCT) strategies for adequate classification of spinal and pelvic injuries.

Material and Methods: 70 intubated patients after multiple trauma underwent conventional radiography (CR) and MDCT. Examinations included the pelvis (P), the lumbar spine (LS) and the thoracic spine (TS). Conventional radiographs, 3-mm (CT5) and 5-mm scans (CT3) and 3-mm and 5-mm scans combined with MPR (CT3R/CT5R) were compared to surgery, autopsy and clinical course.

Results: MDCT led to significantly better results than CR ($p < 0.01$). Correlation coefficients were $r = 1.0$ (CT3R), $r = 0.96$ [TS] to $r = 1.0$ [P/LS] (CT5R), $r = 0.8$ [P] to $r = 1.0$ [TS] (CT3), $r = 0.80$ [P] to $r = 0.86$ [TS] (CT5) and $r = 0.3$ [TS] to $r = 0.69$ [P] (CR). Fractures were identified by CT3R in 100% of cases, by CT5R in 95%, by CT3 in 90% [P] - 100% [TS], by CT5 in 83.3% [LS] - 90% [P] and by CR in 57.1% [TS] - 87.2% [P]. Unstable fractures were identified in 100% by CT3R, CT5R and CT3, 85.7% [TS] - 100% [P/LS] by CT5 and 57.1% [TS] - 80% [P] by CR.

Conclusion: Only overlapping thin-slice multiplanar reformation allows for an adequate classification of spinal and pelvic injuries and thus is highly emphasized in patients after severe blunt trauma.

New technique to avoid an increase in CT radiation dose from metallic prostheses with automatic tube current modulation: Phantom and patient study

T. Dalal¹, S.M.R. Rizzo¹, M.K. Kalra¹, B. Schmidt², C. Suess², M.A. Blake¹, T. Flohr², S. Saini¹; ¹Boston, MA/US, ²Forchheim/DE

Purpose: To evaluate a new technique to avoid increase in CT radiation dose using automatic tube current modulation in patients with metallic prostheses.

Materials and Methods: A Plexiglas phantom with and without metallic prosthesis was scanned using fixed effective mAs (200) and combined automatic tube current modulation. In clinical evaluation, 500 abdominal-pelvic MDCT exams (Sensation 16, Siemens Medical Solution) using combined modulation were reviewed to identify 9 patients (mean age = 66 years, range = 35-86 years) with metallic prostheses. Scanning parameters included 140 kVp, image quality reference mAs

Scientific Sessions

160, 0.5 s rotation time, 16*1.5 mm detector configuration, 24 mm table feed/gantry rotation, and 5 mm reconstructed slice thickness images. Nine age- and abdominal transverse diameter-matched patients (Mean age = 56, range = 36-72) with no metallic prosthesis who underwent abdominal-pelvic CT using identical scanning parameters were included in control cohort. Two radiologists graded phantom and clinical images acquired with combined modulation on 3-point scale based on extent and severity of streak artifacts. Effective mAs were recorded for each slice in all studies. Statistical analysis included Student's t test and Wilcoxon signed rank test.

Results: No significant differences in CTDIvol and DLP values were noted with combined modulation in phantom studies with and without metallic prosthesis ($p > 0.05$). In patients, there was no significant difference in mean effective mAs and artifacts between study and control cohorts ($p = 0.49$). There was almost perfect inter-observer agreement between the two radiologists ($\kappa = 1$).

Conclusion: The new technique successfully avoids increase in CT radiation dose from metallic prostheses in both phantom studies and patients undergoing CT with automatic tube current modulation.

Preoperative TNM staging of esophageal cancer: Comparison of 16-row multidetector CT (MDCT) with endoscopic ultrasonography (EUS) with correlation to the histopathological findings. Preliminary results

A. Ba-Ssalamah¹, W. Schima¹, S. Mehrain¹, A. Puespoeck¹, J. Zacherl¹, R. Sedivey¹, M. Prokop²; ¹Vienna/AT, ²Utrecht/NL

Purpose: To evaluate the preoperative staging of esophageal carcinoma with enhanced 16-row MDCT and compare the findings with results by EUS, in correlation with histopathological findings.

Materials and Methods: Twenty-three patients with esophageal carcinoma (proven by endoscopical biopsy) were preoperatively examined with a MDCT in a prone position. After distending the esophagus (gas granules) and stomach (1.5 l water) the thorax and neck were subjected to MDCT scanning with 16x0.5 mm, the abdomen with 16x1.5 mm and using an individualized contrast injection protocol based on a bolus tracking techniques. EUS were performed using a fibre-optic endoscopy with a 5-10 MHz electronic array and a 360° scanning angle. Our MDCT staging criteria were drawn from a careful review of literature and from personal experience and we used the TNM classification by the AJCC 1987.

Results: Both modalities detected all tumors with a sensitivity of 100%. T staging by MDCT and EUS reached accuracies of 79% and 89%. The diagnosis of local node involvement by MDCT was correct in 76% and in EUS in 82%. The evaluation of distant node involvement and other metastases reached an accuracy of 92% with MDCT and 65% with EUS.

Conclusion: Non-invasive MDCT does provide valuable information in the preoperative staging of esophageal carcinoma producing results which are comparable to EUS results.

B-012 10:39

Preoperative staging of gastric cancer: Value of hydro-enhanced multidetector CT in comparison to endoscopic ultrasound and surgical correlation

A. Ba-Ssalamah¹, W. Schima¹, S. Mehrain¹, J. Zacherl¹, A. Puespoeck¹, B. Happel¹, R. Sedivey¹, P. Pokieser¹, M. Prokop²; ¹Vienna/AT, ²Utrecht/NL

Purpose: To assess the utility of hydro-multidetector CT (HMCT) in the preoperative staging of gastric cancer in comparison to endoscopical ultrasonography (EUS) with post-operative histopathological correlation.

Material and Methods: HMCT and EUS examinations were performed in 57 patients with gastric cancer diagnosed by biopsy prior to surgery, on two different days. Distention of the stomach was achieved with 1 to 1.5 l of water. The HMCT- and EUS-findings were prospectively analyzed. Each case was staged according to the TNM classification and correlated with histopathological findings. HMCT scans were performed with a 16 channel scanner. EUS were performed using a fiber-optic endoscopy with a 5-10 MHz electronic array and a 360° scanning angle.

Accuracy of TNM-staging was calculated for each modality and findings of EUS and HMCT were directly compared to each other and correlated with histopathological findings.

Results: The accuracy for T staging with HMCT was 84%, for N staging 79% and for M staging 97%. The results of EUS were 90%, 69% and 43%. The correct classification was most difficult for CT in differentiating between T2 and T3.

Conclusion: Noninvasive HMCT of the stomach represents a valuable tool for the preoperative staging of gastric cancer. In cases of advanced gastric cancer the full extent of the disease is better visualized with CT than with EUS.

B-013 10:48

FDG PET/CT in staging of esophageal carcinoma

C. Thuerl, D.B. Husarik, G.K. von Schulthess, T.F. Hany; Zürich/CH

Purpose: To evaluate the diagnostic accuracy of FDG PET/CT in staging of esophageal carcinoma.

Material and Methods: Retrospective analysis of 16 patients (11 male/ 5 female, average age 58.5 years) with biopsy- proven carcinomas of the esophagus (EC) who underwent FDG PET/CT (standard dose of 370 MBq F-18 FDG, non-contrast enhanced low-dose CT for attenuation correction and image fusion) and conventional imaging studies for staging. Conventional imaging studies included endoscopic ultrasound (EUS) for T and N staging and contrast enhanced CT. PET/CT were read in consensus by two radiologists/nuclear medicine physicians blinded to the clinical information. Analysis included assignment to N- and M-stage.

Results: In all but one patient, FDG-PET/CT demonstrated the correct localization of the primary tumor. In all patients (n = 16) periesophageal lymph node metastases were suspected in EUS. In only three patients pathological periesophageal FDG-uptake in lymph nodes was observed and in five patients, distant metastases (M1a or M1b) were observed. 4 out of these 5 patients presented with pathological FDG-uptake in celiac lymph nodes (M1a). One patient showed pathological FDG-uptake in periportal lymph nodes.

Conclusion: Periesophageal lymph node staging cannot be improved by PET/CT in EC. Distant metastases, including celiac lymph node metastases, can reliably depicted by PET/CT.

B-014 10:57

The down staging evaluation of neo-adjuvant therapy for advanced esophageal cancer using volume rendered 3D-enhanced CT

S. Okazumi, K. Shuto, Y. Yoshinaga, H. Shimada, H. Matsubara, Y. Nabeya, Y. Gunji, T. Ochiai; Chiba/JP

Purpose: Using enhanced CT with full scale volume rendering analysis, the evaluation of the histological responses of neo-adjuvant therapy for advanced esophageal cancer were performed, and a diagnostic image for the evaluation of down staging was developed.

Methods and Materials: 53 cases of advanced esophageal cancer (pathologically diagnosed T3: 39, T4: 14) were examined. Contrast media (300 mg iodine/ml, 3 ml/kg) was administrated intravenously (3 ml/sec). CT (SIEMENS SOMATOM plus4) scans were performed (slice thickness: 2 mm) at 50 seconds delay. For creating the diagnostic image a SIEMENS 3D-VIRTUOSO was used as the workstation for image reconstruction and the area of complete response was expressed with specially selected colors and opacities. Simultaneous 3-dimensional images displaying inner esophageal or airway spaces, and outer solid organs were obtained. The diagnostic results were compared with the histological findings of specimens after surgery.

Results: The enhanced CT values significantly decreased after the therapies according to the histological responses ($p < 0.01$). As the result of the evaluation of down staging using the newly developed diagnostic image for the area of complete response, 100% of the positive predictive value, 97.4% of the negative predictive value and 98.1% of the overall accuracy were obtained. Especially, the estimation of invasion to the airway, pulmonary vein and pericardium, which were difficult with conventional methods, were markedly improved.

Conclusions: The qualitative diagnosis using an enhanced CT volume rendering method is useful to evaluate the histological response to neo- adjuvant therapy for advanced esophageal cancer.

Computed tomography for assessing the resectability and restaging TNM classification of esophageal carcinoma treated with pre-operative radiotherapy

G. Guo, C.H. Zang, Z.X. Lin, X.G. Zhou, R.H. Wu; Shantou/CN

Purpose: To evaluate the resectability and restaging for patients with esophageal carcinoma treated by radiotherapy using CT scan.

Methods: CT scans of 46 patients with squamous cell esophageal carcinoma treated by pre-operative radiotherapy were analyzed before operation. The aortic invasion, tracheobronchial invasion and positive lymphatic nodes were assessed respectively and compared with the pathologic data. Twenty-six cases had both pre- and post-radiotherapeutic CT data. The changes in aortic invasion, triangle-space, tracheobronchial invasion and lymphatic nodes between pre- and post-radiotherapy were compared.

Results: The accuracy, sensitivity and specificity of CT assessment for patients with esophageal carcinoma treated by radiotherapy in aortic invasion was 80%, 70%, and 88%; in tracheobronchial invasion was 91%, 89% and 94%; and in thoracic positive lymphatic metastases was 86%, 67% and 94%, respectively. There was significant difference in T down-staging between pre- and post-radiotherapy, but no significant difference in N down-staging.

Conclusion: CT was very helpful in restaging TNM classification in pre-operative patients with esophageal carcinoma treated by radiotherapy. The T classification of patients with esophageal carcinoma would be down-staged after radiotherapy. However, the N classification would not. An interval of 3-4 weeks between completion of radiotherapy and operation was recommended.

B-016 11:15

Hydro-multidetector CT in patients with gastric and duodenal lymphoma: Correlation with histopathological results

M. Uffmann¹, A. Ba-Ssalamah¹, C. Schaefer-Prokop¹, S. Mehrain¹, M. Raderer¹, M. Prokop²; ¹Vienna/AT, ²Utrecht/NL

Purpose: To evaluate the performance of hydro-multidetector CT for the characterization of gastric and duodenal lymphoma.

Methods and Materials: We examined 21 patients with endoscopically detected lymphoma using hydro-CT technique. Immediately prior to the examination, the stomach was distended by 1-1.5 l flavoured methylcellulose, and a spasmolytic i.v. agent was administered. The upper abdomen was scanned first with 4x1 mm or 16x1 mm using an individualized contrast injection protocol, followed by a scan of the lower abdomen and the chest for staging of the entire trunk. Interactive multiplanar reformations were used for reading. CT findings were evaluated and correlated with histopathological results.

Results: 12 patients had aggressive lymphoma (9 with diffuse large cell lymphoma, DLCL; 2 with aggressive follicular lymphoma; 1 with T-cell lymphoma). In this group, the thickness of the affected gastric wall ranged from 1 to 17 cm (mean 4.6 ± 5.8 cm). The tumour growth pattern was nodular (n = 6), circular (n = 3) or diffuse (n = 3). In 7 out of the 12 patients, the corpus was affected. 9 patients had indolent lymphoma (7 with gastric MALT lymphoma; 2 with indolent follicular lymphoma of the duodenum). The tumor growth pattern was homogeneous (n = 4) or circular (n = 3), with subtle to moderate wall thickening (0.5 to 1.5 cm, mean 0.9 ± 0.4 cm). In 2 patients with MALT lymphoma, the gastric wall was unremarkable.

Conclusions: For evaluation of gastric and duodenal lymphomas, hydro-multidetector CT is a valuable addition to regular CT-staging. It does not allow the characterisation of different histopathological types, but may assist in the differentiation between aggressive and indolent lymphoma.

B-017 11:24

Lymphoma of the colon: The spectrum of radiological changes

R. Ananthasivan, S. Fataar, A. Derweesh; Muscat/OM

Objectives: Lymphoma of the colon constitutes less than 1% of large bowel malignancies and yet is the second most common malignant disease of the colon. The aim of this study is to present the spectrum of radiological findings in colonic lymphoma.

Materials and Methods: We retrospectively reviewed the radiological investigations in patients with lymphoma of the colon referred to our institution over five year period.

Results: Colonic lymphoma may be either focal or diffuse in form. Caecum and/or ascending colon was the most common site involved, followed by the rectum. Focal forms included gross mural circumferential thickening of the bowel wall, sometimes accompanied by aneurysmal/paradoxical dilatation of the bowel lumen,

polypoid mass, intussusception, annular "apple-core" sticture, mucosal nodularity and mucosal fold thickening. Diffuse forms manifested as irregular thickening of the folds, extensive mucosal ulceration or multiple polypoid protrusions of the entire colon mimicking polyposis. Concomitant enlargement of the aortic, coeliac or retroperitoneal lymph nodes or extension to the surrounding tissues suggests a poor prognosis. An attempt was made to represent pictorially the spectrum of radiological findings in colonic lymphoma.

Conclusion: The imaging findings of colonic lymphoma are quite variable and overlap with other colonic pathology, yet there are some characteristics which help in the radiological diagnosis. Biopsy is required both for confirming the diagnosis and for a more detailed pathological classification.

B-018 11:33

Differentiation of gastric wall thickness between normal and gastric cancer on hydro-multislice CT

Y. Jeong, J. Oh, J. Seo, J. Park, H. Kang; Gwang Ju/KR

Purpose: The purpose of this study was to evaluate the wall thickness of normal and gastric cancer on hydro-MSCT.

Materials and Methods: 122 patients with gastric cancer diagnosed by endoscopic biopsy were scanned by MSCT (Light Speed QXi, GE). The stomach was optimally distended by 1,000 ml water. After administration of 130 ml of nonionic contrast material at 3 ml/sec, arterial and portal venous phases were obtained at 2.5 mm slice thicknesses. One radiologist measured the thickness of normal fundal, body, antral and pyloric wall (n = 488) and the involved wall by gastric cancer (n = 122) on PACS monitor. Two radiologists reviewed the presence of layering and enhancement pattern of the gastric wall.

Results: The mean wall thickness of normal stomach is 2.4 mm (range, 0.5-7 mm). The mean wall thickness of EGC (n = 67) and AGC (n = 55) is 8.9 mm (range, 3.1-17.5 mm) and 11.9 mm (range, 5.6-29.5) respectively. The finding of gastric wall thickness of 5 mm or greater had sensitivity of 90% and specificity of 57% for EGC and a sensitivity of 100% and specificity of 98% for AGC. Although gastric wall thickness on EGC is less than 5 mm, focal or eccentric wall enhancement showed a specificity of 67% and a sensitivity of 94%.

Conclusion: Gastric wall thickness of 5 mm or greater on hydro-MSCT may be a useful indicator for diagnosis of AGC, but not for diagnosis of EGC. Focal or eccentric wall enhancement is more important than gastric wall thickening only in the detection of EGC.

B-019 11:42

High resolution MR imaging of oesophageal cancer with pathological correlation

A.M. Riddell, J. Hillier, D.M. King, A. Wotherspoon, G. Brown; London/UK

Purpose: Currently EUS has higher accuracy than CT for local staging of oesophageal cancer (at 60-80%), but has limitations; restricted sonographic view, reduced accuracy post chemotherapy and failure in up to 20% for stenotic tumours. High resolution MR imaging can potentially delineate tumour and surrounding anatomic structures. Our study aims were: (1) To determine whether anatomical structures and tumour are clearly depicted on MR imaging and (2) To validate accuracy by correlating MR imaging measurements with pathology.

Method: Ten patients with oesophageal carcinoma underwent MR imaging prior to surgical resection. High resolution T2W axial images through the oesophagus were acquired and images matched with histology sections. Three radiologists blinded to histology reports reviewed the MR images. For each image, tumour appearance and location, together with measurements of normal wall and tumour thickness were noted and correlated with histology. Interobserver variability was assessed by analysing repeatability of measurements between different readers.

Results: 50 images had corresponding histology. All readers correctly located tumour in 8 patients; pathology for the other 2 revealed only microscopic disease. Tumour returned intermediate signal intensity distinct from normal tissue. Mean difference between MR imaging and histology for measurements of wall and tumour thickness (in mm) was: 0.54 ($SD \pm 4.19$), 0.86 ($SD \pm 3.93$) and 1.01 ($SD \pm 4.11$) respectively for the 3 readers. Mean difference in measurements between readers ranged from 0.2 to 0.47 mm.

Conclusion: High resolution MR imaging of oesophageal cancer provides detailed imaging of the tumour and surrounding anatomical structures thus confirming the potential as an alternative method of local tumour staging.

Efficacy of multidetector row CT in staging gastric cancer according to the Japanese classification of gastric carcinoma

M. Mazzei, D. Marrelli, E. Pinto, L. Pirtoli, L. Volterrani; Siena/IT

Purpose: To correlate high resolution multidetector row CT with pathological findings in T and N-staging gastric cancer according to the Japanese classification of gastric carcinoma.

Methods and Materials: 44 patients with gastric carcinoma underwent preoperative multislice-CT after drug induced hypotonia and gaseous distention of the stomach. Contrast-enhanced CT after i.v. administration of 160 ml of iodinated contrast media at 4 ml/s and 50-55 sec delay, were acquired at 2.5 mm of slice thickness, 0.8 mm reconstruction interval and a 0.6 s rotation time. The examination was performed from the diaphragmatic domes to the pubis. Precontrast scanning was not performed. Regional lymph nodes were considered involved when the short-axis diameter was > 5 mm for the lymph nodes of group 1 and > 8 mm for the lymph nodes of other groups according to location of the tumor and Japanese classification of gastric carcinoma. All patients underwent laparotomy resection of the primary gastric tumor with complete lymph node group dissection.

Results: Regarding T-stage, in 36/44 (81.8%) there was a good correlation with histological results. Regarding the N-stage a good correlation with pathologic results occurred in 38/44 (86.36%) patients.

Conclusion: Multidetector-row CT improves the accuracy of preoperative staging of gastric cancer according to the Japanese classification of gastric carcinoma and the results can be used to optimize the therapeutic strategy for each individual patient prior to surgery.

Breast MR adding single-voxel proton spectroscopy to dynamic imaging

A. Fausto, F. Sardanelli; Milan/IT

Purpose: To evaluate feasibility and gain in specificity of breast proton MR spectroscopy (1H-MRS) added to dynamic MR imaging (D-MRI).

Methods and Materials: Thirty-seven patients underwent breast D-MRI (1.5 T) using 128 T1-weighted 3D gradient-echo coronal 1 mm partitions (1 mm³ voxel) with 0.1 mmol/kg Gd-DOTA and 120-s resolution (1 pre- and 4 postcontrast). Thereafter, water- and fat-suppressed spin-echo (TR/TE = 1500/136 ms) single-voxel 1H-MRS was obtained for 16 malignancies, 15 benign lesions and 10 normal glands. An intensity cholin peak (Cho) integral at 3.2 ppm equal or higher than 2.0 was considered as a marker of malignancy. D-MRI was interpreted integrating morphologic and dynamic parameters.

Results: Examination time: D-MRI, 10'; 1H-MRS, 7-19 minutes (adjustments, 6'; acquisition 1'36"-13'). No reliable spectrum (low signal-to-noise ratio) was obtained in 3 cases (2 IDCs and 1 benign enhancement). Acceptable spectra were obtained in 38 cases with a median voxel size of 2.2 cc (3.0 ± 2.3 cc). The only false negative at 1H-MRS was a DCIS (Cho 1.42). In the remaining 13 malignancies, median Cho was 3.2 (range 2.0-7.45); 3 false positive cases had a Cho of 12.6 (inflamed lymph node), 9.0 (dysplasia), and 2.3 (benign contrast enhancement); in 21 benign cases, Cho was not distinguishable from noise. Sensitivity was 93% (13/14) for both D-MRI and 1H-MRS, specificity 75% (18/24) and 88% (21/24), respectively, giving a 13% gain in specificity.

Conclusions: Single-voxel 1H-MRS can be performed as a final step after D-MRI and seems to give an interesting gain in specificity.

B-022 10:39

Influence of vascularization of breast lesions on electrical conductance and detection rate using EIS

A. Malich¹, M. Facius¹, J. Boettcher¹, M.G. Freesmeyer², B. Scholz³, W.A. Kaiser¹; ¹Jena/DE, ²Halle/DE, ³Forchheim/DE

Purpose: Currently electrical impedance scanning (EIS) despite its advantages (handling, applicability, no side effects, lack of radiation) is limited in its clinical

relevance due to high number of false positives. Whereas superficial artifacts play a major role inducing these FP, other factors do cause these FP-value furthermore. This study is aimed to analyze whether hypervascularization causes these focal enhanced electrical values as well.

Methods and Materials: All patients undergoing an EIS (TS2000, TransScan, USA) and a MRM-examination (ACSI, Philips, Netherlands), who finally were histopathologically verified or had a follow-up of > 1 year were included. Dynamic enhancement was scored: D1=strong; D2=moderate; D3=similar to glandular tissue; D4=no or subtle enhancement. Type of enhancement was correlated to histopathological outcome and EIS-performance (Chi-Square-Testing).

Results: 88/113 malignant and 107/182 benign findings were correctly detected in EIS (S = 79%; Sp = 59%). MRM was not possible due to contraindications in 17 cases. MR correctly detected 101/104 malignancies and 141/174 benign lesions (S = 97%; Sp = 81%). 22/55 benign lesions with D1 were correctly negative in EIS (44.4%), whereas this value was 82/119 for D2-4 (68.9%, p < .01), being highest in D4 (75%). Taking into account only fibrotic/fibroadenomatous tissue, 10/23 lesions with D1 were correctly unsuspicious and 29/37 lesions of same histology with D2-4 were correctly unsuspicious (43.5% vs. 78.4%, p < .01).

Conclusion: Although impedance scanning uses low frequencies up to 5 kHz, vascularization of the lesion influences the measurable conductance and, thus, induces false positive results in highly vascularized benign lesions.

B-023 10:48

The negative predictive value of electrical impedance scanning in BI-RADS IV breast lesions

M.H. Fuchsäger, D. Flöry, M. Philipp, C.C. Riedl, J. Sylvia, T.H. Helbich; Vienna/AT

Purpose: To assess the value of electrical impedance scanning (EIS) as negative predictor in breast lesions classified as probably malignant (BI-RADS IV) in mammography.

Methods and Materials: EIS (TransScan TS2000, TransScan Medical, Israel, Siemens-Elema, Sweden) was performed on 184 BI-RADS IV lesions in 169 women (51.5 ± 8.1 yrs) using the targeted mode after sonographic and / or mammographic localization. The current EIS-software 2.67 calculates a BI-RADS-like level of suspicion (LOS) on a 5-grade scale (1-negative, 2-benign finding, 3-probably benign finding, 4-suspicious abnormality, 5-highly suggestive of malignancy). LOS 1, 2 and 3 were considered as negative. LOS 4 and 5 were considered as positive. Histopathologic results were obtained in all lesions.

Results: Histology proved 57 lesions to be malignant, 127 benign. Sensitivity, specificity and accuracy rates, PPV and NPV were, respectively, 92.9%, 59.8%, 70.1%, 50.9% and 95.0%.

Conclusion: Our results suggest that EIS is an useful adjunct to mammography in the evaluation of BI-RADS IV breast lesions. With a NPV of 95%, EIS may reduce unnecessary interventions in benign lesions and therefore also minimize costs and patients morbidity, which could occur in a short-time follow-up.

B-024 10:57

Elastosonography of benign and malignant nodular breast lesions

A. Martegani, F. Clarizia, G. Rossini, C. Borghi, C. Del Favero, R. Campi; Como/IT

Purpose: To evaluate if elastosonography can play a significant role in the diagnosis of breast nodular lesions.

Methods: 76 patients, affected by a total of 89 nodular lesions (benign and malignant), were enrolled in our study from January 2004 to August 2004. Each patient was submitted to ultrasound examination followed by elastography, both performed by EUB-8500/Logos-Hitachi/Esaote-Japan, equipped with different linear electronic 7.5-13 MHz transducers. A dedicated device was applied to the transducer in order to improve the contact with skin. The elastographic scan required a short training for the operator; the entire elastographic scan acquisition required generally only few minutes to be performed (2-5 minutes). Breast nodules were classified according to the morphological elastographic Ueno scores. Cytohistologic biopsy, surgical specimen and follow-up were considered as gold standard.

Results: Some reproducible elastographic patterns were found both in cystic lesions and in large (> 2 cm) malignancies. Sensitivity, specificity, positive predictive value, negative predictive value and accuracy were respectively 82.2, 97.7, 97.3, 84.3, 89.8% considering 4-5 score as cut off values and 97.7, 86.4, 88, 97.4 and 92.2% considering 3-5 score as cut off value. A statistical analysis considering the reliability of the method according to lesion diameter (< 1 cm, 1-2 cm, > 2 cm) was performed as well. Elastographic behaviour of small benign and malignant nodules (up to 1 cm) was more uniform compared to those larger than 2 cm.

Scientific Sessions

Conclusion: Elastography demonstrates a high diagnostic accuracy in characterising breast nodular lesions, especially if smaller than 2 cm.

B-025 11:06 ♀

Real-time ultrasound elastography: Diagnostic tool or electronic gadget?

M. Locatelli, R. Chersevani, G. Rizzato; Gorizia/IT

Purpose: To assess the accuracy of in vivo ultrasound elastography in the evaluation of nodular benign and malignant breast lesions.

Methods and Materials: Ninety-seven breast lesions from 68 patients were studied with the EUB 8500 Logos ultrasonic unit (Hitachi, Japan) and a linear array transducer of 7.5-13 MHz. In 54% of lesions we obtained a pathologic diagnosis. All the other cases were well known benign lesions that we had monitored for at least two years. The elastic score was classified according a five-point color scale. The size of the lesions obtained by conventional B-mode was compared with the elastographic size.

Results: 25 lesions resulted as very stiff and 23 of them turned out to be malignant (92%). 19 masses were classified as soft-mixed areas and 16 were fibroadenomas (84%). Typical three-layered areas were found in 93% of cysts. In 21 cases the estimated diameter of the lesion was greater with elastography than with B-mode; most were tumoral masses with infiltrating pathological behaviour. The exam was hampered in 4 cases (5.8%) because of the extremely stiff breast or because the lesion was located in a marginal area with insufficient surrounding tissues.

Conclusions: Real-time elastography is a very quick and easy to perform diagnostic tool. Its online availability helps to increase the diagnostic confidence and to reduce unnecessary biopical procedures in benign masses. Its ability to compare a lesion with the surrounding tissues might also be tested in the evaluation of the therapeutic efficacy for both tumors and inflammation.

B-026 11:15

Multislice galacto-CT versus galactography in the evaluation of nipple discharge

L. Bacigalupo, D. Brizzi, G. Baio, C. Faedda, G. Gaggero, M. Calabrese; Genoa/IT

Purpose: To compare multislice galacto-CT (MSGCT) with galactography (GG) in the evaluation of single lactiferous duct discharge.

Methods and Materials: 16 patients have undergone GG (Siemens, Mammomat) with the intraductal injection of 2 ml of iodinated contrast media (CM). Then, with the iodinated contrast media still inside the duct, the 16 patients have undergone 1 contrast-enhanced MSGCT (Siemens, Somatom sensation 4) acquisition. All the MSGCT examinations have been post-processed with MIP and MPR reconstructions. Both procedures have undergone dosimetric controls.

Results: GG has individuated 5 single intraductal papillomas, 3 multiple papillomatosis, 7 stops to contrast media progression and 1 galactophoritis. MSGCT has confirmed the results of GG in 10 cases. In the remaining 6 cases it has modified the results of GG: 2 cases that appeared as single papillomas at GG (distal stop at CM progression), at MSGCT showed multiple papillomatosis; 3 cases that appeared as proximal stops at CM showed on MSGCT as 1 single papilloma and 2 multiple papillomatosis; in 1 case in which at GG we had observed a proximal stop at CM, at MSGCT showed 1 papilliferous carcinoma and a multiple papillomatosis in different quadrants. The mean glandular dose for the GG was 7.6 mGy, for the MSGCT 10 mGy.

Conclusion: From our preliminary experience MSGCT appears to be a valid alternative to GG, in particular in the evaluation of stops at GG. Furthermore MSGCT glandular mean dose appears comparable to the one of GG.

B-027 11:24

Complementary role of CT-laser-mammography (CTLM) to mammography and ultrasound in patients with breast lesions

D. Floery, C.C. Riedl, S. Jaromi, M.H. Fuchsjaeger, W.K. Matzek, G. Heinz-Peer, S. Leodolter, T.H. Helbich; Vienna/AT

Purpose: To assess the value of Computed Tomography Laser Mammography (CTLM) as an adjunct to mammography (MG) and ultrasound (US) in the detection of malignant breast lesions.

Methods and Materials: In a prospective study, CTLM scans (CTLM scanner Model 1020 by IMDS, Inc. FL), MG and US of 292 patients with 300 breast lesions were obtained. Histopathological diagnosis (biopsy and/or surgery) was performed in all cases. The CTLM images were read as an adjunct to MG and US.

Results: Of 300 lesions, 132 (44.0%) were malignant and 168 (56.0%) benign including 70 invasive ductal carcinoma (IDC), 18 invasive lobular carcinoma (ILC), 35 ductal carcinoma in situ (DCIS) and nine cancers of other types. CTLM achieved

a sensitivity of 64.4% (85/132 true positive) and a specificity of 55.4% (93/168 true negative). Positive and negative predictive value were 54.0%, and 65.6% respectively. Sensitivity, specificity, PPV and NPV were 92.8%, 40.4%, 56.2%, and 87.2% for MG and 65.4%, 53.0%, 53.0%, and 65.4% for US.

Conclusion: The present results indicate that CTLM may have potential adjunctive value to MG and US in the diagnosis of breast cancer.

B-028 11:33

The value of imaging angiogenesis in breast cancer: Is "benign" angiogenesis a diagnostic problem?

E.N.C. Milne; Plantation, FL/US

Purpose: Mammography is fundamentally a triage procedure to decide whether to biopsy. Its results are poor, 40 to 80% of biopsies being negative. Our aim is to reduce the percentage of negative biopsies.

Materials and Methods: Computed tomographic laser mammography, (CTLM), uses the same mechanical principles as X-ray CT. The laser, tuned to 808 nm, selectively visualises hemoglobin to demonstrate normal vessels and angiogenesis. Each of 700 patients received a mammogram, and a CTLM, and 445 were biopsied.

Results: 81 of 445 biopsies were positive. Adding CTLM to mammography did not change sensitivity but increased specificity by over 20% and reduced the percentage of negative biopsies by 42%. Of 351 benign cases with detailed pathology, 23% showed some evidence of angiogenesis as follows. Fibroadenomas (78) 27%, Mastitis (78) 25%, Fibrosis (26) 23%, Apocrine metaplasia (19) 21%, Normal Tissue *(39) 18%, Fibrocystic disease (108) 12%, Cysts (43) 9%, Adenosis (34) 9%. *The "angiogenesis" in 'normal' tissue was not related to hormonal effects but to involution of portions of the breast leading to 'redistribution' of blood flow to normal parenchyma. Benign angiogenesis is not of great clinical import. It does not result in false negatives but simply in a failure to save those cases from biopsy.

Conclusion: Imaging angiogenesis is a valuable approach to reducing negative biopsies but, to assist in the decision whether to biopsy, should be combined with prior imaging and clinical data.

B-029 11:42

Effect of acquisition geometry and radiation dose on lesion visibility in full field breast tomosynthesis

A.P. Smith, G. Hitzke, C. Ruth, B. Ren, Z. Jing, N. Gkanatsios, J. Stein; Bedford, MA/US

Purpose: Clinical use of breast tomosynthesis requires optimization of parameters such as view orientation, scan angles and dose. We have studied the effects of acquisition geometry and patient dose on the conspicuity of lesions and microcalcifications.

Methods and Materials: Patients referred for diagnostic mammography underwent tomosynthesis scans on a modified Selenia full field digital mammography system. Patients and phantoms were acquired with a variety of scan angles, number of views and total radiation dose. Reconstructions were evaluated and rated on feature conspicuity and overall image quality.

Results: Scans angles were varied from 10 to 30 degrees. Number of views ranged from 4 to 11. Doses for a 4.5 cm breast ranged from 1.5 to 5 mGy. For each case, images were reconstructed into 3D volumes with slice separation of 1 mm. Objects with non-zero thickness showed contrast improvement as the scan angle decreased, which also increased the depth of field. Shadows from out-of-plane objects increased as the scan angle decreased and decreased with more views for reconstruction. Individual microcalcification sharpness was mainly independent of scan angle, but cluster visualization improved at smaller scan angles. Similar to 2D digital mammograms, image noise is clearly a function of radiation dose. However, there appears to be a lesser effect of radiation dose on the visibility of lesions.

Conclusions: Many variables affect tomosynthesis acquisitions. Our preliminary results are directing clinical trials to further optimize the system. System design allows technique selection to favor either sharpness or contrast while keeping dose fixed.

B-030 11:51

Contrast-medium enhanced mammography: A twofold approach

P. Baldelli¹, A. Bravin², E. Fabbri¹, M. Gambaccini¹, M. Marziani¹, A. Sarnelli¹, A. Taibi¹; ¹Ferrara/IT, ²Grenoble/FR

Purpose: The aim of the work is to investigate the use of a contrast medium in mammography.

Methods and Materials: There are two different techniques to enhance the

Scientific Sessions

radiographic signal of contrast media. The first one - Contrast enhanced dual energy mammography (CEDEM) - is based on the acquisition of two images at different energies after the contrast medium injection. By combining these images, hybrid images are obtained in which the contrast of relevant structures is preserved while unwanted tissue contrast is largely removed. The second one - K-Edge Subtraction Mammography (KESM) - is based on the K-edge absorption of the contrast medium. Two images are obtained from those acquired at energies below and above the k-edge. The first one is the contrast-medium-concentration map and the second one is the distribution of all other tissues. Experiments have been performed using both conventional systems and monochromatic radiation. A three component phantom with iodine filled details has been developed. A simulation study has been carried out in order to study the relationship between the contrast medium concentration and the SNR achievable on the resulting image.

Results: The SNR (Signal-to-noise-ratio) as a function of the dose to the patient and of the contrast medium concentration has been taken as figure of merit for comparing CEDEM and KESM.

Conclusion: Results of simulations and radiographic tests are in good agreement and show the potential of the two techniques to improve the detection of small details.

Incidental finding of primary lung cancer in patients with atherosclerotic disease: Single-centre retrospective evaluation of MDCT angiography studies over the past three years

A. Napoli, C. Catalano, P.G. Nardis, M. Cavacece, L. Bertoletti, F. Fraioli, R. Passariello; Rome/IT

Purpose: To retrospectively evaluate the incidence of primary lung cancer in patients with symptomatic atherosclerotic disease, undergoing multi-detector row CT (MDCT) angiography.

Materials and Methods: From January 2001 until May 2004, 832 CTA examinations were evaluated. Relevant atherosclerotic disease was observed in 712 patients (158 women and 554 men; age 35-92). CTA was required for carotid arteries stenosis (n = 277), thoraco-abdominal aortic aneurysm (n = 38), thoracic aortic aneurysm (n = 31), abdominal aortic aneurysm (n = 186) and lower extremity arterial disease (n = 180). Scan volume, depending on vascular region, always included: the lung apices and lung bases respectively in the examination of carotid arteries and the abdominal aorta and run off vessels and the entire lung when examining thoracic aorta. Biopsy was performed in each patient with suspected lung nodules. Study population incidence was compared with healthy subjects aged more than 65 years old.

Results: Lung cancer was found in 17 patients, 11 men and 6 women. The incidence of primary lung cancer in our study population was 2.4% with an increased relative risk, compared with healthy subjects, of as much as 8.6-fold for primary lung cancer. When considering each sex separately, we found 2.3% incidence in males and 3.8% in females, where the relative risk was as high as 3.5-fold and 64.6-fold respectively.

Conclusion: Our study showed a higher incidence of primary lung cancer in patients with symptomatic atherosclerotic disease, particularly in female patients. These results might suggest extending the CT scan for vascular patients to include the entire lung parenchyma by means of a very low dose.

B-032 10:39

Chest X-ray vs. multislice CT performed at identical radiation doses for detection and characterization of pulmonary nodules

U. Zaspel, V. Romano, P. Hein, B. Hamm, P. Rogalla; Berlin/DE

Purpose: To compare chest X-ray and multislice CT (MSCT) using identical radiation doses for detection and characterization of pulmonary nodules.

Material and Methods: 42 consecutive patients (age range: 22-87) underwent chest X-ray (pa and lat: 28, pa:14), followed by a minimized-dose chest MSCT (time interval ranged: 1-32 days), performed at 3.5 eff. mAs, 120 kV, collimation 16*1 mm (Toshiba Aquilion), resulting in a dose identical to chest X-ray (0.2 mSv).

Images were reformatted in axial, coronal and sagittal planes. Two experienced radiologists evaluated both studies in consensus (minimum time interval between X-ray and CT: 7 days) with regard to number, size, location, shape and characterization of nodules. Diagnostic confidence in detection and characterization was ranked along a scale from 1 (min) to 10 (max).

Results: Correlation for identifying patients with nodules was 0.43 (kappa) ($p = 0.05$). A total of 52 pulmonary nodules (mean 1.2 per patient, range: 0-10) were diagnosed with chest X-ray and 136 pulmonary nodules (mean 3.2 per patient, range: 0-20) using MSCT (paired Wilcoxon U-test $p = 0.001$). CT classified 59 nodules as benign, 74 as malignant and 3 as undetermined. Chest X-ray categorized 7 nodules as benign, 37 as malignant and 8 as undetermined. Confidence in detection was significantly higher on CT than on chest X-ray ($p < 0.001$) as was the characterization of nodules ($p < 0.001$).

Conclusion: MSCT of the chest performed with X-ray dose detects more nodules at higher diagnostic confidence than chest X-ray and may serve as alternative in patients with suspected pulmonary nodules without an increase in dose.

B-033 10:48

MR imaging of the lung: Comparison of turbo-spin-echo and 3D gradient-echo pulse sequences for the detection of pulmonary metastases

M. Bruegel, J. Gaa, K. Woertler, C. Ganter, S. Waldt, K. Marten, C. Engelke, E.J. Rummeny; Munich/DE

Purpose: Suitable MR pulse sequences for imaging of the lung have become important due to increasing interest in whole-body MR imaging for tumor staging in oncology. We compared different MR pulse sequences for imaging of the lung with respect to lesion detectability in patients with pulmonary metastases.

Material and Methods: 16 patients with pulmonary metastases detected by multislice CT (MSCT) underwent MR imaging of the lungs at 1.5 T. MR imaging included breath-hold T2-weighted TSE, IR-TSE, HASTE and IR-HASTE sequences, a respiratory- and pulse-triggered black-blood-prepared T2-IR-TSE sequence and T1-weighted volumetric interpolated breath-hold (VIBE) 3D-GRE sequences (pre- and post-Gd-DTPA). MR pulse sequences were analyzed quantitatively and qualitatively. MSCT served as the gold standard.

Results: Mean lesion-to-lung contrast-to-noise ratios were highest with T2-TSE (57 ± 12) and post-contrast-VIBE (41 ± 11) and lowest with T2-IR-HASTE (12 ± 4) and pre-contrast-VIBE (18 ± 5). Respiratory/pulse-triggered T2-IR-TSE and pre- and post-contrast-VIBE images showed the lowest rate of artifacts. Lesion conspicuity of 144 pulmonary nodules detected by MSCT was highest with respiratory/pulse-triggered T2-IR-TSE (sensitivity, 76%; PPV, 96%), followed by T2-TSE (sensitivity, 71%; PPV, 95%). With HASTE, IR-HASTE, pre- and post-contrast-VIBE significantly lower ($p < .05$) sensitivities (< 50%) were obtained. Breath-hold T2-IR-TSE produced the highest number of false-positive findings (sensitivity, 60%; PPV, 87%). Sensitivities using respiratory/pulse-triggered T2-IR-TSE were 94% and 100% regarding 5-10 mm-sized and > 10 mm-sized nodules, respectively; however, only 33% of < 5 mm-sized nodules were detected.

Conclusion: Compared to different turbo-spin-echo and 3D-gradient-echo pulse sequences for MR imaging of the lung, respiratory- and pulse-triggered T2-IR-TSE was most sensitive in the depiction of pulmonary metastases and allowed reliable detection of nodules ≥ 5 mm.

B-034 10:57

Detection of malignant pulmonary nodules: Determination of the optimal MR imaging sequence and evaluation of its performance

W. Luboldt, K. Eichler, C. Herborn, T.O.F. Wagner, H.-G. Fieguth, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To determine the optimal MR imaging sequence for detecting malignant pulmonary nodules.

Materials and Methods: On the basis of 6 lung cancer, 46 metastases and one tuberculoma in 13 patients eight MR imaging sequences were compared in terms of contrast-to-noise ratio (CNR), sensitivity and quality in the visualization of pulmonary nodules. The following sequences were used: HASTE, IR-HASTE, fat saturated TrueFISP, STIR, VIBE_{ipat=2}, and contrast-enhanced (CE) VIBE with $ipat = 2, 0, 4$ and performed in high spatial resolution using parallel imaging with 12 coil elements.

Results: The STIR sequence significantly ($p < 0.01$) showed the highest CNR (mean: 22 ± 13) followed by the FS TrueFISP (CNR: 18 ± 18), CE VIBE_{ipat=0} (CNR: 17 ± 15), CE VIBE_{ipat=2} (CNR: 15 ± 17), HASTEIRM (CNR: 12 ± 10), HASTE (CNR: 9 ± 11), CE VIBE_{ipat=4} (CNR: 6 ± 7), and VIBE (CNR: 4 ± 6). The STIR sequence showed 25 of 28 nodules ≤ 5 mm and all nodules > 5 mm. The 19 mm benign nodule was nearly invisible on the STIR-sequences and showed the highest CNR on the TrueFISP, VIBE and HASTE.

Scientific Sessions

Conclusion: The STIR sequence is the optimal sequence for detecting malignant pulmonary nodules, promises not to display benign nodules, and thus, should be used in future studies comparing MR imaging with CT and PET for the early detection of pulmonary malignancies.

B-035 11:06

Evaluation of dynamic contrast enhancement pattern of solitary pulmonary nodules on 3D gradient-echo MR imaging

E. Yekeler, V. Saedi, F. Yildirim Donmez, A. Tunaci, M. Tunaci, G. Acunas; *Istanbul/TR*

Purpose: To evaluate the dynamic contrast enhancement pattern of solitary pulmonary nodules using a 3D-FLASH sequence and to investigate the predictive value of contrast enhancement features of the lesions in differential diagnosis.

Materials and Methods: 40 patients with solitary pulmonary nodules detected on CT underwent MR imaging using T1-W GRE, T2-W spin-echo, pre-contrast and 10 consecutive contrast-enhanced 3D-FLASH sequences obtained every 30 seconds. Using Mean-Curve software, a plot was drawn encircling the lesions and SNR (signal-to-noise) values were measured for each sequence. Final diagnosis of the solitary pulmonary nodules was obtained by CT-guided biopsy, operation or re-imaging after medical treatment.

Results: According to final diagnosis, 10 patients had tuberculoma (25%, size-range, 1-3 cm; mean size, 2.1 cm), 20 patients had lung cancer (50%, size-range, 0.7-7; mean size, 3.8 cm), 10 patients had round atelectasis (25%, size-range, 1-4 cm; mean size, 2.1 cm), and 3 patients had both cancer and atelectasis (7.5%, size-range, 2-4 cm; mean size, 3 cm). The contrast enhancement patterns of all the lesions were significantly different from each other. Tuberculomas had peripheral rim enhancement, round atelectasis had homogeneous intense enhancement, whereas lung cancers enhanced peripherally with slow progressive heterogeneous fill-in of the lesions on late images. Time-to-peak values were 1.6, 4, and 2 minutes for tuberculomas, round atelectasis and lung cancers respectively. Lung cancers showed wash-out after the peak on the curve, unlike the atelectasis and tuberculomas.

Conclusion: Rim contrast enhancement pattern is highly valuable in diagnosing tuberculomas. SNR values are useful in differentiating round atelectasis from other nodular lesions. Time to peak values of round atelectasis, tuberculomas, and lung cancers can be taken into consideration in differential diagnosis.

B-036 11:15

Resolving small pulmonary nodules: CT characteristics

J. Hansen¹, D. Wormanns², S. Diederich¹; ¹Düsseldorf/DE, ²Münster/DE

Purpose: Small non-calcified pulmonary nodules are common. As most of these lesions are benign, non-invasive classification is required, usually based on follow-up with CT. According to current recommendations, growing nodules should undergo biopsy, stable nodules should be followed with CT, whereas resolving nodules do not require further investigation. Our aim was to analyse CT morphology over time of resolving nodules in order seek morphologic features helpful in initial nodule classification.

Material and Methods: Imaging characteristics of 133 consecutive resolving pulmonary nodules detected in 56 subjects in a screening trial for early lung cancer with low-dose CT were retrospectively reviewed by two readers in consensus.

Results: Maximum diameter was ≤ 5 mm in 71/133 (53%), 6-10 mm in 52/133 (39%), and > 10 mm in 10/133 (8%) of resolving nodules, ranging from 1 - 45 mm; (mean 5.9 mm). Location was mainly peripheral with a mean distance to the costal pleura of 10 mm. There was no lobe predominance of nodules. 85% (113/133) of nodules were solid, 10% (14/133) were part-solid and 5% (6/13) were non-solid. 77% (103/133) of nodules were well-defined, and 23% (30/133) were ill-defined. 73% (97/133) were non-lobulated, and 27% (36/133) were lobulated. 80% (107/133) resolved completely within 14 to 1671 (mean 492) days; 20% (26/133) resolved incompletely with residual abnormalities within 51 to 1777 (mean 613) days.

Conclusion: Resolving pulmonary nodules are mostly ≤ 10 mm, peripherally located, solid, well-defined, and non-lobulated. Most resolve completely within a variable interval ranging from several days to years.

B-037 11:24

Pulmonary micronodules (< 5 mm): 3 year follow-up of 238 nodules in 165 smokers

E. De Fiori, S. Ferretti, C. Rampinelli, M. Bellomi; *Milan/IT*

Purpose: Aim of this study is the evaluation of the clinical impact of pulmonary micronodules (diameter < 5 mm) in asymptomatic smokers.

Materials and Methods: Between June 2000 and June 2001, 238 non-calcified pulmonary nodules with diameter < 5 mm, were diagnosed with low-dose CT (ldCT), in 165 subjects enrolled in the observational study for the early diagnosis of lung cancer. All nodules were followed up at 12, 24 and 36 months with ldCT.

Results: 123 subjects (74%) had a single nodule, 42 had 115 nodules. In 39 subjects (23.6%) nodules disappeared during the 3 following years. In 110 subjects (66.6%) nodules remained unchanged. 16 nodules (6.7% of nodules, 9.7% of subjects) grew: 9 in subjects with a single nodule and 7 in subjects with multiple nodules. Only 6/16 nodules (37.5%) grew larger than 5 mm and were biopsied: 3 turned out to be tumors (all T1NO, two adenocarcinoma and one large cell neuroendocrine carcinoma) and 3 were benign lesions (one hamartoma and 2 inflammatory nodules).

Conclusions: Pulmonary micronodules are present in 16% of smokers. Their risk for being a carcinoma is 0.12%, in high risk subjects; these are often slow-growing tumors (doubling time > 200 days) that should not be followed up at intervals of less than 12 months.

B-038 11:33

Detection performance of a portable, large area, indirect flat-panel detector compared with storage phosphor radiography at different exposures in a phantom study

T.M. Bernhardt¹, U. Rapp-Bernhardt¹, H. Lenzen¹, R. Esseling¹, F.W. Roehl², F. Beyer¹, A. Wall¹, W. Heindel¹; ¹Münster/DE, ²Magdeburg/DE

Purpose: To evaluate detection of catheters, pulmonary nodules, simulated interstitial lung disease, and exposure requirements of a portable, indirect flat-panel detector versus storage phosphor radiography.

Materials and Methods: Catheters, nodules and simulated subtle interstitial lung disease (miliary, reticular, linear, ground-glass patterns) were superimposed over an anthropomorphic chest phantom. Images were acquired at 109 kVp and different exposures corresponding to 400 and 800 simulated speed with a portable flat-panel detector (CXDI-50 G, 14*17 inch imaging area, 4.8 kg weight, pixel pitch: 160 µm, Canon Inc.) and printed on hard copies. Images were compared with storage phosphor radiography images (ADC Compact Plus, Agfa Inc.) at 400 simulated speed. Four board-certified radiologists recorded 43,200 observations subjected to an ROC-analysis. Significance level was p = 0.05.

Results: Catheters over obscured chest areas, nodules (\leq and $>$ 10 mm) over lucent lung and nodules \leq 10 mm over obscured chest areas, miliary and linear patterns over lucent lung showed higher areas under curves (Az) with the GadOX-aSi flat-panel detector at 400- and 800-digital speed compared with storage phosphor radiography ($p > 0.05$). Equal or smaller Az values were found for reticular and ground-glass patterns for the flat-panel detector. However, these results were not statistically significant ($p > 0.05$).

Conclusion: Detection performance of a portable flat-panel detector showed higher Az values for detection of catheters, nodules and almost all interstitial lung disease at equivalent and reduced speed compared with storage phosphor radiography. These results suggest the use of the portable flat-panel detector with reduced exposure dose in patients.

B-039 11:42

Potential benefit of computer-aided diagnosis: Detection of subtle pulmonary lung nodules on chest radiography

Z. Huo¹, D. Yankelevitz², C. Henschke², W. Kostis², J. Wandtke¹, N. Paul³; ¹Rochester, NY/US, ²New York, NY/US, ³Toronto, ON/CA

Purpose: To assess the potential benefit of computer-aided diagnosis for lung cancer on chest radiography.

Methods and Materials: Forty-six subtle nodules (avg. size = 20 mm) were selected from 80 consecutive computed radiographic (CR) chest images, each with a CT-documented lung nodule. These images along with 54 CT-confirmed normal chest images were presented on a high-resolution monochrome monitor to five chest radiologists. The radiologists were asked to mark the location of each lung nodule seen, and their confidence level (on a 100-point confidence scale) of the likelihood of the nodule actually being present. Subsequently, they were asked to retrospectively review images on which they had missed nodules in their initial readings. With the nodule locations now marked, they were asked to rate the visibility of the nodule on a 5-point scale, and were asked if their visibility warranted further evaluation with CT.

Results: In their initial readings, radiologists correctly marked, on average, 51% of the CT-determined lung nodules on chest radiographs. Upon re-review of CR images with the nodule locations marked, however, radiologists would recommend a CT exam for more than half of CT-documented nodules that they had missed in their initial reading. Further, one third of these missed nodules were thought to have fair visibility as a nodule.

Scientific Sessions

Conclusion: Radiologists miss both high- and low-visibility nodules. A computer-aided system that proposes these nodules to radiologists should influence their decision to order a CT scan. Thus, potential benefit of using a computer-aided diagnosis system to indicate possible nodule locations is suggested.

B-040 11:51

A study of inter-observer variation of small pulmonary nodule marking on DR by using an interactive computer analysis system

W. Song¹, L. Fan², Y. Xie¹, G.-Q. Wei², J. Xu¹, Q. Si¹, C.-C. Liang², J.-Z. Qian², Z. Jin¹; ¹Beijing/CN, ²Princeton Junction, NJ/US

Purpose: To assess inter-observer variations of marking small actionable pulmonary nodules (5 to 15 mm in diameter) on chest digital radiograph (DR) by using an interactive lung nodule analysis system.

Method and Materials: A total of 194 chest DR PA screening studies were selected. An expert panel of chest radiologists used a computer system (EDDA Technology, Inc.) to mark and characterize small actionable nodules in the data set with consensus. Two additional radiologists independently read the same studies and marked small actionable nodules in two passes: first without reference to the suspicious nodules suggested by the computer but using other analysis functions provided by the system; then with reference to the suspicious nodules suggested by the computer. The five sets of marking and characterizing results were analyzed and compared.

Results: There were 50 small actionable nodules marked by the expert panel. Without consulting the computer suggestions but with usage of other interactive analysis functions the system provided, the two radiologists' detection rates of small actionable nodules were 54% and 40%, respectively. After consulting the computer suggestions, the detection rates increased to 80% and 76%, respectively, with a reduced inter-observer variation. The computer system reached a sensitivity of 70%, with an average FP of 2.8 per study. Statistics of other inter-observer variations also showed clinical significance.

Conclusion: The interactive computer aided analysis system can help to reduce inter-observer variation and to improve detection rates of actionable nodules, especially small nodules which are more likely to be overlooked.

Hepatocellular carcinoma missed on gadolinium enhanced MR imaging, discovered in liver explants: Retrospective evaluation

M.Y.K. Bilgili¹, K. Birchard², D. Gerber², Z. Firat², L. Braga², J. Woosley², R. Shrestha², R. Semelka²; ¹Ankara/TR, ²Chapel Hill, NC/US

Purpose: To determine if hepatocellular carcinomas (HCCs) missed in prospective MR study, but depicted in histopathologic analysis of explanted livers, could be identified in retrospective MR analysis. Also, to determine the cause for the misdiagnosis and MR imaging features of missed nodules.

Material and Methods: Patients with chronic liver disease that underwent liver transplantation between 1991 and 2004 were extracted from the transplant database. Amongst 555 patients, six patients revealed HCCs in explanted livers not depicted in prospective MR examination. From six patients, two were excluded due to the fact that time between prospective MR imaging and liver transplant exceeded 3 months. In total, four patients were analyzed. Liver nodules were characterized by MR imaging based on the signal intensity on T1- and T2-weighted, and degree of enhancement on early and late phase images.

Results: All HCCs missed on MR imaging before liver transplantation were depicted in retrospective analysis by both readers. Histopathologic analysis demonstrated five HCCs in four patients. The mean size of HCCs was 1.4-cm (range, 1 to 2.2 cm). The main cause of missed lesions were suboptimal image quality due to inability of patients to suspend respiration, followed by high-grade dysplastic nodule and HCC with atypical MR features on early phase image.

Conclusions: HCCs prospectively missed on MR examinations were retrospectively identifiable. Reasons for missing HCC include inability of patients to breathhold, categorizing lesion as high-grade dysplastic nodule and failure to

recognize that isovascular early enhancing lesions with subsequent washout and capsule enhancement were HCC.

B-042 10:39

Comparative assessment of Resovist-enhanced MR imaging and Magnevist in the detection and characterization of focal hepatic lesions

W. Cheng, M. Zeng, F. Yan; Shanghai/CN

Purpose: To compare Resovist-enhanced MR imaging with Magnevist in detecting and characterising focal hepatic lesions, and to further evaluate the efficacy of Resovist enhanced MR imaging in focal hepatic lesion diagnosis.

Methods and Materials: A total of 62 patients with suspected focal hepatic lesions (female21, male41) were evaluated. Serial MR imaging of the liver was initially performed using Magnevist, and followed by Resovist 48 hours later. All examinations were concluded with SE T1- and FSE T2-weighted with fat suppression, pre-contrast and contrast dynamic GRE T1 in 10 min, and accumulation-phase FSE T2 or T2* GRE only for the Resovist. All images were randomly analyzed by 2 experienced radiologists.

Results: A total of 105 solid lesions [among 24 micro-lesion (< 1.0 cm)] were verified at the standard-of-reference examinations. Comparison with the plain MR imaging (5/24) and Magnevist enhanced MRI imaging (14/24) in the detection of the micro-lesions, Resovist-enhanced MR imaging (24/24) was highly improved with statistical significance ($P < 0.05$). But there was no significant difference for the detection of the lesions (≥ 1.0 cm). Histopathologic specimens were available for 32 patients, those revealed 51 lesions [including hepatocellular carcinoma (n = 30), dysplastic nodules (n = 3), metastases (n = 9), hemangioma (n = 2), focal nodular hyperplasia (n = 3), inflammatory pseudotumor (n = 1), tuberculoma (n = 1), angiomyolipoma (n = 2)]. The specificity was not significantly different for both MR contrasts (Resovist 92% vs Magnevist 91%). The accuracy of diagnosis reaches 92% for Resovist-enhanced MR imaging which combined T1 GRE dynamic scanning and T2 FSE/T2* GRE in accumulation-phase.

Conclusion: The use of Resovist greatly improves detection of small, focal hepatic lesions (especially for < 1 cm). A combined protocol with dynamic scanning and subsequent accumulation-phase T2-weighted is recommended to enhance the diagnosis in both specificity and accuracy.

B-043 10:48

The added value of the hepato-biliary phase imaging in Gd-BOPTA magnetic resonance study (Gd-BOPTA-MR) of benign liver tumors and metastases in normally functioning livers

I. Sansoni, A. Laghi, M. Di Martino, C. Miglio, M. Celestre, L. Coletta, M. Rengo, R. Passariello; Rome/IT

Purpose: To determine the value of adding hepato-biliary phase imaging to triple-phase dynamic Gd-BOPTA-MR for detection and characterization of focal lesions in non-hepatopathic livers.

Methods and Materials: Fifty patients with liver lesions underwent MR-study on 1.5 T-scanner using the following acquisition protocol: Basal T2-weighted and T1-weighted; post i.v. administration of Gd-BOPTA (0.2 mM/kg), dynamic contrast-enhanced T1-weighted sequence was acquired at 15-seconds, 55-seconds and 135-seconds, and delayed T1-weighted hepato-biliary phase at 60 minutes. Dynamic-MR and Complete-MR study were reviewed independently by three radiologists assessing presence, number and characterization of lesions. Separate reading sessions were performed for images from only Dynamic-phases, and images from all dynamic and hepato-biliary phases, calculating related sensitivities and specificities. The value of Delayed-phase images in lesion characterization was also assessed. The number of lesions at final diagnosis was considered equal to detected lesions at Complete-MR study plus lesions detected by other imaging modalities (CT, US, MR with other specific c.m.). Lesion characterization was established by histopathologic examination after surgical resection or biopsy, or by follow-up imaging and treatment response.

Results: Diagnostic accuracy of MR-study with hepato-biliary phase was significantly higher than that of Dynamic-MR in benign lesions and metastases. Concerning benign lesion identification, the hepato-biliary phase of Gd-BOPTA-MR imaging allowed us to detect 9% more lesions compared to Dynamic-MR. Among lesions identified by both sets of images, delayed hepato-biliary phase images were helpful in lesion characterization in 5% of cases.

Conclusion: The addition of Delayed-phase imaging to dynamic Gd-BOPTA MR-study is valuable for detection and characterization of focal lesions in normally functioning livers.

Detection and characterization of hepatocellular carcinoma (HCC): Value of adding the hepato-biliary phase imaging to dynamic Gd-BOPTA magnetic resonance imaging (Gd-BOPTA-MRI)

I. Sansoni, A. Laghi, M. Di Martino, M. Celestre, C. Miglio, L. Coletta, M. Rengo, R. Passariello; Rome/IT

Purpose: The purpose of our study was to determine the value of adding delayed hepato-biliary phase imaging to triple-phase dynamic Gd-BOPTA MR for detection and characterization of HCC suspected lesions.

Methods and Materials: Eighty-one patients with chronic hepatitis underwent MR study on 1.5 T-scanner using the following acquisition protocol: Basal T2-weighted and T1-weighted; post i.v. administration of Gd-BOPTA (0.2 mM/kg), dynamic contrast-enhanced T1-weighted sequence was acquired at 15-seconds, 55-seconds and 135-seconds, and delayed T1-weighted hepato-biliary phase at 60 minutes. Dynamic-MR and Complete-MR study were reviewed independently by three radiologists assessing presence, number and characterization of lesions. Separate reading sessions were performed for images from only Dynamic-phases, and images from all dynamic and hepato-biliary phases, calculating related sensitivities and specificities. Value of Delayed-phase images in HCC characterization was also assessed. The number of lesions at final diagnosis was considered equal to detected lesions at Complete MR study plus lesions detected by other imaging modalities (CT, US). Lesion characterization was established by histopathologic examination after surgical resection or biopsy, or by follow-up-imaging and treatment response.

Results: MR study with hepato-biliary phase and MRI without hepato-biliary phase had a comparable diagnostic accuracy. The percentage of identified HCC at Complete Gd-BOPTA-MRI (92%) was slightly higher than that at dynamic MR study (89.7%). HCC correct characterization of Delayed-phase images was not statistically different from Dynamic-study.

Conclusion: The addition of Delayed-phase imaging to dynamic Gd-BOPTA-MR study doesn't provide significant additional benefit for the detection and characterization of hepatocellular carcinoma, due to reduced liver function and subsequent inhomogeneous appearance.

B-045 11:06

Double contrast technique in MR imaging of liver: Differential diagnosis compared to histopathologic findings

R. Hammerstingl, S. Parmentier, W. Schwarz, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To prospectively evaluate the value of double contrast-enhanced MR imaging for the differential diagnosis of focal liver lesions in correlation to histopathologic and clinical findings.

Methods and Materials: In this prospective, phase III, single-center clinical study 90 patients with known liver tumors (53 benign and 37 malignant) were investigated using a 1.5 Tesla MR imaging Scanner. Mono-contrast technique (Gd-enhanced MR imaging, 0.1 mmol Gd-DTPA i.v.) was performed from 4 weeks up to 24 h prior to inclusion. Study MR imaging was obtained using SPIO-enhanced imaging (SHU 555 A i.v.) as well as double-contrast technique (Gd-DTPA post SPIO). Sequence protocol included a dynamic evaluation of the complete liver using a high resolution 3D-protocol and static conventional and fat saturated T1-weighted sequences. Using ROI-technique signal intensities of liver parenchyma, liver lesions and vascular structures were measured. Percentage enhancement was calculated and verified using statistical analysis (Friedman and t-test).

Results: Double-contrast technique (DCT) was well tolerated compared to mono-contrast technique. Dynamic imaging using DCT was comparable to Gd-enhanced imaging regarding the flushing and characteristics of the diagnosed liver tumors. A statistically significant improvement in contrast to noise ratio was calculated for focal liver lesions in static DCT versus mono-contrast imaging. Five lesions (FNH n = 2, haemangioma n = 2 and HCC n = 1) were detected additionally in DCT compared to the other technique and evaluated using histopathologic and clinical follow-up. Using a five-point ranking system a statistically significant improvement was stated for diagnostic confidence levels regarding delineation and differential diagnosis.

Conclusion: The use of double contrast techniques is an excellent tool for the delineation and differential diagnosis of focal liver lesions and allows the acquisition of additional information compared to mono contrast technique in the pretherapeutic work-up.

B-046 11:15

Diagnostic work-up in the liver using SPIO-enhanced MR imaging:

Comparison with histopathologic and clinical findings

W.V. Schwarz, R. Hammerstingl, F. Marquardt, B. Götz, M. Heller, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To prospectively evaluate the diagnostic potential of SPIO particles (SHU 555A, Resovist, Schering AG, Berlin, Germany) in MR imaging for the diagnostic work up of focal liver lesions and to evaluate classification and characterisation in correlation to histopathologic and clinical findings.

Materials and Methods: In a clinical phase III/IV study, MR imaging was obtained in patients with a suspicion of focal liver lesions diagnosed by biphasic Spiral-CT or Gd-enhanced MR imaging. 100 patients were investigated using a high field MR imaging scanner. Sequence protocol included T2-weighted HASTE/TSE-sequences as well as T1-weighted fat saturated GRE-protocols using unenhanced, dynamic, and SPIO-enhanced studies.

Results: Histopathology and clinical follow-up diagnosed malignant [HCC (n = 38), metastases (n = 29)] and benign liver lesions [FNH (n = 15), adenoma (n = 5), hemangioma (n = 9) and regenerating nodules (n = 4)]. Patients underwent liver resection, liver transplantation, biopsy or clinical verification using MR imaging as a follow-up examination.

Using SPIO-enhanced MR imaging a sensitivity of 91.5% and a specificity of 92.9% was calculated for malignant lesions. In benign lesions a sensitivity of 95.8% and a specificity of 93.5% was assessed. Benign liver tumors showed a significant loss in signal intensity using T2-weighted sequences ($p < 0.05$, Wilcoxon-signed rank test) compared to malignant primary lesions. For malignant tumors no significant decrease in signal was documented. The overall therapeutic decision (transplantation, resection or interventional procedures) changed statistically significantly using combined T2- and T1-weighted SPIO-enhanced studies compared to previous diagnostic imaging.

Conclusion: SPIO-enhanced MR imaging is an effective imaging tool for the diagnostic work up of focal liver lesions. Combined T2- and T1-weighted SPIO-enhanced imaging enable a sufficient classification and characterisation.

B-047 11:24

Evaluation of the detectability of HCC in patients with liver cirrhosis by means of Gd-EOB-DTPA: Results of a qualitative and quantitative phase III study

B. Schulte¹, P. Reimer¹, J. Kuehnen², E. EOB Study Group²; ¹Karlsruhe/DE, ²Berlin/DE

Purpose: To study whether the hepatobiliary contrast agent Gd-EOB-DTPA shows decreased uptake and detectability of hepatocellular carcinoma in patients with liver cirrhosis.

Methods and Materials: Within a prospective multicenter phase III trial, 20 patients with HCC (11 patients with cirrhotic liver - 9 patients with non-cirrhotic liver) proven by histopathology as a standard of reference were enrolled. Parameters of T1-W GRE pulse sequences were systematically varied for spatial resolution (128 phase x 256 frequency matrix versus 160 x 512) and fat saturation for the 128 x 256 matrix within all patients. All pulse sequences were measured before and 20 min post injection (p.i.) of 25 µmol Gd-EOB-DTPA/kg bodyweight. Data were quantitatively analyzed to calculate for relative signal change, signal to noise ratio (SNR) and lesion-liver contrast (CNR).

Results: Relative signal changes were 41% in liver and 16% in tumor for non-cirrhotic liver vs. 47% in liver and 13% in tumor in cirrhotic liver. SNR (18.80 in the non-cirrhotic and 16.05 in the cirrhotic group; FS T1 GRE with 128 x 256 matrix) and CNR (0.2281 vs. 0.2074) for both groups were not significantly different. At higher resolution (160 x 512), CNR significantly increased from 8 min p.i. to 20 min p.i. (0.137 vs 0.207) in the cirrhosis group.

Conclusion: Liver cirrhosis appears to have only a minor impact on the uptake of Gd-EOB-DTPA. Tumor-contrast and thus detectability of lesions can be achieved by proper pulse sequence selection and scanning after a sufficient long period of time (20 min) post injection.

B-048 11:33

Diagnostic imaging of primary liver tumors: Evaluation of the hepatocyte-specific contrast agent Gd-EOB-DTPA

R. Hammerstingl¹, W. Schwarz¹, J. Breuer², T. Balzer², T.J. Vogl¹;

¹Frankfurt a. Main/DE, ²Berlin/DE

Purpose: To prospectively compare the efficacy of the liver-specific hepatobiliary MR imaging contrast agent Gd-EOB-DTPA versus standard Gd-DTPA for the diagnosis of primary liver tumors within individuals.

Scientific Sessions

Methods and Materials: In a phase II trial, 57 patients with known focal liver lesions were prospectively investigated using a high field MR imaging scanner. The sequence protocol included T1-GRE weighted ultrafast sequences before, during, and post i.v. administration of Gd-EOB-DTPA. Within one week Gd-DTPA was performed in the same patient (0.1 mmol/kg b.w.).

Results: Histopathology/clinical follow-up (within 12 months) revealed the diagnosis of malignant primary tumors in 24 cases [HCC (n = 22), CCC (n = 2)] and benign primary lesions in 7 cases [FNH (n = 4), hemangioma (n = 3)]. Secondary infiltrations were detected in 26 patients. Dynamic Gd-EOB-DTPA-enhanced images revealed a biphasic dose-dependent enhancement in liver parenchyma with lower but diagnostic signal increase in liver cirrhosis. In the hepatobiliary phase a significant increase in liver signal with a plateau phase was evaluated. FNH-nodules provided a prolonged high signal intensity, whereas HCC documented a specific rim-enhancement in the early phase. In the hepatobiliary phase Gd-EOB-DTPA-enhanced imaging yielded an increased detection rate (HCC: 79% increase) compared to standard extracellular MR imaging (Wilcoxon-signed rank test: p < 0.05).

Conclusion: The liver specific MR imaging enables improved detection of primary hepatic lesions, especially HCC, when compared to standard MR imaging. Benign primary tumors have specific morphologic criteria for tissue characterization using hepatobiliary MR imaging.

B-049 11:42

MR with different liver specific contrast media in the evaluation of hepatic adenoma (HA) and liver adenomatosis (LA): Imaging and pathological findings in an intra-individual comparison group

L. Graziolii¹, G. Morana², L. Romanini¹, G. Mazza¹, M. Morena¹, G. Schneider³, ¹Brescia/IT, ²Verona/IT, ³Homburg a.d. Saar/DE

Purpose: To compare the imaging findings of different MR liver specific contrast materials (Gd-BOPTA, Mn-DPDP, and ferumoxides) in the diagnosis of hepatic adenoma.

Methods and Materials: 37 patients with either confirmed HA (n = 32) or LA (n = 9) were evaluated. MR imaging was performed in all patients before and after administration of Gd-BOPTA. In 21 patients T1W GRE pre and 1 h after Mn-DPDP and in 17 patients T2W TSE and T2W' pre and at 30 min post ferumoxides were acquired. The qualitative enhancement evaluation was assessed and compared after Gd-BOPTA administration in 122 HA, in 74 HA after Mn-DPDP administration, and in 61 HA after ferumoxides.

Results: The signal intensity on pre contrast T1 and T2W sequences didn't show a typical pattern. 99/107 lesions were either slightly hyperintense or isointense to the surrounding parenchyma on precontrast T2W images. A more varied behaviour was noted on precontrast T1W images. 94/122 lesions appeared isointense or slightly hypointense, and 21/107 slightly hyperintense. Dynamic evaluation after Gd-BOPTA in all cases showed homogeneous (118/122) or heterogeneous (4/107) hypervascularity. In the delayed hepatobiliary phase all 122 lesions after Gd-BOPTA appeared hyperintense, differently to that observed in FNH. All 74 HA after Mn-DPDP appeared iso or hyperintense similarly to the FNH. After ferumoxide administration 44/46 HA showed homogeneous signal drop.

Conclusion: Gd-BOPTA is a more appropriate contrast agent than ferumoxides and Mn-DPDP for the characterization of HA. The enhancement pattern on dynamic phase imaging provide information on the hypervascular nature. The hypointensity on the delayed hepatobiliary phase permits us to differentiate HA from FNH.

B-050 11:51

Does dual contrast MR imaging of the liver with ferucarbotran and gadolinium chelates improve the detection rate of focal liver lesions?

Results of an investigator initiated prospective multicenter study

C. Wirth¹, P. Reimer¹, W. Schima², T. Vestring³, S.O. Schoenberg⁴, C. Zech⁴, P.J. Robinson⁵, D. Study Group¹; ¹Karlsruhe/DE, ²Vienna/AT, ³Rotenburg/DE, ⁴Munich/DE, ⁵Leeds/UK

Purpose: To investigate whether dual contrast MR imaging with the new SPIO ferucarbotran (Schering AG, Berlin, Germany) and a gadolinium chelate improves the detection rate of focal liver lesions.

Methods and Materials: Following ethics committee approval, patients with focal liver lesions demonstrated by dual phase CT were enrolled. Within this study 74 patients with 202 liver lesions proven by standard of reference procedures were analysed. Following a precontrast MR imaging consisting of T1-W GRE, T2-W TSE, T2-W HASTE, and T2*-W GRE 1.4 ml ferucarbotran was IV-injected. The same pulse sequences were repeated > 10 min postinjection. Finally, a dynamic T1-W GRE gadolinium study (0.1 mmol/kg bw) was performed (30 s, 70 s, and

120 s). Images were qualitatively analysed on-site for the presence of focal lesions and quantitatively to calculate for lesion-liver-contrast. The non-parametric Wilcoxon test (p ≤ 0.05) was applied for statistical analysis.

Results: The detection rate of hypervascular lesions like HCC significantly increased by dual contrast MR imaging from 47 lesions precontrast, to 63 lesions post ferucarbotran, and 85 lesions post gadolinium. Within this group, contrast was highest during the arterial phase (0.236) and portalvenous phase (0.233) of the gadolinium-enhanced acquisition. The detection rate of hypovascular lesions like metastases did not improve with 33 lesions precontrast, 35 lesions post ferucarbotran, and 39 lesions post gadolinium. Within this group, contrast was lowest during the portalvenous phase (0.101) of the gadolinium-enhanced acquisition.

Conclusion: Dual contrast-enhanced MR imaging with a SPIO like ferucarbotran and gadolinium chelates significantly improves the detection rate of hypervascular liver lesions.

Functional imaging of parotid glands: Diffusion-weighted echo-planar MR imaging before and after stimulation

C.R. Habermann, M.C. Cramer, J. Graessner, P. Gossrau, F. Reitmeier, J. Fiehler, M. Jaehne, G. Adam; Hamburg/DE

Purpose: Investigate the feasibility of using diffusion-weighted (DW) echo-planar imaging (EPI) for measuring different functional conditions of the parotid gland and to compare different measurement approaches.

Methods and Materials: Parotid glands of 27 healthy volunteers were examined with a DW EPI sequence with a 1.5 T system before and after oral stimulation with commercially available lemon juice. The b factors used were 0, 500, and 1,000 sec/mm². ADC maps were transferred to MR imagingcro (Rorden, University Nottingham, Great Britain) and evaluated with a manually placed circular region of interest (ROI) consisting of 100-200 pixels. Additionally, ROIs including the entire parotid gland were placed bilaterally. For comparison of the results, the Student's t test was used. Comparing both measurement approaches the Pearson's correlation coefficient (r) was calculated.

Results: With use of ROIs containing 100-200 pixels, the median for both parotid glands prior to stimulation was 1.06×10^{-3} mm²/sec ± 0.07×10^{-3} mm²/sec. After stimulation, the median ADC for both parotid glands was measured at 1.15×10^{-3} mm²/sec ± 0.08×10^{-3} mm²/sec. For evaluating the entire parotid gland, the ADC prior to stimulation was 1.13×10^{-3} mm²/sec ± 0.05×10^{-3} mm²/sec, whereas after stimulation with lemon juice, the ADC increased to 1.22×10^{-3} mm²/sec ± 0.09×10^{-3} mm²/sec. For both measurement approaches, the increase in ADC after stimulation proved to be significant ($P < 0.001$). High correlations between measurement approaches were found ($r > 0.83$).

Conclusion: Diffusion-weighted echo-planar MR imaging allows quantification of functional changes in the parotid glands.

B-052 10:39

Dynamic contrast-enhanced MR imaging studies in parotid tumors

H. Greess, S. Alibek, J. Zenk, A. Bozzato, H. Iro, W. Bautz; Erlangen/DE

Purpose: To evaluate the value of dynamic contrast-enhanced MR imaging to differentiate several parotid tumor entities.

Methods: 110 patients with 113 parotid tumors were examined with dynamic contrast-enhanced MR on a 1.5-T Symphony over a period of 18 months. An axial T1-weighted SE sequence was performed to determine 5 selected slices for the dynamic study. Subsequently a T1-weighted FLASH sequence was used for the dynamic contrast study with 0.2 ml Gadolinium per kilogram bodyweight administered intravenously. Contrast agent application and the FLASH sequence were started simultaneously. 10 acquisitions of 10 seconds scan time were performed. Intensity versus time studies were performed in the region of interest. The examination was completed by axial T2 STIR and axial and coronal T1 SE FATSAT sequences.

Scientific Sessions

Results: Tumor entities were pleomorphic adenomas (40%), adenolymphomas (Warthin tumors) (21%), carcinomas (11%), lymph nodes (7%), oncocytomas (4%) and cysts (3%). Four typical intensity curves were observed: Pleomorphic adenoma showed a gradual increase in signal intensity, followed by a plateau phase on a low intensity level; cysts showed a vacillate course at a low signal intensity level; adenolymphomas as well carcinomas showed a rapid increase in signal intensity followed by a plateau phase, but peak values were strikingly different with > 500 in adenolymphomas versus > 1000 in carcinomas. Together with the other MR criteria (contrast enhancement, sharp or blurred border) and clinical criteria a differentiation between adenolymphomas and carcinoma was possible.

Conclusions: With dynamic contrast-enhanced MR studies, differentiation between the common parotid tumors before surgery is possible.

B-053 10:48

Ultrafast MR-sialography: Sequence optimization and evaluation of parallel acquisition techniques and different functional conditions of the salivary glands

M.C. Cramer¹, C.R. Habermann¹, J. Graessner², F. Weiss¹, K. Petersen¹, M. Jaehne¹, G. Adam¹; ¹Hamburg/DE, ²Erlangen/DE

Purpose: To develop a fast and reproducible sequence for MR-sialography requiring no post-processing, to compare parallel and non-parallel acquisition techniques, and to evaluate the effects of oral stimulation.

Methods and Materials: Examinations were performed on a 1.5-T system. The lower part of CP-head coil and standard two-element CP neck array coil were used. After developing a sufficient sequence for MR-sialography an ss-TSE with an acquisition time of 2.8 sec was used in transverse and oblique sagittal orientation, with and without parallel imaging techniques and oral sialogogue. Images were evaluated by four independent radiologists using a 1 to 5 visual scale. For statistical comparison of the results, an ANOVA with post-hoc comparisons was used. Inter-observer variability was computed with an intraclass correlation.

Results: Ducts were visualized with an overall rating for all ducts of 2.26 ($SD \pm 1.09$). Between the four raters a high correlation has been obtained (intraclass correlation = 0.948). For axial orientation the proximal Stensen duct showed best visualization (1.35-1.74; $SD \pm 0.72-1.17$), using an oblique sagittal orientation. The intra-glandular submandibular ducts showed best visualization (1.18-2.62; $SD 0.81-1.14$). Significant influence regarding the slice angulations could not be obtained ($p = 0.74$). Visibility of ducts improved significantly after oral application of a Sialogogue ($p < 0.001$; $\eta^2 = 0.049$). Using parallel imaging technique showed significant loss of image quality ($p < 0.001$; $\eta^2 = 0.049$).

Conclusion: The developed ss-TSE sequence is a fast and sufficient technique for visualization of ducts of main salivary glands, with no post-processing. To improve results of MR-sialography it is reasonable to use oral Sialogogue.

B-054 10:57

Effect of window settings of dental-CT images on visualization of the tooth tissues

A. Mangov, L. Dakhno; Kiev/UA

Purpose: To investigate the proper window settings for the tooth tissues on dental-CT images.

Methods and Materials: We investigated 43 jaws (24 maxillae and 19 mandibles) in 37 patients with various dental pathologies. Spiral CT in axial plane with low-dose dental protocol (120 kVp; 40 mAs; slice thickness: 1 mm; pitch: 1.3; rotation time: 1 sec; reconstruction interval: 0.8 mm) was performed on a spiral single-slice "Asteion VF" scanner (Toshiba Medical Systems, Japan). All axial images were reconstructed with a high spatial frequency algorithm and with five window settings: settings-1 - width = 2500, level = 500 HU; settings-2 - width = 4000, level = 750 HU; settings-3 - width = 5000, level = 1000 HU; settings-4 - width = 7000, level = 1000 HU; settings-5 - width = 18000, level = 3000 HU. Two observers assessed the teeth status; they estimated the quality of visualization of enamel, dentin and root of tooth, adjacent bone and artificial metal structures.

Results: We found that the tissues of a tooth were not differentiated on images performed with settings-1. Images obtained with settings-2 provided good visualization of the root, adjacent bone and dentin of the crown; enamel was intensively white and it was hard to distinguish a radiopaque filling from enamel. Settings-3 clearly depicted the dentinoenamel junction of the tooth. Settings-4 provided good visualization of a radiopaque filling in a pulp space. Metal artificial structures were well depicted with settings-5.

Conclusion: We suggest that the appropriate window settings (width, 5,000; level, 1,000 HU) should be applied to visualization of the tooth tissues and their pathologies.

B-055 11:06

Imaging cortical bone by MR imaging: A new approach to image-guided planning for reconstructive surgery of the face

S.J. Golding, R. Saeed, C. Alvey, I. Evangelou, A. McIntyre, S. Watt-Smith; Oxford/UK

Purpose: CT and 3D reformatting, are widely used for supporting reconstructive surgery of the face but incur absorbed radiation. We report a new approach using an MR imaging sequence to replace CT in the demonstration of cortical bone.

Methods and Materials: The characteristics of Gradient Echo imaging of cortical bone on MR imaging were manipulated to define a sequence in which contrast differences between soft tissues were suppressed and cortical bone was demonstrated with high resolution as a black image. The sequence is weighted to Proton Density, utilising a flip angle of 5 degrees and in-phase echo time. Post processing allows image data acquired with a matrix of 256 x 256 to be displayed at 512 x 512. Biomorphometric accuracy of the sequence compared to CT was achieved using a geometric test object and an anthropomorphic head phantom developed in-house. Comparison included caliper measurements from a variety of anatomical structures and this was repeated in a pilot study on 15 patients undergoing investigation for facial disease.

Results: The new sequence showed good definition and resolution of bone. Linear measurements between 8 anatomical landmarks showed less than 1 mm variance between CT and MR imaging, within surgical tolerance. Further, data from the MR imaging sequence were found to be compatible with 3D imaging processing software. Exploration of the clinical value continues.

Conclusion: The new MR imaging sequence offers a promising means of replacing CT in support for reconstructive surgery of the face, with acceptable accuracy and improved radiation protection for the patient.

B-056 11:15

Serial contrast-enhanced MR imaging in the assessment of the temporomandibular joint disorders

T. Otani, N. Tomura, T. Ohnuki, S. Takahashi, I. Sakuma, J. Watarai; Akita/JP

Purpose: To determine the usefulness of serial contrast-enhanced MR imaging (SCE-MRI) in the assessment of temporomandibular joint disorders (TMD).

Materials and Methods: SCE-MRI was performed in 114 patients (103 unilateral joint disease, 11 bilateral) with various TMD. For the control group, 50 asymptomatic joints of patients with unilateral clinical symptoms were included. SCE-MRI was performed in a total of 175 joints. Four series of SCE-MRIs using fat-suppressed SE-T1WI were bilaterally started at 0, 5, 10, and 15 minutes after bolus injection of contrast material. The peak of contrast enhancement (P-CE) was evaluated from SCE-MRIs, and maximum signal intensity ratio (MSIR) with the reference to the signal intensity of pre-contrast images was calculated in the region of the condyle (CON) and posterior disc attachment (PDA). The relationships among P-CE, MSIR, and clinical symptoms were studied.

Results: P-CE of the CON was seen in the first or second SCE-MRI in 123/125 of affected joints and 49/50 of asymptomatic joints, while P-CE of PDA was seen in the third or fourth SCE-MRI in 103/125 of affected joints and 40/50 of asymptomatic joints. In the affected joints, mean MSIR of the CON (1.41 ± 0.54) and PDA (0.97 ± 0.64) was significantly ($p < 0.001$) higher than that of asymptomatic joints (CON: 1.01 ± 0.42 , PDA: 0.60 ± 0.45). In patients with disc displacement without reduction, MSIR of the CON (1.49 ± 0.59) and PDA (1.07 ± 0.66) was significantly higher than patients without disc displacement (CON: 1.02 ± 0.39 , p < 0.01; PDA: 0.46 ± 0.27 , p < 0.005).

Conclusion: MSIR obtained by SCE-MRI reflects clinical symptoms and are of diagnostic value to assess various TMD.

B-057 11:24

Differential analysis of vascularization of thyroid nodules examined with volume rendered 3D power Doppler ultrasound

R.Z. Slapa, J. Slowinska-Szrednicka, W. Jakubowski, M. Serafin-Krol, K.T. Szopinski, M. Gietka-Czerniel, H. Jastrzebska, I. Kozicki, E. Stachlewska-Nastfeter; Warsaw/PL

Purpose: Analysis of vascularization of thyroid nodules with volume rendered three-dimensional power Doppler ultrasound and possible establishment of features characteristic for thyroid carcinoma.

Methods and Materials: Fifty-seven thyroid nodules (10 papillary thyroid carcinomas, 47 benign) were evaluated with 3D power Doppler ultrasound. A dedicated 3D ultrasound machine with automatic linear transducer 11.5-4 MHz was applied. PRF and color gain were set just above noise level (usually PRF = 0.9 kHz). Vessel configuration was evaluated interactively in volume mode within

Scientific Sessions

a thin slab of tissue. The pattern, regularity and density of vessels were evaluated.

Results: There were 3 cancers with no central vessels and in 5 cancers there were a few central vessels with a peripheral-central pattern. The vessels with spoke and wheel alignment were observed in 6 cancers. In one cancer chaotic vessels were observed with a central pattern; this configuration was not observed in benign nodules. In one follicular type papillary cancer that was devoid of classical B mode suspicious features, moderately increased peripheral-central vessels with spoke and wheel alignment were the only features suggesting FNA. Vessels with spoke and wheel alignment were observed in 82% of benign nodules.

Conclusion: 1. Papillary thyroid carcinoma can present with different patterns of vessels; in most cases peripheral-central and only rarely peripheral or central. 2. There is a large overlap of vascularity patterns between papillary carcinomas and benign nodules. 3. Vascularization of thyroid nodules can be a complementary criteria in indication of the nodule for FNA.

B-058 11:33

Thyroid nodules: Evaluation with color Doppler and duplex Doppler ultrasound

M. Chammas, R. Gerhard, O. Saito, I.R. Oliveira, A. Widman, G.G. Cerri; São Paulo/BR

Purpose: To study thyroid nodules with power Doppler and duplex Doppler ultrasound (US) in order to determine its' value in predicting malignancy.

Materials and Methods: 177 nodules were analysed by B-mode scanning, power Doppler and spectral analysis and were related to the cytological findings (FNAB obtained by US). The equipment is GE, Logiq 500. Nodular analysis with color Doppler was classified in 5 vascular patterns: I) no vascularization; II) peri-lesional vascularization; III) peri-lesional vascularization \geq central vascularization; IV) central vascularization > peri-lesional vascularization; V) only central vascularization. Spectral analysis considered resistive index (RI). Univariate and multivariate logistic regression analysis were performed.

Results: The echogenicity parameter did not present significant statistical association at the univariate analysis, therefore only at the multivariate analysis, was it really identified as significant. Malignant nodules without vascularization or only peri-lesional vascularization were not observed; 2 malignant nodules showed pattern III; 6 showed pattern IV and 5 showed pattern V. This showed that the incidence of malignancy is larger where the central vascularization is predominant. This parameter presented statistically significant correlation with cytological results. The spectral analysis demonstrated that nodules with RI > 0.77 are at high risk of malignancy.

Conclusions: The multivariate analysis showed that to select malignant nodules the vascular patterns and RI are enough and significant. The nodules with high risk showed patterns IV and V, independent of RI; the nodules with other vascular pattern (II/ III) demonstrated high risk when the RI > 0.77, this model had sensitivity = 92.3%; specificity = 88%.

B-059 11:42

Follow-up of thyroid nodules with inadequate cytologic diagnosis

C. Avigo, S. Carizzoni, M. Zampedri, M.R. Cristinelli, F. Pittiani, A. Marconi, E. Archiati; Brescia/IT

Purpose: To analyze the follow-up of patients with a thyroid nodule and an inadequate cytologic diagnosis.

Materials and Methods: From January 1999 to June 2003 we subjected 93 patients (67 females and 26 males) to FNAC of a thyroid nodule, in 2 sessions (at least 1 month apart) with inadequate cytologic diagnosis. They were followed-up by ultrasound (US) periodically (from 7 to 51 months, with an average of 24.06 months).

Results: 80 nodules remained unchanged in size and structure. The other 13 that increased in volume, were submitted to surgical operation or to FNAC repetitions (4/13 resulted benign for cytology). After surgical operation, 9 patients showed: 2 thyroiditis, 1 hyperplastic nodule, 2 follicular adenomas, 1 follicular carcinoma, 2 papillary carcinomas, 1 medullar carcinoma.

Conclusions: Of the 93 patients followed-up, 13 changed (increase of volume); of these 4 (30.7%) resulted in malignancy (15.53 months of follow-up). This demonstrated that the ultrasound follow-up in inadequate thyroid nodules is necessary.

B-060 11:51

Accuracy of CT-SPECT image fusion in the pre-operative detection of parathyroid adenomas

P. Kovacs, K. Rapf, R. Prommegger, C. Profanter, T. Sauper, R.J. Bale, W.R. Jaschke; Innsbruck/AT

Purpose: To determine the accuracy of multiplanar CT, MIBI-SPECT and image fusion (IF) of both data sets in the detection of parathyroid adenomas in comparison with intra-operative data.

Materials and Methods: In 43 patients (Age: 14-81) with primary hyperparathyroidism, parathyroid adenomas were found intra-operatively at the upper ($n = 5$) and lower pole ($n = 9$) of the right thyroid gland and at the upper ($n = 7$) and lower pole ($n = 13$) of the left thyroid gland. 6 glands were detected in ectopic positions without connection to the thyroid gland. 3 patients with multiple adenomas were excluded from the study. Accuracy of pre-operative detection was determined using intra-operative data as gold standard. In a retrospective study all data sets were reinterpreted alone in a blinded fashion. Sensitivity, specificity and correlation (Kappa) were calculated.

Results: Sensitivity, specificity and correlation increased from SPECT (0.71/0.87/0.84) to CT (0.76/0.96/1.00) to IF (0.82/0.93/0.92) in the detection of the side (ectopic glands excluded) and increased from SPECT (0.41/0.90/0.34) to CT (0.59/0.91/0.51) to IF (0.69/0.93/0.62) in the detection of the site of adenoma. In 16 patients SPECT and CT showed the identical result. Only CT detected 3 out of 5 ectopic glands, but also misinterpreted 6 to be ectopic glands.

Conclusions: Although less than half of the patients show exactly the same results in both methods, IF allows for a more accurate detection of parathyroid adenomas in patients with primary hyperparathyroidism than CT and SPECT alone. Ectopic glands are still difficult to detect exactly, especially if they are situated near the thyroid gland.

Endovascular stent graft placement in patients with traumatic rupture of thoracic aorta

D. Monaco, P. Larini, C. Marcato, S. Saccani, A. Agostinelli, M. Zompatori; Parma/IT

Purpose: To evaluate the effectiveness of endovascular treatment in patients with traumatic rupture of thoracic aorta following vehicle accident.

Materials and Methods: Between March 1998 and September 2004, 16 patients (12 male, 4 female, mean age 40 years) were recovered for traumatic rupture of the thoracic aorta with associated visceral lesions and bone fractures. All cases were managed by endovascular means, implanting in the ruptured thoracic aorta one or more stent graft segments (Medtronic-Talent). Two patients required also concomitant procedures for associated cardiovascular or visceral lesions. One patients for concomitant traumatic pseudoaneurysm of brachiocephalic trunk was submitted to aortic and supraaortic vessel stenting.

Results: The endovascular procedure was technically successful in all cases. In a mean follow-up time of 2.5 years, 13 out of 16 patients are alive and in good health. In 2 patients death occurred respectively few hours and two days after stent graft implantation as consequence of post-traumatic multi organ failure, while another patient died for a not related cause (pulmonary cancer).

Conclusions: Our experience suggests that stent graft placement, a minimally invasive procedure, can be proposed in patients with traumatic rupture of thoracic aorta and impending risk of massive hemorrhage as an emergency procedure.

B-062 10:39

Emergency stent-graft repair for blunt thoracic aortic injury

P. Castelli, R. Caronno, G. Piffaretti, M. Tozzi, C. Lomazzi, D. Laganà, G. Carrariello; Varese/IT

Purpose: Blunt thoracic aortic rupture (BTAI) are highly lethal; up to 80% of patients with acute aortic rupture die at the scene of injury or before reaching the

Scientific Sessions

operating room. Of those that survive to reach medical attention, prognosis is still poor, with a 30% mortality rate within the first 6 hours and a 40% to 50% mortality rate within the first 24 hours after injury. In this series, we report our experience with the endovascular treatment of 7 patients treated with SG for BTAI in the acute phase.

Methods: Out of a series of 29 thoracic aortic stent-graft implantation, 8 patients (mean age: 27 ± 10 years, range 17-69) were treated on an emergency basis for blunt thoracic aortic injuries. 4 out of 8 patients (50%) were hemodynamically unstable. The mean ISS was 56 (range 33-75). Mean elapsed time among E.R. admission and emergency repair was 4 hours. All patients had regular follow-up with CT-angiography and chest X-ray.

Results: Primary technical success rate was 100%; in-hospital mortality rate was 0. We did not observe spinal cord ischemia events. We performed a spiral-CT follow-up at 1, 3, 6, 12 months from the procedure. Mean follow-up was 17 months (range 1-48): the complete exclusion of the injury was achieved in all the patients with no sign of stent-graft complication.

Conclusions: Our experience confirms that endovascular repair is a feasible, safe and effective timely treatment approach emerging as the preferred method of repairing blunt thoracic aortic injuries in trauma patients.

B-063 10:48

Endovascular repair of aneurysm after previous tube graft interposition due to coarctation or traumatic transection

M. Gawenda, J. Heckenkamp, K. Krüger, J. Brunkwall; Cologne/DE

Purpose: Despite primary success, nearly 10% of patients develop aortic aneurysm after open surgical tube-graft interposition due to coarctation of the thoracic aorta and graft interpositions due to traumatic transections at the aortic isthmus. Formation of the false aortic aneurysm carries a significant risk of rupture and lethal outcome. The repeat surgical procedure is associated with more or less 15% in-hospital mortality rate and morbidity from recurrent laryngeal nerve paralysis (~20%), phrenic nerve injury (~5%), or from bleeding. The potential of endovascular repair by the use of stent-grafts instead of redo surgery for post-surgical aortic isthmus aneurysm is unknown.

Methods: prospective clinical study.

Results: The concept of postsurgical endovascular stent-graft placement was evaluated with respect to feasibility and safety in 4 consecutive patients with late aneurysm formation after coarctation repair and traumatic transections at the aortic isthmus. All patients had aneurysm formation late after graft interposition. Patients' ages were 36, 38, 40, and 50 years. Transluminal placement of customized stent-grafts was successful, with no 30-day or 1-year intervention-related mortality or morbidity. Follow-up survey of 13 months in median (range, 1 to 28) revealed optimal reconstruction of the thoracic aorta; 1 case of type-I-endoleak was treated by proximal stent extension, 1 case of type-II-endoleak is still under observation.

Conclusions: Nonsurgical aortic reconstruction of postsurgical thoracic aneurysms forming late after coarctation repair or traumatic transection at aortic isthmus is safe and feasible; interventional stent-graft placement has the potential to avoid repeat surgery of postsurgical aortic aneurysm.

B-064 10:57

Early and mid-term results of endovascular stent-graft in the treatment of descending thoracic aorta diseases

L. Lovato, V. Russo, M. Renzulli, K. Buttazzi, G. Gavelli, R. Fattori; Bologna/IT

Purpose: To report our experience with stent-graft repair in the treatment of descending thoracic aorta diseases.

Methods and Materials: From July 1997 to September 2004, 117 patients underwent thoracic endovascular repair (aortic dissection 38 patients, atherosclerotic aneurysms 25 patients, post-traumatic aneurysms 35 patients, penetrating atherosclerotic ulcers 13 patients and pseudoaneurysms 6 patients). 24 patients, with clinical and/or imaging features of impending aortic rupture, were treated on an emergency basis. CT or MR imaging were performed before the procedure and at 1, 3, 6, 12 months and yearly thereafter.

Results: Successful stent-graft advancement and deployment occurred in 112/117 patients (95%). There was no intraoperative mortality. Complete aneurysm exclusion was obtained in 105/112 cases (6.5% of primary endoleak). In-hospital procedure-related complications consisted of left transient paraparesis (2 patients, 1.7%), bilateral cerebellar ischemia for left subclavian artery occlusion (1 patient) and extension of dissection (1 patient). Secondary endoleaks were observed in 11 cases, 8 successfully treated with secondary procedure. Long-term procedure failure (aortic rupture or conversion to surgery) occurred in 8 cases (7.1%). 13 patients deceased during follow-up for other than aortic causes. 96 patients are alive and well after a mean follow-up time of 27 months (range 1-86).

Conclusion: Endovascular stent-graft repair is technically feasible, highly effective and minimally invasive in the treatment of both acute and chronic descending thoracic aorta diseases. Accurate selection of cases and strict imaging follow-up are necessary to obtain reliable long term results.

B-065 11:06

Thoracic aorta diseases: Stent-graft repair

G. Piccoli, A. Marzio, M. Sponza, R. Frassani, U. Livi, A. Vit, D. Gasparini; Udine/IT

Purpose: Aim of the study is the review of our experience in order to assess the feasibility, safety and efficacy of this technique in acute and chronic aortic lesions.

Materials and Methods: 47 pts have been treated for acute (16 pts) and chronic (31 pts) aortic pathologies. The acute lesions includes 9 pts with aortic traumatic rupture, 4 pts with complicated acute type B dissection and 3 pts with rupture of atherosclerotic thoracic aneurysm. The second group (chronic lesions) includes 27 pts with thoracic or thoracic-abdominal aortic aneurysm and 4 pts with complicated chronic type B dissections.

Results: All patients were treated successfully; two of them needed a second procedure. One pt died of ICD following surgical reconstruction of abdominal aorta after implantation of thoracic stent-graft. There were an accidental rupture of the external iliac artery requiring surgical reconstruction and one major stroke 24 hours after the procedure. One pt suffered medullary ischemia. Two pts died 2 months after the procedure; in both, death was unrelated to the procedure but secondary to other complications of the original pathology. All survivors, at a mean follow-up of 12 months (range, 2 to 42) were asymptomatic: 6-month or 1-year CT controls demonstrate neither prosthesis dislocation nor leaks.

Conclusions: Surgical repair of both aneurysms and dissection of the descending thoracic aorta is often associated with considerable morbility and mortality. On the contrary, endovascular treatment seems to be a feasible, safe and reliable technique for both chronic and acute lesions.

B-066 11:15

Improving early and long term survival in the treatment of type B dissection: Comparison among medical, surgical and endovascular therapy

L. Lovato, K. Buttazzi, E. Angeli, V. Russo, M. Renzulli, G. Gavelli, R. Fattori; Bologna/IT

Purpose: The optimal treatment strategy for aortic type B dissection continues to be controversial.

Methods and Materials: 133 patients admitted to our hospital with type B aortic dissection from 1994 to 2004 and treated with medical or surgical or endovascular therapy, were retrospectively analysed with respect to clinical and imaging outcome. Clinical conditions and two series of CT/MR data (before the treatment and at the last control) were reviewed. Kaplan-Meier method's and the log-rank test were used to compare curves for survival analysis, Mann-Whitney and Kruskall-Wallis's non-parametric tests to compare non-continuous data.

Results: Survival at 30 days was 76% in surgical group and 100% between stent and medically treated patients. The actual cumulative survival estimated for stent-graft, surgical and medical patients were 96%, 67% and 92% at 1 year, 82%, 50%, and 67% at 5 years. Surgical and medical survival became more similar at 9 years (respectively 50% and 55%, p = 0.0098) Survival in stent group was high (93%) also for patients in ASA 4-5 (p = 0.021) or treated under emergency conditions (100% at 3 month vs 27% in surgical group; p = 0.0027). Thoracic aortic diameter reduced in average by 1.03 mm in stent group while increased by 4.25 mm in medical group. 80% of surgical patients developed post-prosthetic dilatation, compared with 22% of stent patients (p < 0.0001).

Conclusion: In the management of this catastrophic disease, stent-graft repair of type B aortic dissection confirms to be a safe and efficacious procedure, providing important alternative to surgical and medical treatment also in the long term.

B-067 11:24

Endoluminal repair of type B aortic dissection

J.P. Morales, N. Fotiadis, T. Sabharwal, R.E. Bell, M. Aukett, S. Thomas, P.R. Taylor, J.F. Reidy; London/UK

Purpose: Aortic dissection is a challenging clinical condition. Surgical resection carries a high risk of paraplegia and death. We have studied the safety and efficacy of endovascular stenting.

Materials and Methods: 27 patients (23 male), mean 66 years (42-86), presented with acute (15) and chronic dissection (12). Indications were increasing size (12), persistent pain (5), ruptured (8), and limb ischaemia (2). 41 stents were deployed

Scientific Sessions

(Gore 23, Talent 7 and Endofit 11) and the left subclavian was covered in 6. CT follow-up was at 3-6 months and yearly thereafter. Diameter change was considered significant if greater than 4 mm.

Results: Technical success was achieved in all patients. 1 patient with an acute MI died at 2 day (30 day mortality 3.7%). Paraplegia occurred in 1 patient and fully recovered after CSF drainage. Otherwise no significant complications. Follow-up in 26 patients was 3-60, mean 27 months. 5 patients (19.2%) were not measured (1 was lost to follow-up and 4 are awaiting CT). Diameter decrease was observed in 13 (50%), increase in 4 (15.4%) and no change in 4 (15.4%). 2 patients had late open repair for increasing size (1 died). Late mortality was 3.7%. False lumen thrombosis occurred in all except 1.

Conclusion: Endovascular repair of type B aortic dissection is associated with significantly lower morbidity and mortality compared with open surgery. The encouraging early results require long term follow-up.

B-068 11:33

Emergent endovascular stentgraft implantation for perforated acute type B dissections and ruptured thoracic aortic aneurysms

J.O. Balzer, M. Doss, A. Thalhammer, M.G. Mack, A. Moritz, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To demonstrate the effectiveness of endovascular stent grafts in the treatment of acutely ruptured thoracic aortic aneurysms and type B dissections as an alternative to the conventional surgical approach in an emergency setting. **Materials and Methods:** From January 2001 to September 2004, we treated 47 patients with either ruptured aortic aneurysms ($n = 28$) or acutely perforated type B dissections ($n = 19$) with endovascular stentgraft implantation. Aortic rupture was confirmed preoperatively by spiral computed tomography. In all cases, hemothorax as well as periaortic hematoma was present. The mean interval from onset of symptoms to treatment was 18.5 hours. We used 58 Talent (Medtronic Inc.) and six Excluder (W.L. Gore Inc.) stent grafts. All interventions were performed in an angiographic suite in general anesthesia and cardiac arrest in 34 cases.

Results: Stentgraft implantation was successful in 45 patients. Access failure due to small caliber of iliac arteries was encountered in one case, and one patient died before endograft implantation could be achieved. Complications encountered were paraplegia ($n = 1$), primary endoleak ($n = 3$), temporary renal failure ($n = 1$), and prolonged mechanical ventilation ($n = 2$). All patients with endoleaks could be successfully treated by a second Stentgraft implantation. At the 12 months follow-up 1 patient had died due to multiorgan failure, and two patients needed conversion to conventional surgical repair. All other patients were alive and free of symptoms.

Conclusion: Our experiences with emergency endovascular stent grafting show that the procedure is technically feasible, with less morbidity and mortality than conventional open surgery, in high-risk patients.

B-069 11:42

Midterm results of the thoracic Excluder: Does it has the same problems as the infrarenal device?

J.P. Morales, P.R. Taylor, J. Deguara, R.E. Bell, M. Aukett, S. Thomas, T. Sabharwal, J.F. Reidy; London/UK

Purpose: Despite good technical results, the Excluder AAA device is associated with sac enlargement in 37% of patients. We have studied the efficacy of the Excluder for aneurysms of the descending thoracic aorta.

Materials and Methods: 30 patients (15 male), mean 70.2 years (44-90) were followed up with computed tomography (CT) at 3-6 months and yearly thereafter. Procedures were urgent in 4 and elective in 26 patients. Sac increase or decrease was considered significant if greater than 4 mm.

Results: 8 patients were not measured. 1 urgent patient died (30 day mortality 3.3%), 1 graft was removed for type I endoleak, 2 were lost follow-up and 4 are awaiting CT scans. Follow-up was 1/12 - 7 years, mean 35 months. Sac increase was observed in 7 (23.3%), decrease in 7 (23.3%), and no change in 8 (26.6%). Late mortality was 13.3% (4 patients) but none were stent related (cerebral infarct 1, MI 1, Bronchopneumonia 1, Haemoptysis 1). Endoleaks were seen in 3 patients (2 spontaneous closures).

Conclusion: The Excluder seems to have similar problems in the thoracic aorta with a significant number of patients having an increase in the aneurysm sac diameter. Careful follow-up is essential.

B-070 11:51

Impaired renal flow resulting from aortic dissection - What is the most effective endovascular treatment?

M. Januszewicz, O. Rowinski, K. Milczarek, M. Jaworski, R. Maciąg, J. Szmidt, Z. Galazka; Warsaw/PL

Purpose: To estimate the effectiveness of endovascular treatment in patients with aortic dissection and renal hypoperfusion.

Material: 56 patients with aortic dissection (33 acute and 23 chronic) of descending aorta and impaired flow in renal arteries. 21 patients showed poor management of hypertension and rise of serum creatinine level. 35 patients manifested only poor management of hypertension. Renal malperfusion was confirmed in Duplex Doppler Sonography. All patients were diagnosed by means of spiral CT and angiography. Depending on the type of renal artery involvement we diagnosed impaired flow in static mechanism (15 cases) or dynamic mechanism (29 cases). In 2 patients we diagnosed renal artery dissection with re-entry site within the branch. In 10 patients renal hypoperfusion was anticipated after stentgraft placement in cases of renal artery arising from the false lumen.

Methods: 36 stentgraft implantations, 3 stentgraft and fenestrations or renal stenting, 1 stentgraft and additional surgical treatment, 4 renal stenting, 2 covered renal stents, 4 fenestrations.

Results: In 54 cases improvement of renal perfusion has been achieved. In 20 cases renal function and hypertension management has been improved. In 1 case we encountered unsuccessful fenestration. In 1 case covered renal stent implantation has become complicated with renal artery occlusion.

Conclusions: In most cases successful closure of the entry tear by stentgraft is sufficient for restoring renal flow. Approximately 20% cases require additional intervention combining of fenestration, peripheral stenting or open surgery. In chronic and stable dissection fenestration or peripheral stenting may be sufficient methods of treatment.

Superabsorbent polymer microspheres: A new embolic agent. An experimental study with pig kidneys

E. De Luis¹, J.-I. Bilbao Jaureguizar¹, P. Martínez-Miravete¹, J.J. Noguera¹, A. Martínez-Cuesta¹, J.A. García de Jalón², ¹Pamplona/ES, ²Zaragoza/ES

Purpose: Superabsorbent Polymer Microspheres (SAPM) are a new embolic agent that adapts itself to the arterial wall. SAPM alter their shape and size depending on the contrast media in which they are diluted. These spheres induce an inflammatory reaction and local necrosis that depend on the contrast media used for the dilution and the particle size.

Methods and Materials: We performed a study with 19 pigs (38 kidneys) that were embolised with SAPM. We used two different sizes of particles (50 and 150 microns) and two contrast media (Iodixanol and loxaglate). These organs were extracted right after the procedure (4 pigs) or one-month later (15 pigs). Samples of the kidneys stained with hematoxylin-eosin were evaluated.

Results: SAPM do not induce thrombosis around particles. The necrosis resulting from the embolization is due to the plasticity of particles that perfectly adapt themselves to the arterial wall. This necrosis depends on the particle size and the contrast media used for the dilution, being more intense when 150 microns SAPM are used mixed with loxaglate.

Conclusion: This new embolic agent alters its properties and its therapeutic effect depending on the size of the particles and the type of contrast media in which they are mixed. Clinical applications should be evaluated with new studies.

Influence of hepatic vessel size on volume and shape of percutaneous thermoablative lesions: In-vivo evaluation in a porcine model

B.B. Frericks, K.S. Lehmann, J.P. Ritz, S. Valdeig, H.J. Buhr, K.J. Wolf; Berlin/DE

Purpose: To investigate the effect of hepatic vessel size on volume and shape of percutaneous thermoablative lesions in an in-vivo model.

Methods and Materials: 10 pigs were examined and treated in general anesthesia. After contrast enhanced multiphasic 16-detector row CT (Sensation 16, Siemens; slice thickness 1 mm, RI 0.8 mm), CT-guided laser-induced thermotherapy (LITT) with a power setting of 28 W for an exposure time of 15 minutes was performed. The distal end of the applicator was positioned either in close contact to major hepatic vessels or centrally within liver parenchyma. Immediately after LITT a second CT-scan was obtained. After extraction and fixation the liver was cut in 2 mm slices and the volume and shape of the coagulation area was determined using a digital macro camera and subsequent image analysis. Distance and diameter of the adjacent vessels were measured. Results were compared to CT and histologic findings.

Results: The macro imaging system allowed the determination of vessel diameter and the according cooling effects. Depending on vessel size and the position of the laser applicator relative to the vessel, lesion sizes and shapes were significantly altered, leading to horse-shoe- or sand-glass-like lesions. If the LITT-catheter ran parallel to a large vessel an asymmetry of the thermal lesion was observed.

Conclusion: In this porcine model size and shape of thermal ablation lesions are influenced by larger portal and hepatic veins. Based on these results, a software tool for semi-automatic simulation of the expected lesion morphology is currently under investigation.

B-073 10:48

MR guided intramyocardial injection using an MR imaging compatible catheter: Feasibility and changes of T1 values after injection of extracellular contrast medium

G.A. Krombach, J.E. Pfeffer, S. Kinzel, R.W. Günther, A. Buecker; Aachen/DE

Purpose: To assess the feasibility of MR-guided intramyocardial injection of Gd-DTPA-BMA using real-time imaging and to quantify T1-values and the size of the enhanced region for different concentrations of contrast agent for 30 min.

Material and Methods: A catheter with a needle tip was advanced into the left ventricle of 7 pigs using real-time MR imaging (radial true-FISP). After intramyocardial injection of 2 ml Gd-DTPA-BMA solution at concentrations of 0.05 or 0.1 mmol/ml, local changes of T1 and size of enhanced region were measured 3, 15 and 30 min after injection, using the Look-Locker sequence.

Results: Catheter guidance and visualization of contrast medium distribution were feasible in all animals. Local changes in T1 values were significantly different for both concentrations (0.05 mmol/ml: 456 ± 5 ms; 0.1 mmol/ml: 228 ± 4 ; $p < 0.001$) measured 3 min after injection. T1 values increased significantly to 720 ± 7 ms for 0.05 mmol/ml Gd-DTPA-BMA and 445 ± 6 ms for 0.1 mmol/ml Gd-DTPA-BMA, 30 min after injection, but remained significantly lower than those of remote myocardium (879 ± 8 ms). The size of the enhanced region increased from 13 ± 2 mm^2 at 3 min to 30 ± 3 mm^2 at 30 min ($p < 0.05$).

Conclusions: MR-guided intramyocardial injection of Gd-DTPA-BMA is feasible using real-time imaging and passive delineation of the catheter. The resulting increase of signal intensity at the injection site allowed for delineation of distribution of the injected solution for the time of the intervention. Thus repeated injections into the same region can be avoided.

B-074 10:57

Initial in vivo results with flat panel detector C-arm CT

R. Fahrig, N. Strobel, J.C. Hellinger, J.K. Frisoli, H. Arakawa, M. Marks, H.M. Do, M. Kukuk, G.M. Glazer; Stanford, CA/US

Purpose: A new 3D C-arm CT system (Siemens Artis dTA DynaCT, 30x40 cm flat panel (3D-FD)) extends the capabilities of C-arm CT to soft-tissue imaging, allowing detection of low-contrast objects. We report initial experience in a porcine model for a range of *in vivo* imaging applications with comparison to conventional CT.

Methods and Materials: Five animal investigations compared 3D-FD image quality with conventional CT. Each animal was imaged using a Siemens Sensation-16 clinical scanner (80 kVp, 100-150 mAs, 1 mm slice) before and 70 s after an injection into the femoral artery (30 s injection, 3 ml/s, 300 mg/ml Iodine). The FD system was used to acquire 3D CT volumes (30 s rotation, 0.25-0.5 mm slice, 70 kVp, 190 views) of: 1.) liver during intravenous injection and during selective hepatic artery injection (3 ml/s, 30 s); 2.) brain after injection of 5 cc's autologous

blood (hematocrit ~18%); 3.) abdominal aorta after the placement of nitinol stent; 4.) thorax.

Results: In the liver 3D-FD images clearly depicted the major portal and hepatic veins to the 200 micron level comparable to conventional CT; 3D-FD images obtained during hepatic arterial injection showed vessels below 100 microns (partial volume). In the brain, autologous blood clot was visualized. Individual struts of the abdominal stent could be seen in 3D-FD images. Images of the thorax showed vascular and bronchial detail with excellent clarity.

Conclusions: C-arm CT with FD (Artis dTA DynaCT) has been demonstrated to possess sufficient soft-tissue contrast to support broad clinical applications in the brain, thorax and abdomen, and enables new capabilities for 3D guidance.

B-075 11:06

Effect of laser-induced thermotherapy (LITT) on liver metastasis of varying size

A. Maataoui, J. Qian, M.G. Mack, M.F. Khan, R. Straub, E. Oppermann, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To assess the effect of laser-induced thermotherapy (LITT) of liver metastasis of varying size from colon carcinoma in an animal model.

Materials and Methods: Liver metastases were implanted in 20 Wistar Albino Glaxo (WAG) rats by sub capsular injection of cells from a colorectal strain (CC531) (day 0). The animals were divided into two groups having regard to the measured tumor size varying from $0.05 - 0.06 \text{ cm}^3$ (Group A) and $0.10 - 0.12 \text{ cm}^3$ (Group B). On day 14 after laparotomy and intratumoral placement of the laser applicator set tumors were exposed to 1064 nm Nd:YAG laser light at 2 watts for 5 minutes. The tumor volumes before (V1, at day 13) and after treatment (V2, at day 28) were determined by MR imaging and the mean tumor growth ratio (V2/V1) was calculated.

Results: The mean tumor volumes V1 and V2 were $0.05 \pm 0.003 \text{ cm}^3$ and $0.23 \pm 0.016 \text{ cm}^3$ in group A, $0.11 \pm 0.006 \text{ cm}^3$ and $0.68 \pm 0.037 \text{ cm}^3$ in group B, respectively. The mean tumor growth ratio (V2/V1) was 4.31 ± 0.19 in group A, 6.11 ± 0.14 in group B, respectively. The mean volume of the induced necrosis ($0.15 \pm 0.01 \text{ cm}^3$) was for both groups alike ($P > 0.05$). Compared to group B liver metastases of group A showed a significant slower tumor growth velocity (double side t-test, $P < 0.0001$).

Conclusion: The interventional treatment of big hepatic tumors with LITT leads to a faster tumor growth compared to smaller lesions.

B-076 11:15

Parallel wet bipolar radiofrequency ablation of the liver: In vivo and ex vivo experiments with perfused-cooled electrodes

J. Lee, J. Han, S. Kim, J. Lee, K. Shin, B. Choi; Seoul/KR

Objective: To compare the performance of wet bipolar radiofrequency ablation (RFA) with that of wet-monopolar RFA *ex vivo* in bovine liver and *in vivo* in canine liver.

Materials and Methods: RFAs were performed using a 200 W generator and a 15-gauge perfused-cooled electrode with infusion of 6% hypertonic saline at 2 mL/min. In *ex vivo* experiments, 20 thermal ablation regions were created in wet monopolar (group A), and in wet bipolar mode (group B) with a 3-cm inter-electrode spacing. In *in vivo* experiments, a thermal ablation region was created by wet bipolar RFA using two perfused-cooled electrodes in each of 8 dogs via laparotomy. The volumes of the RF-induced ablation regions were measured, and lesion shapes were evaluated by computing their isoperimetric ratios.

Results: No significant difference in mean current was observed in groups A and B: 1543 ± 53.7 mA, and 1520 ± 89.6 mA, respectively ($p > 0.05$). However, the mean volumes of the ablation regions produced in group A ($33.9 \pm 12.7 \text{ cm}^3$) were lower than those produced in group B ($54.0 \pm 16.5 \text{ cm}^3$) ($p = 0.007$). In *in vivo* experiments, the mean volume of the coagulation necrosis created by wet bipolar radiofrequency ablation was $39.4 \pm 15.6 \text{ cm}^3$, with an isoperimetric ratio of 0.75 ± 0.1 .

Conclusion: Parallel wet bipolar radiofrequency ablation showed better performance in terms of creating a larger region of coagulation necrosis than wet-monopolar ablation.

B-077 11:24

Combined radiofrequency tumor ablation and acetic acid-hypertonic saline solution injection in a rat N1S1 liver tumor model: Effects on tissue coagulation

J. Lee, J. Han, S. Kim, J. Lee, B. Choi; Seoul/KR

Purpose: To determine whether 15% acetic acid-hypertonic saline solution (AHS)

Scientific Sessions

instillation before radiofrequency ablation (RFA) can increase the extent of coagulation necrosis in a rat N1S1 liver tumor model compared to RFA alone or combined RFA and ethanol injection therapy.

Materials and Methods: N1S1 tumors were implanted in the livers of 50 rats. Rats were assigned to one of five groups: (a) RFA using an internally cooled electrode with a 1-cm tip (20 watt; 3 mins); (b) combined RFA with the instillation of 0.3 mL of 15% acetic acid diluted in a saturated NaCl solution; (c) combined RFA with 0.3 mL of 100% ethanol instillation; (d) 15% AHS injected alone; and (e) a sham operated control group. We compared the resultant coagulation achieved by these different ablative strategies and RF parameters, such as impedance, current, and power.

Results: The combination of RF ablation with AHS or ethanol resulted in greater coagulation than by either therapy alone: 14 ± 2 mm (group A), 25 ± 3 mm (group B), 19 ± 4 mm (group C), 10 ± 5 mm (group D) ($P < 0.05$). However, maximum coagulation was observed with AHS, which ablated the entire tumor in eight cases. Significantly greater current deposition was observed when the tumors were pretreated with 15% AHS than with ethanol: 411 ± 66 mA and 281 ± 88 mA ($P < 0.05$).

Conclusion: The combination of AHS instillation with RFA substantially increases tumor destruction compared with RF or injection therapy alone.

B-078 11:33

Radiofrequency ablation of hepatic malignancies: Percutaneous insertion of an MR imaging-compatible application probe

C. Rosenberg, C. Weigel, N. Hosten; Greifswald/DE

Purpose: To evaluate efficacy and advantages of a new MR imaging-compatible probe for radiofrequency ablation (RFA) of primary and secondary liver malignancies. CT for needle placement can not be used if lesions are not seen in plain CT. Results from an ongoing study are presented.

Materials and Methods: RFA was performed using a 17 G saline-cooled single probe (Cool-tip®, Radionics). Optimal conditions for cooling, energy and ablation time were retrieved testing the system in porcine liver. Patients were strictly evaluated for insufficient CT imaging. 19 Patients received ablative therapy in a standardized manner. Percutaneous insertion and therapy monitoring were performed in a closed high-field scanner using a breath-hold T1-weighted GRE sequence.

Results: Lesions were well visualized in plain or contrast-enhanced MR imaging. Ablation time of 15 minutes and energy elevation to a maximum 200 W were found suitable to achieve safe and sufficient ablation of targeted malignant tissue. Maximal induced coagulative necrosis was 15.7 ccm in a single application. Lesion ablation was technically and clinically successful. Miniaturized design and surface profile of the application probe benifited its handling. The needle was well visualized in TRUEFISP and 2dFLASH sequences with minimal imaging artifacts not limiting the intervention.

Conclusion: MR imaging-guided RFA of liver malignancies is a safe and feasible procedure in an interdisciplinary multimodal cancer therapy. Advantages are evident for lesions not seen in plain CT. Probe insertion and therapy can be performed in one setting using a single imaging modality. Safety and feasibility of critical positioning maneuvers are increased using multiplanar imaging.

B-079 11:42

Accuracy of combined PET/CT in image-guided interventions of liver malignancies: An ex-vivo study

P. Veit, C. Kuehle, C. Herborn, H. Stergar, T. Beyer, A. Bockisch, H. Kuehl, G. Antoch; Essen/DE

Objective: Positioning of interventional devices for biopsy or radiofrequency ablation of liver lesions is a challenging task if only morphological data are available. We investigated the potential benefit of co-registered PET/CT data in liver interventions.

Materials and Methods: 90 lesions were injected in 15 ex-vivo pig livers, two hypodense, two isodense, and two hyperdense lesions each per liver. Each lesion was composed of 20 mL gelatine, different amounts of an iodine-based contrast agent, and 0.5 MBq of [¹⁸F]-2-Fluoro-2-deoxy-D-glucose (FDG). RF-probes were placed in these lesions under CT-guidance. CT and PET/CT imaging were performed to all lesions after needle placement. The accuracy of CT and PET/CT for determining the needles' position within the lesion was assessed by measuring the distance of the needle tip from the lesions' margins on CT and PET/CT. Imaging findings were correlated with macroscopic measurements after lesion dissection which served as the standard of reference.

Results: In hypo- and isodense lesions PET/CT proved significantly more accurate in defining the position of the interventional device ($p < 0.05$) based on the

additional functional data. There was no statistically significant difference between the two imaging procedures when determining the needles' position in hyperdense lesions.

Conclusion: Combined PET/CT adds additional information to CT alone when assessing the position of interventional devices within iso- and hypodense liver lesions. PET/CT can be recommended for planning of liver interventions, but should be limited to potentially curative procedures based on its additional complexity and cost.

B-080 11:51

Development and experimental testing of a percutaneous temporary pulmonary stent device for severe pulmonary embolism

R.K. Verma, J.E. Pfeffer, R.W. Günther, T. Schmitz-Rode; Aachen/DE

Purpose: Development of a percutaneous temporary stent device with adequate steerability and quick placeability for recanalization of central pulmonary embolism.

Methods and Materials: After developing a self-expandable Nitinol-stent, which was mounted at the cathetertip and could be placed across the thrombotic occlusion, in-vitro tests were performed in a benchtop pulmonary circulation model. In-vivo tests followed in 6 sheep. Partially organized thrombus material was introduced via the right jugular vein to produce pulmonary embolism. The catheter device was inserted via the right femoral vein and the stent deployed bridging the thrombus. During stent placement pulmonary angiography was performed to image the extent of recanalisation. After the procedure the stent catheter was removed. **Results:** Stent placement was successfully tested in-vitro. In-vivo the catheter device could be placed quickly and navigated adequately in all 6 sheep pulmonary arteries by bridging the whole embolus. Angiography confirmed recanalization in all cases to a certain amount, depending on the stretching quality of the stent and the consistency of the thrombus. After the procedure the stent was gently removed into the catheter with no trouble. Macroscopically slight wall damages in the pulmonary trunk and the left descending artery were found in one case.

Conclusion: The newly developed self expandable and removable stent can be placed quickly and adequately in case of central pulmonary embolism and allows an instant partial pulmonary recanalization. After circulatory stabilization the device can be removed trouble-free.

MR imaging gadolinium enhancement in cardiac amyloidosis as potential expression of the disease severity

V. Russo, E. Perugini, L. Lovato, M. Renzulli, C. La Palombara, C. Rapezzi, G. Gavelli, R. Fattori; Bologna/IT

Purpose: The aim of this study was to investigate prevalence and distribution of MR imaging gadolinium enhancement in patients with cardiac amyloidosis (CA) and its possible associations with clinical, morphological and functional features.

Methods and Materials: Eighteen patients with definitely diagnosed CA underwent gadolinium Cardiac MR imaging (Gd-CMRI). In all patients a breath-hold cine MR sequence was performed, covering the whole left ventricle in short axis plane and in four-chamber view. A segmented inversion recovery fast gradient echo sequence (IR-FGE) was performed in the short-axis plane of the left ventricle and in four-chamber view after Gadolinium injection.

Results: Gd enhancement was detected in 14/18 (77%) patients. Fifty-four of 306 (16.7%) segments were enhanced, more often at mid-ventricular level. Transmural extension of enhancement within each patient significantly correlated with left ventricular (LV) end-systolic volume ($r = 0.53$). Number of enhanced segments correlated with LV end-diastolic volume ($r = 0.76$), end-systolic volume ($r = 0.6$) and left atrial size ($r = 0.58$). Patients with enhancement in > 50% transmural extension more often had severe hypokinesia or akinesia ($p = 0.0001$). Patients with > 2 enhanced segments showed significantly lower 12-lead QRS voltage.

Conclusions: Gd enhancement is common in CA, probably due to expansion of infiltrated interstitium. The segmental and transmural distribution of the

Scientific Sessions

enhancement is highly variable, and midventricular regions are more frequently involved. Enhancement appears to be associated with impaired segmental and global contractility and larger atrial size. Gd-CMRI provides a unique opportunity for non-invasive study of amyloid myocardial infiltration and its pathophysiological consequences.

B-082 10:39

Correlation between phosphocreatine (PCr) to ATP ratio (PCr/ATP) at cardiac ^{31}P -MR spectroscopy and fibrosis at delayed-contrast enhanced MR imaging in hypertrophic cardiomyopathy (HCM)

A. Esposito, F. De Cobelli, G. Perseghin, E. Belloni, M. Pieroni, C. Chimenti, A. Frustaci, A. Maseri, A. Del Maschio; *Milan/IT*

Purpose: Reduced PCr/ATP myocardial ratio has been described in patients with HCM. Also known in these patients is the presence of delayed-gadolinium enhanced regions representing areas of increased myocardial collagen. Our specific purpose was to determine the relationship between these two features. **Methods and Materials:** 13 HCM patients underwent cardiac ^{31}P -MR-Spectroscopy (^{31}P -MRS) and cardiac-MR imaging on a 1.5 T system (Gyroscan Intera, Philips Medical System). 13 normal subjects underwent cardiac ^{31}P -MRS as control group. ^{31}P -spectra were acquired by using 10 cm-diameter surface-coil and corrected for partial saturation effects and blood contribution. PCr/ATP was normalized for left ventricular (LV) mass. ECG-gated black-blood TSE sequences were acquired for morphologic evaluation and cine-balanced-FFE for wall motion and functional analysis. 15 minutes after gadolinium-DTPA (0.2 mmol/Kg) injection, delayed MR-images were obtained with 3D-T1w-TFE sequence, adjusting inversion time to null normal myocardium. All HCM patients underwent cardiac catheterization with LV endomyocardial biopsy to verify histological features of delayed enhanced tissue.

Results: PCr/ATP was lower in HCM patients compared to control subjects (1.05 ± 0.12 vs 1.63 ± 0.17 ; $P < 0.05$). Delayed-enhanced areas were found in 11 HCM patients. The biopsies obtained from these areas showed abnormal presence of fibrosis. The volume of enhanced tissue (range = $0.1\text{--}40.4 \text{ cm}^3$; mean value = $14.60 \pm 3.51 \text{ cm}^3$) was inversely related to LV ejection fraction ($R = -0.58$; $P < 0.05$). Strong negative correlation was found between the volume of enhanced tissue and PCr/ATP ($R = -0.76$; $P < 0.005$).

Conclusion: Delayed-contrast enhanced MR-images allow the identification of fibrotic areas in LV wall of HCM patients. The presence of fibrotic regions could partially explain the low PCr/ATP showed in HCM patients.

B-083 10:48

Magnetic resonance angiography and phase-shift velocity mapping of the pulmonary veins compared to transesophageal echocardiography before and after radiofrequency catheter ablation for atrial fibrillation

A. Koops, B. Lutovsky, A. Stork, S. Willems, C. Nolte-Ernsting, G. Adam; *Hamburg/DE*

Purpose: Pulmonary vein (PV) stenosis is a known complication of radiofrequency catheter ablation for the treatment of atrial fibrillation. The aim of this prospective study was the early detection of PV stenosis by MRA and TEE.

Methods and Materials: Twenty-five patients underwent MRA and TEE prior to catheter ablation; 6 months follow-up was accomplished in 9 patients. MRA involved contrast-enhanced, FLASH-sequences for angiography and ECG-triggered phase-shift velocity mapping orthogonal to the distal PV section for flow measurements. Likewise, during TEE the Doppler sample volume was positioned in the PV adjacent to the venoatrial junction.

Results: MRA allowed reliable visualization of the morphology of all PV, whereas TEE showed an unreliable depiction of the left inferior PV with inconsistent venous flow detection. Maximum flow values calculated by magnetic resonance measurement for the left superior, left inferior, right superior and right inferior PV were 37.3, 38.9, 41.4 and 34.6 cm/s, respectively. On average, the maximum flow values assessed by TEE were 27.5% higher. Mean flow was 10.4, 11.6, 10.0 and 10.2 cm/s, respectively, which measured 54.0% higher by TEE. Post-interventionally one PV stenosis of a left superior PV was detected by MRA with a maximum flow increase to 82.1 cm/s (90.0 cm/s by TEE).

Conclusion: Flow differences between MRA and TEE may be explained by superior anatomical depiction thus allowing more exact positioning for in-plane measurement. MRA is capable of visualisation of all PV, while TEE lacks depiction of the left inferior pulmonary vein, in which stenosis commonly occurs.

B-084 10:57

Utility of real-time cine-MR imaging in the differential diagnosis between constrictive pericarditis and restrictive cardiomyopathy: Preliminary results

M. Francone, M. Kalantzi, F. Rademakers, M. Herregods, S. Dymarkowski, J. Bogaert; *Leuven/BE*

Purpose: Since pericardial thickness is not unfrequently normal (< 2 mm) in patients with surgically-proven constrictive pericarditis (CP), this morphologic parameter may not be reliable to diagnose CP. Assessment of the functional impact of CP on ventricular filling with real-time MR imaging may be more reliable to differentiate CP from restrictive cardiomyopathy (RCM).

Materials and Methods: In 15 CP, 10 RCM patients and 15 normal subjects, real-time MR imaging using a SSFP sequence in the midventricular cardiac short-axis (temporal resolution: 60 ms) was performed during continuous breathing with deep in- and expiration. The influence of respiration on ventricular septal position and total septal excursion normalized to total biventricular diameter was evaluated.

Results: Inspiratory flattening/inversion was found in CP: 15; normals: 1; RCM: 0. Flattening/inversion during early ventricular filling was always most prominent during onset of inspiration. Total respiratory septal excursion was significantly large in CP ($18.7 \pm 1.2\%$) than in normals: ($7.1 \pm 2.4\%$) $p < 0.0001$ and RCM ($5.8 \pm 2.1\%$) $p < 0.0001$. A cut-off value of 11.9% (mean $\pm 2 \text{ SD}$) is useful to discriminate CP patients from normal subjects and RCM patients, even in the presence of a normal pericardial thickness on MR imaging (present in 33% of CP in this series).

Conclusions: Pathologic ventricular coupling, ie, abnormal ventricular septal flattening or inversion during onset of inspiration and increased total respiratory septal excursion, is a reliable criterium to differentiate CP from RCM patients.

B-085 11:06

Evolution of MR imaging findings of arrhythmogenic right ventricular cardiomyopathy at follow-up

N. Limbucci, V. Pupillo, L. Mancini, E. Stavroulis, E. Di Cesare, C. Masciocchi; *L'Aquila/IT*

Purpose: To assess the evolution of MR imaging findings of arrhythmogenic right ventricular cardiomyopathy (ARVC) after 5 year follow-up in patients with diagnosed ARVC.

Methods and Materials: We studied 26 patients with diagnosed ARVC according to the international criteria. All patients underwent cardiac-MR imaging 43-60 months (average 49.8 months) after a previous MR imaging suggestive for ARVC. All examinations were performed with the same 1.5 T GE unit, with black-blood morphologic sequences and bright-blood breath-hold cine sequences.

Results: 15 patients (57.7%) presented right ventricular dilation, fat infiltration and dyskinetic areas at first MR imaging. 12 of 15 cases (80%) showed similar findings at follow-up. In 3 of 15 patients (20%) we observed evolution of the previously described findings with extension of the infiltrated and dyskinetic areas. In one of these cases the outflow tract diameter increased from 37 to 41 mm. In 6 patients (24%) the first MR imaging showed fat infiltration and dyskinetic areas, in 4 of them (66.6%) follow-up MR imaging showed comparable findings, in 1 case (16.7%) the fat infiltration was not evident, in 1 patient (16.7%) the dyskinetic area extended. In 5 patients (19.2%) with isolated fat infiltration evidence, follow-up MR imaging confirmed the findings in 2 cases (40%) but in 3 cases (60%) the new MR imaging could not confirm the finding.

Conclusion: Most of patients with MR imaging findings of ARVC presented a stable pattern at follow-up, but in some cases MR imaging showed disease evolution. Fat infiltration was not always confirmed at follow-up, agreeing with previous studies about the low specificity of this finding.

B-086 11:15

Myocardial tissue characterization by magnetic resonance imaging (MRI) in Anderson-Fabry disease

M. Imbriacomo, G. Sica, S. Maurea, M. Quarantelli, A. Cuocolo, M. Salvatore; *Naples/IT*

Purpose: Anderson-Fabry disease (AFD) is a multisystem X-linked disorder of lysosomal metabolism frequently associated with left ventricular (LV) hypertrophy. This study aimed to assess whether myocardial T2 relaxation time (MT2RT), determined by a black-blood multi-echo MRI sequence could help to evaluate cardiac involvement in AFD.

Materials and Methods: Nine patients with AFD (M/F: 7/2; mean age: 35 ± 10 years) and nine age-matched healthy controls (M/F: 7/2; mean age: 34 ± 14 years) underwent MRI. MT2RT was calculated using a T2 weighted black-blood TSE sequence at different echo times (TE): 45, 60, 75 and 90 msec in the

Scientific Sessions

4-chamber horizontal long-axis. Regions of interest were placed along interventricular septum, apex and lateral walls on the first echo image and reproduced on the other echo images. MT2RT was calculated using a linear least-square fit applied on the logarithm of myocardial signal intensity versus echo time according to the formula $M(TE)=M e^{-TE/T}$. A balanced-fast field echo multiphase-multislice sequence covering the left ventricle with 9-10 slices across the biventricular short axis from apex to base was obtained for evaluation of LV mass; LV mass index (LVMI) was subsequently calculated.

Results: In patients with AFD, MT2RT was 75 ± 7 msec in the interventricular septum, 78 ± 11 msec in the apex and 77 ± 11 msec in the lateral wall vs 51 ± 7 msec, 54 ± 5 msec and 51 ± 6 msec of the controls ($p < 0.001$). LVMI was 120 ± 32 g/m² in patients with AFD and 63 ± 9 g/m² in the controls ($p < 0.001$).

Conclusion: MT2RT is significantly prolonged in patients with AFD compared to controls. MRI may be useful for characterization of myocardial tissue in such patients and for monitoring the effects of enzyme replace therapy.

B-087 11:24

MR planimetry in aortic valvular stenosis

M. Lederlin, P. Reant, M. Montaudon, O. Corneloup, S. Lafite, F. Laurent; *Pessac/FR*

Purpose: Measurement of aortic valve area (AVA) is essential to evaluate the severity of aortic stenosis. The objective of this study was to evaluate the reliability of direct planimetry by MR imaging to measure aortic valve area in aortic stenosis and to compare MR imaging measurements with values obtained by current diagnostic techniques ie. transthoracic echocardiography (TTE), transoesophageal echocardiography (TOE), and cardiac catheterization.

Methods and Materials: 45 consecutive patients with aortic stenosis (ranging from 0.4 to 1.9 cm²) underwent TTE, TOE, cardiac catheterization, and MR imaging. By TTE and cardiac catheterization, AVA was indirectly assessed by the continuity equation (Doppler velocity-time integral) and the Gorlin equation (available in 27 subjects), respectively. By TOE and MR imaging, absolute AVA was measured by direct planimetry. We used steady-state-free-precession (SSFP) sequences on a 1.5 T Siemens system to perform the MR planimetric quantification of the stenosis.

Results: Mean AVA was 1.19 ± 0.88 cm² by TTE, 1.13 ± 0.78 cm² by TOE, and 1.21 ± 0.85 cm² by MR imaging. No significant difference was observed between TOE and MR imaging measurements, with a strong correlation coefficient ($r = 0.94$). Bland-Altman analysis evaluating intraobserver and interobserver variability showed a very small bias for both absolute measurements.

Conclusion: Magnetic resonance planimetry of the aortic valve area can be used alternatively to TOE as a reliable and reproducible tool for assessing absolute measurements of aortic valve area in subjects with aortic stenosis.

B-088 11:33

Myocardial scarring in beta thalassemia major by late gadolinium-enhanced magnetic resonance imaging: Correlation with myocardial iron overload and ECG-changes

F. Sorrentino¹, A. Pepe¹, V. Borsellino¹, M. Galia¹, M. Midiri¹, M. Lombardi²; ¹Palermo/IT, ²Pisa/IT

Purpose: Aims of this study were a) to determine in patients (pts) with beta thalassemia major (TM) whether myocardial scarring (MS) can be detected by late gadolinium-enhanced magnetic resonance imaging (MRI); b) to correlate the presence of MS with myocardial iron overload (MIO) and ECG-changes.

Materials and Methods: 38 beta TM pts were enrolled. Myocardial fibrosis was determined by late gadolinium-enhanced MRI. Images were evaluated by a visual assessment of two independent observers and by a semi-automatic post-processing software tool for objective pixel quantification. MIO was determined by a gradient T2-star (T2*) multi-echo sequence on three parallel short axis views (basal-medium-distal) of left ventricle. Twelve lead ECG was performed in 30 patients before the MRI study.

Results: Scarring was present in 15 patients, and it was predominantly patchy. Out of the 15 pts, 11 had two or more foci of scarring. Out of the 36 areas of scarring, 19 involved the interventricular septum. Scarring did not follow coronary distribution. No asynergic segments were detectable. Myocardial fibrosis did not significantly affect the T2* value. A significant correlation was found between the presence of MS and ECG changes (atrio-ventricular block, right bundle-branch block, ST segment depression, T wave inversion, abnormal Q-waves or decreased R waves). The sensitivity, specificity, negative and positive predictive value of ECG in detecting MS were 90%, 63%, 92% and 58%, respectively.

Conclusion: MS is detectable in a significant percentage of patients with beta TM. MS did not correlate with MIO. ECG-changes showed a significant accuracy to predict MS.

B-089 11:42

T2* measurement in patients with beta thalassemia major: Effect of heterogeneity of myocardial iron overload, myocardial fibrosis and blood oxygenation

F. Sorrentino¹, A. Pepe¹, C. Lo Pinto¹, V. Di Salvo¹, M. Midiri¹, M. Lombardi²; ¹Palermo/IT, ²Pisa/IT

Purpose: Aims of this study were: 1) to assess tissue iron concentration using the T2* multiecho technique; 2) to determine whether T2* measurements are influenced by heterogeneity of iron distribution, presence of myocardial fibrosis (MF) and blood oxygenation (BO).

Materials and Methods: 43 regular transfused patients (pts) with beta thalassemia major were enrolled. Three parallel short axis views (basal-medium-distal) of left ventricle were obtained by a gradient T2* multiecho sequence. Segmentation into four regions (anterior, lateral, posterior, septal) and T2* values within them were automatically obtained in order to evaluate the heterogeneity of iron distribution. MF was assessed by late gadolinium-enhanced magnetic resonance imaging (MRI). The BO was assessed by the non invasive measurement of oxygen pressure (P_{O₂}) during MRI exam.

Results: We identified three groups: A) with an homogeneous myocardial iron overload (MIO); B) with no MIO and C) with an heterogeneity of iron distribution. A correlation between the average of T2* values in all the 12 segments and the T2* value in the mid-ventricular septum was found; the latter showed a significant difference between A and C group and between C and B group. The range of the T2* value in the mid-ventricular septum showed an overlap between A and C group and between C and B group. MF did not significantly affect the T2* mean value. The P_{O₂} did not correlate with the T2* value.

Conclusion: MIO showed an heterogeneous distribution in about 50% of pts. MF and BO do not effect T2* cardiac measurements.

B-090 11:51

Use of inversion recovery contrast-enhanced MR imaging (IR-CE-MRI) in the evaluation of patients with clinically suspected pericarditis

M. Francone, A. Taylor, M. Kalantzi, S. Dymarkowski, J. Bogaert; *Leuven/BE*

Purpose: Diagnosis of pericarditis with current imaging techniques is not always straightforward. As pericarditis is an inflammatory process, IR-CE-MRI (similar to late enhancement myocardial MRI) may be of value for detecting pericardial inflammation.

Materials and Methods: An MRI study that included late enhancement acquisitions after contrast-administration (0.2 mmol/kg bodyweight Gd-DTPA) was performed in 31 patients with clinical suspicion of pericardial disease (PD group), 22 patients with a recent history (< 3 weeks) of acute MI (AMI group), and 12 patients with no clinical evidence of pericardial disease (CON group). Images were analyzed for the presence of pericardial effusion, pericardial thickening and pericardial enhancement.

Results: Enhancement of the pericardial layers was found in 11/31 (moderate: 4, strong: 7) patients in the PD group, which was not related to the concomitant presence of pericardial fluid. Enhancement was helpful for demonstrating acute inflammation of the pericardial layers, differentiating inflammatory from fibrosing forms of chronic pericarditis, and defining the different components of pericardial thickening (e.g. pericardial layers vs pericardial effusion). Although in the AMI group minimal pericardial effusion was found in 12 patients, in only 4 was pericardial enhancement detected (moderate: 2, slight: 2). The two patients with moderate pericardial enhancement had clinical evidence of post-infarction pericarditis. In all 12 patients in the CON group, no pericardial thickening or enhancement was demonstrated.

Conclusions: The present study results suggest a more versatile use for IR-CE-MRI, enabling visualisation of pericardial inflammation in patients with clinical suspicion of pericardial disease and detection of post-infarction pericarditis in patients with recent acute MI.

Diffusion tensor imaging (DTI) in patients with multiple sclerosis (MS):

Correlation with perfusion imaging

E. Papadaki, N. Papanikolaou, S. Karampekios, M. Spilioti, T. Maris,

N. Gourtsoyiannis; Iraklion/GR

Purpose: To perform DTI and dynamic susceptibility contrast (DSC) techniques in MS patients and healthy volunteers and investigate possible correlation between diffusion and perfusion properties.

Methods and Materials: A T2SE-EPI sequence with 6 different diffusion gradients and a single shot T2*GRE-EPI sequence with 50 dynamic axial scans after a single dose of Gd administration were applied to 36 MS patients and 10 healthy volunteers on a 1.5 T scanner. 677 measurements of Apparent Diffusion Coefficient (ADC), Fractional Anisotropy (FA) and relative Cerebral Blood Volume (rCBV%) were performed concerning focal white matter lesions (213), "Dirty" White Matter (DWM=96), Normal Appearing White Matter (NAWM=288) and Normal White Matter (NWM=80). Possible linearity between ADC or FA and rCBV% values of the different white matter regions was evaluated by linear regression analysis.

Results: ADC and rCBV%, or FA and rCBV% values demonstrate poor to moderate correlation coefficient for NWM, NAWM and most of the focal white matter lesions, while a very good correlation between ADC and rCBV% ($r = 0.86$, $p = 0.04$), or FA and rCBV% ($r = -0.85$, $p = 0.01$) of DWM was evaluated. There is also an excellent correlation between ADC and rCBV% ($r = 0.98$, $p = 0.01$) of enhancing lesions (EL).

Conclusion: There is poor to moderate correlation between ADC or FA and rCBV% values for most of the white matter regions, with the exception of DWM and EL. These findings suggest that the combination of diffusion and perfusion imaging techniques may improve the characterization of white matter lesions in patients with MS.

B-092 10:39

Quantitative study of fractional anisotropy of the corticospinal tract and corpus callosum in patients with relapsing-remitting MS

C.S. Yu, K.C. Li; Beijing/CN

Purpose: To investigate the differences in fractional anisotropy (FA) of the corticospinal tract (CST) and corpus callosum (CC) between remitting-relapsing multiple sclerosis (RRMS) patients and normal volunteers and whether these indices correlate with EDSS or pyramidal scores.

Methods and Materials: Single shot echo-planar diffusion tensor imaging was performed in 36 volunteers and 64 patients with RRMS. Then the fibers of CST and CC were reconstructed and FA values of them were computed by using a tractography software package. Differences in FA of individual tracts between RRMS patients and normal volunteers were investigated, and correlation of these indices with EDSS was also determined.

Results: FA of CST is 0.497 ± 0.028 without sex or lateral difference ($p > 0.05$), and FA of CC is 0.506 ± 0.020 without sex difference either ($p > 0.05$). FA of CC (0.465 ± 0.033) and CST (0.472 ± 0.037) of RRMS are significantly lower than normal volunteers. FA of CC of cerebral type of RRMS (0.456 ± 0.036) prominently lower than that of spinal type (0.475 ± 0.025), but this phenomenon does not exist in CST. In RRMS patients, there exists no correlation of FA of CC with EDSS ($r = -0.104$, $p > 0.05$). FA of CST correlate with EDSS ($r = -0.193$, $p < 0.05$) and pyramidal score ($r = -0.218$, $p < 0.05$), and higher in pyramidal score. Among them, FA of CST of cerebral type of MS correlate with EDSS ($r = -0.273$, $p < 0.05$) and pyramidal score ($r = -0.268$, $p < 0.05$), but this correlation does not exist in spinal type.

Conclusion: FA of CC and CST of RRMS can reflect pathological status of MS. FA of CST can be used to evaluate functional status of cerebral type of MS patients.

B-093 10:48

Diffusion-weighted MR imaging of the spinal cord in multiple sclerosis

A. Dirisamer¹, R. Bammer², K. Vass¹, M. Thurnher¹; ¹Vienna/AT, ²Stanford, CA/US

Purpose: To evaluate diffusion characteristics of multiple sclerosis (MS) lesions in the spinal cord, and compare the results with findings on conventional MR sequences.

Material and Methods: Nine patients with proven MS and lesions in the spinal cord were included in the study. MR studies were performed on 1.5 T clinical scanner with the following imaging protocol: T2WI, T1WI pre and postcontrast, and DWI in sagittal and axial planes. For DWI multi-shot EPI with fat suppression and max b factor of 600 was used. Slice thickness was 5 mm, fold over direction AP and scanning time was 3:05 min. For axial images performed with a surface coil (14 x 17 cm) single-shot EPI with 40 slices and 4 mm slice thickness was used. Signal intensities on DWI were recorded and ADC measurements were performed in all patients.

Results: All MS lesions showed high signal on T2WI, marked enhancement was present in 3/9 patients, faint enhancement was observed in 3/9 patients. In 3 patients no enhancement was present on postcontrast scans. In 8 of 9 patients, high signal was observed on DWI with low ADC values consistent with restricted diffusion. One patient did not show a diffusion abnormality despite enhancement on the postcontrast image.

Conclusion: DWI may provide new structural information in relation to spinal cord pathology in MS. Further work with comparison between DWI/ADC and signal intensities on T1WI, the presence or absence of enhancement and MTR is needed.

B-094 10:57

Cerebral lesion load in neuropsychiatric systemic lupus erythematosus: A longitudinal study

B.J. Emmer, S.C.A. Steens, M.G. Steup-Beekman, F. Admiraal-Behloul, G.P.T. Bosma, S. Le Cessie, W.J.N. Ouwendijk, T.W.J. Huizinga, M.A. van Buchem; Leiden/NL

Purpose: Magnetization transfer imaging (MTI) analysis detects brain parenchymal abnormalities in patients with neuropsychiatric systemic lupus erythematosus (NPSLE). The aim of this study was to assess whether clinical changes in NPSLE patients are reflected in changes of MTI parameters.

Methods and Materials: 19 female patients (mean age 37.5 years; range 19-64) were subjected to MTI. Following segmentation, whole brain magnetization transfer ratio (MTR) histograms were generated. The peak height (Pht) of these histograms was used as an estimate of cerebral lesion load. MTI data were generated on at least two separate occasions (mean time between scans 25.4 months; range 5.4-52.3). 25 pairs of scans were available from 19 patients. Clinical course was defined as improvement, stable, or deterioration, based on an expert panel scoring. Change in clinical classification was compared with Pht change, between first and second MR imaging. Differences in Pht change between the three groups were compared using a linear mixed model with random person effect.

Results: 4 pairs deteriorated, 15 were stable, and 6 improved. Clinically deteriorated patients showed a relative Pht decrease of 8.1%, in stable disease the relative Pht increase was 0.3%, and clinically improved patients showed a relative Pht increase of 12.5% (p -value < 0.001). Pair wise comparison detected significant differences between all groups (p values < 0.05 , with Bonferroni correction).

Conclusion: These findings demonstrate that MTI correlates with changes in clinical status in individual patients. This suggests that MTI parameters could serve as markers of NPSLE activity and that cerebral damage in NPSLE is, in part, reversible.

B-095 11:06

Brain metabolism in HIV-infection assessed by proton and ³¹phosphorus magnetic resonance spectroscopy

E.Z. Kovacs¹, S. Buchthal¹, R. Shin¹, B. Shelton², B.A. Bush¹, M.J. Kilby¹, H. Zeng¹, J. den Hollander¹, D.J. Benos¹; ¹Birmingham, AL/US, ²Lexington, KY/US

Purpose: Impaired energy-metabolism has been implicated in the pathogenesis of HIV-associated dementia (HAD). We combined ³¹phosphorus magnetic resonance spectroscopy imaging (³¹PMRSI) to measure high-energy phosphates in the brain, and high resolution proton magnetic resonance spectroscopy (¹HMRS) of the cerebrospinal fluid (CSF) to better understand the metabolic processes occurring in HAD.

Materials and Method: 25 HIV+ and 20 HIV- subjects underwent ³¹PMRSI in a

Scientific Sessions

4.1 T whole-body MR imaging/MRSI system. Metabolite ratios from PCr, ATP and Pi were measured and calculated in six brain regions. Following $^{31}\text{PMRSI}$, CSF was obtained from 19 HIV+ and 10 HIV- subjects. Specimens of CSF were analyzed by $^1\text{HMRS}$ in a 500 MHz Bruker Magnet. Lactate, organic- and amino-acid concentrations were measured.

Results: No significant difference was found between HIV+ and HIV- subjects in PCr/ATP, Pi/PCr and Pi/ATP in any brain regions. In contrast: lactate ($p = 0.008$), alanine ($p = 0.002$), citrate ($p = 0.036$), creatine and creatinine ($p = 0.044$) concentrations were significantly elevated in the CSF of HIV+ subjects. Pyruvate also tended to be elevated in CSF of patients ($p = 0.052$).

Conclusion: Elevation of citrate, alanine, lactate and pyruvate in the CSF of HIV+ subjects suggest impaired energy metabolism and the inhibition of tricarboxy-acid cycle, despite normal values of high energy phosphate metabolite-ratios measured *in vivo*. Our results suggest that CSF composition assessed by high resolution $^1\text{HMRS}$ may be a more sensitive indicator of disturbance in energy metabolism than alterations of PCr/ATP, Pi/PCr and Pi/ATP in HAD. Supported by NIMH grant MH50421 and NCI grant CA-13148.

Clinical diagnosis of sporadic Creutzfeldt-Jakob disease: Reliability of MR imaging and comparison with EEG and 14-3-3 protein analysis

H.J. Tschampa¹, K. Kallenberg², I. Zerr², B. Meissner², H.A. Kretzschmar³, M. Knauth², H. Urbach¹; ¹Bonn/DE, ²Göttingen/DE, ³Munich/DE

Purpose: Technical investigations included in the clinical diagnosis of sporadic Creutzfeldt-Jakob Disease (sCJD) are EEG and CSF-analysis for 14-3-3 protein. MR imaging is not a criterion for the diagnosis of sCJD, although typical changes have been described. We investigated the reliability of MR imaging in the sCJD diagnosis, evaluated MR imaging sequences and compared MR imaging with EEG and 14-3-3.

Methods and Materials: This study includes 193 consecutive suspected sCJD patients who had been referred to the German CJD Surveillance Unit during 2001 to 2003. Three observers independently analyzed MR imaging scans, blinded to clinical data. MR imaging was rated as "typical for sCJD" if increased signal intensity was detected in the caudate nucleus and putamen.

Results: We analyzed 442 MR imaging scans (184 T2-, 132 FLAIR, 75 diffusion- and 51 proton-density weighted sequences). Inter-observer agreement was good (123/193 patients or 63.7%, overall $\kappa = 0.53$). Sensitivity of MR imaging in clinically probable or autopsy-proven sCJD was 59.7%, 58.3% and 70.8% (observers 1-3). Specificity was high (84.2%; 89.5%; 81.6%). Diffusion weighted sequences best showed the pathologic changes, followed by FLAIR. MR imaging results were in the range of EEG (sensitivity 32%, specificity of 94%) and 14-3-3 data (sensitivity 91%, specificity 44%).

Conclusion: We propose to incorporate MR imaging in the diagnostic criteria for sCJD, equivalent to EEG and 14-3-3 analysis.

B-097 11:24

High b value diffusion MR imaging of the brain and the spinal cord in patients affected by amyotrophic lateral sclerosis: Preliminary results

L. Manfrè¹, M. Bonetti², T. Piccoli³, C. Cristaudo¹; ¹Catania/IT, ²Brescia/IT, ³Palermo/IT

Purpose: To evaluate segmental ADC values of white matter at the level of the motor area and the internal capsule (Upper Motor Neuron - UMN), anterior and lateral spinal columns (UMN), spinal gray matter of the anterior horns (LMN) in patient affected by ALS.

Materials and Method: From October 2003 to April 2004, we examined 14 ALS patients. All the patients underwent brain and spinal cord MR imaging and diffusion MR imaging study: b value was 2500 for brain evaluation, and 450 for spine study. ADC values of motor strip area, internal capsule and white and gray matter of the spinal cord were calculated on caudo-cranial (ADCcc), left-right (ADCr) and antero-posterior (ADCap) DWI images, as for isotropic image (ADCi).

Results: No significant abnormalities of ADC values were detected at the level of subcortical pre-central white matter. On the contrary, when the ADC ratio between anterior 1/3 and posterior 2/3 of the posterior limb of the internal capsule was evaluated, significant decrease in ADC ratio occurred in caudo-cranial DWI, suggesting UMN disease. Patients showed statistically significant increase in ADC values along all the direction of the b gradient at the spinal cord. Anisotropic index demonstrated prevalent distraction of caudo-cranial fibers of white matter (UMN disease), and gray matter of anterior horn (LMN disease).

Conclusion: Diffusion-weighted imaging appears to be a very sensitive MR technique in depicting selective white matter tract destruction secondary to neuronal and axonal degeneration as occurs in ALS patients.

B-098 11:33

MR proton spectroscopy of the brain in Tourette syndrome

W. Szczkowski, M. Golebiowski, P. Janik; Warsaw/PL

Purpose: The aim of this study was to assess the use of MR proton spectroscopy (MRS) in the examination of patients with Tourette syndrome (TS).

Methods and Materials: 15 patients (5 women, 10 men) with TS diagnosed according to the clinical criteria were examined. 11 patients had moderate motor and phonic tics, the others were classified as patients with mild tics. A control group consisted of 17 healthy, age-matched volunteers (5 women, 12 men). Single-voxel spectroscopy was performed using PRESS sequences with parameters of 22/2000 ms (TE/TR). Voxels (15x15x15 mm) were located in the left and right globi pallidus and thalamus. The calculations were expressed and analyzed as ratios to Creatine (Cr). Statistical significance of any differences was assessed with the t test for unpaired data.

Results: A significant increase in Glx/Cr ratios for the left ($p < .00001$) and right thalamus ($p < .0001$) and increase in Lip level for both globi pallidus and thalamus ($p < .0001$) compared to the control group was found. The most pronounced increase of Cho and mI levels ($p < .05$) was observed in the thalamus. No statistically significant differences were found in NAA/Cr ratios between TS patients and healthy volunteers.

Conclusion: The statistically significant increase of Glx, Lip, Cho and mI levels could reflect the dysfunction within the basal ganglia, especially increased glutamate mediated thalamo-cortical and -striatal transmission and elevated metabolism in these structures. MRS seems to be helpful as a better explanation of TS pathogenesis.

B-099 11:42

X-linked Charcot-Marie-Tooth disease: MR imaging of brain changes

J. Lisy, R. Mazanec, M. Bojar, P. Seeman, J. Neuwirth; Prague/CZ

Purpose: X-linked Charcot-Marie-Tooth disease is the second most common hereditary demyelinating neuropathy. Casuistic reports about these patients in the literature describe ADEM-like changes in white matter and changes in the splenium of the corpus callosum. We attempted to identify the spectrum of brain changes on MR imaging examination in a larger group of patients.

Methods and Materials: All 15 patients (5 female:10 male) with genetically proven X-linked Charcot-Marie-Tooth disease underwent MR imaging examination of the brain.

Results: The splenium of the corpus callosum was involved in 9 patients. Diffuse T2 hyper intense changes in the parietal lobes were seen in 2 patients with the splenium of the corpus callosum the most severely involved. The corpus callosum had a normal appearance in 6 patients. Focal ADEM like changes were not seen in any patient.

Conclusion: The splenium of the corpus callosum is the most commonly involved brain structure; 60% of patients with X-linked Charcot-Marie-Tooth disease. Diffuse T2 hyper intense changes in the white matter of the parietal lobe are associated in some cases with a most severely involved splenium. Changes in the splenium of the corpus callosum likely represent chronic involvement, ADEM like changes can represent acute involvement.

A multimodal neuroimaging approach in patients with early diagnosis of Parkinson's disease: Correlations between f-MR imaging with fine motor tasks, EEG and clinical tests

A. Sias, A. Balestrieri, L. Barberini, M. Fraschini, M. Puligheddu, F. Marrosu, G. Mallarini; Cagliari/IT

Purpose: Our study introduces a systematic multi-modality approach to Parkinson's disease (PD), combining functional MR imaging and EEG, to evaluate cognitive and movement disease symptoms. The aim is to depict alterations in physiological responses in relation to disease development and treatment.

Methods and Materials: We have acquired brain cortical activation maps in 10 patients with early diagnosis of PD, and 10 normal individuals, using both EEG and functional MR imaging. Using statistical methods we have established an integrated database of the two investigations, which will be helpful in the diagnosis and monitoring of the disease, also correlating to the pharmacological treatment aiming to strengthen the dopaminergic system.

Results: Our results appear to show a contralateral hyper activation which correlates to the degree of disease development.

Conclusion: This approach seems to be a promising diagnostic tool in patients with Parkinson's disease.

Accuracy of liver superimposition in different ways of whole body image fusion of CT and PET datasets

P. Kovacs, D. Putzer, T.B. Lang, M. Knoflach, C. Hinterleitner, R.J. Bale, W.R. Jaschke; Innsbruck/AT

Purpose: To determine accuracy of liver superimposition in whole body image fusion (IF) of CT and PET datasets using a navigation system which allows IF by means of external fiducials, anatomical landmarks and automatic detection of similar voxels.

Materials and Methods: In 18 patients (range 24-77 y) thoraco-abdominal CT (2.5 mm slice thickness) and whole body PET datasets were obtained in exactly the same posture using BLUEBAG immobilization devices (Medical Intelligence, Germany). IF was performed on TREON StealthStation navigation system (Medtronic, USA) using 4-6 anatomical landmarks, 4-6 external fiducials fixed to the immobilisation device and in an automatic fashion via pair-point-matching of similar voxels. In all IFs a cuboid was superimposed to the liver. The distances of their centers were measured in the x-, y- and z-axis and totally. These distances were compared in all three ways of IF.

Results: The mean distances of the centers were 8.1/9.0/50.9 mm in anatomical/fiducial based/automatic IF. No significant differences were found between the measurements in anatomical and fiducial based IF, whereas significant differences were found in comparison to automatic IF. Fiducial based IF was more accurate in x-axis and less accurate in z-axis. These distances ranged between 0.9 and 3.8 mm.

Conclusions: Automatic pair-point-matching is not suitable for accurate whole body IFs, yet. In comparison with anatomical landmarks external fiducials can be used in combination with immobilisation devices to gain highly accurate IFs. To our experience in routinely practice external fiducials are easier to detect in both datasets and allow for faster gained IFs on navigation systems.

Quality maps for automated phase unwrapping of MR images

S. Witoszynskyj¹, A. Rauscher², J.R. Reichenbach², M. Barth¹; ¹Vienna/AT, ²Jena/DE

Purpose: MR sequences acquire complex information at the same time. Usually, phase images are discarded due to phase wraps and only magnitude information is used. With the advent of MR imaging techniques that employ phase information for enhancement of anatomical and/or functional contrast the need for solving these ambiguities arises. The aim of the study was to investigate different criteria or optimizing phase unwrapping.

Methods: Based on a region-growing algorithm a 2D phase unwrapping program for MR images was developed and implemented in C. For automated seed finding and unwrapping the algorithm depends on local quality criteria of the images. The following measures were used and their performance compared: local coherence used by the original algorithm (LCC), the average of the complex signal (ACS), the average of the magnitude (AM), the variance of the complex signal (VCS) and the variance of the phase (VPH). The algorithm with these different measures was implemented in an in-house developed software package with an IDL (RSI,USA) interface and a GUI for ParaVision (Bruker,Germany) and tested on high-resolution brain data sets.

Results: Best performance (minimum number of remaining phase wraps) was obtained with AM, followed by ACS and LCC. VCS and VPH did not produce reasonable results. AM performed best in areas of steep phase topology. AM and ACS perform better than LCC due to usage of magnitude information which helps to better separate signal from noise.

Conclusion: For automated phase unwrapping using region growing quality maps should include magnitude information to obtain meaningful results.

B-103 10:48

How to determine the quality of unsupervised functional MR imaging data analysis methods?

A. Wismueller¹, O. Lange¹, G. Leinsinger¹, A. Meyer-Baese², D. Auer³, M. Reiser¹; ¹Munich/DE, ²Tallahassee, FL/US, ³Nottingham/UK

Purpose: Unsupervised fMRI imaging image processing methods, such as clustering, Principal or Independent Component Analysis (PCA, ICA) are increasingly used as an alternative to model-based (MB) methods, e.g. cross-correlation or statistical regression. The aim was to develop and apply a method for quantitative comparative evaluation of unsupervised fMRI imaging analysis algorithms.

Methods and Materials: Functional MR imaging was performed in 11 healthy volunteers on a 1.5 T system (GE-EPI sequence, TR/TE = 4000/66 ms, 64 scan photic stimulation experiment). fMRI imaging time-series were analyzed by several unsupervised techniques: Minimal Free Energy Vector Quantization (MFE-VQ), Self-Organizing Maps (SOM), Fuzzy C-Means clustering (FCM), PCA, and ICA, employing 36 component time-series each. Stimulus-induced neural activation was determined by cross-correlation, serving as MB gold standard reference for ROC curve analysis. The area under the ROC curve (AUC) was used to determine the ability of unsupervised methods to properly detect activated brain regions.

Results: MFE-VQ performed best (AUC=0.98 ± 0.01), and provided the advantage of hierarchical data analysis on different scales of resolution. SOMs were slightly inferior (AUC=0.96 ± 0.02). In contrast to the other methods, FCM results were highly dependent on initial conditions (AUC=0.97 ± 0.05). Clustering methods clearly outperformed the data projection methods PCA (AUC=0.82 ± 0.03) and ICA (AUC=0.83 ± 0.04) that may be useful for preliminary screening, dimensionality reduction, or noise filtering.

Conclusion: Quantitative ROC plot quality assessment of unsupervised fMRI imaging data analysis can be based on stimulus-induced brain activation, i.e. relevant physiological information extracted from conventional MB methods. It is a valuable tool for the radiologist to reliably evaluate unsupervised fMRI imaging analysis methods.

B-104 10:57

A novel non-rigid mono-modal registration algorithm reducing motion artifacts at CE MR investigations

T.W. Vomweg¹, C. Hintze¹, D. Mayer¹, H. Faber¹, E. Grossi², A. Teifke¹, T. Achenbach¹, O. Rieker¹, M. Thelen¹; ¹Mainz/DE, ²Milan/IT

Purpose: To reduce artifacts within subtraction series of dynamic contrast enhanced (CE) MR-investigations caused by patient movement without compromising lesion morphology.

Material and Methods: The algorithm calculates a quality called 'eigenvalue' based on three-dimensional analysis of each voxel and its neighbours in a given volume. Comparing and filtering all volume elements by means of 'eigenvalue' results in a set of features of a given volume. By tracking these features in timely consecutive series of the same 3d-block it is possible to calculate motion vectors. In a next step registration is done by vector based morphing of original image information into a new image volume. This approach was applied to consecutive 50 studies of dynamic, bilateral CE MR-investigations of the breast using statistical and subjective tests. The mean signal intensity of all pixels of subtraction series before and after the application of the registration algorithm was calculated and compared. Lesion morphology was assessed and compared visually.

Results: Movement artifact correction reduced mean signal intensity of subtraction images by 35.78% significantly (SSD: 24.9%), while CE lesions remained as bright as without registration. Contrast of defined structures was raised; morphological features of lesions remained unchanged.

Conclusion: Using 'eigenvalue' based morphed images in non-rigid registration of CE MR-Mammography leads to significant improvements in image quality by reducing motion artifacts. Subtracted series that were generated in this manner are superior to conventional, non-registered subtractions and could proof helpful in detection and characterization of lesions. This project is financed by Bracco Imaging, Milan, Italy.

B-105 11:06

A graphical user interface for SWI-reconstruction

A. Deistung¹, A. Rauscher¹, J. Sedlacik¹, S. Witoszynskyj², M. Barth², W.A. Kaiser¹, J.R. Reichenbach¹; ¹Jena/DE, ²Vienna/AT

Purpose: Although BOLD-MR-venography (also named susceptibility weighted imaging, SWI), has been established for the examination of tumors and for studying physiological processes, its evaluation has not been implemented routinely in

Scientific Sessions

MR scanners yet. Therefore, a platform independent easy-to-use graphical user interface (GUI) has been developed for fast generation and extensive analysis of SWI data.

Material/Methods: High-resolution 3D scans were acquired with a first-order, flow compensated gradient echo sequence on 1.5 T MR imaging scanner (Magnetom Vision, Siemens, Erlangen, Germany) (TR/TE/alpha=67 ms/40 ms/25°). The GUI was developed using IDL (RSI, Boulder, USA). The interface allows scanner independent reconstruction of complex raw-data. Interactive setting of parameters for zero filling, hamming filtering and algorithms for phase unwrapping (homodyne filtering or phase unwrapping in image-space) are available. After automatic creation of phase masks computed from phase images and their manifold multiplication with the corresponding magnitude images, the data are displayed by minimum intensity projections (mIP) over a freely selectable number of slices.

Results: The software tool allows to visualize image data computed from raw k-space data as well as image data in DICOM-format. With this user interface it is possible to quickly generate venograms in different orientations and to set reconstruction and analysis parameters in a flexible manner, thereby facilitating data analysis for physicians and medical technicians. Since the software is executed on the IDL-Virtual-Machine platform it can be used without having to purchase an IDL-license.

Discussion: The software helps to make the wide range of possible applications of SWI more accessible to a larger group of users.

B-106 11:15

Effect of new non-linear, three-dimensional, noise reduction filters on image quality and lesion characteristics to improve image quality of low-dose abdominal CT

M.K. Kalra¹, S.M.R. Rizzo¹, M.M. Blake¹, M.M. Maher¹, B. Schmidt², C. Suess², S. Saini¹; ¹Boston, MA/US, ²Forchheim/DE

Purpose: Acquisition of low-dose CT images is limited by image noise and compromised image quality. Previously reported two-dimensional noise reduction filters (NRF) decreased lesion conspicuity. Non-linear, 3D-NRF was developed to reduce image noise without decreasing lesion conspicuity. Our purpose was to assess the effect of 3D-NRF on image quality and lesion characteristics in low-dose abdominal-CT.

Materials and Methods: Low dose abdominal/pelvic CTs of 40 patients (age range = 28-86 years) acquired with reduced tube current (60-120 eff.mAs) at 5 mm (n = 20) and 2 mm (n = 20) reconstructed slice thickness were processed with 3D-NRF at three levels of noise reduction. Baseline low-dose and post-processed image series were randomized and evaluated by two radiologists for image noise, contrast and sharpness at porta hepatis and acetabulum using a 5-point scale. Images were assessed for lesion number, conspicuity, margins, attenuation and calcification, as well as for edge-enhancement and artifacts.

Results: Regardless of slice thickness, compared to baseline images, significant noise reduction was noted with all settings of 3D-NRF ($p < 0.0004$). Significant reduction in image contrast was noted with application of two 3D-NRF settings to 5 mm images ($p < 0.005$) and one 3D-NRF setting to 2 mm images ($p < 0.05$). Baseline and post-processed images identified 128 lesions. Although 3D-NRF with the strongest noise reduction was diagnostically unacceptable ($p = 0.006$), no significant differences between remaining 3D-NRF and baseline images were found.

Conclusion: 3D-NRF improves image noise without affecting lesion conspicuity and detection in low-dose abdominal/pelvic CT. Although 3D-NRF reduce contrast in 5 mm images, they are helpful in improving noise while maintaining sharpness and contrast in thinner slices.

B-107 11:24

Automatic quantification of carotid artery stenosis: Preliminary results of a new vascular software module

M. Celestre, I. Sansoni, M. Rengo, M. Di Martino, L. Coletta, A. Laghi, R. Passariello; Rome/IT

Purpose: To show the feasibility and usefulness of a new automatic vessel quantification software (Viatronix V3D-vascular module), to aid physicians to analyze carotid arteries stenosis.

Methods and Materials: We retrospectively analysed 2D MSCT angiography examinations of 15 patients, with carotid arteries stenosis, to compare the percentage of stenosis diagnosed by sight, on the basis of MSCTA 2D images, with the automatic quantification evaluated using this new kind of vascular software module in the post processing analysis. Both values was referred to NASCET criteria (calculated on 2D CTA images) assumed as the gold-standard.

Results: For the extracranial carotid artery, our experiences indicated that there is a good correlation between Viatronix automatic vessel quantification and MSCTA. Although this accuracy is heavily depending on the dimension and morphology of calcification, that limits the automatic measurements.

Conclusion: Viatronix V3D-vascular module provides excellent image quality and appears to be an accurate, non-invasive tool in the assessment of carotid lumen stenosis, but technical improvements could perfect this software and the accuracy of its analysis.

B-108 11:33

Accuracy of computer based measurements in endovascular stent-graft planning: Experimental in vitro evaluation in an aortic aneurysmal phantom

S. Klein, M.H. Hoffman, D.T. Boll, H.J. Brambs, A.J. Aschoff; Ulm/DE

Purpose: The aim of this study was to evaluate the accuracy of automated software applications in endovascular stent-graft planning of abdominal aortic aneurysms with multidetector row Computed Tomography.

Methods and Materials: A vascular phantom of the abdominal aorta including the iliac arteries with an infrarenal aortic aneurysm was constructed and filled with an iodine based contrast medium solution. CT scan was performed with different slice thickness and increment using a 16-slice scanner. After transferring CT data to a workstation 3D Volume renderings were generated. Diameter and distance measurements were performed at specific vessel points for endovascular stent-graft implantation using a manually and an automatically generated centerline. The results were compared with the known dimension of the phantom and mean fractional errors were calculated. Necessary time of postprocessing was evaluated for both methods.

Results: Using the automatic software the mean fractional error for all diameter measurements combined was 0.054 (Standard deviation 0.018), respectively 0.061 (SD 0.049) for the manual method. Regarding the distance the mean fractional error was 0.027 (SD 0.026) for the automatically respectively 0.034 (SD 0.038) for the manually generated results. Using the automated measuring method 34% shorter postprocessing time was necessary.

Conclusion: Automated software application enables accurate measurements of diameter and distance used for stent-graft planning of abdominal aortic aneurysms in shorter postprocessing time than manually performed measurements.

B-109 11:42

Improving reproducibility of small structure segmentation by isotropic resolution filtering

R.M. Lapp, M. Kachelrieß, W.A. Kalender; Erlangen/DE

Purpose: Reproducibility of small volume segmentation in CT examinations suffers from a strong dependence on the orientation of the object. This results from the often anisotropic spatial resolution observed in CT image stacks, depending on selected effective slice width and reconstruction kernel, and influences the quality of e.g. calcium scoring or vessel segmentations. We introduce an image post-processing technique that compensates for this effect.

Methods and Materials: We simulated CT rawdata of a set of cylinders (10 mm length, 2 mm diameter, 300 HU) at angular directions of 0°, 30°, 60° and 90° to the x/y-plane and reconstructed the volumes using a smooth reconstruction kernel. The volume of the cylinders was determined as the voxel volume after thresholding. Our post-processing technique performs an image filtering in z-direction compensating for differences in the in-plane and axial resolution of the images. The determination of the spatial resolution is performed by measuring the response to a delta impulse. All investigations were conducted using dedicated CT simulation and image reconstruction software (www.vamp-gmbh.de).

Results: Without the proposed filtering technique measured volumes for the cylinders differed from 20.9 to 24.0 mm³ as a function of the angular direction with a standard deviation of 1.35 mm³ at a 150 HU threshold. After isotropic filtering values differed from 19.8 to 20.5 mm³ with 0.29 mm³ standard deviation showing a significantly lower dependence on the spatial orientation.

Conclusion: Isotropic resolution filtering significantly reduces the influence of object orientation on volume segmentation results and can be used to increase reproducibility.

Scientific Sessions

Three-dimensional visualization and calculation of lesional volume in patients of multiple sclerosis. Fundamentals and preliminary results
E. Gomez-Gonzalez, J. Aguilera-Navarro, A. Castela-Murillo, M. Vera-Valencia, M. Dominguez-Marín, A. Cano-Rodríguez; Seville/ES

Purpose: To present a new method, implemented as a computer program to evaluate absolute and relative lesional volume in patients of multiple sclerosis (MS) by computerized measurement of hyperintense findings. To evaluate the possibilities of interactive segmentation and three-dimensional visualization of lesions in clinical applications.

Methods and Materials: Three-dimensional visualizations of segmented hyperintense lesions in MR-studies (1.5 T GE-Signa) of 20 patients with confirmed MS are generated. Each study comprises an average of 15 slices having 4.42 lesions/slice. Using developed computer program, i) bone is segmented and total cranial volume is calculated, ii) hyperintense lesions are segmented using a semiautomated tool (user selects to include/exclude findings) and iii) absolute and relative volumes of demyelinated parenchyma are calculated.

Results: Segmentation thresholds for delimitation of bone regions and ventricles were obtained. 5 different segmentations (varying thresholds) were performed to isolate hyperintense lesions. Total and relative volumes of damaged parenchyma were calculated. Intraobserver correlation is very high ($K=0.83$) and statistically significant ($p < 0.0001$). Definition of the lower limiting threshold is very important.

Conclusion: Proposed method allows for precise calculation of total and relative volumes of lesions in patients suffering from MS. Semiautomated processing is controlled by user. It presents a potentially useful application in follow-up of response to treatment. (As a representation of the Cooperative Group for Research in Multiple Sclerosis of Seville: Univ.Hospital "V.Macarena", Univ. Hospital "V.Rocío", Univ.Hospital "N.S.Valme" and E.S.Ingenieros-University of Seville. Method by EGG, patented by the University of Seville. Microstructural imaging with optical coherence tomography: Comparison with intravascular ultrasound and histology in coronary artery specimens

O.A. Meissner¹, J. Rieber¹, M. Oswald¹, S. Reim¹, G. Babaryka¹, U.G. Mueller-Lisse¹, T. Redel², M. Kleen², M. Reiser¹; ¹Munich/DE, ²Forchheim/DE

Purpose: Optical Coherence Tomography (OCT) is a new intravascular imaging modality providing real time ultrastructural information of tissue with a resolution of 10 µm. Intravascular ultrasound (IVUS) as the current reference standard for in-vivo vessel characterization has limited spatial resolution. This study compared OCT, IVUS and histology of coronary arteries *in vitro*.

Methods and Materials: OCT (Lightlab Imaging Inc.) and IVUS images of 480 coronary artery specimens were obtained (normal [$n = 319$], moderate [$n = 75$] and severe atherosclerosis [$n = 86$]). Quantitative measurements comprised lumen area (LA), vessel wall area (VA), minimum and maximum wall thickness (T_{min}, T_{max}). OCT findings in fibrous, fibrocalcific and lipid-rich plaques were correlated with IVUS and histology as standards of reference.

Results: Paired (OCT, IVUS) LA measurements were in close agreement: the Bland-Altman mean bias in LA was 0.1 mm² with a precision of ± 1.7 mm² ($p = 0.9$). VA measurements correlated moderately ($r = 0.76$; $p < 0.0001$) with a trend towards lower values with OCT. T_{min} and T_{max} showed a good correlation for atherosclerotic coronary segments ($r = 0.89$; $p < .0001$); however, no significant correlation was observed in normal coronary segments ($r = 0.48$; $p < 0.06$). Overall sensitivity for plaque type characterization ranged from 75 to 98% for OCT and from 50-98% for IVUS when compared to histology.

Conclusion: Due to its superior resolution, OCT provides unique histology-like images of coronary arteries and accurately quantifies vessel dimensions *in vitro*. Concerning plaque components, high agreement was found between OCT, IVUS, and histology.

B-112 10:39

Determination of components in atherosclerotic plaques from human carotid endarterectomy specimens by multislice computed tomography imaging ex vivo

A. Trojanowska, A. Drop, B. Jarosz, T. Jargiello, J. Wronski; Lublin/PL

Aim: To evaluate if multislice computed tomography (MSCT) can help accurate characterization of atherosclerotic plaques.

Materials and Methods: 21 carotid endarterectomy specimens from 23 patients underwent MSCT examination (scanner GE Light Speed Ultra Advantage 8-row, 1.25 mm slices, 0.6 mm overlap, 120 kV, 140 mAs) in a specially designed phantom filled with water. Thereafter, all specimens were stained and examined histological at selected levels, corresponding to MSCT axial slices. Based on CT examination, plaque density was measured in Hounsfield units (HU) and colour-coding density maps were automatically created, using a dedicated software (GEMS). Observations were compared with histological findings at corresponding levels. Presence or absence of ulcerations was also noted. Data were analyzed with 2-sample t-test and ANOVA analysis of variance.

Results: Based on computer-created maps coding HU in colours, it was possible to distinguish 3 major areas of different HU density range. Comparing to histological findings, they represented lipid core, fibrotic tissue and calcifications. Sensitivity and specificity, respectively, were: lipid core 80% and 83%, fibrotic tissue 72% and 75%, calcifications 100% and 100%. Plaque ulcerations were detected with sensitivity of 65% and specificity of 76%.

Conclusions: MSCT evaluation of carotid endarterectomy specimens based on HU colour-coding program helps in determining the type of plaque and shows very good correlation with histological analysis for the visualization of calcifications, lipid core and fibrotic tissue. The results in identifying major components of plaque *ex vivo* suggest its value for these measurements *in vivo* as well.

B-113 10:48

Detection of atherosclerotic plaques with low dose Gadofluorine-enhanced MR imaging at 3 T

H. Ittrich¹, A. Priest¹, C. Jahntz¹, C. Weber¹, B. Misselwitz², G. Adam¹, ¹Hamburg/DE, ²Berlin/DE

Purpose: To determine of the lowest plaque-enhancing concentration of Gadofluorine M (GdF, Schering AG) in atherosclerotic aortic plaques, using a 3 T clinical MR imaging scanner.

Method and Materials: High resolution MR imaging of the aorta was performed on 9 WHHL (16-28 months) and 6 NZW rabbits (control, 16 months) before, after and 24 h post administration of GdF on a 3 T MR scanner (Philips Intera), using an 8-channel head array coil. 3 groups with injection dosages of 50, 25, 12.5 µmol GdF/kg BW were used (each of 3 WHHL/2 NZW). 3D MRA (TR/TE = 5.6/2.1 ms, FA25°, matrix256×179×70, resolution 0.7×0.7×0.7 mm) and 3D IR-TurboFLASH sequences (TE/TR = 2.2/7.2 ms, TI 120 ms, FA20°, matrix256×195×19, resolution 0.55×0.72×1.6 mm) were used to investigate luminal diameters and uptake of GdF in the aorta. SNR-measurements were performed by placing ROIs in the aortic wall. All WHHL/NZW groups were compared by Student's t-test.

Results: In all animals luminal diameters of the aortic arch showed no significant differences (6.7 ± 0.7 mm). Enhancement of aortic wall was detected in all WHHL of the 50 µmol/kg group (SNR before administration (ba): 2.6 ± 1.3 , post administration (pa): 14.4 ± 2.5) and of 25 µmol/kg group (SNR ba: 3.4 ± 1.7 , pa: 12.2 ± 1.4). No significant uptake was shown in 12.5 µmol/kg WHHL group (SNR ba: 3.2 ± 1.4 , pa: 4.0 ± 1.5) and in NZW rabbits (SNR ba: 3.6 ± 0.4 , pa: 3.4 ± 0.6). The 50 and 25 µmol/kg groups showed significant differences in SNR (WHHL to NZW) at a level of 5%.

Conclusion: Contrast enhanced MR imaging techniques at 3 T using low dose GdF are able to identify nonstenotic atherosclerotic plaques. This technique holds promise for detection of lipid plaques and long term evaluation of plaque progression in atherosclerosis in clinical practise.

B-114 10:57

MR vessel wall imaging of abdominal aorta at 3 T: Understanding and minimising plaque-mimicking flow artifacts

A.N. Priest, S. Hegerfeldt, C. Weber, G. Adam; Hamburg/DE

Purpose: To investigate black-blood imaging of abdominal aortic vessel wall, in particular the appearance of plaque-mimicking flow artifacts as a function of cardiac trigger-delay time.

Methods and Materials: The abdominal aortas of 4 healthy volunteers were imaged with a 3 T clinical scanner (Philips) using a 6-element array coil, at varying delay times following cardiac triggering by either vector-ECG or peripheral pulse

Scientific Sessions

(PP) oximetry. A turbo-spin echo sequence was used with TE/TR = 70 ms/3RR for a 3-slice interleaved package. Abdominal motion artifacts were reduced using respiratory phase-encode ordering and an anterior saturation band. Two blood-suppression methods were compared: double-inversion recovery (DIR) and out-of-slice saturation (OSS) using superior and inferior saturation bands.

Measurements were made of mean blood signal-to-noise ratio (MB-SNR), apparent vessel wall thickness (AVWT) and subjective quality of vessel wall visualisation (scale 0-5).

Results: Using OSS, MB-SNR was 3.4/1.9/2.8 and quality was 2.2/3.6/2.8 at trigger-delays 150/300/450-470 ms using ECG. Using DIR, MB-SNR was 2.6 with quality 2.1 at trigger-delay 450-470 ms. Corresponding mean AVWT were 1.04/1.12/1.06 (OSS) and 0.96 (DIR). Imaging during mid-late diastole, OSS gave poorer blood suppression and apparently broader vessel walls than DIR (e.g. MB-SNR 5.5/2.5, AVWT 1.52/1.17, quality 3.2/2.8 for delays 400-475 ms after PP trigger).

Conclusions: In this preliminary study, optimum image-quality occurred for ECG delay-time 300 ms, when DIR cannot be used but OSS blood suppression is effective in volunteers. However DIR must be used for mid-late diastolic imaging, as OSS does not always adequately suppress slow-flowing blood and gives artefactually increased AVWT, which could be erroneously interpreted as plaque.

B-115 11:06

Lower limb MR venography with true FISP for suspected deep venous thrombosis

C.P. Cantwell, J. Bruzzi, A. Cradock, S. Eustace, J.G. Murray; Dublin/IE

Purpose: To compare True FISP MR venography for suspected deep venous thrombosis with conventional venography.

Materials and Methods: This was a prospective study of 16 patients with a clinical suspicion of deep venous thrombosis of the lower limb. Standard contrast venography was performed and compared to MR venography using True FISP (TR 3.6 ms, TE 1.8 ms) sequences. MR imaging was performed from the inferior vena cava to the feet. Standard protocol was axial imaging at 6 mm slice thickness, at three stations. Total scan time was 8 minutes. Twenty venous segments on the MR studies were independently read by two radiologists unaware of venography findings. Low signal in a vein on multiple slices was regarded as thrombosis.

Results: MR venography identified the site and extent of acute thrombosis in the 5 cases with venous thrombosis on venography. The presence of secondary signs of vein distension, peri-venous swelling and fascial high signal aid diagnosis. MR imaging identified another cause for calf pain and swelling in 4 cases including 3 calf muscle tears and chronic venous insufficiency.

Conclusion: MR venography with axial true FISP allows non-invasive rapid diagnosis of acute deep venous thrombosis without the need for IV contrast. Demonstration of the central extent of the thrombus is possible to the inferior vena cava. In patients without a DVT it may show an alternative cause for patient symptoms.

B-116 11:15

3D-Gd-enhanced MR angiography (MRA) for diagnosing venous thromboembolic disease: One-stop-shop imaging of pulmonary arteries, vena cava, pelvic and both lower extremity veins in 30 minutes

M. Aschauer, A. Obernosterer, R.H. Portugaller, R. Stollberger, J. Raith, F. Ebner; Graz/AU

Background: Treatment of patients with acute pulmonary embolism depends also on the extent of venous thrombosis. An emergency diagnosis is made routinely by spiral-CT and bipedal i.v. conventional venography (CV), especially when Doppler-ultrasound of pelvic veins and IVC is uncertain. Performing both investigations takes more than 1 hour, including internal transportation.

Purpose: To assess the feasibility and image quality for diagnosis of PAE and venous thrombosis in a one-stop-shop after PAE has been diagnosed, with CT and/or V/Q scan, within the last 48 hours.

Material and Methods: 21 patients underwent a one-stop-shop MR pulmonary angiography and a repeated 3-station MR-angiography (MRA/MRV) using a moving-table technique in early arterial and equilibrium phase of the abdomen, pelvis and lower extremities.

Results: The examination was feasible in 19/21 patients. The thrombi we found confirmed diagnosis in 13/14 patients. One patient had fibrinolysis and the thrombi resolved completely within 48 hours. One patient showed no thrombi, and it was retrospectively confirmed that the patient was misdiagnosed on the initial CT. With MRV we found additional large thrombi in the internal iliac vein in 2 patients, and gastrocnemius vein thrombi in 3. The extent of pelvic thrombi was much more reliably assessed with MRV than CV. In two patients additional thrombi were found in the IVC.

Conclusion: The high sensitivity and specificity of MRA for detection of acute pulmonary emboli can be confirmed. MRV is feasible in the same session in the majority of patients. MRV detects more thrombi than conventional phlebography and Doppler-ultrasound, especially in the IVC and pelvic veins, which are clinically relevant sites.

B-117 11:24

Direct thrombus MR imaging: Preliminary experience at 3 Tesla magnetic field strength

D. Gibson, D.P. O'Regan, S. Allen, D. Larkman, J. Zeka, J. Allsop, S. Schmitz; London/UK

Purpose: Direct visualization of blood degeneration products with heavily T1-weighted techniques has shown promise for imaging deep venous thromboses at 1.5 Tesla magnetic field strength. MR imaging scanning at 3 Tesla may improve this approach owing to its potential for higher spatial resolution. However, T2* effects of organizing thrombus also increase with field strength. We therefore tested the feasibility of direct thrombus MR imaging at 3 Tesla.

Methods and Materials: We included 4 patients with deep venous thrombosis, 2 patients with thrombophlebitis and 9 healthy volunteers. The presence or absence of thrombus was assessed by compression ultrasound in all cases. MR imaging was performed at 3 Tesla (Philips Intera) using a fat-suppressed magnetization prepared rapid gradient echo sequence. Regions-of-interest were placed in muscle and thrombosed vein segments of patients, or in muscle and patent veins of volunteers to measure signal intensity (SI). In a qualitative analysis, a blinded reader assessed the presence of thrombus.

Results: The sequence allowed excellent suppression of flow, blood and fat, and thrombi were clearly visible as high signal intensity structures. The signal intensity ratio in thrombosed vessels, defined as SI(thrombus) / SI(muscle), was significantly higher than in patent vessels, defined as SI(blood) / SI(muscle): 2.6+0.6 vs. 0.6+0.1, p = 0.0005. The blinded reader correctly diagnosed all positive and negative cases, but overlooked a superficial thrombophlebitis in a small vein.

Conclusion: This preliminary study shows the feasibility of direct thrombus MR imaging at 3 Tesla. The contrast properties of thrombus at 3 Tesla are similar to those known at lower field strength.

B-118 11:33

The usefulness of 3-D sonography in the analysis of collateral circulation in the course of deep vein thrombosis

M. Myjor, P. Grzelak, L. Stefanczyk; Lodz/PL

Purpose: The inability to produce visual documentation has been the major obstacle to ultrasonography of the venous system becoming the gold standard diagnostic method. Introduction of three dimensional (3-D) sonography could change this situation. Our analysis of usefulness of 3-D sonography in the visualisation of collateral circulation in the course of deep vein thrombosis (DVT) is presented.

Methods and Materials: Examinations were performed using GE Logiq 500 Pro in Color Doppler mode. Convex 3-6 MHz probes for the lower abdominal region and 4-9 MHz linear probes for lower extremities were used. The consecutive images in transverse planes were collected and reconstructed into longer sequences using the popular graphic program Corel. A total of 104 3-D examinations were performed in 61 patients in both iliac and femoro-popliteal segments and in different phases of the disease - acute, chronic and the post-thrombotic syndrome.

Results: DVT creates favourable conditions for 3-D presentation - increased velocities and reduced pulsation of the venous flow. In the lower abdominal region the presentation is hindered by the bowel gas and motion artefacts (peristaltic movements and pulsation of great vessels), whereas in the femoro-popliteal segment lack of artefacts and superficial course of vessels result in images similar to those acquired by venography.

Conclusion: The 3-D reconstruction of venous collateral flow enables better interpretation of images by the examiner in some cases. However, the main advantage of this method is the creation of image documentation, which is more acceptable to clinicians than a written report and selected images.

B-119 11:42

Arterial remodeling: In vivo analysis of femoral arterial atherosclerosis using computed tomographic angiography (CTA)

A. Napoli¹, A. Pezeshkmehr², D. Fleischmann², G.D. Rubin²; ¹Rome/IT, ²Stanford, CA/US

Purpose: To assess the ability of CTA to characterize arterial wall remodeling in

Scientific Sessions

the presence of atherosclerosis and to assess the relationship of positive and negative remodeling to degree of luminal narrowing and patient age.

Material and Methods: 48 superficial femoral arteries from 25 patients referred for assessment of lower extremity arterial occlusive disease were analyzed by CTA (16-row CT, 1.25-mm thickness). The cross-sectional area of the arterial lumina and outer walls were measured every 10 mm sections reformatted orthogonal to the median centerline. In each arterial segment, the cross-section that contained the least amount of plaque was the reference site. Measurements were expressed relative to the reference values. Patient population was sub-divided according to age; remodeling indices were examined in locations that presented a > 50% stenosis.

Results: A total of 1403 cross-sections were analyzed (29 sections per artery). In the most stenosed parts arterial remodeling was present in 153 observations and it was positive in 60(40%), while it was negative in 93(60%). Reference vessel area was not significantly different between the age-related groups. Patients > 70 y.o. (n = 15) had a greater proportion of stenotic segments ($p = 0.003$) when compared to patients < 70 y.o. For regions with > 50% luminal stenosis, positive to negative remodeling was observed 4:1 in < 70 y.o. and 1:2 in > 70 y.o. patients - an 8-fold difference between the two groups ($p < 0.01$). These ratios were not significant in regions of < 50% stenosis.

Conclusions: CTA allows simultaneous measurement of luminal narrowing and arterial wall remodeling. Significant age-related differences in arterial wall remodeling behavior are observed in regions of > 50% luminal stenoses.

B-120 11:51

Multicenter weighted magnetic resonance imaging of atherosclerotic plaques at 3.0 and 1.5 Tesla: Comparison ex vivo and with histopathologic correlation

A. Koops, H. Ittrich, S. Petri, A. Priest, A. Stork, C. Weber, G. Adam;
Hamburg/DE

Purpose: The purpose of this study was to analyze the image quality and histological correlation of atherosclerotic plaque MR imaging at 3.0 and 1.5 Tesla.

Method and Materials: In analogy to a screening protocol, MR imaging of the abdominal aorta and the femoral artery was performed on seven cadavers using T1-weighted, T2-weighted, and PD-weighted sequences at 3.0 Tesla and at 1.5 Tesla. Cross-sectional images at the branching of the inferior mesenteric artery and the profunda femoris artery were rated with respect to their image quality in a blinded reading by three radiologists. In addition, the images and the exact match of histological cross sections were classified according to the criteria of the American Heart Association and analyzed for differences.

Results: Multicenter weighted MR imaging at 3.0 Tesla offers a superior depiction of the arterial wall composition in all performed sequences, as compared to imaging at 1.5 Tesla. While the highest differences were observed in the T2-weighted ($p = 0.00058$) and T1-weighted ($p = 0.00067$) techniques, the differences in the PD-weighted sequence ($p = 0.0344$) were still significant. In the comparison of the atherosclerotic plaque types, it was found that MR imaging overrates the calcified plaques (type Vb) in up to 21% of the cases.

Conclusions: In future atherosclerotic plaque screening of patients, magnetic resonance imaging at 3.0 Tesla field strength should be preferred for its superior depiction of arterial wall components.

European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB) guidelines for contrast-enhanced US of the liver: Validation in characterization of incidental liver lesions

C. DellaPina, R. Lencioni, L. Crocetti, D. Cioni, J. Lera, S. Montagnani, C. Bartolozzi; Pisa/IT

Purpose: To validate European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB) guidelines for contrast-enhanced ultrasound (CEUS) of the liver in characterizing focal lesions of incidental detection.

Methods and Materials: A series 153 solid focal lesions 1.0-11.5 cm in diameter (mean $3.3 \text{ cm} \pm 2.2$) incidentally detected, but not characterized, by baseline US in 91 patients with neither history of malignancy nor chronic liver disease, were examined with CEUS by using real-time low MI (0.06-0.09) scanning (Contrast Tuned Imaging; Esaote Biomedica, Italy) after bolus injection of 2.4 ml of SonoVue (Bracco, Italy). Videotapes of CEUS studies were reviewed by three blinded readers who were asked to reach a consensus. The image interpretation was based on the enhancement patterns reported in EFSUMB guidelines for CEUS of the liver. Final diagnosis was established in 85/91 patients (132/153 lesions) by imaging findings (MR, CT, or both) in combination with clinical-laboratory data ($n = 75$) or US-guided biopsy ($n = 10$). Final diagnoses included hemangioma ($n = 71$), focal nodular hyperplasia ($n = 48$), metastasis from unknown primary malignancy ($n = 5$), hepatocellular adenoma ($n = 2$) and primary malignant tumors ($n = 6$).

Results: The application of EFSUMB guidelines allowed correct differentiation of benign versus malignant lesions in 128/132 cases (97%). No malignant tumor had a false benign diagnosis. Correct lesion characterization was achieved in 102/132 (77%) lesions, including 60/71 hemangiomas, 39/48 focal nodular hyperplasias and 3/5 metastases.

Conclusion: Characterization of incidental liver lesions can be obtained at a high level of probability by CEUS in combination with clinical and laboratory data if typical enhancement patterns are present.

B-122 14:09

Small nodules in liver cirrhosis: Correlation between contrast-enhanced US and pathologic examination of explanted liver

D. Cioni, R. Lencioni, A. Conti, J. Lera, D. Campani, F. Filipponi, S. Montagnani, C. DellaPina, C. Bartolozzi; Pisa/IT

Purpose: The purpose of this study is to evaluate the ability of contrast-enhanced US (CEUS) to characterize small nodules in cirrhotic livers detected during US surveillance.

Methods and Materials: A series of 34 small (3 cm or less) nodular lesions detected by baseline US in 51 cirrhotic patients were examined with CEUS as part of an on-going prospective clinical trial. CEUS examinations were performed by using continuous, low MI (0.06-0.09), real-time scanning (Contrast Tuned Imaging; Esaote Biomedica, Italy) after bolus injection of 2.4 ml of a second-generation contrast agent (Sonovue; Bracco; Italy). All patients underwent liver transplantation within 6 months of the US examination. Findings at CEUS were correlated lesion-by-lesion with pathology findings.

Results: At pathology examination, the 34 lesions were classified as HCC ($n = 24$), high-grade dysplastic nodule (HG-DN, $n = 4$), and low-grade dysplastic nodule (LG-DN, $n = 6$). CEUS studies showed arterial contrast uptake (within 30 sec after the start of contrast injection) in 19/24 HCCs and in 2/4 HG-DNs. No arterial enhancement was seen at CEUS in 5/24 HCCs, 2/4 HG-DNs and 6/6 LG-DNs. In the delayed phase (120-240 sec after the start of contrast injection) 16/24 HCCs, 4/4 HG-DNs and 6/6 LG-DNs were isoechoic (undetectable) with respect to liver parenchyma. Delayed lesion hypoechogenicity was observed in 8/24 HCCs and none of the DN.

Conclusion: CEUS findings overlap in small hepatocellular nodules in liver cirrhosis. Nevertheless, detection of arterial hypervascularity at CEUS appears to be a reliable indicator of either a malignant or a premalignant lesion.

B-123 14:18

Very small focal liver lesions appearing uncharacteristic at conventional US: Does it make sense to investigate with contrast-enhanced US in attempt to further characterize the lesions? Comparison with multi-phase spiral CT

T. Rettenbacher¹, A. Hollerweger², J. Hoflehner¹, D. zur Nedden¹;
¹Innsbruck/AT, ²Salzburg/AT

Purpose: To evaluate if it is reasonable to perform contrast-enhanced-US in cases of very small liver lesions appearing uncharacteristic at conventional-US.

Methods and Materials: In a prospective study, 166 liver lesions < 25 mm with uncharacteristic appearance at conventional US as first imaging modality, underwent additional contrast enhanced US and contrast enhanced CT to further characterize the lesions. The lesions were divided into 4 groups as follows: group 1: < 10 mm, group 2: 10-15 mm, group 3: 15-20 mm, group 4: 20-25 mm. Contrast enhanced US was performed continuously for 5 minutes after a 2.4-4.8 ml SonoVue (Bracco) bolus. CT exams were carried out in 4 phases after a 120-150 ml Ultravist 370 (Schering) bolus. The results of the exams were categorized as being either confidently diagnostic, probably diagnostic or uncharacteristic.

Results: In group 1 contrast US was confidently diagnostic in 50%(22/44),

Scientific Sessions

probably diagnostic in 14%(6/44) and uncharacteristic in 36%(16/44) whereas contrast CT was confidently diagnostic in 30%(13/44), probably diagnostic in 25%(11/44) and uncharacteristic in 45%(20/44). In group 2 the corresponding numbers for contrast US were 60%(30/50), 22%(11/50) and 18%(9/50) whereas the numbers for CT were 46%(23/50), 42%(21/50) and 12%(6/50). In group 3 we calculated 74%(32/43), 14%(6/43) and 12%(5/43) for contrast US and 63%(27/43), 28%(12/43) and 9%(4/43) for contrast CT. In group 4 we calculated 79%(23/29), 14%(4/29) and 7%(2/29) for contrast US and 62%(18/29), 28%(8/29) and 10%(3/29) for contrast CT.

Conclusions: In very small liver lesions the probability that contrast-enhanced-US is diagnostic is decreased markedly, however, it is superior to contrast-enhanced-CT. Nevertheless, in lesions < 10 mm contrast-enhanced-US can be recommended since it enables a reliable diagnosis in 50%.

B-124 14:27

Characterization of focal liver lesions with contrast-enhanced ultrasound:

Clinical utility in cancer patients

L. Romanini, M. Cristinelli, P. Cabassa, V. Portugalli, F. Venturelli, L. Grazioli; Brescia/IT

Purpose: To evaluate the impact on the clinical practice of the use of contrast-enhanced ultrasound with SonoVue in the characterization of focal liver lesions in cancer patients.

Methods and Materials: 71 cancer patients with at least one focal lesion, but less than three, were studied before, with base-line (B-Mode and color-doppler) ultrasound, and after with contrast-enhanced ultrasound. The resulted 73 lesions were confirmed by MR study and biopsy for metastasis and indeterminate lesions. **Results:** 35/73 lesions (47.9%) were benign and 38/73 (52.1%) were malignant. With baseline ultrasound 37/73 lesions (50.7%) were correctly characterized: 11/35 (31.4%) benign and 26/38 (68.4%) malignant. After dynamic study the characterization was correct in 69/73 lesions (94.5%): 31/35 (88.5%) benign and 38/38 (100%) malignant. The lesions wrong or indeterminate were: 1 hemangioma, 2 FNHs and 1 adenoma with atypical enhancement behaviour. All malignant lesions were correctly characterized. Diagnostic gain for the characterization after SonoVue was 57.1% for benign lesions and 31.5% for malignant.

Conclusions: In the oncological patients the differential diagnosis between benign and malignant lesions is crucial. In our group the benign lesions were about 50% and they were correctly characterized in the 88.5% of the cases after the SonoVue study, allowing the final diagnosis at the same time as the ultrasound discovery.

B-125 14:36

Contrast enhanced harmonic sonography (CEUS) of focal liver lesions:

Discordance with contrast enhanced CT or MR

V. Portugalli, E. Archiati, P. Cabassa, L. Grazioli, L. Romanini, M. Cristinelli; Brescia/IT

Purpose: To evaluate the type and causes of discordant enhancement patterns between CEUS and CT/MR during vascular phases.

Methods and Materials: Over a three year period, 280 patient had CEUS, spiral CT or gadolinium-enhanced MR (or both) for characterization of focal liver lesions. CEUS was performed with second generation contrast media (Sonovue, Bracco) at the standard dose of 2.4 ml with continuous real time scanning at low mechanical index. Arterial and portal phase enhancement patterns on each imaging modality were assessed by comparing the relative echogenicity/attenuation/intensity of a lesion relative to adjacent liver. Data recorded prospectively in a database was analyzed retrospectively. Delayed phase were not compared due to the different timing.

Results: 79 patients showed discordance with triphasic spiral CT or MR imaging. Lesions include 44 HCCs, 9 metastases, 6 colangiocarcinomas, 5 FNHs, 5 hemangiomas and 10 others. Discordant enhancement was founded especially during portal (64/79 patients; 79.5%) phase (11/79 had both different). 40/44 HCCs showed discordant pattern in portal phase, resulting isoechoic at CEUS and hypodense/intense on CT/MR. Differences during arterial phase were observed most frequently in metastases and cholangiocarcinomas. An explanation of most of these findings is that microbubbles are confined in the intravascular space whereas CT or MR agents can distribute in the extracellular fluid space. A discrepancy in timing may explain other cases.

Conclusions: Recognition of the potential for discordance of enhancement patterns with explanation of their cause helps in the characterization of focal liver lesions using CEUS.

B-126 14:45

Fundamental nonlinear imaging versus harmonic imaging with contrast medium sonovue in the evaluation of the hepatic focal lesions: Preliminary results

V. Migaleddu, A. Manca, D. Turilli, P. Luciano, N. Canu, G. Campisi, G. Virgilio; Sassari/IT

Purpose: To compare the results obtained with contrast medium (SonoVue) and ultrasonography using two different low mechanical index softwares (CCI and CPS).

Methods and Materials: Fifty one patients (28 males; mean age 57.2; age range 32-79 years) were included. 78 lesions examined: 33 HCC, 2 FNH, 1 adenoma, 20 haemangioma, 15 metastasis and 7 regenerative nodules. Fundamental nonlinear imaging (CPS) was compared with harmonic imaging (CCI); both softwares used low mechanical index. Exams were performed with Sequoia 512 (Acuson-Siemens) after venous bolus injection of SonoVue (Bracco-I) (2.5 ml/8 ml/ml). Penetration, detail and contrast resolution were evaluated independently on stored clips by two blinded observers using Wilcoxon sign sum rank test.

Results: CPS with nonlinear fundamental contrast imaging, in some cases associated with tissue fundamental response, permit to obtain more information than CCI harmonic contrast imaging considering penetration, detail and contrast resolution ($P < 0.0001$ at Wilcoxon sign rank test). In all the cases CPS render intensity response up to 30 dB higher than CCI. The differences between the two observers were negligible and non significant from the statistical point of view ($P > 0.05$).

Conclusion: Contrast nonlinear fundamental imaging gives us more information than contrast harmonic imaging. Coupled tissue and contrast responses present in this new modality of imaging, allow to obtain a higher diagnostic confidence.

B-127 14:54

Parametric perfusion imaging with contrast-enhanced ultrasound in thyroid gland focal lesions differential diagnosis

R. Lanocita¹, F. Calliada², F. Berton², G. Gola², A. Parisio², P. Arcuti²; ¹Milan/IT, ²Pavia/IT

Purpose: Sonography (US) and fine needle aspiration biopsy (FNAB) are common diagnostic procedures in thyroid gland examination which, if used in conjunction, are economic and accurate in differential diagnosis of solid thyroid masses. The presence of multiple nodules should reduce the tolerability of FNAB in multinodular goiter. Perfusion maps can be calculated from ultrasound harmonic imaging data after ultrasound contrast agent injection to analyze thyroid tissue perfusion to improve US differential diagnosis.

Method and Materials: Thirty consecutive patients, (23 women, 7 men) with solitary (13 patients) or multiple (17 patients) nodules were investigated with HDI 5000 scanner before and after 4.8 mg SonoVue® (Bracco, Italy) i.v. injection. Perfusion maps were calculated from the ultrasound data with a research software developed by Amid and R&D Bracco. Microvascular blood volume (A), microbubble velocity (β) and blood flow ($A\beta$) were calculated from signal intensity versus time curves. FNAB was performed on each single nodule.

Results: FNAB evidenced 38 hyperplastic nodules in 23 patients, 5 follicular adenoma in 4 patients and 3 papillary carcinomas in 3 patients. Mean value of A, blood volume values was 9 (± 3) in patients with papillary carcinoma, 11 (± 3) in follicular adenomas and 18 (± 4) in hyperplastic nodules. The mean value of the A differed significantly with hyperplastic nodular goiters and both carcinomas and adenomas patients ($p < 0.01$).

Conclusions: Amid/Bracco parametric software seems to provide an easy tool to evaluate quantitative microvascular blood volume and velocity data after SonoVue® injection with possible clinical value in thyroid nodules differential diagnosis.

B-128 15:03

Doppler ultrasonography with contrast agent injection and perfusion software to assess the efficiency of radio-frequency in recurrent breast cancer

M. Lamuraglia, J.R. Garbay, M.C. Mathieu, P. Opolon, S. Jaziri, A. Roche, J. Leclère, N. Lassau; Villejuif/FR

Purpose: To determine the efficiency of radiofrequency (RF Generator - Boston Scientific) (RF) treatment of the local recurrent breast cancer using Doppler-ultrasonography with Sonovue (Bracco) and perfusion software (Toshiba) (DUSSP).

Methods and Materials: Ten patients with locally recurrent breast cancer will be included in this prospective phase II study. To date, 8 patients have been included.

Scientific Sessions

DUSSP was performed before and after treatment by RF for each patient. The RF procedure was followed by a total mastectomy. Treatment efficacy was assessed according to the destruction of the tumor neovascularisation analysed with DUSSP. The results were compared to histopathological findings.

Results: Before treatment, DUSSP depicted vascularization in the 8 tumors. Contrast agent injection and the use of perfusion software enhanced the conspicuity of neovascularization in all cases. Immediately after RF, DUSSP allowed us to confirm that tumor vascularization had been totally eradicated. Results obtained in 10 patients will be presented.

Conclusion: DUSSP is a promising technique for the immediate evaluation of response to RF treatment of local recurrent breast cancer, in the operating room.

B-129 15:12

Value of contrast enhanced gray scale sonography in rheumatoid arthritis patients: A multicenter study

A. Klauser¹, J. Demharter², D. Sureda³, A. Barile⁴, C. Faletti⁵, C. Masciocchi⁴, M. Schirmer¹, K. Bohndorf²; ¹Innsbruck/AT, ²Augsburg/DE, ³Barcelona/ES, ⁴L'Aquila/IT, ⁵Turin/IT

Purpose: To evaluate, in a multicenter study, the feasibility of contrast enhanced gray scale ultrasound (US), for characterization of joint distension in patients with rheumatoid arthritis (RA) by 5 European centers.

Methods and Materials: We assessed 113 patients (44 men and 69 women; mean age 51 ± 14 years) with established RA in different stages, in different joints, by the continuous mode and low pressure technique of CnTI™ (Contrast tuned Imaging using a EsaTune or Technos MPX US unit, Esaote, Genoa, Italy) using 4.8 mL intravenous administration of SonoVue® (Bracco, Milan, Italy), flushed with 10 mL saline. Unenhanced US, power Doppler US and CnTI™ was evaluated for differentiation of the presence of active synovitis or effusion in the joint distension. Further measurement of maximal thickness of active synovitis and effusion was performed before and after contrast administration.

Results: Joint thickening could not be differentiated in 45/103 (40%) joints by the unenhanced US. In 42/45 joints after contrast administration a differentiation between effusion and active synovitis could be obtained (96%). Maximal thickness measurement of synovial thickness and effusion improved after contrast administration ($p < 0.001$).

Conclusion: Sonovue-enhanced CnTI™ in comparison to unenhanced US showed a better confidence in differentiation of effusion from synovitis and in measurement of thickness of active synovitis in patient with RA. Therefore, this technique has shown to be of value for assessment of disease activity in patient with RA and may be useful in monitoring therapeutic response.

B-130 15:21

Contrast-enhanced US in the assessment of sacroiliac joint vascularity

A. Klauser, M. Schirmer, D. zur Nedden, F. Frauscher; Innsbruck/AT

Purpose: To assess quantitative measurement of vascularity in the sacroiliac (SI) joints of patients with active sacroiliitis and of healthy volunteers using dynamic contrast-enhanced ultrasound (US).

Methods and Materials: Twenty-two patients with active sacroiliitis (15 women, 7 men) based on the clinical criteria described by Calin et al. (JAMA 1977; 237:2613-4), and 10 healthy volunteers (7 women, 3 men) were studied. All patients and volunteers were examined with gray-scale fundamental US and gray-scale harmonic US, before and after injection of intravenous US contrast agent (SonoVue, Bracco, Italy). Both SI joints were imaged in a single transverse scan at three different levels using a 2.5 MHz curved array transducer (Esaote Ultrasound Systems, Italy). Quantitative estimation of the vascularity of the SI joints was performed with time-intensity curves and calculation of the area under the curves. We correlated the contrast US findings with age and disease duration.

Results: Mean value of the area underlying the time-intensity curves was 242 (± 41) in patients with active sacroiliitis and 34 (± 35) in healthy volunteers. The mean value of the areas differed significantly between the patients with active sacroiliitis and the healthy control group ($p < 0.01$). No correlation was found with age and disease duration ($p = 0.2$).

Conclusion: Dynamic contrast-enhanced US is sensitive to the presence of increased vascularity associated with active sacroiliitis and might therefore be useful in the diagnostic evaluation of patients with inflammatory lower back pain.

US-guided percutaneous treatment of calcific tendinitis of the rotator cuff.

Results in 651 patients over 8 years

F. Pugliese¹, N.G. Gandoifo², L. Dogliotti², C. Martinoli¹, G. Serafini²; ¹Genoa/IT, ²Pietra Ligure/IT

Purpose: To evaluate the treatment of calcified tendinitis of the shoulder by using an ultrasonography (US)-guided large-needle aspiration-irrigation technique (NAIT).

Materials and Methods: 651 subjects (421 women and 231 men; age range 31-72 years) with acute or chronic shoulder pain were treated percutaneously by US-guided large-needle aspiration-irrigation technique from May 1996 to February 2004. Two 16 G-diameter needles were positioned within the tendon at the level of the calcification. Irrigation and aspiration were alternatively performed through the two needles until calcific deposits were completely cleared. After 1 month, subjective shoulder pain and functional Constant's score were evaluated and compared to those obtained before the treatment. According to these criteria, results were thus classified as excellent, satisfactory and unsatisfactory. At 3 months, a shoulder radiograph was also obtained in all patients.

Results: The mean Constant's score before treatment was 57.2. The mean value after treatment was 91.5, therefore an average increase of 34.3 in Constant's score was observed. 75% of the patients reported the treatment subjectively as beneficial (satisfactory) or extremely beneficial (excellent). At 3 months, 70% of the calcifications were not visible anymore, 23.4% had decreased at least 50% in diameter and 6.6% had decreased less than 50% in diameter. These results indicate a significant clinical response.

Conclusion: This modified US-guided technique for calcified tendinitis of the shoulder is less invasive than previously described percutaneous therapies and appears to be an effective treatment option.

B-132 14:09

MR-arthrography of the scapholunate ligament: Correlation with arthroscopy

H. Guerini, A. Feydy, J.-L. Drapé, A. Chevrot; Paris/FR

Purpose: To describe the normal and pathologic appearances, and the variants of the scapholunate ligament (SLL) at MR-arthrography. To evaluate the effectiveness of the MR-arthrography with arthroscopy as gold standard.

Materials and Methods: Multi-centre retrospective study of 70 arthrograms and MR-arthrograms in 70 patients. Correlation with arthroscopy was performed in 29 patients. The sequences carried out were 3D DESS, 3D FSPGR and FIESTA. Images were assessed for the presence of linear and diffuse signal abnormalities within the SLL.

Results: The sensitivity of combined standard arthrography and MR-arthrography for the lesions of the SLL was 69% and the specificity was 94%. The NPV for SLL perforation was 90%, and the PPV was 70%. The accuracy was 83%. The combination of a diffuse and linear signal abnormality within the SLL improved the sensitivity of MR-arthrography (92%), while preserving a good specificity (83%). The T2-weighted sequences included in our MR-arthrography protocol allowed detection of poorly-opacified cysts within the SLL. MR-arthrography pitfalls are related to the variable signal of the SLL depending on the MR sequence used. The variable bony or cartilaginous insertion of the SLL can also be a source of misleading images.

Conclusion: Combined standard arthrography and MR-arthrography is an accurate method for the diagnosis of SLL perforations. The diagnostic criteria of perforations should include linear and diffuse abnormalities.

Scientific Sessions

Three-compartment wrist MR arthrography: Impact on diagnostic thinking and treatment plan

D.V. Guntern, N. Favarger, P. Schnyder, N.H. Theumann; Lausanne/CH

Purpose: To determine if three-compartment wrist MR arthrography has an impact on the orthopedic surgeons diagnosis and treatment plan.

Materials and Methods: Three-compartment MR arthrography was performed in 30 wrists of 30 patients. All patients were addressed to us form a clinic for hand surgery. First three-compartment injection of diluted gadolinium was performed under fluoroscopic control. Then a sagittal and an axial T1-weighted sequence, a coronal T2-weighted fat suppressed sequence and a coronal FISP sequence were acquired with a dedicated wrist coil and a 1.5 T scanner. Before and after MR imaging the orthopedic surgeons had to complete a questionnaire, that evaluated their diagnoses and treatment plans. The pre- and post MR questionnaires were compared. Changes in diagnoses and treatment plan were noted.

Results: MR arthrography changed orthopedic surgeons diagnostic thinking in 21 of 30 cases (70%). Without MR arthrography the orthopedic surgeons would have done an arthroscopy in all patient. Knowing the results of MR arthrography arthroscopy was planned in only 12 patients corresponding to a reduction of 66%.

Conclusion: Wrist MR arthrography has an important impact on orthopedic surgeons diagnostic thinking and treatment plan. The number of arthroscopies was reduced significantly.

B-134 14:27

Evaluation of rotator interval pathology in athletes with MR arthrography

E. Genovese, A. Leonardi, L. Callegari, M. Angeretti, S. Indrinella, C. Fugazzola; Varese/IT

Purpose: Rotator interval is an important anatomic and functional region commonly subject to overuse injuries in athletes participating in repetitive overhead sports. The aim of this study was to assess the role of MR Arthrography in detecting rotator interval lesions in chronic overuse-type disorders.

Materials and Methods: 23 athletes (swimmers, tennis players, pitchers) with rotator interval syndrome (chronic shoulder pain and dysfunction) underwent MR Arthrography. All patients were investigated with SET1, 3DT1-FATSAT, FSE FATSAT PD/T2 sequences before and after intrarticular injection of 20 cc of diluted contrast medium.

Results: MR Arthrography revealed rotator interval lesions in 11 athletes (in 3 cases laxity of rotator interval, in 3 cases contractures of the rotator interval, in 2 cases rotator interval synovitis, in 2 cases coraco-humeral ligament lesions and in 1 case rotator interval calcification). In 3/11 cases MR Arthrography identified rotator interval pathology with a SLAP lesion and in 2/11 cases rotator interval lesion associated with anterior instability. All results were compared with arthroscopic and surgical findings.

Conclusion: MR Arthrography enables an accurate evaluation of rotator interval lesions in chronic overuse-type disorders in athletes.

B-135 14:36

Shoulder MR-arthrography in the follow-up after surgery repair: Inter-individual comparison of anterior palpitory and posterior US-guided access

M. Barini, A. Stecco, F. Bruculeri, P. Neri, P. Fornara, A. Carriero; Novara/IT

Purpose: To compare efficacy, procedure time and patient discomfort between anterior palpitory and posterior US guided approach for intra-articular injection in the shoulder after rotator cuff surgical repair.

Methods and Materials: Gleno-humeral injection of contrast solution was performed in 35 consecutive patients, all treated for rotator cuff surgical repair. The first 15 patients underwent palpitory-guided anterior access; while the other 20 had a posterior US-guided intra-articular injection. Efficacy, procedure time and patient discomfort were evaluated in all patients, and a statistical test (t-student) was applied to evaluate the significative differences.

Results: Anterior palpitory-guided glenohumeral approach resulted in 9/15 correct intra-articular injections and 6/15 extra-articular injection, with severe discomfort in 8/15, moderate discomfort in 5/15 and mild to nothing in 2/15. Procedure mean time was 1.5 minutes. Posterior US-guided injection provided an intra-articular access in 19/20 of patients, with severe discomfort in 1/20, moderate in 6/20 and mild to nothing in 13/20. The mean time of the procedure was 3.2 minutes. Statistical analysis of effective intra-articular injection rate, and procedural time between the two modalities resulted in a significative difference ($P < 0.005$) between the two modalities, with better efficacy in intra-articular injection for the US-guided approach and a longer procedure time for the US-guided protocol.

Conclusion: In the post-operative shoulder, due to the post-surgical anterior scar, the posterior US-guided access to perform the intra-articular injection results are more accurate, though more time consuming, with less pain or discomfort with respect to the anterior palpitory access.

B-136 14:45

Labral lesions of the hip: Assessment with MR arthrography in symptomatic patients

E. Wiener, K. Wörtler, H. Rechl, L. Gerdesmeyer, E. Rummey; Munich/DE

Purpose: To evaluate the accuracy of MR arthrography in the detection and classification of acetabular labral lesions in symptomatic hips.

Material and Methods: MR arthrography of the hip was performed in 32 symptomatic patients who underwent subsequent surgical exploration. Following intraarticular injection of 10-15 ml of gadopentetate dimeglumine solution (2.5 mmol/l) MR imaging was performed on a 1.0 T system using triplanar T1 weighted SE sequences and WE 3D-DESS sequence. Images were evaluated by two experienced radiologists (agreement by consensus) with regard to degeneration (grade I), tear (grade II) and detachment (grade III) of the anterior, lateral and posterior labrum. Articular cartilage surface irregularities (grade I) or full thickness defects (grade II) were also assessed. The results of the radiological evaluation were compared with intraoperative findings (gold standard).

Results: 49/56 surgically proven labral lesions were depicted by MR arthrography, and 33/40 intraoperatively normal labral parts were assessed correctly. 62% of grade I, 79% of grade II and 84% of grade III lesions were classified concordant with surgical findings. For detection of labral lesions MR arthrography showed a sensitivity of 87.5%, a specificity of 82.5% and an accuracy of 85.4%. Articular cartilage lesions were diagnosed with a sensitivity of 57% and a specificity of 67%.

Conclusions: MR arthrography enables accurate detection and classification of acetabular labral lesions but appears to be limited in the evaluation of articular cartilage of the hip.

B-137 14:54

New arthro-MR imaging technical approach in the evaluation of intra-articular structures of the postero-lateral corner of the knee

N. Limbucci, A. Barile, L. Zugaro, G. Bonanni, V. Calvisi, C. Masciocchi; L'Aquila/IT

Purpose: To assess the role of a new oblique sagittal scan plane to evaluate by arthro-MR imaging the anatomy and the pathological findings related to post-traumatic instability of the ligamentous structures of the posterolateral corner (PLC) of the knee.

Methods and Materials: 28 patients entered the study. 16 patients, already submitted to ACL reconstruction and still complaining of posterolateral instability, and 12 patients with acute post-traumatic instability (9 ACL and 3 PCL lesions) underwent arthro-MR imaging to evaluate the capsulo-ligamentous structures of the PLC. All patients underwent arthroscopy. We evaluated 5 more patients with no traumatic history, submitted to arthro-MR imaging for cartilage assessment, to study the anatomical setting; after that they underwent arthroscopy. Arthro-MR imaging was performed with a 1.5 T unit (Signa Horizon, GE) employing SE-T1W and SE-T1W fat-sat sequences on conventional scan planes. In all cases we acquired the same sequences on a new 45° oblique sagittal plane. We compared arthro-MR imaging and arthroscopic findings.

Results: In all patients complaining of posterolateral instability of the knee, arthro-MR imaging discovered a lesion of the inferior posteromedial menisco-popliteal ligament. In one case the popliteus tendon was also involved. In all patients studied for anatomical setting, it was possible to identify the ligamentous components of the PLC (lateral and medial menisco-popliteal ligaments, popliteus tendon). Arthroscopy confirmed arthro-MR imaging findings in all cases.

Conclusion: We consider arthro-MR imaging as the method of choice in the evaluation of the PLC of the knee. We propose a new 45° oblique plane that can add further information respect to standard arthro-MR imaging.

B-138 15:03

Histological changes at the bone cement interface after kyphoplasty - comparison of PMMA and CaP with histomorphometry and high resolution CT

M. Libicher, M. Vetter, C. Kasperk, P.J. Meeder, G. Nöldge; Heidelberg/DE

Purpose: To quantify formation of new bone at the bone cement interface of PMMA and CaP in a dog model. To quantify signs of resorption of biocompatible CaP cement with high resolution CT and dedicated software. To compare changes of CaP vs. PMMA during follow-up over a period of 12 months.

Material and Methods: Three osteopenic foxhounds received cement implants

Scientific Sessions

into 3 thoracic and 2 lumbar vertebrae under intubation anaesthesia. The dogs were sacrificed 5, 10 and 15 months. The number of osteonal structures was counted at the bone cement interface. In a clinical trial, 20 vertebrae (10 CaP, 10 PMMA) were examined with HR-CT-volumetry using an identical imaging protocol. CT scans were obtained after kyphoplasty and after 12 months (collimation 0.5 mm, slice thickness 1 mm, in plane resolution 0.5 mm). To quantify the volume in sub voxel resolution we analyzed each cement fragment with a density-weighted algorithm.

Results: Histomorphometric analysis revealed in CaP a significant increase of osteons at the bone cement interface within 15 months indicating formation of new bone. In PMMA no signs of cement resorption or bone formation were discernible. CT measurements showed a significant decrease of border density between 1.5-6% in CaP compared to PMMA ($p < 0.05$). CT data are confirmed by histomorphometric analysis.

Conclusion: There are signs of resorption in biocompatible CaP cement that can be quantified by histomorphometric measurement. These changes at the bone cement interface can be detected by high resolution CT and dedicated software.

B-139 15:12

Temperature changes in surrounding soft tissue during CT-guided radio frequency ablation (RFA) of osteoid osteoma in an ex vivo animal model

R.-G. Bitsch, M.D. Daniels, R. Rupp, L. Bernd, K. Ludwig; Heidelberg/DE

Purpose: Examination of the temperatures in soft tissue surrounding bone during radio frequency ablation (RFA) of osteoid osteomas in an ex vivo animal model.

Materials and Methods: Intra-cortical cavities were created in fresh bovine long bone specimens as models for osteoid osteomas. The thickness of the cortical bone lamella separating nidus from periosteum was set at 1/3/5 mm. Three temperature probes were inserted into soft tissue surrounding bone at 0/5/10 mm from the periosteum. Before RFA, the thickness of the cortical bone lamella was documented by CT. Specimens were heated in a basin to 37 °C. RFA was performed with a target temperature of 95 °C for six minutes. During RFA, the temperature was continuously monitored at all temperature probes. No simulation of vessel perfusion was used.

Results: For a cortical bone lamella between the nidus and periosteum of 1 mm, maximum temperatures of 69.1/51.3/42.5 °C, for a cortical bone lamella of 3 mm 59.2/46.5/41.1 °C and for a cortical bone lamella of 5 mm 50.6/44.8/40.0 °C were measured at 0/5/10 mm from the periosteum within surrounding soft tissue.

Conclusion: In our model of osteoid osteomas, soft tissue temperature during RFA was shown to be dependent on thickness of cortical bone lamella as well as on distance from periosteum. Results demonstrate that with a cortical bone lamella of at least 1 mm thickness, there is no severe risk of nerve damage at distances of more than 10 mm from the periosteum.

B-140 15:21

Arthro-MR imaging evaluation and incidence of supranequatorial gleno-humeral lesions in athletes affected by acquired instability of overstressed shoulder

C. Bultrini, N. Limbucci, R. Manetta, A. Barile, V. Calvisi, C. Masciocchi; L'Aquila/IT

Purpose: To assess the diagnostic accuracy of arthro-MR imaging in the evaluation of supranequatorial anatomical variations with respect to pathological findings in athletes clinically suspected of acquired instability of overstressed shoulder (AIOS) using arthroscopy as a gold standard.

Methods and Materials: 29 patients (18-35 years, mean age 23), all athletes, entered the study. All patients presented, clinically suspected non-traumatic shoulder instability due to overstrain related to sport activity. Before arthroscopy, all patients underwent arthro-MR imaging. We employed SE T1-w and FSE T2-w sequences for standard examination, after the intrarticular injection of 10-15 ml of contrast agent (obtained from the dilution of 0.6 ml of Gd-DTPA in 250 ml of saline) SE T1-w and fat-sat SE T1-w sequences were acquired.

Results: In 14 of 29 patients (48.2%) we found supranequatorial lesions. We detected anatomic variations in 5 of 14 cases (35.7%): in 3 patients arthro-MR imaging showed the presence of Buford complex; in one patient the presence of sub-labral foramen and in one patient a type II bicipital labral complex. In the remaining 9 of 14 patients (64.3%), arthro-MR imaging allowed the diagnosis of acquired abnormalities: 2 type II and 1 type III SLAP lesions, 2 paralabral posterior cysts, 4 rotator interval lesions. Arthroscopy confirmed arthro-MR imaging findings in all cases.

Conclusion: Arthro-MR imaging appears to be the method of choice in the pre-operative study of the supranequatorial lesions of the glenoid labrum, allowing the correct identification of anatomic variations: in our experience this technique is as accurate as arthroscopy.

Double contrast barium enema: Critical analysis of reported performance in the era of virtual colonoscopy

J. Sosna, T. Sella, E. Libson; Jerusalem/IL

Objective: CT colonography and conventional colonoscopy may have similar efficacy for detection of polyps > 6 mm. In this era the role of double contrast barium, an accepted screening tool for colorectal cancer, might be in doubt. The purpose of this study is to use meta-analysis to assess the accuracy of double contrast barium enema for detecting colorectal polyps and cancers.

Materials and Methods: Prospective studies comparing double contrast barium enema with conventional colonoscopy/ flexible sigmoidoscopy or clinical follow-up were identified and a standard form was used to extract relevant study data. Fisher's exact test and the Cochran-Mantel-Haenszel test were used for pooling of data. A 95% confidence interval (CI) was selected to determine sensitivity. Meta analysis methods were used to test robustness of results. Comparisons were made for the percentage of cancers and polyps detected.

Results: Only ten studies published since 1980 fulfilled all the inclusion criteria. Eighteen other studies were excluded due to their retrospective design. The pooled sensitivity for colorectal carcinoma was 0.80 (95% CI: 0.69, 0.91) and for polyps greater than or equal to 10 mm it was 0.73 (95% CI of 0.65, 0.83). The sensitivity for polyps 1-9 mm in size could not be calculated as only 4 of the 10 studies published such data and pooling was not statistically justified.

Conclusion: The scientific data on the overall performance of double contrast barium enema is scarce. Its performance might not be accepted as a screening tool especially when CT colonography might perform better.

B-142 14:09

The role of computed tomography, magnetic resonance imaging and positron emission tomography in the diagnosis of liver metastases: A meta-analysis

S. Bipat¹, M.S. van Leeuwen², E.F. Comans¹, M.E. Pijl³, J. Stoker¹;

¹Amsterdam/NL, ²Utrecht/NL, ³Groningen/NL

Purpose: To obtain summary estimates on the diagnostic performance of Computed Tomography (CT), Magnetic Resonance Imaging (MRI) and Positron Emission Tomography (PET) in assessing colorectal liver metastases.

Materials and Methods: The MEDLINE, EMBASE, Web of Science, CANCERLIT and Cochrane databases from the beginning of 1990 till December 2003 were searched for relevant original articles. Articles were included based on following criteria: 1) CT, MRI or PET to identify and characterize colorectal liver metastases; 2) findings at surgery, biopsy, autopsy, intra-operative findings and/or follow-up used as reference standard; 3) data presented to calculate true-positive and false-negative values. A random effects model was used to obtain summary estimates of sensitivity (lesion-based) in assessing liver metastases.

Results: Of 165 identified relevant articles, 61 fulfilled all inclusion criteria. Sensitivity estimates for nonhelical CT, helical CT, MRI at 1.0 T, MRI at 1.5 T and PET were 52.3% (95%CI:52.2, 52.4), 63.5% (95%CI:54.3, 71.9), 66.1% (95%CI:66.0, 66.3), 64.3% (95%CI:57.7, 70.4) and 75.8%(95%CI:61.1, 86.2) respectively. The estimates for nonenhanced MRI, Gd-enhanced MRI, SPIO-enhanced MRI were 59.8% (95%CI:49.0, 69.7), 78.2%(95%CI:63.0, 88.3) and 73.2% (95%CI:62.3, 81.9) respectively. Sensitivity estimates for GD-enhanced MRI ($p = 0.0186$) and SPIO-enhanced MRI ($p \leq 0.0001$) were significantly higher compared to nonenhanced MRI.

Conclusion: The diagnostic accuracies of MRI with contrast agents and PET were higher compared to helical CT for assessing colorectal liver metastases (not significantly). However, the availability of MRI and PET scanners in daily practice is limited and therefore it is most likely that only selected cases will undergo either MRI or PET.

Scientific Sessions

Careful CT and MR serial imaging review with a defined reporting protocol in follow-up colorectal cancer patients and correlation with ¹⁸FDG-PET-CT findings

K.C. Potter, G. Brown, B. Sharma, S.L. Houghton, J.E. Husband; Sutton/UK

Purpose: To evaluate the added value of ¹⁸FDG-PET-CT imaging over careful serial CT and MR imaging review in follow-up colorectal cancer patients.

Methods: Colorectal cancer patients at high risk of recurrence undergo regular follow-up CT and/or MR imaging in our institution. Indications for ¹⁸FDG-PET-CT include suspicion of recurrence due to elevated tumour marker (CEA) or equivocal findings on CT/MR. Over 4.5 months, 17 such patients underwent ¹⁸FDG-PET-CT within 4 weeks of CT/MR. CT/MR imaging was reviewed in detail using a defined reporting protocol for all prior serial imaging including baseline imaging with detailed criteria for scoring. Interobserver agreement was measured. Reviewers were blinded to the original reports, ¹⁸FDG-PET-CT findings and follow-up. Diagnosis was established by follow-up, biopsy, surgery or response to treatment.

Results: 10/17(59%) patients with normal CEA levels underwent ¹⁸FDG-PET-CT imaging for equivocal findings on original CT/MR investigations. Detailed review reduced the number of equivocal scans to 3(30%) ($p < 0.05$). No false negatives for CT/MR were demonstrated by ¹⁸FDG-PET-CT imaging. Of the 7/17(31%) patients with elevated CEA, CT/MR imaging alone was correct in 5/7 patients. ¹⁸FDG-PET-CT provided additional diagnostic information in 2/7 patients. Thus, the presence or absence of recurrence was resolved by detailed review in 12/17 (70.6%, 95% CI 48.9%-92.2%) patients referred for ¹⁸FDG-PET-CT.

Conclusion: We recommend careful review of all previous imaging prior to undertaking ¹⁸FDG-PET-CT imaging since this significantly decreases the number of equivocal reports in patients with normal CEA and confirms the cause of CEA elevation in the majority of patients.

B-144 14:27

Colorectal hepatic metastases: Evaluation using Magafodipir Trisodium enhanced MR imaging and breath-hold single-shot echo-planar diffusion-weighted MR imaging

D.-M. Koh¹, G. Brown¹, A. Riddell¹, D. Collins², E. Scurr¹, N. Karanji³, J. Husband¹; ¹London/UK, ²Sutton/UK, ³Guildford/UK

Purpose: To determine the sensitivity and specificity of T1-weighted Magafodipir Trisodium (Mn-DPDP) enhanced MR imaging and diffusion-weighted MR imaging (DWI) in the detection of colorectal hepatic metastases.

Method and Materials: 20 patients with potentially resectable colorectal hepatic metastases were prospectively evaluated using pre-contrast T1-weighted, T2-weighted and DWI (breath-hold single shot echo-planar imaging with three b values) of the liver was performed. Following Mn-DPDP administration, axial/coronal T1-weighted MR imaging of the liver were acquired. Two readers independently assessed DWI images and Mn-DPDP T1-weighted images separately and in combination. Histopathology and follow-up imaging were used as gold standards.

Results: There were 47 metastases and 33 benign lesions as determined by our gold standard. 40/47 metastases were confirmed at histopathology. The mean sensitivity and specificity of Mn-DPDP MR imaging for detecting metastasis were 87% (95% CI 73 - 96%) and 85% (95% CI 67 - 96%). The mean sensitivity and specificity of DWI were 85% (95% CI 71 - 94%) and 77% (95% CI 55-92%). The lower sensitivity and specificity of DWI alone could be attributed to motion and susceptibility artefacts obscuring lesions within the left lobe. The use of a combination of Mn-DPDP enhanced MR imaging and DWI yielded a mean sensitivity of 89% (95% CI 76 - 96%) and specificity of 94% (95% CI 91 - 100%).

Conclusions: Mn-DPDP enhanced T1-weighted MR imaging of the liver has a high sensitivity and specificity in detecting colorectal hepatic metastases. However, the addition of DWI improves the sensitivity and specificity of lesion detection.

B-145 14:36

CT perfusion as index of angiogenesis of rectal cancer

G. Petralia, L. Funicelli, S. Ferretti, A. Sonzogni, M. Bellomi; Milan/IT

Purpose: The aim of this study was to evaluate the different Computed Tomography (CT) parameters, characterizing tissue perfusion by contrast medium in rectal carcinomas and to define their relation with angiogenetic activity.

Materials and Methods: 41 patients with rectal cancer (24 of them before and after neo-adjuvant Radio- and Chemo-therapy) were studied by dynamic CT (16 slice light-speed G.E., scanned every second for 150°, after i.v. 2 ml/sec injection of 40 ml of 350 mg/dl iodine contrast medium). Semi-automatic calculation of time to peak (TTP), positive enhancement integral (PEI), maximum slope of

increase (MSI), maximum slope of decrease (MSD), blood flow (BF), blood volume (BV), mean transit time (MTT) and permeability surface (PS) were performed. Value distributions in the normal and neoplastic wall, their variation after therapies and their relation to pathological vessel density (MVD) were evaluated.

Results: BF, TTP, PS were higher in tumor than in normal wall, respectively in 68, 76 and 100% of patients; PS was > 20 ml/min/100 g in 100% of patients. PS decreased in 78% of patients submitted to neo-adjuvant Radio-chemotherapy. Significant correlation between TTP and MVD was found ($R = 0.679$).

Conclusion: CT perfusion could be reliable in the study of the neo-angiogenetic process, characterized by an increase in vessel number, vascular permeability and flow into extravascular spaces, better than pathological MVD count. Imaging will gain a role in monitoring targeted therapies, in the assessment of different angiogenetic patterns in tumors and in the selection of patients eligible to be treated by antiangiogenic therapy.

B-146 14:45

Comparison of MR imaging and CT for staging of advanced rectal carcinoma

J.C. Stollfuss, F. Zimmermann, K. Wörtler, F. Auer, E. Rummeny; Munich/DE

Purpose: To compare Magnetic-Resonance-Imaging (MRI) and Computed-Tomography (CT) for pre-operative staging in patients with advanced rectal carcinoma ($\geq T3$) after combined radio-chemotherapy.

Materials and Methods: 136 patients (98 male, 38 female, mean age 61 ± 9 yrs) with $\geq T3$ tumors at initial presentation were included in the study. All patients received pre-operative combined radio-chemotherapy. Contrast-enhanced and T2W MRI was performed after adequate bowel preparation. CT was performed after i.v. and rectal contrast application using conventional ($n = 70$) and multislice techniques ($n = 66$). Images were analyzed by two radiologists (consensus reading) according TNM categories using local tumor invasion and the presence of lymph-node metastases as the main parameters. Histopathological correlation was available in all cases. The accuracy of T2W and contrast-enhanced T1W-images were compared in a subgroup of 91 patients.

Results: The overall accuracy for prediction of local tumor invasion ($\geq T3$) by MRI was significantly higher when compared to that of CT ($p < 0.01$). There was no significant difference between T2W and T1W images after gadolinium-DTPA administration (n.s.). Compared to MRI, CT tends to be more specific regarding the prediction of nodal status ($p < 0.05$).

Conclusion: MRI is superior to CT for the prediction of local tumor invasion in patients with advanced rectal carcinoma, and may replace CT as the primary staging modality. Intravenous contrast administration in MRI was not superior to T2W imaging.

B-147 14:54

CT colonography in the follow-up of patients with partial colectomy

E. Neri, P. Vagli, S. Picchietti, F. Vannozi, A. Bardine, C. Bartolozzi; Pisa/IT

Purpose: To evaluate the role of CT colonography in the follow-up of patients submitted to surgical resection of the colon and who are intolerant of conventional colonoscopy.

Method and Materials: Four-row CT colonography was performed in a series of 24 subjects who had a previous partial colectomy for diverticulitis ($n = 4$) and colorectal cancer ($n = 20$). Patients were submitted to CTC because of incomplete conventional colonoscopy, for intolerance to endoscope insertion or stenosis of the lumen. In 22 cases pneumocolon was achieved via a rectal tube and in 2 cases through a cutaneous anastomosis. Colectomy involved the rectum ($n = 6$), the right colon ($n = 6$), descending colon ($n = 5$) and sigmoid colon ($n = 7$). In all cases CTC analysis included the combined evaluation of 2D images, 3D volume rendering of the external colon and endoluminal views simulating colonoscopy.

Results: CTC detected 3 cases of stenosis of the anastomosis in the sigmoid colon (1 neoplastic and 1 fibrotic) and in the ileo-colic junction in the transverse colon (neoplastic). The study of the residual colon showed 3 polyps - 8, 6 and 5 mm respectively - confirmed by CTC. In all cases the residual colon was entirely visualized. In 2 patients fecal residuals were present at the level of the ileo-colic anastomosis. The post-surgical anatomy was correctly depicted. In all cases with right colectomy the pneumocolon also involved the ileum through the ileo-colic junction, leading to difficulties in image interpretation.

Conclusions: CT colonography is a valid alternative to CC in patients with partial colectomy and who are intolerant to the introduction of the endoscope into the colon.

Preoperative TN staging of rectal carcinoma: Prospective comparison of transrectal US (TRUS) and endorectal MR imaging

M. Scialpi, V. Cenciarini, P. Landi, L. Regi, C. Galuppo, L. Lupattelli; Perugia/IT

Purpose: To compare the diagnostic potential of transrectal US (TRUS) and endorectal MR imaging (EMRI) in the preoperative assessment of the spread of rectal cancer and the nodal status in order to evaluate and recommend an appropriate imaging strategy.

Methods and Materials: 19 consecutive patients with proven carcinoma of the rectum were included in this prospective study. TRUS was performed with a 9-5 MHz transrectal probe. MR images were obtained with a 0.5-T superconducting magnet using an endorectal coil. In all patients FSE and TSE sagittal, axial and coronal T1 and T2-weighted images were performed.

Results: TRUS and EMRI accurately assessed the depth of rectal wall invasion by carcinoma. The results were correlated with histopathology in 18/19 cases (94.7%) and 1 case was understaged. Lymph nodes as small as 2-3 mm were identified by TRUS and EMRI, but benign from malignant lymph nodes were not differentiated.

Conclusion: TRUS and EMRI shows similar results in preoperative T staging of rectal carcinoma, however detection of nodal disease is still a diagnostic problem. TRUS and EMRI can be recommended for routine clinical application.

B-149 15:12

Colorectal cancer perfusion measurement using dynamic contrast

enhanced MDCT: Effect of acquisition time and implications for protocols

V.J. Goh¹, S. Halligan², J.-A. Hugill², L. Gartner², C. Bartram²; ¹Northwood/UK, ²Harrow/UK

Purpose: To determine the effect of acquisition time on colorectal cancer perfusion measurement using MDCT.

Material and Methods: 10 patients with histologically proven colorectal cancer were examined prospectively using 4-detector row CT (Lightspeed Plus, GE). A dynamic contrast enhanced scan was performed through the mid tumour (cine mode; 4 x 5 mm collimation) and tumour blood flow, blood volume, mean transit time and permeability recorded for acquisition times of 45, 65 and 130 seconds using commercial software (Perfusion 3.0, GE). Differences in the four perfusion parameters studied, for each of the three acquisition times, were determined using the paired T test after confirming parametric distribution.

Results: The mean (standard deviation, SD) for tumour blood volume, blood flow, mean transit time and permeability was 5.7 (1.3) ml/100 g tissue, 82.2 (31) ml/100 g tissue/min, 7.9 (3.4) seconds and 11.7 (2.2) ml/100 g tissue/min respectively at 45 seconds; 6.3 (1.6) ml/100 g tissue, 84.9 (36.5) ml/100 g tissue/min, 8.2 (3.9) seconds and 14.2 (2.4) ml/100 g tissue/min at 65 seconds; and 6.2 (1.5) ml/100 g tissue, 82 (30.6) ml/100 g tissue/min, 8.2 (3.4) seconds and 14.9 (3.1) ml/100 g tissue/min respectively for a 130 second acquisition. Significant differences in permeability was noted between acquisitions of 45 seconds, and 65 and 120 seconds respectively ($p = 0.02$; 0.007). There was no significant difference in blood volume, blood flow, and mean transit time measurements for any of the acquisition times.

Conclusion: Values for tumour permeability are contingent upon data acquisition time, which should be long enough so that measurements are accurate. Other perfusion parameters are unaffected.

B-150 15:21

Multislice spiral CT for the prediction of an involved circumferential resection margin in primary rectal cancer

S.V.R.C. Wolberink¹, R.G.H. Beets-Tan², D.F.M. de Haas-Kock², M. Oudkerk¹, T. Wiggers¹; ¹Groningen/NL, ²Maastricht/NL

Purpose: To determine accuracy of multislice CT scan (MSCT) in the preoperative prediction of the circumferential resection margin (CRM) in rectal cancer.

Methods and Materials: 200 patients with primary rectal cancer underwent a MSCT scan of the abdomen. Scans were scored for yes (R1=distance to mesorectal fascia ≤ 1 mm) or no (R0 = distance > 1 mm) involved CRM by two teams consisting of two specialist readers, reading in consensus. The teams were blinded for each other's and the histological results, the latter of which were taken as the gold standard.

Results: There were 2 T0Nx, 7 T1Nx, 43 T2Nx, 126 T3Nx and 22 T4Nx tumors. A total of 400 predictions were made, 44 incorrect (11%) and 356 correct (89%). Sensitivity for team A was 65.6% with a specificity of 93.7%. Sensitivity for team B was 81.3% with a specificity of 94.7%. Discrepancies occurred in 33 patients, 16 false positive and 14 false negative. 16 of these had an anteriorly located

distal tumor with a close CRM in the direction of the seminal vesicles or uterus. 7 had an distal tumor with the distal margin close to the anal sphincter. Interobserver agreement was high ($\kappa 0.69$).

Conclusion: MSCT can predict the CRM in rectal cancer with high accuracy and high interobserver variability. Overstaging errors mostly occurred in either anteriorly located distal tumors or in tumors with a distal margin close to the anal sphincter, indicating that caution is needed when predicting the CRM in these types of tumors.

Is CAD/CAC performance affected by breast tissue composition?

R. Lederman¹, I. Leichter¹, S. Fields¹, S. Buchbinder², B. Novak¹, M. Sklar-Levy¹, P. Bamberger¹; ¹Jerusalem/IL, ²Staten Island, NY/US

Purpose: To compare the performance of a two-tiered system with computerized detection (CAD) and classification (CAC), in high-density and low-density breast tissue.

Methods and Materials: 222 cases with pathologically-proven mammographic lesions (140 malignant) were retrospectively interpreted using a two-tiered CAD/CAC system. The CAD scheme automatically detected suspicious findings on digitized mammograms. The CAC scheme calculated the level-of-suspicion based on automatically extracted features. The CAC scheme was applied whenever the finding was retrospectively considered suspicious, whether detected or not, and for each biopsied lesion detected by the CAD tier even if it was retrospectively considered benign by the radiologist. Independently, all cases were ranked by breast composition. Fatty breasts were combined with scattered fibroglandular densities (low-density), while heterogeneously dense cases were combined with extremely dense cases (high-density).

Results: High-density breasts were found in 115 cases (88 malignant). For malignant masses, the detection sensitivity was 96.0% (48/50) in low-density breast tissue and 89.5% (34/38) in high-density breast tissue. For malignant clusters the detection sensitivity was 100% (21/21) in low-density breast tissue and 96.9% (30/31) in high-density breast tissue. The CAC scheme, increased the sensitivity of classification from 94.2% to 97.1% in dense breasts, while in low-density breast tissue it decreased from 100% to 98.6%. The specificity of classification with CAC increased from 13.9% to 63.9% in low-density breast tissue and from 17.4% to 60.9% in dense breasts.

Conclusion: Overall the CAD/CAC device performed similarly in low-density and high-density breast tissue. In dense breast, the CAD/CAC device increased both sensitivity and specificity.

B-152 14:09

A new approach for adjunct computerized assessment of mammographic findings, using a CAC system

I. Leichter¹, S. Buchbinder², R. Lederman¹, S. Fields¹, B. Novak¹, P. Bamberger¹; ¹Jerusalem/IL, ²Staten Island, NY/US

Purpose: To test the diagnostic performance of an adjunct use of Computer-Assisted-Classification (CAC), which assesses breast lesions by a differential weighting of BI-RADS categories.

Methods and Materials: 171 cases of mammographic lesions, with proven pathology (88 malignant) were retrospectively interpreted in a conventional manner, each by four radiologists. After digitizing the films, findings were automatically classified by a CAC system, which calculated the level-of-suspicion of each lesion. This level-of-suspicion yielded a CAC-modified assessment by potentially modifying each conventional BI-RADS category by one step only, in either direction. Subsequently, a CAC-adjunct assessment was attained by allowing BI-RADS categories modifications by more than one, depending on the level-of-concern expressed by the radiologist and never swapping non-actionable categories ("2" and "3"). The radiologist's and the two different computerized assessments were compared.

Results: For each radiologist, the ROC curves of both CAC-modified and CAC-adjunct assessments showed higher AUC compared to conventional interpretation.

Friday

Scientific Sessions

While the ROC curves for the limited CAC-modified assessment crossed those of conventional interpretation, the ROC curves for the CAC-adjunct assessment were consistently higher. The mean area for both the CAC-modified and CAC-adjunct assessments (0.86) was significantly higher ($p < 0.005$) than for the conventional interpretation (0.77). The average specificity increased from 26.8% for conventional interpretation to 47.0% ($p < 0.001$) for both CAC-modified and CAC-adjunct assessments.

Conclusion: For the same improvement in sensitivity and specificity compared to the conventional interpretation, the diagnostic performance of a CAC-adjunct assessment is superior to that of a CAC-modified assessment because the CAC-adjunct ROC curves do not cross the conventional curves.

B-153 14:18

The evaluation of image quality and dose on computed radiography systems for mammography

C.P. Lawinski, H. Cole, P. Blake, A. Mackenzie, A. Pascoal; *London/UK*

Purpose: Following recent concerns raised in Europe regarding the use of computed radiography (CR) in mammography, a comparative evaluation of the systems currently offered in the UK has been performed. CR for mammography was initially based on systems for general radiography. More recently, dedicated mammography systems are available with improved imaging capability, particularly in terms of spatial resolution.

Methods and Materials: Image quality data was obtained using a range of test objects. All acquired images were scored both as softcopy and as hardcopy. Breast and receptor dose were also assessed. The results were compared to typical data for screen-film mammography and to recent UK guidance on the introduction of CR for mammography.

Results: All of the systems evaluated met the requirements of UK guidance for visibility of the TOR MAX details. All TOR MAM softcopy scores were at least as good as typical screen-film results and in all cases were better than the associated hardcopy values. CDMAM results showed that, in general, contrast detail detectability was better for softcopy presentation than hardcopy. For all of the systems evaluated, limiting resolution measurements were close to the theoretical values derived from the pixel pitch and poorer than for typical screen-film systems.

Conclusions: All of the CR systems for mammography evaluated met the current UK minimum levels of performance in terms of test object image quality and radiation dose. Therefore any of these systems can undergo clinical evaluation as described in this guidance. Softcopy reporting may offer significant benefits over hardcopy.

B-154 14:27

Number and reasons for additional views (mosaic) at full-field digital mammography (FFDM) with a 19x23 digital detector

R. Gullien, A. Haakull, S.J. Kristiansen, M. Loevstad, P. Skaane; *Oslo/NO*

Purpose: To determine the number and reasons for women in the randomized Oslo II study requiring more than two standard views (cranio-caudal and mediolateral oblique) of each breast at mammography with a 19x23 digital detector.

Methods and Materials: 7005 women underwent digital mammography with a Senograph 2000D (GE Medical Systems). The women were examined by any two radiographers employed in the screening program at that time. Each of the woman's breasts was positioned by a different radiographer. In an on-site protocol, the radiographers registered all women who had taken more than four views and the reason for this deviation. The reasons for deviation were classified as: Breast size incompatible with detector size, positioning failure/error or need for additional axillary views or other reasons. Disabled women, women with implants and women after mastectomy were excluded from analysis.

Results: Of the 7005 women examined, 6705 (95.71%) women required standard views, 135 (1.92%) 5 views, 84 (1.19%) 6 views and 81 (1.15%) 7 views or more. Of the 297 (4.23%) women requiring more than standard views, 234 (78.78%) women required additional views due to breast size incompatible with detector size, 46 (15.48%) due to positioning error or need for axillary views and 17 (5.72%) due to other factors.

Conclusion: Relatively few women (4.23%) in Oslo aged 50-69 required a mosaic examination at FFDM. A further reduction of this number could be achieved with improved positioning techniques.

B-155 14:36

Digital luminescence mammography (CR) versus full-field digital mammography (DR): A phantom study

R. Schulz-Wendtland, E. Wenkel, M. Lell, K. Imhoff, W. Bautz; *Erlangen/DE*

Purpose: The objective of this phantom study was to compare the high resolution digital phosphor storage plate system (18x24 cm²) (Siemens) with the full field digital mammography system (Fischer) in diagnostic mammography.

Method and Materials: RMI-mammography-phantom X-ray studies were acquired with two different systems. A set of digital acquired images (Mammomat 3000 N (Siemens), storage phosphor plate IP HR BD, image reader FCR 5000 MA (Fuji / Siemens), resolution 8-9 lp/mm, printer FM DP L (Fuji), resolution 12.9 lp/mm) (CR) were compared as hardcopies to full-field digital images (SenoScan (Fischer), CCD-detector, resolution 10 lp/mm, printer TM 8600 (Kodak), resolution 12.9 lp/mm) (DR) by using the same parameters and exposure data (standard crano-caudal position, 100 mAs, 28 kV) of the same objects. Five in mammography experienced radiologists read the images with regard to recognizability of details like grains of aluminum oxide (200 to 740 micrometers), threats of nylon (0.4 to 1.6 mm) and round lesions / masses (diameters 5 to 14 mm).

Results: 225 right positive decisions were possible to detect for every system. We found 193 right positive decisions for the digital phosphor storage plate system (CR) and the maximum of 225 for the full-field digital system (DR) (significance $p < 0.001$).

Conclusion: The results of this study demonstrate a higher detectability rate of lesions for full-field digital mammography with a CCD-detector (DR) in comparison to the high resolution digital phosphor storage plate mammography (CR) in an experimental setting.

B-156 14:45

Experimental investigations in comparison of full-field digital mammography (a-Se detector) with a Mo/Mo and W/Rh filter: Is a dose reduction possible?

R. Schulz-Wendtland, K.-P. Hermann, E. Wenkel, C. Böhner, M. Lell, M.-S. Dassel, W. Bautz; *Erlangen/DE*

Purpose: Experimental investigations of a full-field digital mammography system with the question of a possible dose reduction.

Methods and Materials: The digital mammography system Novation® (Siemens) is based on a a-Se detector with a Mo/W double anode and Mo/Mo resp. W/Rh filter: spatial resolution 7 lp/mm, effective quantum efficiency (DQE) (0) 65%, memory depth 12-bit. The object of investigation was the Wisconsin Mammographic Random Phantom, Model 152A (Radiation Measurements Inc., Wisconsin). The radiograms were acquired using the digital mammography system with the filter combination Mo/Mo (28 kV; 59.0 mAs; 1.4 mGy (MGD - median glandular dose)) as AEC (automatic exposure control) in comparison to W/Rh (28 kV; 40.1 mAs - 100.1 mAs resp. 0.6 mGy - 1.5 mGy) and W/Rh (29 kV - 35 kV; 54.0 mAs - 24.8 mAs resp. 0.9 mGy - 0.7 mGy).

Results: Equivalent results (219 of 225 possible details) were detected with Mo/Mo (28 kV; 59.0 mAs; 1.4 mGy) and W/Rh (28 kV; 61.8 mAs; 0.9 mGy).

Conclusion: Based on these experimental results, the W/Rh filter in combination with the full-field digital mammography system and a-Se detector seems to give the possibility to reduce the dose of up to 25% in comparison to the standard filter with Mo/Mo.

B-157 14:54

Image quality of a prototype full-field digital mammography system based on amorphous selenium

A. Fischmann¹, K. Nykänen², M. Esslinger¹, K.C. Siegmann¹, A. Wersebe¹, T. Xydeas¹, C.D. Claussen¹, S. Miller¹; ¹Tübingen/DE, ²Tuusula/FI

Purpose: To evaluate the image quality of a novel Full-Field Digital Mammography (FFDM) System.

Methods and Materials: Image quality of a prototype FFDM System with a detector based on amorphous selenium a-Se (Instrumentarium Diamond FFDM) was compared to a FFDM system based on amorphous Silicon a-Si (General Electric Senographe 2000D). Images of a contrast detail phantom (CDMAM 3.4, St. Randout, NL) were taken at 28 kVp and 16 to 125 mAs, with Mo/Mo and Mo/Rh anode-filter-combination. To simulate different breast thicknesses phantom thickness was set to 2.5 and 4.5 cm. Images were evaluated by three readers independently. Correct observation ratio (COR) and image quality figures were calculated.

Results: Both FFDM systems showed comparable image quality with COR between 38 and 78% with the aSe system and between 41 and 75% with the aSi

Scientific Sessions

system for the 2.5 cm phantom. For the 4.5 cm phantom COR ranged between 13 and 54% with aSe and between 24 and 57% with aSi. With Rh-filter COR ranged from 53 to 81% with the aSe system and from 48 to 77% with the aSi system for thin phantom. For the thick phantom ranges were from 29 to 60% with aSe and from 30 to 60% with. Inter-reader variability ranged from 0.88 to 0.95. Omission of the grid lead to a dose reduction of 10 to 30% depending on breast thickness and beam quality.

Conclusion: In conclusion the prototype FFDM system based on a-Se is equal to an established FFDM system in contrast-detail resolution.

B-158 15:03

Comparison of full-field digital mammography (FFDM) and CR mammography: Physical imaging properties and contrast-detail characteristics

T. Ideguchi¹, Y. Higashida¹, K. Himuro¹, M. Ohki¹, R. Takagi², H. Hatano², R. Kuwahara², I. Tanaka¹, F. Toyofuku¹; ¹Fukuoka/JP, ²Kumamoto/JP

Purpose: An amorphous silicon-based flat panel detector for full digital mammography and a new computed radiography (CR) system with a pixel size of 50im were compared with respect to physical imaging properties and contrast-detail characteristics.

Methods and Materials: The presampled modulation transfer functions (MTF) of the flat panel detector and the CR system were measured using the slit method. Their noise power spectra were determined under various X-ray exposures. Their contrast-detail curves were obtained from observation experiments using a contrast-detail phantom. Image quality figures (IQF) were also calculated from the individual observer performance tests.

Results: The MTFs of the flat panel digital mammography system showed significantly higher values than those of the new CR digital mammography system with a pixel size of 50 im. The flat panel system showed a lower noise level compared with the CR system under the same exposure conditions. The contrast-detail curves and the IQFs of the flat panel system were superior to those of the new CR system.

Conclusion: The full-field digital mammography system had superior physical imaging properties and contrast-detail characteristics compared to the new CR digital mammography system with a pixel size of 50 im.

B-159 15:12

Clinical study to evaluate the diagnostic value of AGFA CR system: Comparison of mammographic hardcopy images to screen-film mammographic images

C. Van Ongeval¹, A. Van Steen¹, V. Celis¹, M. Van Goethem², I. Verslegers², K. Joossens¹, G. Marchal¹; ¹Leuven/BE, ²Antwerp/BE

Purpose: To compare the diagnostic value of a full field CR based mammography system (CRM), AGFA CR750.0 & CRMM2.0 plates to screen-film mammography (SFM) with hard copy viewing.

Methods and Materials: A series of 100 patients, scheduled for a diagnostic mammography, underwent a SFM and a CRM (double exposure, without removing compression of the corresponding breast). The CR images were processed with dedicated Musica processing. The sets of hard copy images were read by 6 radiologists (3 on-site and 3 independent). The primary efficacy parameter was the overall diagnostic value. The secondary efficacy parameters are lesion conspicuity and details (for masses and calcifications), tissue visibility at chest wall and at skin line, axillary details, overall density, overall noise and sharpness impression.

Results: The proportion of subjects with an overall diagnostic value greater or equal to zero was 100%. Pooled analysis of the 10 features for image quality comparison demonstrated for all, but one feature (detail of the calcifications) that CR was equal to SFM. Wilcoxon's exploratory analysis showed for lesion conspicuity of masses ($p = 0.021$), lesion detail of masses ($p < 0.001$), tissue visibility at skin line ($p < 0.001$) and overall density impression ($p = 0.003$) CR was statistically, significantly more confident than SFM. The same analysis for lesion detail of calcifications ($p < 0.001$) showed that the observers felt less confident with CR than with SFM.

Conclusion: Non-inferiority of AGFA CR system compared to SFM images could be concluded. Only in evaluating the detail of microcalcifications did the observer feel less confident with the CR system.

B-160 15:21

First experiences with iodine-based contrast medium in digital full-field mammography

F. Diekmann¹, S. Diekmann¹, F. Jeunehomme², S. Muller², B. Hamm¹, U. Bick¹; ¹Berlin/DE, ²Buc/FR

Purpose: To evaluate the potential of dynamic intravenous administration of an iodine-based contrast medium in digital full-field mammography.

Methods and Materials: Ten patients with 12 suspicious lesions of the breast (2 benign, 1 borderline, 9 malignant) underwent mammography with an iodine-based contrast medium (Ultravist 370, Schering AG, Berlin, Germany). Three sequential images of the lesion-bearing breast were acquired 60, 120, and 180 sec after administration at a dose of 1 ml/kg body weight at a flow of 4 ml/sec with digital full-field mammography (GE Medical Systems, Milwaukee, USA). Subsequently, the precontrast image was logarithmically subtracted from the postcontrast images. Lesion enhancement was correlated with enhancement of the breast tissue. The subtracted images were evaluated for lesion depiction and enhancement kinetics were analyzed. The lesion size and enhancement kinetics were compared with the histologic findings.

Results: All malignant lesions were detected by contrast-enhanced digital mammography. Three of the tumors were depicted on the contrast-enhanced images but not on the standard mammography images. The contrast medium kinetics of benign and malignant tumors in contrast-enhanced digital mammography is comparable to that known from magnetic resonance imaging using gadolinium-based contrast medium. This is true in particular for comparison of tumor kinetics with the enhancement of normal breast tissue.

Conclusion: The results of this preliminary study suggest that contrast-enhanced digital mammography has a great potential in the detection and characterization of breast lesions.

Influence of the CT reconstruction kernel on the performance of a CAD system for the detection of pulmonary nodules

M. Salganicoff¹, G. Kohl², D.P. Naidich³, P. Herzog⁴, M. Wolf¹, P. Cathier¹, J. Stoeckel¹; ¹Malvern, PA/US, ²Forchheim/DE, ³New York, NY/US, ⁴Munich/DE

Purpose: To assess the performance of a computer aided diagnosis (CAD) system for the detection of pulmonary nodules on MDCT datasets with different CT-reconstruction kernels.

Methods and Materials: 20 MDCT datasets reconstructed with section thicknesses of 1.0 - 1.25 mm and a B60f (Siemens Somatom system) high frequency reconstruction kernel were reviewed by a chest radiologist and processed on a prototype CAD system. The images on the CAD system were evaluated first originally, then consecutively after applying an image smoothing tool with 3 increasing levels of smoothing.

Results: The chest radiologist identified a total of 56 nodules with diameters from 3 - 8 mm.

The robustness of the CAD system to different smoothing levels was assessed by comparing the average sensitivity and false positive (FP) rate for each group of filtered scans to the group of unfiltered scans. For the small filter setting (corresponding to a B50f kernel) there was no difference in sensitivity or specificity. A medium filter (corresponding to B45f kernel) also did not affect sensitivity, but the number of false positives increased from 2.5 to 4.6 FP/case. The strongest filter setting (corresponding to a B40f kernel) showed increased sensitivity by 10% but at the cost of doubling the FP rate to 5.7 FP/case.

Conclusion: Overall the CAD system performed well for the smoothed CT volumes. Although strong noise reduction slightly improved sensitivity it also caused an increase in the number of false positives. CT-protocol changes should always be considered as possible influences on performance of CAD tools.

B-162 14:09

Comparison of two different algorithms for the detection of pulmonary nodules on MDCT datasets

M. Salganicoff¹, P. Herzog², D.P. Naidich³, J. Stoeckel¹, H. Shen⁴, G. Kohl⁵, A. Krishnan¹; ¹Malvern, PA/US, ²Munich/DE, ³New York, NY/US, ⁴Princeton, NJ/US, ⁵Forchheim/DE

Purpose: To compare the sensitivity and false positive rate of two computer-aided detection systems for pulmonary nodules on MDCT datasets: Nodule Enhanced Viewing (LungNEV) vs. computer aided detection (LungCAD) using artificial intelligence (AI) methods.

Methods and Materials: 20 MDCT studies with section thicknesses ranging from 1.0-1.25 mm were evaluated by a radiologist who initially marked all nodules greater than 3 mm using the LungCARE Software (Siemens, Forchheim, Germany) prior to processing the datasets with both CAD systems, the commercially available LungNEV and the prototype LungCAD.

Results: 56 nodules with diameters from 3 mm - 8 mm were identified of which 8.9% were groundglass opacities (GGOs), 16.1% were vessel-attached, 28.6% were pleural-based, 12.5% were adjacent to fissures and 64.3% were solitary. LungCAD had a small improvement in sensitivity of 10% compared to LungNEV. A distribution-analysis of the true positives of LungCAD compared to LungNEV showed that improvement in sensitivity resulted for vessel-attached and solitary nodules rather than for pleural-based nodules. LungNEV identified a mean of 8 FP/case (median 7.5) while LungCAD only identified a mean of 2.3 FP/case (median 2) which proved to be statistically significant. Interpretation times for LungNEV and LungCAD were equivalent.

Conclusion: AI methods can achieve a very small false positive rate for the detection of lung nodules from multi-slice CT studies while maintaining an equivalent sensitivity. The use of AI technologies has the potential to further improve the benefits to radiologists derived from CAD both for preventive care medicine as well as routine clinical practice.

B-163 14:18

Computer-aided detection of pulmonary metastasis: Influence of nodule characteristics on detection performance

K. Marten¹, T. Seyfarth², E.J. Rummeny¹, C. Engelke¹; ¹Munich/DE, ²Forchheim/DE

Purpose: To evaluate the influence of pulmonary nodule location, size and morphology on the performance of a computer-aided diagnosis (CAD) tool using multislice CT (MSCT).

Materials and Methods: MSCT scans of 20 patients were separately evaluated by a CAD system and two blinded chest radiologists for pulmonary nodules. Nodule presence, size, position, margin, matrix characteristics, vascular and pleural attachments were recorded and compared to an independent reference standard. Statistical analysis included chi-square, retrograde stepwise logistic regression with nodule detection proportion estimates (DPE), and ROC analysis.

Results: 135 nodules were included (median diameter = 4.4 mm; range = 1-30.6 mm). Detection rates for CAD and readers were 76.3%, and 52.6%, respectively. False-positive rates were 0.55 and 0.15-0.25 per scan, respectively. Reader detection rate improved in consensus with CAD (93.3%, p < 0.05); the false-positive rate decreased (0.1/scan). Absence of vascular attachment significantly predicted nodule detection by CAD ($p = 0.001-0.008$). Pleural and vascular attachments predicted reader nodule detection ($p = 0.0005-0.02$). Reader sensitivity was higher for vascular attached vs. non-attached nodules (sensitivities = 0.725 and 0.354, 95% CI=0.604-0.825 and 0.239-0.482, respectively). DPEs for nodules ≤ 5 mm were higher for ICAD than for the readers ($p < 0.05$).

Conclusion: CAD outweighs deficient reader performance in detection of smallest lesions and nodules without vascular or pleural attachment.

B-164 14:27

Clinical evaluation of a computer aided pulmonary nodule detection system

P. Herzog¹, S. Buhmann¹, D.P. Naidich², J. Stoeckel³, M. Wolf³, H. Shen⁴, M. Salganicoff³, A. Krishnan³; ¹Munich/DE, ²New York, NY/US, ³Malvern, PA/US, ⁴Princeton, NJ/US

Purpose: To evaluate the effect of a prototype computer aided detection system (LungCAD) on the sensitivity of a cohort of community radiologists for detecting pulmonary nodules on MDCT datasets.

Methods and Materials: 16 MDCT studies with section thicknesses ranging from 1.0-1.25 mm were evaluated by a cohort of 6 community level radiologists from two sites (NYU Medical Center and University of Munich). The cohort members were instructed to mark all nodules greater than 3 mm using the LungCARE

Software (Siemens, Forchheim, Germany). The datasets were then processed with a prototype version LungCAD. Community radiologists then reviewed and accepted or rejected computer identified nodules. Ground truth was defined as any nodule marked by one of the community readers or by CAD that was also validated by a single expert's blinded review.

Results: The mean sensitivity of community radiologists without LungCAD was 53.5% with 4.63 FP/case while the sensitivity assisted with LungCAD was 66.5% with a mean of 5.98 FP/case. The difference of sensitivity proved to be statistically significant ($p < 0.021$, t-Test) while the change in FP/case was not. Additionally, the spread of sensitivity (excluding best and worst performing outliers) within the LungCAD assisted community reader cohort was less than that for the unassisted readers (12.5% versus 7.5%), implying less inter-observer variability.

Conclusion: The CAD assisted method yielded a higher sensitivity among community radiologists with no significant change in FP. Equally importantly, the variation in sensitivity was reduced, leading to a more predictable detection rate across radiologists.

B-165 14:36

Computer-aided detection of pulmonary metastasis using multislice CT: Performance evaluation in consensus with experienced versus inexperienced chest radiologists

K. Marten¹, T. Seyfarth², E.J. Rummeny¹, C. Engelke¹; ¹Munich/DE, ²Forchheim/DE

Purpose: To evaluate the performance of experienced versus inexperienced radiologists in comparison with a computer-aided detection (CAD) system for pulmonary nodules using multislice CT (MSCT).

Materials and Methods: Eighteen consecutive patients (age range: 29-83 years) prospectively underwent 16-row MSCT. Four blinded radiologists (experienced: readers 1, 2; inexperienced: readers 3, 4) assessed image data against CAD for pulmonary nodules. Thereafter, consensus readings of readers 1+3, reader 1+CAD and reader 3+CAD were performed. Data were compared against an independent gold standard. Statistical tests used to calculate interobserver agreement, reader performance and nodule size were Kappa, ROC and Mann-Whitney U.

Results: CAD as well as experienced readers outperformed inexperienced readers ($Az = 0.72, 0.71, 0.73, 0.49$ and 0.23 for CAD, readers 1-4, respectively; $p < 0.05$). Performance of reader 1+CAD was superior to single readers' and reader 1+3 performances ($Az = 0.93, 0.72$ for reader 1+CAD and reader 1+3 consensus, respectively, $p < 0.05$). Reader 3+CAD did not outperform experienced readers or CAD ($Az = 0.72$ for reader 3+CAD; $p > 0.05$).

Conclusion: Consensus of reader 1+CAD significantly outperformed all other readings, demonstrating a benefit as an inexperienced reader replacement. Inexperienced observers did not perform adequately to justify routine replacement of an experienced radiologist by CAD.

B-166 14:45

Computer-assisted detection (CAD) of pulmonary nodules at MDCT: Can CAD be used as concurrent reader?

F. Beyer¹, L. Zierott¹, J. Stoeckel², W. Heindel¹, D. Wormanns¹; ¹Münster/DE, ²Malvern, PA/US

Purpose: CAD can improve the sensitivity of radiologists in detection of pulmonary nodules at MDCT when used as a second opinion. CAD is also reported to save reporting time when used as "concurrent reader" but the influence on sensitivity is not clear. Our study is aimed to compare sensitivity and reporting time of second and concurrent reading.

Material and Methods: Fifty MDCT scans of the chest were randomly selected from the clinical routine. Two radiologists independently read the CT scans using CAD as concurrent reader (CAD results were displayed at the time of reading). More than one week later the same cases were read again using CAD as second reader (cases were first read without CAD; CAD results were displayed after completing the reading). A prototype of Siemens LungCAD (Siemens, Malvern, USA) was used. Times needed for concurrent reading, for reading without CAD (as part of second reading) and for using CAD as second opinion were recorded.

Results: A total of 225 nodules were detected. Combined sensitivity of one radiologist and CAD for concurrent versus second reading was 52% vs. 57% for reader A (McNemar's test: $p = 0.07$) and 69% vs. 74% for reader B ($p = 0.13$). Average reporting time was 206 ± 97 s for concurrent and 251 ± 98 s for second reading (Wilcoxon test: $p < 0.001$).

Conclusion: CAD as concurrent reader can save reporting time with some but not significant loss of sensitivity. However, if the clinical setting requires highest sensitivity, the use of CAD as second opinion is recommended instead.

Scientific Sessions

B-167 14:54

Impact of a computer-aided detection system (CAD) on a lung cancer screening program with low-dose multislice CT (MSCT)

P. Domínguez Echávarri, G. Bastarrika Alemán, D. Cano Rafart, M. Pons Renedo, J. Larrache Latasa, A. Alonso Burgos, J. Zulueta Francés; Pamplona/ES

Purpose: To evaluate the utility of CAD in the detection of lung nodules in screening low-dose MSCT chest exams (I-ELCAP screening program), previously dual-read by an expert radiologist and a radiology resident.

Methods and Materials: 114 already reported low dose MSCT chest exams (120 kv, 20 mAs, 1.3 slice thickness, 1.2 mm reconstruction interval) were analysed with the CAD system (ImageChecker CT, R2 Technology Inc). I-ELCAP and clinical reports were evaluated. All exams were carefully reviewed again by both another expert CT radiologist and a resident, evaluating each nodule and detecting new nodules, using overall as the standard of reference. Evaluation was focused on the detection of solid non-calcified 5 mm or bigger nodules, as only these change clinical action.

Results: Total of 285 nodules, 183 non-calcified. CAD detected 136 total (S 0.47) and 93 non-calcified (S 0.51), radiologists 166 (S 0.58) and 104 (S 0.57) and both 242 (S 0.84) and 155 (S 0.85). If we focus on solid non-calcified 5 mm or bigger nodules there were 19 nodules in 14 patients. CAD detected 17 (S 0.89), radiologists 16 (S 0.84), and both detected 19 (all of them, S 1). CAD changes clinical action in 3 patients of 114 (3 months follow-up instead of 12 months follow-up). CAD marked 2.1 false positive results per nodule, 2.5 per exam.

Conclusion: This CAD system is a valuable aid in the detection of lung nodules in a low-dose MSCT screening program, notably increasing the sensitivity of radiologists alone.

B-168 15:03

Computer aided detection of incidental pulmonary nodules in emergency thoracic CT angiography

G. Bartal¹, J.M. Gomori², T. Gaspar³, E. Rivlin³, R. Goldenberg³, E. Walach³, N. Peled³; ¹Hadera/IL, ²Jerusalem/IL, ³Haifa/IL

Purpose: CT angiography for the detection of pulmonary emboli (PE) or aortic dissection is performed and reported in an emergency setting. This may distract the radiologist from detecting incidental pulmonary pathology. Our aim was to assess the sensitivity of pulmonary nodule detection by radiologists with the assistance of an automatic computer aided detection (CAD) system.

Materials and Methods: We retrospectively evaluated written reports and images of 114 patients with suspected PE and 30 patients with suspected pathology in the thoracic aorta. CT angiograms were performed on 16-slice Philips Mx8000 IDT CT scanner bolus-tracking contrast injection method, and scan parameters: 16x1.5, 2 mm reconstructed slice thickness, pitch 1.3. Five certified radiologists interpreted these studies as an emergency. CAD of lung nodules was performed using an automatic CAD system (Netzview, RCADIA Ltd., Haifa, Israel). We used the evaluation by CAD and two experienced radiologists (GB, NP) as the gold standard.

Results: GB+NP+CAD (gold standard) found lung nodules in 18 patients. Five reporting radiologists diagnosed lung nodules in 10/18(56%) cases in PE and in 2/2 (100%) cases in aorta with only 2.9 and 2.2 false positives per case respectively. CAD detection rate was 78% higher than the radiologists ($p < 0.003$). Results of the evaluation by the reporting radiologists and CAD reached a sensitivity of 100%.

Conclusions: Emergency pulmonary and aortic CT angiography detect potentially actionable lung pathology. CAD significantly improves incidental pulmonary nodule detection rates of radiologists in these patients.

B-169 15:12

Phantom evaluation and patient correlation of computer-aided volumetry of small pulmonary nodules in MDCT chest examinations

M. Das¹, G. Mühlenbruch¹, A.H. Mahnken¹, L. Gundel², O. Hauenstein², J. Eckert¹, R.W. Günther¹, J.E. Wildberger¹; ¹Aachen/DE, ²Forchheim/DE

Purpose: To evaluate volumetry of pulmonary nodules in a lung phantom for different CT parameter settings and to compare the results to patient pulmonary nodules.

Methods and Material: A lung phantom with five different categories of nodules (intraparenchymal, around a vessel, attached to a vessel, pleural, attached to the pleura) each category with different sizes (3-10 mm, total nodules: 40) were scanned on a MDCT scanner (Somatom 64, Siemens Medical). Scan protocol: 64*0.6 mm collimation, 120 kV, 120 mAs_{eff}/20 mAs_{eff}. Reconstruction: slice

thicknesses (0.6 - 5 mm), algorithms (B45f, B50f, B60f). Volumetry (volume and size measurements) was performed for all nodules and compared for the different settings. Reproducibility with different clicking points was tested. MDCT data (Somatom Sensation 16, Siemens) from a patient with multiple nodules was chosen and the nodules were correlated to the different categories of the nodules in the phantom and measurements were compared.

Results: Average relative volume error for the different parameters was 9.64% ($\pm 6.4\%$). Average relative diameter error for the different parameters was 7.6% ($\pm 5.4\%$). No differences of the measurements could be detected regarding varying dose, slice thickness, reconstruction algorithm and clicking points. The error remained constant for slice thicknesses between 30 and 50% of the diameter. The patient data showed the same results.

Conclusion: The algorithm tested showed highly reproducible results over different dose settings, at multiple measurements and with different reconstruction algorithms. Correlation with real patient data indicates highly accurate and reproducible measurements of the algorithm also for nodules in real patients.

B-170 15:21

Measuring lung nodules: Inter-observer variability

H.A. Gietsma, M. Prokop, W.P.T.M. Mali; Utrecht/NL

Purpose: In the NELSON-project (Dutch-Belgian lung cancer screening), discrimination between malignant and benign for nodules < 500 mm³ is done by assessing the presence of growth on follow-up CT. *Inter-observer variability* can be an important factor causing an increase in measured volume without growth of the nodule. In this study we have measured *inter-observer variability* for automatic volume measurements.

Materials and Methods: To determine *inter-observer variability* we collected 230 nodules < 500 mm³ for which a first and second reading was available and compared the volumes of both readings. Volume of the nodules was assessed on a Leonardo© workstation (Siemens AG, Erlangen, Germany) using Lungcare© software. The difference was calculated by subtracting the volume on second scan from the first one and given in mm³ and as percentage of the mean volume of each nodule.

Results: For 174 lung nodules no *inter-observer variability* was seen. Mean volume was 84.4 mm³, mean difference between first and second reading was 0.4 mm³ (± 6.2 mm³, range (-52.7) – 36.9 mm³) or 0.79% ($\pm 9.54\%$).

Conclusion: Automatic measurement of volume by Lungcare© is highly reproducible by a second reader. In 75% of the cases no difference was seen.

MRCP in primary sclerosing cholangitis

C. Weber, G. Krupski, U. Seitz, R. Kuhlencordt, X. Rogiers, G. Adam; Hamburg/DE

Purpose: To evaluate MR-Cholangiopancreaticography (MRCP) as a low risk alternative to Endoscopic Retrograde Cholangiopancreaticography (ERCP) in diagnosing primary sclerosing cholangitis (PSC) and to compare diagnostic accuracy of different T2 W sequences.

Methods and Materials: Ninety-five patients (59 males and 36 females; mean age 41 years, range 16 to 71 years) with suspected PSC were examined in a 1.5 T MR unit using breath hold, transverse and coronal HASTE (TR/TE 4.4/90 ms), coronal-oblique RARE (TR/TE 5000/1100 ms) and thin-sliced HASTE (TS-HASTE; TR/TE 11/95 ms) sequences. Applying a five point scale, two investigators assessed the image quality blind. Morphologic criteria of PSC were documented and correlated with ERCP, which served as the gold standard, and sensitivity, specificity and diagnostic accuracy were calculated.

Results: PSC was confirmed in 69 of 95 patients (ERCP 95 of 95, liver biopsy 40 of 95). Qualitative analysis of the image quality showed no significant difference between RARE, HASTE and TS-HASTE sequences (3.4/3.5/3.2). The RARE sequence had the highest sensitivity (86%), specificity (78%) and diagnostic accuracy (84%) for the detection of PSC. The difference between HASTE and

Scientific Sessions

TS-HASTE was statistically significant ($p < 0.01$). A Klatskin tumor and a cholangiocellular carcinoma, which were misdiagnosed by MRCP, were diagnosed by brush biopsy in 2 of the 69 patients with confirmed PSC. Interobserver variability was adequate to good (kappa 0.4 to 0.7).

Conclusion: MRCP is proven as a reliable non invasive imaging method to diagnose and follow PSC. For a streamlined MRCP protocol the RARE sequence is mandatory and the HASTE sequence recommended.

B-172 14:09

Endoscopic ultrasound or MR cholangiography for bile duct calculi and strictures? An evaluation using 'evidence-based radiology' methods

C.J. McMahon, R.G. Gibney, D.E. Malone; Dublin/IE

Purpose: To evaluate the relative roles of endoscopic ultrasound (EUS) and MR cholangiography (MRC) in the diagnosis of common bile duct (CBD) calculi and in distinguishing malignant vs. benign extra-hepatic biliary strictures (EHBS).

Materials and Methods: Two focused clinical questions were constructed. A structured search of Pubmed and RSNA Index was performed. Retrieved studies were appraised for validity, strength and level of evidence (Oxford/CEBM scale: 1-5). Standard test properties and conditional probability graphs (CPG) were analysed. CBD calculi literature was divided into group A; MRC slice thickness ≥ 5 mm; group B; MRC slice thickness = 3 mm or 3D MRC sequences. Results expressed; sensitivity (95% confidence intervals), specificity (95% confidence intervals), positive likelihood ratio (LR+), negative likelihood ratio (LR-).

Results: CBD calculi:

Four studies merited inclusion (two level 1b, two level 3b).

Group A:

EUS: 0.80(0.45,1.15), 0.96(0.88,1.04), LR+ 18.4, LR- 0.21.

MRC: 0.40(-0.03,0.83), 0.96(-0.87,1.04), LR+ 9.2, LR- 0.63.

Group B:

EUS: 0.90(0.83,0.98), 0.99(0.97,1.01), LR+ 92.70, LR- 0.10.

MRC: 0.87(0.78,0.95), 0.95(0.91,0.99), LR+ 17.85, LR- 0.14.

EHBS:

Three studies merited inclusion (two level 3b, one level 4).

EUS: 0.80(0.63,0.97), 0.80(0.62,0.97), LR+ 4, LR- 0.25.

MRC: 0.90(0.77,1.029), 0.65(0.48,0.86), LR+ 2.51, LR- 0.15.

CPG analysis: with a pre-test probability > 60%, EUS or MRC can confirm, but neither can alone adequately exclude, a malignant obstruction.

Conclusion: CBD calculi: EUS and MRC are equivalent when 3 mm slices or 3D sequences are used. 5 mm MRC slice-thickness has poor sensitivity for CBD calculi. EHBS: Either EUS or MRC can confirm malignant EHBS. Neither test alone adequately excludes malignant EHBS; multi-modality imaging is required.

B-173 14:18

Value of magnetic resonance cholangiography in iatrogenic biliary

stenosis: Comparative study with surgery

P. Ottaviani, L. Menchini, F. Giulante, R. Manfredi, L. Bonomo; Rome/IT

Purpose: To determine the accuracy of Magnetic Resonance Cholangio-pancreatography (MRCP) in the assessment of iatrogenic biliary stenosis after laparoscopic cholecystectomy, compared to surgery.

Method and Materials: 28 patients (13M, 15W; median age 55.1 years; range 28-79) with clinically suspected iatrogenic bile duct stenosis were prospectively included. Magnetic resonance cholangiography was performed within six months before surgery and was considered to be the gold standard. Image analysis included site and length of the stenosis according to Bismuth classification and were independently determined by 2 radiologists. Discrepancies were resolved by consensus. MRCP/surgery concordance was assessed using K statistics.

Results: At MRCP 1/28 (3.6%) patients had type I stenosis, 5/28 (17.6%) type II, 18/28 (64.3%) type III and 4/28 (14.3%) type IV. Compared to surgery, MRCP correctly identified the level of biliary ductal obstruction according to Bismuth classification in (20/28) 71.4% patients. K-value was 0.82. MRCP overestimated level of biliary ductal obstruction in 5 patients and underestimated in 3 patients. Our purpose is to evaluate in which type of stenosis there is more discrepancy.

Conclusions: MRCP can accurately diagnose postoperative biliary strictures and can characterize and anatomically classify these injuries for the planning of reparative surgery.

B-174 14:27

Value of magnetic resonance cholangiography in sclerosing cholangitis:

Comparative study with ERCP

C. Liguori, L. Menchini, M. Mutignani, R. Manfredi, L. Bonomo; Rome/IT

Purpose: To evaluate the accuracy of magnetic resonance cholangio-pancreatography (MRCP) for the detection of sclerosing cholangitis (SC) and to compare MRCP findings to endoscopic retrograde cholangiography (ERCP) used as the gold standard.

Method and Materials: MRCP findings were evaluated in 27 patients with clinical symptoms and/or laboratory values as signs of cholestasis, who consecutively underwent magnetic resonance imaging. Two observers independently classified bile duct abnormalities and established the MRCP diagnosis in a consensus reading. The results of MRCP were compared with the definitive diagnosis based on the clinical history and laboratory and histological data and ERCP findings. The observers compared the biliary system seen with MRCP and ERCP in patients with confirmed SC to determine the main biliary obstruction.

Results: All exams were diagnostic (27/27). The diagnosis of SC was confirmed by clinical data and ERCP in 20 of 27 patients (74%). The sensitivity and specificity of MRCP were 95% (19/20) and 100% (7/7) respectively. Different bile duct abnormalities leading to the diagnosis of SC were depicted by MRCP and ERCP; more bile duct stenoses and pruning were seen with ERCP and more skip dilation with MRCP, which has been more useful in the localization of the main stenoses in the biliary tree.

Conclusions: In patients with SC, MRCP is a highly sensitive method and its diagnostic accuracy is comparable to that of ERCP. MRCP can be used as the preliminary non-invasive imaging modality for the diagnosis of SC.

B-175 14:36

"All-in-One" multislice computed tomography (MSCT) of potential living liver donors

T. Schroeder¹, A. Radtke¹, J.F. Debatin², M. Malago¹, E. Wembacher¹, S.G. Ruehm³; ¹Essen/DE, ²Hamburg/DE, ³Los Angeles, CA/US

Purpose: To assess parenchymal, vascular and biliary anatomy of potential living liver donors in a single diagnostic step.

Methods and Materials: 250 potential living liver donors underwent three-phase, dual-enhancement MSCT to delineate biliary, vascular and parenchymal morphology. For display of the biliary system the first image set was collected following the infusion of a biliary contrast agent. Subsequently, CT angiography was performed for display of the arterial as well as the portal and hepatic venous systems following automated injection of a conventional iodinated contrast agent. All data sets were reconstructed in 1 mm slices. Data analysis was based on source images, MPRs and 3D postprocessings, focussing on detection of biliary and vascular variants, exclusion of focal lesions in the liver and determination of hepatic volumes. Preoperative findings were correlated with intraoperative findings (available in 67 subjects).

Results: Technical failures were experienced in 7/250 examinations. 27 subjects presented with moderate adverse reactions on the biliary contrast agent. Incidental lesions were detected in 61 patients (59 x benign, 2 x malignant). The underlying biliary and vascular anatomy were displayed at least to the second intrahepatic branch in all but 7 cases. Detected anatomical variants involved the biliary (n = 121), the arterial (n = 101), the portal venous (n = 57) and the hepatic venous (n = 72) system. Correlation with intraoperative findings was excellent.

Conclusion: This outlined approach allows the reliable collection of all relevant pre-op data in a single diagnostic step. The comparatively high incidence of adverse reactions to the biliary contrast agent has to be considered.

B-176 14:45

Sonographic and histological liver changes induced by intraportal islet transplantation in diabetics

E. Angeli, M. Venturini, P. Maffi, F. Bertuzzi, A. Secchi, A. Del Maschio; Milan/IT

Purpose: No imaging modality can demonstrate islet presence, survival and function after intraportal transplantation in diabetics. Recently, we recognized at sonography liver echotexture abnormalities due to focal fatty changes (FFC) and related to islet survival. Our purpose was to determine prevalence and meaning of these abnormalities.

Methods and Materials: 30 diabetics submitted to 35 procedures of percutaneous intraportal transplantation of pancreatic islets had a regular sonographic follow-up. Liver sonograms and color Doppler of portal vasculature were performed before islet transplant, immediately after, at one month and every 6 months. Sonograms

Scientific Sessions

were evaluated for possible hyperechoic FFC and portal vein abnormalities. Liver biopsies were recently performed in 8 patients positive at sonographic evaluation. Results were correlated with serum liver enzymes, fasting C-peptide (fCP), glycated haemoglobin (HbA1c) and Exogeneous Insulin Requirement (EIR).

Results: No major alteration of liver enzymes and portal vein patency was observed. FFC consisting in micro (< 5 mm) or macro focal hyperechogenicity were found after 12/35 (34.3%) procedures, mostly with diffuse distribution. FFC were generally detectable at 6 months, lasting from 6 months to 7 years. FFC positively correlated with islet viability and function. Liver biopsies showed mild to moderate, mainly macrovesicular steatosis, focally and randomly distributed, and focal nuclear glycogen accumulation.

Conclusion: FFC are relatively frequent after intraportal islet transplantation. Clinical and histopathologic data show that FFC must be considered the expression of a prolonged islet over-working, determining the storage of fat in the liver cell, as already shown in the animal model.

B-177 14:54

Changes in splenic volume and correlation with platelet counts in healthy patients following hepatic resection for living liver donation

K. Khalili¹, S. Roach¹, M. Khalili²; ¹Toronto, ON/CA, ²San Francisco, CA/US

Purpose: To evaluate changes in splenic volumes (SV) in healthy living liver donors with correlation with splenic function through platelet values.

Materials and Methods: A retrospective review of 30 healthy adults undergoing right hepatectomy for living liver donation was undertaken. All patients had a preoperative and one post-operative CT scan performed and 10 patients had 2 post op CTs. The 1st scan was performed at a mean of 102 and the 2nd scan mean post-op day (POD) of 84 days. SV's were measured using previously validated techniques. Pre-op and all post-op platelet levels were also recorded and clinical charts reviewed.

Results: An increase in splenic volume (SV) was seen in 28/30 (93%) patients following liver donation. Overall, mean% SV rise was 45.9% (range -14.2 to 113.5%), the rise being significant ($p < 0.0001$, 95% CI 35.4 to 56.4%). In 5/10 (50%) patients of with 2nd post op CT, there was a continued rise in SV (mean 13.5%, range 2.9-23.8%, CTs obtained mean POD 56), in 5 patients there was a drop in splenic volume (mean 14.7%, range 7.0-30.2%, 2nd CTs obtained mean POD 133). We noted an inverse relationship between splenic volumes and number of days post-op. Calculated Correlation Coefficient (Pearson) for all CT scans ($r = -0.55$ (95% CI -0.74 to -0.30, $p < 0.0002$). There was no correlation between changes in platelet values and SV, ($r = 0.04$). No patient had evidence of hypersplenism.

Conclusion: The majority of liver donors undergo a *subclinical splenomegaly* which is greatest closer to the surgical date.

B-178 15:03

Prediction of the appropriateness of a donor liver with respect to hepatic macrosteatosis by phase-contrast MR imaging: Correlation with histopathologic findings

S. Kim, J. Lee, J. Han, J. Lee, B. Choi, K.-S. Shin; Seoul/KR

Purpose: To determine whether phase-contrast MR could reflect hepatic steatosis qualitatively and to analyze MR performance in predicting the appropriateness of potential liver donors in LDLT.

Materials and Methods: Fifty-seven candidates underwent 1.5 T-MR. A radiologist calculated mean hepatic and splenic signal intensity by 25 and three ROI measurements, respectively. The percent decrease (PD) in liver signal on the opposed-phase relative to in-phase was calculated. Linear regression analysis was used to correlate PD with degree of total, macro-, and microsteatosis. The distributions of PD in appropriate and inappropriate donors were compared. The accuracy for predicting the appropriateness of donor liver using PD was analyzed.

Results: Fifty-two and five of 57 candidates were categorized into appropriate and inappropriate groups for macrosteatosis by histology respectively. With linear regression analysis, PD was correlated with only the degree of total steatosis. There was a significant difference in PD between two groups. When the criteria of PD for inappropriateness was set to 20, PD correctly predicted the appropriateness as a liver donor in 53 of 57 cases. In 48 of 48 cases, PD below 20 correlated with < 30% macrosteatosis. In five of nine cases, PD above 20 correlated with > 30% steatosis. Three of remaining four cases with an overestimated degree of macrosteatosis by PD were revealed to have microsteatosis of various degrees.

Conclusion: Although MR reflects total steatosis regardless of its type, potential donors with normal PD may be exclusively appropriate for liver transplantation. However, core biopsy is necessary in donors with high PD to exclude the microsteatosis.

B-179 15:12

A novel method for analysis of postoperative liver regeneration in the adult live liver donor

C. Wald¹, H. Bourquin², J. Pomposelli¹, H.-O. Peitgen², E. Pomfret¹; ¹Burlington, MA/US, ²Bremen/DE

Aims: Novel image-analysis software conveys better understanding of the determinants and dynamics of liver regeneration after right lobe live donor hepatectomy which could lead to optimization of surgical technique and improve prediction of expected regeneration in an individual patient.

Methods: Dynamic spiral CT was performed preoperatively and 1 week, 1, 3, 6 and 12 months after right lobe liver donation. 60 datasets were analysed with Hepavision2 (© MeVis, Bremen, Germany). Quantification of total liver volume, portal venous territory volume, as well as portal venous branch length (PVBL) and diameter growth analysis in regenerating liver segments was performed.

Results: Most volume restoration occurred during the first 60 days postop with a continued significant increase throughout the first year. Female donors regenerated more slowly with a lesser end result, this difference was statistically significant at 6 and 12 months postop. Compromise in PV supply or HV drainage of the medial left lobe lead to asymmetric regeneration in 4 patients. PVBL consistently increased over time in all patients and the normalized volume to length growth ratio changed from 1.0 to 0.8 ($p = 0.005$) suggestive of an allometric growth pattern. Increase in PV branch diameter over time, though exceeded by growth of PVBL, suggests true vessel growth rather than passive stretching during liver regeneration.

Conclusions: Donor liver remnant regeneration is characterized by allometric growth. Compromise of the Segment IV vasculature may lead to asymmetric regeneration of the remnant lobe. Increase of both portal vein length and diameter suggests true vessel growth during regeneration rather than mere passive stretching phenomenon.

B-180 15:21

Sensitivity and specificity of multidetector spiral CT in the detection of hepatocellular carcinoma in patients undergoing transplant for cirrhosis

D. Cioni, R. Lencioni, J. Lera, A. Conti, C. DellaPina, D. Campani, F. Filipponi, L. Crocetti, C. Bartolozzi; Pisa/IT

Purpose: To assess the sensitivity and specificity of multidetector spiral CT (MDCT) in the detection of small hepatocellular carcinomas (HCC) in patients undergoing transplant for cirrhosis.

Materials and Methods: Eighty-three cirrhotic patients were examined with MDCT who proceeded to liver transplantation within 3 months. CT was performed with a LightSpeed Plus scanner (GE Medical System) by injecting 120 ml iodixanol (Vispaque, Amersham Health) at 5 ml/sec. Following a timing bolus (25 ml, 5 ml/sec), early arterial (pitch 6; 1.25 mm collimation), delayed arterial, and portal-venous phases (pitch 3; 5 mm collimation) were acquired. Two readers prospectively assessed number, location and size of HCC. CT findings were correlated lesion-by-lesion with findings at pathology examination.

Results: Pathology examination showed 69 HCCs ranging 0.5-5 cm in diameter (mean, 2.8 cm) in 36/83 patients. MDCT studies detected HCCs in 31/36 patients with 5 false-negative and 5 false-positive results (sensitivity, 86%; specificity, 89%; accuracy 88%; NPV, 89%; PPV, 86%). At lesion-by-lesion analysis, pathology examinations showed 13 HCCs < 1 cm, 35 HCCs ranging 1-2 cm, and 21 HCCs > 2 cm. MDCT detected 6/13 HCCs < 1 cm with 5 false-positives (sensitivity, 46%; PPV 54%); 25/35 HCCs ranging 1-2 cm with 10 false-positives and 20/21 HCCs > 2 cm with 1 false-positive. False-positives included dysplastic nodules (n = 7), fibrosis (n = 2), hemangioma (n = 1) and transient arterial enhancing pseudo-lesions (n = 6).

Conclusion: MDCT shows high sensitivity for detecting HCCs larger than 1 cm but is insensitive in depiction of sub-centimetre lesions. MDCT seems to have a substantial false positive detection rate, in particular in cases of 1-2 cm hyperenhancing arterial phase lesions.

Reassessing the MR signal findings of sinonasal adenocarcinoma versus (non-adenocarcinoma) epithelial malignancies

C. Ghirardi, R. Maroldi, D. Farina, B. Piazzalunga; Brescia/IT

Purpose: To evaluate MR signal on T2-weighted images in sinonasal adenocarcinoma versus non-glandular malignant tumors.

Materials and Methods: The pre-treatment MR images of 22 patients with histologically proved sinonasal malignancies examined from 1995 to 2004 were reviewed. Eleven cases were adenocarcinomas (10/11 intestinal-type adenocarcinoma, 1/11 a poorly differentiated adenocarcinoma); 11 tumors were non-glandular carcinomas (8/11 squamous cell carcinomas, 3/11 sinonasal undifferentiated carcinomas). Eight out of 9 males with adenocarcinoma were exposed to wood and leather dust, known as a carcinogen. Seven out of 11 adenocarcinomas arose within the nasoethmoid cavities. On T2-weighted images, the value of the most intense and the least intense tumor areas, and the intensity of a normal medial pterygoid muscle were recorded. To standardize measurements, the absolute values of tumor areas were related to the pterygoid muscle.

Results: The hyperintense components within adenocarcinomas were greater than those measured in non-adenocarcinomas (739.54 ± 267 vs. 459 ± 101 ; t-test, $p = 0.0039$). Standardized values (6.97 ± 1.27 vs. 4.16 ± 0.81 ; t-test, $p = 0.000091$), and the ratio between the greatest and the lowest signal value (RGL) within the tumor (1.86 ± 0.5 vs. 1.1 ± 0.08 ; t-test, $p = 0.000077$) differed significantly. If a threshold value of RGL equal or greater than 1.3 is chosen, sensitivity, specificity, positive predictive value, and negative predictive value for adenocarcinoma are 90.91%, 100%, 100% and 91.67% respectively.

Conclusion: Although tissue characterization is a challenge for imaging techniques, quantitative data provided by MR may help to differentiate adenocarcinomas from squamous cell carcinomas and sinonasal undifferentiated carcinomas.

B-182 14:09

Quantitative and qualitative characterization of vascularization and hemodynamics in head and neck tumors with a 3D magnetic resonance.

Time-resolved echo-shared angiographic technique (TREAT). Initial results
H.J. Michaely, K.A. Herrmann, H. Kramer, M.F. Reiser, S.O. Schoenberg;
Munich/DE

Purpose: To determine the additional diagnostic value of a 3D- time-resolved echo-shared angiographic technique (TREAT) for monitoring of dynamic contrast enhancement in the differential diagnosis of head and neck tumors.

Material and Methods: In 16 patients with head and neck tumors contrast agent administration was monitored with a 3D TREAT sequence on a 1.5 T MR-scanner using parallel imaging techniques (GRAPPA, factor 2). A frame rate of 1/2.3 sec was employed with a total of 20 frames. A regular 0.1 mmol/kg BW bolus of Gadolinium-DTPA was injected followed by a 20 ml flush of saline at a flow rate of 4 ml/sec. TREAT imaging was started 5 seconds after the bolus injection. Pre and post-contrast T1w GRE images were acquired. Two radiologists assessed the type of tumor vascularization, enhancement pattern and secondary effects (collaterals, early venous drainage). A semi-quantitative analysis was derived from software based signal intensity (SI) versus time curves of the tumor and the carotid arteries. SI measurements were also performed within the tumor on T1w GRE sequences for comparison.

Results: The high temporal resolution of the TREAT allowed visual and semi-quantitative differentiation of hypervasculated tumors (glomus tumor, nasopharyngeal fibroma) from hypovascularized tumors (squamous cell carcinomas). For different tumor types distinctive patterns of enhancement were found on SI measurements while post-contrast T1w GRE images showed no differences.

Conclusion: The application of TREAT imaging to monitor the passage of the contrast agent bolus yields additional information about the tumor vascularization and characterization without additional scan time or additional contrast media application.

B-183 14:18

Detection and delineation of laryngeal tumors using MR imaging with parallel acquisition technique (PPI MRI) and 16 row multidetector CT (MDCT)

W.H. Flatz, L. Jäger, M.J. Hempel, R. Brüning, R. Helmberger, S. Pfennig, S.O. Schönberg, M.F. Reiser; Munich/DE

Purpose: The aim of our study was to evaluate tumor detection and delineation of laryngeal tumors using parallel magnetic resonance imaging (MRI) acquisition methods (PPI) with GRAPPA reconstruction algorithm and 16-row multislice computed tomography (MDCT).

Materials and Methods: We examined prospectively 30 patients with suspected laryngeal carcinoma using both modalities. MDCT images were acquired at rest and during e-phonation using a 16 row MDCT. Axial and coronal reconstructed images with 1 mm slice thickness were obtained. T1-, T2-weighted, STIR and fat-sat images using Gd-DTPA were acquired on a 1.5 T MR scanner using a high resolution matrix of 512x384 and 3.5 mm slice thickness employing parallel MRI with GRAPPA reconstruction algorithm. Three radiologists evaluated the images. The imaging findings were compared with the clinical and histopathological details. For statistical analysis Crosstabs procedures and Kappa test were applied.

Results: The statistical evaluation of image interpretation shows sensitivity of 86%, specificity of 91% and negative predictive value of 96% for MRI. The corresponding values were 73%, 93% respectively 92% for the MDCT examinations.

Conclusion: Imaging of suspected laryngeal carcinoma using MRI with parallel imaging employing the GRAPPA reconstruction algorithm and 16 row MDCT are suitable for detecting and delineating laryngeal tumors.

B-184 14:27

Histological diagnosis of the endolaryngeal tumours through ultrasound-guided transcutaneous tru-cut biopsy

E. De Fiori, L. Preda, M. Ansarin, M. Bellomi; Milan/IT

Purpose: To evaluate the technical feasibility and the results of transcutaneous ultrasound-guided tru-cut biopsy of endolaryngeal lesions in patients with tumors impairing respiration and/or with relative contraindications to general anaesthesia, not suitable for laryngoscopic biopsy in the operating room.

Material and Methods: From August to December 2003, 7 patients (6 males/ 1 female, age range 53-78) with suspect endolaryngeal bulky neoplasm or recurrent disease were submitted to ultrasound-guided tru-cut biopsy. All had stress dyspnoea due to the tumoral airway stenosis associated with post-radiotherapy oedema in 5 patients treated previously by external beam radiotherapy. The diagnosis was based on clinical examination, with fibre optic laryngoscopy, and 16-slice CT examination.

Results: All biopsy specimens were obtained and were significant for diagnosis: In 6 cases the histological diagnosis confirmed the clinical hypothesis of malignant disease (invasive SCC). In one patient, previously treated by endoscopy and radiotherapy, the US biopsy specimen demonstrated granulomatous inflammatory tissue obstructing the laryngeal lumen at the glottic region. The patient underwent laser-assisted endoscopic therapy to alleviate the obstruction which caused a clinical deterioration and respiratory difficulties. Final pathologic examination confirmed biopsy diagnosis in all cases.

Conclusion: Our preliminary experience demonstrates the feasibility of the procedure in outpatient setting, with low costs and good accuracy. This procedure is indicated in patients with high risk for general anaesthesia and candidate for non-surgical treatment of laryngeal neoplasms.

B-185 14:36

Unexpected internal carotid artery (ICA) atherosclerotic stenoses at biphasic MDCT for neck cancer

N. Flor, G. Castellazzi, C. Missiroli, A. Curti, S. Soldi, G. Franceschelli, F. Sardanelli, G.P. Cornalba; Milan/IT

Purpose: To evaluate the frequency of unexpected atherosclerotic ICA stenoses in patients undergoing biphasic MDCT for neck cancer.

Materials and Methods: Fifty-seven patients (10 females, 47 males; age 64.4 ± 10.5 years, median 67; range 44-88) underwent four-row MDCT (LightSpeed Qx/i, General Electric) for neck cancer diagnosis, staging or follow-up. Protocol: 4x1.25 mm collimation, pitch 3, kVp 120, mAs 140, effective slice width 1.25 mm, reconstruction index 0.8 mm; 90-100 ml of non-ionic contrast agent at 2 mm/l, arterial (20-s) and late (50-s) phases. Postprocessing: multiplanar reconstruction; maximum intensity projection; volume rendering. Vessel stenoses were classed as severe (70-99%), moderate (30-69%), or mild (< 30%).

Scientific Sessions

Results: Atherosclerotic ICA with vessel stenosis was found in 38 patients (age 67.1 ± 9.8 , median 69) and 67 ICAs. Five patients (age 68.5 ± 3.8) had severe stenosis, bilateral ($n = 1$) or associated with contralateral moderate stenosis ($n = 4$). Seventeen patients had moderate stenosis (age 70.4 ± 9.8), bilateral ($n = 9$), associated with contralateral mild stenosis ($n = 5$), unilateral ($n = 3$). Sixteen patients had mild stenosis (age 64.8 ± 9.8), bilateral ($n = 10$) or unilateral ($n = 6$). Out of the 5 patients with unexpected MDCT-detected severe stenosis, four had a newly diagnosed neck cancer and in 2 of them the treatment planning was changed (one endarterectomy before neck tumor surgery, one combined oncologic/vascular surgery), while one patient with a previously treated neck cancer had carotid stenting.

Conclusions: Of 57 patients, 5 (9%) had unexpected severe ICA stenoses, three of them with a relevant impact on therapy. ICAs should be carefully evaluated for atherosclerotic disease during MDCT for neck cancer.

B-186 14:45 ♂

MR imaging of adenoid cystic carcinoma in the head and neck after carbon ion therapy

S. Kandatsu, R. Kishimoto, S. Komatsu, J. Mizoe, H. Tsujii;
Chiba-ken Chiba-shi/JP

Purpose: To evaluate the changes of MR imaging of head and neck adenoid cystic carcinoma after carbon ion therapy.

Materials and Methods: Follow-up MR imaging at 1.5 T was performed in 39 patients (17 men and 22 women; mean age 51 years; age range 27-80 years) with head and neck adenoid cystic carcinoma having received carbon ion therapy. The patients underwent T1-weighted and T2-weighted imaging including post contrast enhanced imaging. Perineural invasion was suspected if high signal intensity after contrast enhancement was seen along the cranial nerves. Size and signal changes in the tumor were observed for more than one year after the therapy.

Results: The mean tumor size before therapy was 36 mm (range 6-75 mm) in diameter. After one year of carbon ion therapy, the mean tumor size was 18 mm in diameter. Continuous reduction in size was recognized for more than one year. Low intensity areas on T2 weighted MR image became high intensity after therapy. Almost all of the local tumor sizes were reduced. In one case, new peripheral neural invasion which was not apparent before the therapy, occurred. Local recurrence within one year after the therapy was seen in one case.

Conclusion: Adenoid cystic tumors in the head and neck were quickly reduced after carbon ion therapy. Low intensity areas in the tumor became high intensity after the therapy on T2 weighted MR image, suggestive of tumor necrosis. Carbon ion therapy is effective even if perineural invasion is recognized.

B-187 14:54

Evaluation of local recurrence in re-staging of head and neck cancer: A comparison between PET and PET/CT

B.S. Halpern, M.A. Auerbach, K. Yeom, B.J. Fueger, W.A. Weber, O. Ratib, R.B. Lufkin, J. Czernin; Los Angeles, CA/US

Background: ^{18}F -FDG PET has a high accuracy in re-staging of head and neck cancer. The purpose of this study was to determine whether additional gains in diagnostic performance arise from the use of integrated PET/CT.

Materials and Methods: A total of 49 patients with a mean age of 59 ± 18 years were enrolled in our study. Histo-pathological verification served as the reference standard for tumor detection. This was defined as complete mass resection \pm radical lymph node dissection in 27 patients, direct endoscopical biopsy in 16 patients and sonography-guided biopsy in 6 patients. Two blinded reviewers analyzed in consensus all PET images and an experienced radiologist was also recruited to assess integrated PET/CT images.

Results: A total of 110 lesions were analyzed by histopathology and were therefore available for further evaluation. Of these, 67 sites (61%) were positive for malignancy and 43 (39%) negative for disease. PET and PET/CT showed an overall accuracy for lesion detection of 84% and 88% ($p = 0.06$), respectively. Sensitivity and specificity for PET were 78% and 93% vs. 84% and 95% with PET/CT. Values were similar when calculated on a patient-by-patient analysis. Accuracy, sensitivity and specificity for PET were 80%, 83% and 67% compared to 86%, 88% and 78% for PET/CT.

Conclusion: PET/CT tended to re-stage patients with recurrent head and neck cancer with a higher accuracy, sensitivity and specificity compared to PET alone.

B-188 15:03

Detailed ultrasound study of the angioarchitecture in superficial lymphomatous lymph nodes. Preliminary results

E.J. Bialek, W. Jakubowski, A.B. Szczepanik, R.K. Maryniak, R. Bilski, M. Prochorec-Sobieszek, K.T. Szopinski; Warsaw/PL

Purpose: To assess possible vascular patterns in lymph nodes confirmed on histopathologic evaluation to be affected by lymphoma, in order to obtain an adjunct to ultrasound differential diagnosis of lymph nodes diseases.

Methods and Materials: Prospective sonographic classification of angioarchitecture (power-Doppler) in 53 superficial lymph nodes intended for diagnostic excision was performed. Thirty seven patients with histopathologically recognized lymphoma were selected for this study (25 cervical lymph nodes, 11 axillary and 1 inguinal).

Results: The angioarchitecture regarded as characteristic for reactive lymph nodes was found in 41% of lymphomatous lymph nodes in this study; 32% showed the distribution of vessels described in metastases; others had angioarchitecture not previously classified or equivocal. A longitudinal vessel was found in 13 lymphomas: single (1) or branching (symmetric = 2; asymmetric = 7; irregular = 3). Multiple vessels, partially branching, entering the node in a few rows from its longitudinal side were present in 5. Short vessel segments ($n = 5$): regularly (1) or irregularly (4) distributed in the hilum area or centrally. Multiple vessels branching irregularly with avascular areas were visible in 4 nodes. Peripheral vessel distribution was found in 8 lymphomas: vessel segments (3); chaotically branching vessels (3); concomitant single central segments (2). Peripheral and central vessels were shown 2 lymphomas.

Conclusion: The angioarchitecture in lymphomatous superficial lymph nodes is diverse and difficult to classify. It may vary from patterns met in normal or reactive lymph nodes to patterns found in metastases. *Work was financially supported by grant from State Committee for Scientific Research.*

B-189 15:12

Improved sentinel node detection and pre-operative planning in oral cavity cancer by image fusion of CT and SPECT versus planar imaging

M. Nuyens, F.G. Fuechsel, P. Zbaeren, T. Krause; Berne/CH

Purpose: Sentinel lymph node (SLN) scintigraphy for oral cavity carcinoma is a recently described method, mainly done with planar scintigraphy (pISc) and γ -probe detection. Precise SLN localisation is difficult, particularly around the injection site. We aim to evaluate the feasibility of fusion imaging of CT and SPECT (FICT) in pre-surgical planning and the advantages over pISc only.

Materials and Methods: SLN scintigraphy (Technetium-99m nanocolloid) was performed in 30 patients (mean: 65 yrs, 16 male, 14 female) with oral cavity squamous cell carcinoma (cT1/cT2, cN0). All patients underwent pISc and 10 patients had pISc and FICT. SPECT/CT were overlain with commercially available software utilising body markers for co-registration. All patients underwent intraoperative SLN detection, frozen-section histology and neck dissection level I-III. Predicted number, side, and anatomical level were compared between pISc versus FICT and both with intra- and post-operative findings. SLN resection time was recorded.

Results: SLN dissection revealed metastases in 39%. Pre-operative pISc and FICT was feasible in all cases. All 90 SLN were identified and resected. The predicted number of SLN was correct in 68% with pISc and in 98% with FICT. Both methods predicted the side correctly in 100%. The level was incorrectly diagnosed by pISc in 16% of all SLN versus 9% by FICT. The mean resection time per SLN was 13 min after pISc reduced to 8 min after FICT.

Conclusions: FICT is a feasible and reliable tool in SLN localisation. Compared to pISc it allows better prediction of number and anatomical localisation and significantly improves SLN resection.

High resolution superparamagnetic iron oxide enhanced MR imaging for the diagnosis lymph node metastases in patients with head and neck cancer

M.G. Mack, J. Rieger, M. Baghi, J.O. Balzer, R. Knecht, M. Helbig, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To evaluate the diagnostic accuracy of Sinerem® enhanced MR imaging compared to standard MR imaging for the detection of lymph node (LN) metastases in patients with head neck cancer using histology as a gold standard.

Methods: 35 patients (mean age 57 years, range 39-76 years) were examined with unenhanced and intravenous Sinerem®-enhanced (2.6 mg Fe/kg b.w.) MR imaging with T1w, high resolution TSE T2w and T2w MEDIC sequence to detect possible LN metastasis. Resected LNs were analyzed by a pathologist and results

Scientific Sessions

were compared with MR findings. Clinical evaluation included ultrasound and palpation.

Results: A total of 560 LN were histopathologically evaluated, of which 48 were determined to be metastatic based on histopathology. MR imaging demonstrated 44 of the 48 LN metastases. The sensitivity was 91.7% and the specificity 100%. Standard MR imaging classified 34 of 48 lymph node metastases correctly based on the evaluation of size using a cut off of 10 mm for the short axis diameter, resulting in a sensitivity of 71% and a specificity of 96%. Using a cut off of 7 mm on plain MR imaging the sensitivity was 89%, however the specificity dropped down to 67%. Clinical N-staging was correct in 46%, Sinerem enhanced MR imaging was correct in 94%. 4 of 14 histologically N0 patients were clinically staged as N0. MR imaging staged 13 patients correctly as N0. Clinical examination staged 4 patients, Sinerem MR imaging 12 of 13 patients with contralateral LN metastases correctly.

Conclusion: Sinerem MR imaging improves the N-staging of patients with head and neck cancer.

Pancreatic mass biopsy: Comparison 20 G fine needle trucut biopsy (FNTB) with fine needle aspiration cytology (FNAC)

A.-M. O'Connell, M.C. Hurley, A.N. Keeling, M.J. Lee; Dublin/IE

Purpose: Historically, FNAC has varying sensitivity, specificity, and accuracy in diagnosing abdominal lesions. A 15-20% insufficient sampling rate is associated with FNAC. We compared 20 G FNTB with historic FNAC results.

Materials and Methods: A retrospective review of 37 patients (M:F=25:12, mean age 60.78 yrs) (39 biopsies) was performed (US guidance in 38 and CT guidance in 1). Masses were located in the head (58%), body (12%), tail (3%) and uncinate process (27%). The mass size ranged from 1.5-4 cm (mean 2.2). No cyologist was available on-site. Comparison was made between 20 G FNTB and historic FNAC results regarding positive diagnostic rate, insufficient sampling rate and complications.

Results: An average of 2.03 passes (range 1-3) was performed. An accurate diagnosis was made in 32 of 39 biopsies (82%). Malignant diagnoses consisted of primary adenocarcinoma (25), focal pancreatitis (2), metastases (1), and lymphoma (1). 8 patients had either benign diagnoses (3), insufficient sampling (2) or inflammatory pathology (3). Seven of these latter 8 patients had a laparotomy. Benignity was confirmed in 3 and malignancy found in 4. The remaining patient had a repeat biopsy which identified malignancy. No significant complications were encountered. Sensitivity of 86.48% and specificity of 100% for FNTB is observed.

Conclusion: 20 G FNTB under ultrasound-guidance yields a significantly higher diagnostic accuracy (82%) than FNAC (69-76%), without an increase in complication rate. A greater insufficient sampling rate for FNAC (15-20%) than for FNTB (5.1%) is observed. 20 G FNTB is the method of choice for biopsy of pancreatic tumours, especially where no onsite cytology is available.

B-192 14:09

Percutaneous drainage of infected pancreatic fluid collections

M. Navalho, F. Pires, A. Duarte, A. Gonçalves, P. Alexandrino, I. Távora; Lisbon/PT

Purpose: The objective of our study was to review and report the results of percutaneous drainage of infected pancreatic fluid collections in patients with severe acute pancreatitis.

Methods and Materials: A retrospective review was performed of 30 patients with infected pancreatic fluid collections from complicated acute pancreatitis that were drained percutaneously under sonographic guidance. The patients were managed between 1993 and 2003, in a gastroenterology intensive care unit, and had a mean age of 58.4 years old. Gallstones were the most common cause of the pathologic process. The diagnosis was based on imaging, laboratory and bacteriological findings.

Results: Of the 30 patients, 19 (63%) were cured with percutaneous drainage and antibiotic therapy. In this group the mean c-reactive protein (CRP) value at the beginning of treatment was 172.8 mg/L and 102.5 mg/L at the end. Of the patients who were not cured with percutaneous drainage, one died (3.3%) and 10 (33.3%) required surgery. In this last group the mean initial CRP value was 190.9 mg/L, and 145.4 mg/L when the catheter was removed and the patient sent to surgery. There were four hospital deaths (40%) on the patients submitted to surgery. The catheterization had a mean duration of 21 days, and cultures were positive in 29 (96.7%) patients at the beginning of drainage. The most frequently seen organisms were *Escherichia coli*, *Staphylococcus aureus* and *Enterococcus faecium*.

Conclusion: This study confirms that infected pancreatic fluid collections can be safely and effectively treated, in most patients, with percutaneous catheter drainage.

B-193 14:18

Percutaneous cysto-gastrostomy using a combined, 2 steps, sonographic-endoscopic procedure in the treatment of pancreatic pseudocysts

Z. Spirchez, M. Tantau, R. Badea; Cluj-Napoca/RO

Purpose: To evaluate the efficacy of a modified echoguided percutaneous catheter drainage (PECD) in the management of pancreatic pseudocysts.

Methods: 10 patients (8 men and 2 women, mean age 40) with symptomatic large (median diameter 8 cm, range 6-16 cm) pseudocysts were treated. The underlying diagnosis was acute (8) and chronic pancreatitis (2). PECD was performed using 8-10Fr pigtail catheters, which were placed into the PSC under ultrasound guidance using a transgastric approach. The catheters were left in situ for a few days (mean 4, range 3-6) until no residual pseudocyst was demonstrated on ultrasound. The amount and aspect of the drained fluid were noted. The external end of the catheter was then cut and pulled-in the stomach using upper endoscopy. The patients were followed-up for 6 weeks and in case of no recurrence, the catheter was removed from the stomach and PSC using endoscopy.

Results: The transgastric approach was successful in all but 2 patients, in which the catheter did not pass through the stomach. There were no procedure-related complications. During the follow-up (6-24 months) the drainage was successful in 9 cases, including those with transabdominal approach. One patient developed an abscess 1 week after the catheter was endoscopically removed and was operated.

Conclusions: PECD of pancreatic pseudocysts with endoscopic internalization of the external end is a safe, minimal invasive and simple procedure with good results at follow-up. Maintaining an external drainage for short period allows monitoring the patency of the catheter and the aspect of aspirate.

Percutaneous gastrostomy (PG) with T-fastener gastropexy: Reduction in complication rates with early removal of T-fasteners

A. Foster, M. Given, E. Thornton, M. Lee; Dublin/IE

Purpose: T-fastener gastropexy has been shown to prevent peritoneal leaks and the literature recommends removal at 10 days. We reviewed a series of patients in whom T-fasteners were removed at shorter time intervals after PG to see if there was a reduced complication rate.

Methods and Materials: 113 patients (M:F=68:45 age range 18-81; mean age 67 years) were reviewed. Indications for PG included oesophageal cancer, head and neck cancer, and a variety of neurological disorders. Four T-fasteners were inserted in each patient using standard technique. T-fasteners were removed at different time intervals depending on the procurement of nursing home beds. In our study we defined 'early' removal as less than 2 days and 'delayed' removal as 3 days or more.

Results: In the overall cohort, minor complications were recorded in 30/113 patients (27%) with no complications in the remaining 83 patients. In 10/30 patients local infection occurred requiring antibiotic therapy, and 20/30 patients experienced pain at the gastrostomy site. In 69/113 patients (61%) T-fasteners were removed within 2 days. There was a statistically significant reduction in complication rate with 'early' removal compared to 'delayed' removal [8/69 (12%) vs 22/44 (50%) p < 0.05]. In the early removal group 6 patients experienced pain and 2 infection. In the delayed group there were 22 minor complications- infection (n = 8) and pain (n = 14). No peritubal leaks or other major complications were seen.

Conclusion: Removing T-fasteners earlier than 10 days is feasible. Minor complications including local pain and infection, increase in incidence with longer T-fastener dwell times.

Super selective percutaneous treatment of liver transplantation cholangitis (LTC). Technical aspects and biochemical parameters for graft salvage

R. Lopez-Benitez¹, H.M. Barragan-Campos², G.M. Richter¹, G. Kauffmann¹, T. Marinelli¹, P.J. Hallscheidt¹; ¹Heidelberg/DE, ²Paris/FR

Purpose: Cholangitis is a well known and common complication in liver transplantation, specially in those cases with prolonged intraoperative times. We present here a short series of cases treated percutaneously, with an radiologically interventional superselective approach, that clearly demonstrate the benefits of a prolonged and prompt treatment as an effective therapeutic option for the salvage of liver transplant.

Materials/Methods: A total of 570 patients had undergone partial related or total cadaveric liver transplantation in a 16-year period (1987-2003). A total of ten patients complicated with chronic colangitis where included in this study. Study patients where treated in a percutaneous technique, but only half of the group (study group) was treated with a superselective lavage of the biliary tree branches. Liver function parameters (ALT, AST, AP, GGT and bilirubin) and systemic inflammatory parameters (CRP, Leucocytes) where assayed, and correlated with the number of interventions and clinical status of the study group. When required, complications such as stone removal or stenosis dilatation where performed.

Results: At the time of this report, 80% of the cases treated with this technique had prolonged graft survival. Almost all of this cases were treated as ambulatory patients with clear improvement in their clinical and biochemical parameters. Those patients treated with conventional techniques had a 100% mortality in less than a year.

Conclusion: Despite the high mortality rate of conventional LTC percutaneous treatment, our technique demonstrated a significant higher survival rate. However, this approach requires prolonged treatment times with several minimally invasive interventions and multidisciplinary care.

B-196 14:45

Palliation of pancreatic cancer by combined biliary and duodenal stenting

S. Profili, C. Urigo, A. Manca, F. Meloni, L. Canalis, F. Salaris; Sassari/IT

Purpose: To assess usefulness of combined biliary and duodenal stenting for the palliation of inoperable pancreatic cancer.

Materials and Methods: We report our experience on 5 patients (2 men, mean age 61.8 years) with inoperable pancreatic cancer, causing stricture of the common bile duct and second portion of duodenum, treated by implantation of 9 self-expandable metal stents and one plastic prosthesis inserted exclusively under fluoroscopic view. All patients presented with dysphagia and jaundice. Percutaneous insertion of the biliary stent (3 Memotherm, 1 biliary Wallstent, 1 Carey-Coons) was performed immediately before or 2-3 days after the duodenal stent (2 AV-Wallstent, 2 enteral Wallstent, 1 Choo) which was placed perorally.

Results: Technical and clinical success were obtained in all cases. All patients had a rapid improvement of dysphagia and were able to resume a semi-solid diet; serum bilirubin regressed to normal values in about 10 days. Mean follow-up was 7 months. Duodenal stent migration occurred in 1 case after 18 days; urgent laparotomy revealed colonic perforation: stent removal and sigmoid resection were performed. One patient developed recurrent dysphagia because of tumor in- and overgrowth after 4 months; a second coaxial stent was inserted with only partial relief of symptoms.

Conclusion: Despite the limited number of cases treated and the complications observed, combined recanalization of biliary and duodenal strictures allowed good palliation of symptoms and should be considered an effective alternative to palliative resection for advanced pancreatic cancer.

B-197 14:54

Follow-up of percutaneous transhepatic biliary drainage for malignant obstructive jaundice

X. Qian, D.C. Dai, R. Zhai; Beijing/CN

Purpose: To investigate the therapeutic efficacy of percutaneous transhepatic biliary drainage (PTBD) for malignant biliary obstruction and its affecting factors.

Materials and Methods: A total of 233 patients with malignant biliary obstruction were treated in our hospital with PTBD by placement of the metallic stents and/or plastic tubes. The patients were followed up with clinical and radiographic evaluation. Meanwhile, the serum level of total protein, hemoglobin, ALT, HBDH, ALP, GGT, BUN, and Cr were determined. Procedure- and device-related complication were recorded. The patients' survival and stent patency rate were calculated with Kaplan-Meier survival analysis.

Results: PTBD were successfully performed in all the patients. Stent placement

were conducted in 136 cases. One hundred cases were treated with only 1 stent, 20 cases had 2 stents for bilateral drainage and 16 had 2 stents for long strictures, made stent in stent. The other 97 patients received plastic catheters. The serum level of total bilirubin reduced from 349.2 ± 155.6 mmol/l before to 178.9 ± 141.2 mmol/l after PTBD ($t = 17.90$, $p = 0.000$). Sixty-two patients had incorporate infection before procedure and 23 of them were cured after procedure. Twenty-nine patients got inflammation after procedure. Thirty cases died within 30days. The mortality within 30days was related to age and serum level of bilirubin, protein and BUN etc. After PTBD, the re-occlusion occurred in 51 patients, and catheters broke off in 7. The median survival time was 7.3 months and median patency time was 14 months.

Conclusion: PTBD can provide good palliative drainage. It can also improve other condition caused by biliary obstruction.

B-198 15:03

Role of covered stents in biliary intervention

A. Bruni, F. Fanelli, M. Bezzi, S. Vagnarelli, M. Corona, L. Di Reze, G. Orgera, P. Rossi, R. Passariello; Rome/IT

Purpose: Evaluate the efficacy of e-PTFE covered stent (VIABIL-Gore) in the treatment of malignant biliary strictures.

Material and Methods: From 2001, 65 patients (mean age 69.4 y) with malignant common bile stricture were treated with an e-PTFE covered stent-graft (Viabil-Gore). The Viabil is a self-expandable stent-graft with an inner ePTFE/FEP lining and an outer supporting a structure of nitinol wire. Biliary obstruction was secondary to pancreatic carcinoma (n = 38), cholangiocarcinoma (n = 10), gallbladder cancer (n = 6), metastatic lymphadenopathy (n = 11). The stricture was located in the upper third of the common bile duct in eight patients, in the middle portion in 43, and in the lower third in 14. Sixty-nine stent-graft were implanted: 20 with side holes and 49 without holes. In 62/65 patients the distal end of the device was deployed in the duodenum. Clinical evaluation and assessment of serum bilirubin and liver enzyme levels were done before stnt placement and at 1, 3, 6, 9 and 12 months.

Results: Stent-graft placement was successful in all cases. The 30-day mortality rate was 11%. The survival rates were 40% at 6 months and 20.2% at 12 months. The stent patency rate were 91%, 78% and 78% at 3, 6 and 12 months respectively. After a mean follow-up of 37.2 months we reported acute cholecystitis in 6 cases (9.2%). Complications other than stent occlusion occurred in 12 patients (18.4%). No migration of the stent-graft was observed.

Conclusion: e-PTFE covered stent-graft seems to be an effective tool in case of malignant strictures of the common bile duct.

B-199 15:12

Percutaneous treatment of urological complications occurring after renal transplant

D. Righi, A. Doriguzzi Breatta, S. Barbero, A. Ruffino, A. Calvo, G. Gandini; Turin/IT

Purpose: To value the efficacy of Interventional Radiology in the treatment of urological complications post renal transplant.

Materials and Methods: Between November 1981 and January 2004 in our Renal Transplant Unit surgeons performed 1637 transplants. The incidence of urological complications was 9.4% (154/1637); of these, 134 cases underwent percutaneous treatment: 71 ureteral obstructions, 37 urinary fistulas, 25 collections and 1 urinary incontinence. In all the obstructions and fistulas first we performed a percutaneous pyelostomy; 55 obstructions underwent uretheroplasty. The collections were treated by percutaneous drainage and aspiration.

Results: We achieved technical success in 128/134 cases (95.5%). The follow-up (median 57 months) showed clinical success in 79/128 cases (61.7%). The specific results in case of obstruction showed a complete success in 3 cases of clot obstruction an 1 mycetoma. The complication was solved by urotheroplasty in 37/55 cases (67.3%). We achieved complete success in 21/35 urinary fistulas (60%) and in 17/22 collections. The procedure related major complications were 2/134 (1.5%).

Conclusions: The immediate and late results of percutaneous treatment in the urological complications post renal transplant show the efficacy of Interventional Radiology procedures. Because of its poor traumaticity, low incidence of complications and mortality rate close to 0%, percutaneous approach could be considered as the first choice in the therapy of urological complications post renal transplant. Even in unsuccessful cases, Interventional Radiology allows a reliable diagnosis of the complication and to delay the surgical procedure in conditions of election.

Ultrasonography-guided intraneural injection for intractable limb contracture control

J. Lee, Y. Lee; Daegu/KR

Purpose: To evaluate the feasibility of ultrasonography-guided intraneural nerve block to control intractable contracture of extremity.

Materials and Methods: Thirty-two patients showing muscular contracture of their extremities were controlled by 50 intraneural injections of nerve conduction inhibiting drugs. Among the 32 patients, male and female were 28 and four, subsequently. The age of patients ranged from two to 75 years old with mean age of 21. The target nerves were sciatic ($n = 30$), tibial ($n = 7$), musculocutaneous ($n = 9$) and other nerves ($n = 4$). Injected drugs were 2–5 ml lidocaine or phenol. Lidocaine ($n = 41$) was used for temporary nerve block and Phenol ($n = 9$) was for permanent block. Ultrasonography was done using 7–15 MHz linear transducers. After identification of the nerve, 22-gauge needle was inserted into the nerve and the drug was injected until the target nerve expanded to double in its diameter. The success of intraneural injection was confirmed by checking the increased nerve size and immediate improvement of the muscular contracture. The follow-up study was performed until the recurrence of spasticity.

Results: In 50 injections, nerve expanded and immediate release of the contracture occurred. No complication occurred by intraneural injection. In Lidocaine injection group, the effective period ranged from one to 70 days (average = 13 days). In Phenol injection group, the effect lasted from 23 to 765 days (average = 297 days).

Conclusions: Ultrasonography-guided intraneural nerve block showed perfect success rate in extremities. Lidocaine injection showed favorable effect for temporary nerve block. Phenol injection was feasible to control muscular contracture of extremities in long-term follow-up.

Passive guidewire tracking on road maps - a phantom study

R. Meckle, O. Bieri, C. Hashagen, K. Scheffler, D. Bilecen; Basle/CH

Purpose/Introduction: The purpose of this study was to overlay images obtained with fast MR imaging scans onto a previously acquired roadmap for the passive visualization of a guidewire/balloon catheter for MR-guided endovascular interventions.

Subjects and Methods: All examinations were performed on a whole-body MR scanner at 1.5 Tesla. A magnetization prepared 2D FISP sequence was used to generate a contrast-enhanced roadmap. The first images were averaged to generate a mask, subsequent time frames were complex subtracted. All complex subtracted images were added up to create a roadmap. For passive tracking of a new guidewire prototype, data were rapidly acquired using a balanced steady-state free precession (b-SSFP) sequence and images were overlaid in near real time onto the roadmap. The entire procedure was performed in a phantom study. A single high-grade stenosis was modeled in the phantom to allow balloon angioplasty.

Results: Preliminary results indicated sufficient contrast between the passive guidewire and a contrast-enhanced MR-roadmap. A near real-time guidance of the tip of the guidewire was feasible. Inflation and deflation of a conventional balloon catheter was also monitored at the level of the artificial stenosis.

Discussion/Conclusion: The information from fast b-SSFP acquisitions was successfully overlaid onto a roadmap to visualize the tip of a guidewire in phantom studies.

Validation of a fixed model as a method of training in interventional radiology

P.R. Healey, A.E. Healey, S. Johnson, T. How, D.A. Gould; Liverpool/UK

Purpose: Simulator models are increasingly being used in medical training. The

commonest type are fixed models. Few medical training models have been validated as a method to train. Quantitative appraisal and assessment has been suggested as a method for maintaining standards. At present no criteria for assessment and no method of reproducible testing has been formulated.

Materials and Methods: A transparent polymer model of a female vascular tree used with optical cameras, light through transmission and a plain radiograph back drop was used to simulate the appearances of fluoroscopy during an interventional radiological procedure. A range of volunteers of varying interventional radiological experience were set tasks to complete and were videoed using the model. Two cohorts of trainees, both groups trained conventionally, and one trained on the model were assessed on the model. The time to completion of tasks and assessment of the operator's ability by several independent blinded expert interventional radiologists were performed.

Results: There was a significant difference between experts and trainees ability to perform tasks on the model. A rapid improvement and then plateau in ability in both experts and trainees was seen. The model seems to be a valid training tool for the development of basic interventional radiological skills. An improvement in the confidence of the trainees in dealing with real world interventional radiological tasks was also demonstrated.

Conclusions: Fixed models of this type does show some benefit in training, however the model does lack inherent flexibility that is required for convincing simulation.

Minimally invasive close-chest method for creating myocardial infarction in swine

G.A. Krombach, S. Kinzel, A. Mahnken, R.W. Günther, A. Buecker; Aachen/DE

Objectives: To evaluate a closed-chest model for reperfused and occlusive myocardial infarction (MI) in pigs and to report experiences and pitfalls.

Material and Methods: In 44 pigs, a balloon catheter was advanced into the left coronary artery (LAD), under fluoroscopic guidance. The balloon was inflated and occlusion of the vessel angiographically confirmed, while ECG was monitored. If ventricular fibrillation occurred, direct current defibrillation was performed. In 6 animals, the balloon was left inflated, to obtain occlusive infarction. In all other cases, the balloon was deflated after 45 min. After the experiments were finished, the hearts were stained with TTC for assessment of infarct size.

Results: MI was successfully induced in 34 animals. Mean size of MI was $15.8 \pm 5.1\%$ of left ventricular surface area for reperfused and $21.5 \pm 8.7\%$ for occlusive infarcts. In one pig, TTC did not confirm infarction. In 26 pigs, ventricular fibrillation occurred. Defibrillation was successful in 17 pigs. Failure rate due to ventricular fibrillation decreased from 42% (6) in the first 14 to 10% (3) in the following 30 animals. One animal died due to technical failure of the ventilator. After initial experiences, we used balloon catheters with a diameter of 2 - 3 mm, instead of 4 mm. The smaller balloon sizes were used so as to decrease the incidence of fibrillation.

Conclusions: The described technique of LAD occlusion presents a less invasive alternative to open chest models. The major pitfall, causing fatal arrhythmia, was over-dilatation of the LAD.

B-204 14:27

Photodynamic therapy of arthritis: An in vitro feasibility study

I. Hilger, S. Graefe, A. Hansch, O. Frey, W.A. Kaiser; Jena/DE

Purpose: To investigate if arthritis could be treated minimal-invasively using photodynamic therapy and to elucidate the effects of 2 different photodynamic agents in different cell systems which are present in arthritic joints.

Materials and Methods: Endothelial cells, fibroblasts and macrophages from mouse were incubated with Foscarn® and Fospeg® (Biolitec, Jena) at different concentrations (0.01 to 100 microM) and incubation times (30 min to 48 h). Cytotoxicity was determined by measuring the activity of cellular dehydrogenases with and without application of laser light ($\lambda = 652$ nm; power density: 10 J/cm², 50 sec). The intracellular localization of the agents was determined using confocal laser scanning microscopy (CLSM), the mechanisms of cell death by FACS analysis after propidium iodide and annexin-V staining.

Results: All investigated cells showed a distinct decrease of cell viability with increasing concentration and incubation times with the photodynamic agent (e.g. no viable cells at concentrations higher than 10 microM and after more than 2 h incubation time). Moreover, compared to the dark cytotoxicity (no laser light), a distinctly higher cytotoxicity was observed after light application. CLSM showed an intracellular agent accumulation in cytoplasmatic regions in the proximity of the cell nucleus. Cell death was predominantly induced by necrosis.

Conclusions: Local concentrations of at least 10 microM photodynamic agent should be effective for the minimal-invasive treatment of arthritic joints.

Efficacy of alternative embolisation devices in an experimental aneurysm model

C. Roth, I.Q. Grunwald, T. Struffert, B. Romeike, R. Eymann, W. Reith; Homburg a.d. Saar/DE

Purpose: The most commonly used embolization device for intracerebral aneurysms are GDC-Coils. Other embolization devices like Matrix-Coils or the liquid embolization system ONYX (EVOH) are not used in daily routine for the treatment of intracranial aneurysms because they seem to bare more risks like thrombembolic events (ONYX) or harder handling (MATRIX). The aim of the study was to evaluate the efficacy and safety of both alternative embolization devices under anticoagulation in comparison to GDC-Coils in an experimental aneurysm model in rabbits.

Materials and Methods: 35 aneurysms were induced. 5 Animals serve as a control group. 10 aneurysms were treated with GDC-Coils, 10 were treated with Onyx and 10 with Matrix-Coils. Heparine was administered during embolization. Aspirine was administered until sacrifice. Occlusion rate, recanalization rate und histologic evaluation are being analysed.

Preliminary Results: Excellent occlusion rates (100%) could be achieved in all embolized aneurysms so far. Radiologically determined recanalization rate is up to now low (0). Histologic evaluation of 2 animals from the Onyx group and one of the Matrix group did not show recanalization. Anticoagulation either during embolization or long-time anticoagulation doesn't seem to affect the occlusion or recanalization rate of aneurysms treated with GDC-Coils, Matrix-Coils or ONYX.

B-206 14:45

Restenosis inhibition by non-stent-based local drug delivery

U. Speck¹, B. Scheller², C. Abramjuk¹; ¹Berlin/DE, ²Homburg a.d. Saar/DE

Purpose: Drug-eluting stents have shown promising anti-restenotic effects in clinical trials. Their efficacy is believed to depend on the sustained release of antiproliferative drugs. Animal studies by our group indicate persistent efficacy of drugs even after very short exposure of the vessel wall.

Methods and Materials: Paclitaxel was dissolved in CM or coated on balloons. Stents were crimped on paclitaxel coated balloons. 5-6 pigs each received 2 coronary stents applying slight overstretch by using either (a) uncoated balloons, bare stents, and plain CM, (b) the same but paclitaxel in CM, (c) paclitaxel-coated PTCA balloons with premounted bare stents and plain CM, (d) commercial premounted Cypher stents and plain CM. Restenosis was assessed 4 weeks later by angiography and histomorphometry. Based on the results of comprehensive animal experiments clinical trials were initiated.

Results: Treatment was successful in all animals. No adverse events attributable to paclitaxel in the CM or balloon coating were observed. Reangiography indicated pronounced restenosis in the control group and least restenosis in the animals treated with a coated balloon. Histomorphometry confirmed the efficacy of the 3 routes of drug delivery with the most impressive effect of the coated balloons. The structure of clinical trials and first results will be presented.

Conclusions: Paclitaxel added to CM or coated on PTCA catheters is effective in inhibiting restenosis in the porcine coronary overstretch model. Non-stent-based drug delivery may overcome some problems associated with stent coating and provide additional flexibility in restenosis inhibition.

B-207 14:54

Evaluation of balloon expanded stents in a cone-beam flat-panel volumetric-CT (FP-VCT)

G. Heidrich, S. Wenzel, K.-P. Hermann, C. Dullin, E. Grabbe, M. Funke; Göttingen/DE

Purpose: An experimental study was preformed to compare the visualisation of balloon expanded stents using a cone-beam flat-panel volumetric-CT (FP-VCT) with high isotropic spatial resolution and an 8-row multidetector-CT (8-MDCT). **Methods and Materials:** Seven different balloon expanded stents from 2 to 5 mm diameter were implanted in a flexible plastic tube of a vessel phantom. This phantom was examined with the 8-MDCT and the FP-VCT applying different acquisition protocols. The datasets were postprocessed on a workstation including 3D-reconstructions in Volume-rendering-technique (VRT) with axial and sagittal projections and overviews. Based on an evaluation score data analysis was performed.

Results: The visualisation of the stents was substantial superior using the FP-VCT as with the 8-MDCT. The stents material as well as the stent lumen could be exactly depicted. The smallest commercial available stent with a diameter of 2 mm could be excellently illustrated.

Conclusion: In experimental preclinical setting FP-VCT is an excellent diagnostic tool for the evaluation of balloon expanded stents and their lumen. Due to the high isotropic spatial resolution FP-VCT could also clearly depict the smallest 2 mm commercial available cardiac stent.

B-208 15:03

Development and animal experimental testing of a percutaneous thrombectomy device

R.K. Verma, J.E. Pfeffer, R.W. Günther, T. Schmitz-Rode; Aachen/DE

Purpose: To develop a thrombectomy device which is adequately steerable, quickly placeable and allows removal of large thrombus amounts in cases of extensive pulmonary embolism or deep venous thromboembolism.

Materials and Methods: The developed device consists of a self-expandable plastic-coated basket, mounted at the catheter-tip, which allows to suck and extract thrombus material. A small metal probe is manually moved within the suction channel to prevent obstruction. In vitro-tests in a stationary pulmonary circulation model were performed, followed by experimental tests in 6 sheep. Consolidated thrombus material was introduced over the right jugular vein to produce pulmonary embolism. The extraction catheter was inserted over the right jugular and femoral vein, the basket was placed in contact to the head of the thrombus. After the extraction procedure pulmonary angiography was performed to document the extent of pulmonary recanalization.

Results: In in-vitro tests embolus material could be extracted by suction over the basket-channel system without obstruction due to the moving metal probe. In vivo pulmonary thrombus material could be extracted in all cases. However, the amount extracted varied between 30% and 100% according to angiographic findings. Limiting factors were steerability and positioning of the basket.

Conclusion: Extraction of pulmonary embolism with a self-expanding, plastic-coated suction-basket is possible. Yet the extent of recanalization is limited due to restricted catheter maneuverability in the pulmonary arterial system. Nevertheless, the device may have potential in deep venous thrombectomy (iliac and femoral veins), where steerability is less crucial.

B-209 15:12

Treatment of experimental saccular aneurysms of carotid arteries with three covered stents in canine models

Y.S. Cheng, M.H. Li, H.X. Zhang; Shanghai/CN

Purpose: To assess the effectiveness and safe of balloon-expanding stainless steel stents (SSS) system covered with polyurethane membrane (PUM) and expanding poly teflon ester membrane (ePTFEM) and biomembrane (BM) in the treatment of experimental saccular aneurysms of carotid arteries in canine models.

Methods: Experimental aneurysms were treated with covered stents. Altogether there were twelve PUM-SSS and ePTFEM-SSS and BM-SSS respectively, they were placed endovascularly in the common carotid arteries covering the orifice of the aneurysms. Control angiography was performed immediately after the procedure and after 2 weeks, 4 weeks and 12 weeks. All treated canines were given conventional anticoagulation. The animals were sacrificed according to grouping time. Stented arteries were removed for histopathological examination.

Results: 36 experimental saccular side-wall aneurysms of carotid arteries were opened. Model success rate is 90%. All stents were placed successfully in target arteries. The complete patency rates of PUM-SSS and ePTFEM-SSS and BM-SSS were 25.00% and 41.67% and 91.67% respectively. Histological analysis indicated that all treated aneurysmal pouches were almost filled with thrombus. Stent wires were found to be located deep within the vessel wall and encased by an extension of the tunica intima; Endothelialization of BM-SSS already began at 2 weeks which was earlier than that of PUM-SSS and ePTFEM-SSS; Various degree of degenerate cells were seen under the transmission electron microscopy. Surface erosion of stents was not found in this study.

Conclusion: Placement of covered stent endovascularly proved expedient, safe, and effective. BM-SSS has better mechanical behavior, physiochemical stability, anticoagulative ability and biocompatibility and open than PUM-SSS, ePTFEM-SSS.

B-210 15:21

Radiofrequency thermal ablation in canine femur: Evaluation of coagulation necrosis reproducibility and MR-histopathologic correlation

J. Lee, J. Han, S. Kim, J. Lee, B. Choi; Seoul/KR

Objective: To determine whether a single application of radiofrequency (RF) energy to normal bone can create coagulation necrosis reproducibly and to assess the accuracy of MR imaging at revealing the extent of RF-induced thermal bone injury.

Scientific Sessions

Materials and Methods: Using a 200 W generator and a 17gauge cooled-tip electrode, a total of 11 RF ablations were performed in the distal femurs of seven dogs under fluoroscopic guidance. RF was applied at 100 W for 10 minutes. MR imaging including, precontrast T1- and T2-weighted images and post-contrast fat suppressed T1-weighted images, was performed to evaluate ablation regions. After MR imaging, six dogs were killed on day 4 after the procedure and one dog on day 7.

Results: In all animals, RF ablation created a well-defined coagulation and no significant complications were noted. The mean long-axis diameter and the mean short-axis diameter of the coagulation zones produced were 45.9 ± 5.5 mm and 17.7 ± 2.7 mm. On MR imaging, the ablated areas showed multilayered zones with signal intensities that differed from normal marrow on precontrast images, and a perfusion defect on postcontrast T1-weighted images. The correlation between the diameter of coagulation necrosis and lesion size at MR imaging was strong, with correlation coefficients ranging from 0.89 for T1-weighted images and 0.97 for T2-weighted images, to 0.98 for postcontrast T1-weighted images ($P < 0.05$).

Conclusion: RF ablation created well defined coagulation necrosis in a reproducible manner, and MR imaging accurately determined the extent of the RF-induced thermal bone injury.

Contrast enhanced magnetic resonance imaging of acute myocardial infarction: Optimization of image contrast

K.-U. Walterling, T. Schlosser, K. Gaida, O. Bruder, P. Hunold, J. Barkhausen; Essen/DE

Purpose: Variable T1 times of normal and infarcted tissues require individual adjustment of the inversion time to optimize contrast of late enhancement images. However, the time course of T1 times after contrast administration has not been investigated yet. Aim of our study was to measure T1 values of normal and acutely infarcted myocardium after contrast injection using IR-SSFP sequences.

Methods and Materials: 38 patients (30 male, 8 female, mean age 56.0 ± 13.0 years) with first acute ST-elevation myocardial infarction were enrolled in the study. T1 values of non-infarcted myocardium, the area of late enhancement (LE) and the no-reflow zone were estimated 1, 3, 5, 10, 15, 20 and 25 minutes after Gadodiamide injection (0.2 mmol/kg BW, Omnipaque, Amersham) using an inversion recovery steady state free precession sequence (TR 2.5 ms, TE 1.1 ms, FA 50°) with incrementally increased inversion times. T1 values were obtained using the following equation: $T1 = T1_{(min)} / \ln 2$, where $T1_{(min)}$ is the inversion time of the image with the minimum signal intensity of the tissue.

Results: The T1 times of normal myocardium and LE showed a maximum difference 15 minutes after contrast administration (LE: 264 ± 38 ms; normal myocardium: 354 ± 33 ms). The maximum difference between the no-reflow zone and the surrounding tissues was found immediately after contrast administration (no-reflow T1=347 \pm 167 ms, normal myocardium T1=206 \pm 41 ms, LE T1=211 \pm 86 ms).

Conclusion: To optimize image contrast in acute myocardial infarction measurements of the no-reflow zone should be performed immediately after contrast injection, whereas the area of LE should be assessed about 15 minutes after contrast injection.

B-212 14:09

Evaluation of left ventricular (LV) remodelling after acute myocardial infarction with MR imaging: The role of no reflow

L. Natale, A. Porcelli, A. Bernardini, A. Meduri, A. Lombardo, L. Bonomo; Rome/IT

Purpose: LV remodelling is crucial after PTCA for acute myocardial infarction. Aim of the study is to assess using MR imaging the role of edema, no-reflow and myocardial viability in the remodelling process.

Methods and Materials: 25 pts with AMI and primary PTCA (21 LAD, 2 CX, 3 RCA; 22: TIMI 3, 4: TIMI 2) were studied by MR imaging to measure end-diastolic

(EDV) and end-systolic (ESV) volumes immediately and 1-month later. A $> 20\%$ increase of EDV and/or ESV was considered indicative of remodelling. Triple IR-FSE for edema evaluation, steady-state free precession cine (FIESTA) for contractile function, fast-gradient echo train (FGRET) for first-pass perfusion study and IR-prep fast GRE for delayed enhancement assessment were obtained. A score for edema, no-reflow and hyperenhancement was calculated in each segment (17-segments LV model) based on number of segments and transmural extension ($< 25\%$, $25\text{--}50\%$, $50\text{--}75\%$, $> 75\%$).

Results: 11 pts had remodeling. EDV and ESV increased from 106 ± 30 ml to 153 ± 36 ml and from 60 ± 17 ml to 91 ± 23 ml respectively in pts with remodelling. No-reflow was detected in 22 pts (88%). The scores for edema, no-reflow and hyperenhancement were 4.0 ± 1.6 , 2.4 ± 1.1 , 3.3 ± 1.6 respectively in pts with remodelling and 2.9 ± 2.2 (p:NS), 1.4 ± 0.9 (p:0.04), 2.6 ± 1.7 (p:NS) respectively in patients without remodelling.

Conclusions: First-pass MR imaging detects a high incidence of no-reflow after PTCA. Its extension was more significantly related to remodelling compared to edema and necrotic myocardium.

B-213 14:18

Value of T2-weighted-, first-pass-enhancement and delayed-enhancement-MR imaging to differentiate between acute and chronic myocardial infarction

A. Stork, G.K. Lund, K. Muellerleile, P.M. Bansmann, J. Kemper, G. Adam; Hamburg/DE

Purpose: Assessment of diagnostic accuracy of T2-weighted (T2w)-, first-pass-enhancement (FPE), delayed-enhancement (DE)-MR imaging and cine-MR imaging to differentiate acute (AMI) from chronic myocardial infarction (CMI).

Material and Methods: 50 patients were imaged at 1.5 T 5.0 ± 3.3 days and 7.9 ± 2.7 months after AMI using cine- and T2w-MR imaging. FPE- and DE-MR imaging were performed during and 10 minutes after injection of Gd-DTPA, respectively. Images were acquired in short-axis planes. In a blinded consensus-reading wall-thinning on cine-MR imaging, enhancement-defects on FPE-MR imaging, central hypointensities on DE-MR imaging and edema on T2w-MR imaging were graded as present or absent. Signal-intensity (SI)-ratios for infarcted/normal myocardium on T2w-MR imaging were assessed quantitatively. Sensitivity, specificity and accuracy for the imaging findings were calculated. SI-ratios were compared by a t-test.

Results: The sensitivity and specificity, respectively, for detecting AMI were 96% and 98% for edema on T2w-MR imaging, 58% and 80% for an enhancement-defect on FPE-MR imaging, 48% and 96% for a central hypointensity on DE-MR imaging and 92% and 40% for the absence of wall-thinning on cine-MR imaging. Edema on T2w-MR imaging was more sensitive to AMI than an enhancement-defect on FPE-MR imaging ($p < 0.0001$) and a central hypointensity on DE-MR imaging ($p < 0.0001$). Edema on T2w-MR imaging and a central hypointensity on DE-MR imaging were more specific for AMI than an enhancement-defect on FPE-MR imaging ($p < 0.0001$). The SI-ratios for T2w-MR imaging in the acute stage were 1.48 ± 0.21 and 1.08 ± 0.11 for the chronic stage ($p < 0.0001$).

Conclusion: T2w-MR imaging can reliably differentiate between AMI and CMI. A central hypointensity on DE-MR imaging is more specific for AMI than an enhancement-defect on FPE-MR imaging. Wall thinning has a high specificity for CMI.

B-214 14:27

Presence of Q waves on the ECG predicted by MR imaging

T.A.M. Kaandorp¹, J.J. Bax¹, H.J. Lamb¹, E. Viergever¹, E. Boersma², D. Poldermans¹, E.E. van der Wall¹, A. de Roos¹; ¹Leiden/NL, ²Rotterdam/NL

Purpose: Studies have demonstrated that Q wave infarctions frequently have non-transmural scar formation, whereas non-Q wave infarctions may have transmural scars. The precise pathophysiological substrate underlying the Q waves remains unclear. MR imaging is the preferred technique to evaluate patients with infarction, since information can be obtained on function, contractile reserve and scar tissue. Therefore, we used MR imaging to predict the presence of Q waves on the ECG.

Methods and Materials: Consecutive patients ($n = 69$) with coronary artery disease and history of myocardial infarction underwent MR imaging investigation. The protocol included resting-, low-dose dobutamine- and contrast-enhanced MR imaging. Parameters included: LVEF, LV volumes, end-diastolic wall thickness and contractile reserve in the infarct region, transmurality and spatial extent of scar tissue, total scar score and the quantified percentage of scar tissue of the LV. The MR imaging data were related to the presence/absence of Q waves on the ECG.

Scientific Sessions

Results: Q waves were present in 39 (57%) patients. Univariate analysis identified the transmurality, the spatial extent, the total scar score and the quantified percentage scar tissue as predictors of Q waves. Multivariate analysis demonstrated that quantified percentage scar tissue was the single best predictor. A cutoff value of 17% infarcted tissue of the LV yielded a sensitivity and specificity of 90% to predict presence/absence of Q waves. When the quantified percentage scar tissue was removed from the model, the spatial extent of infarction was the best predictor.

Conclusions: Q waves on the ECG are best predicted by the quantified percentage scar tissue on contrast-enhanced MR imaging.

B-215 14:36

3 Tesla MR for myocardial viability evaluation with emphasis on comparison with 1.5 Tesla

G. Ligabue, A. Barbieri, F. Fiocchi, S. Ferraresi, L. Rossi, M.G. Modena, R. Romagnoli; *Modena/IT*

Purpose: To compare 3 Tesla cardiac imaging with 1.5 Tesla for myocardial viability evaluation in nearly identical experimental conditions.

Methods and Materials: 35 patients (mean age 58; 71% male) underwent both 3 T and 1.5 T MR cardiac examination within 2 weeks. Comparison between both scanners was made on the basis of the same study protocol which includes: cine b-FFE 2 and 4 chamber views multiple short-axis views (every 1 cm throughout the entire LV). Perfusion is evaluated after Gadolinium injection (0.15 mmol/kg). Delayed Enhancement evaluation is performed after 15 minutes with a segmented inversion-recovery technique. Image quality was assessed measuring Signal-to-Noise Ratio and Contrast-to-Noise Ratio in four left ventricle points in a cine b-FFE end-diastolic mid-ventricular image.

Results: Measured functional parameters were as follows respectively for 1.5 T and 3 T: ejection fraction 48.3 ± 12 and 49.2 ± 11 , stroke volume 87.99 ± 22 and 89.45 ± 21 ml, cardiac output 6.6 ± 1.5 and 6.7 ± 1.3 l/min, end diastolic volume 182 ± 45.5 and 179.6 ± 46.7 ml, end systolic volume 94.01 ± 23.5 and 90.15 ± 22.9 ml. Qualitative viability parameters were as follows respectively: kinesis score 6.7 ± 2.1 and 6.1 ± 2.6 , perfusion score 7.9 ± 1.9 and 8.1 ± 2.2 , DE score 15.4 ± 3.9 and 16.2 ± 4.1 , percentage of left ventricular dysfunctional but viable 14.77% and 12.35% , summed scar score 3.9 ± 1 and 4.1 ± 0.9 . SNR and CNR were respectively 23.64 ± 4.94 and 80.8 ± 4.69 and 81.88 ± 12.3 and 185.13 ± 21.4 ($p < 0.005$).

Conclusion: 3 T showed high concordance with 1.5 Tesla regarding functional and viability parameters while measured SNR is 3.92 times higher. Measured CNR is 2.26 times higher that leads to better anatomical structural representation.

B-216 14:45

Assessment of coronary artery lesion by MR perfusion of the myocardium and pressure derived fractional flow reserve

A.M. Huber, M. Schweyer, J. Rieber, I. Erhard, K. Theisen, S. Schönberg, M. Reiser; *Munich/DE*

Purpose: To compare semiquantitative MR perfusion parameters with results from intracoronary pressure derived fractional flow reserve (FFR) in the functional evaluation of known coronary artery lesions for assessment of their hemodynamic relevance.

Materials and Methods: 21 patients with CAD underwent MR imaging (Siemens Sonata, Erlangen) conventional coronary angiography (CA) with intracoronary pressure wire examination for determination of fractional flow reserve (FFR) in 23 stenotic lesions. SI curves of the first pass MR perfusion imaging (IPAT SR-turboFLASH) were analysed at rest and under adenosine-induced hyperemia. A 0.5 mmol/kg Gd-DTPA bolus was applied at rest and during hyperemia (Adenosin) with a flow rate of 5 ml/sec. Time-to-peak (TTP), maximum signal intensity (MSI) and upslope (US) values were determined. A lesion < 50% diameter reduction was defined as normal, a lesion > 50% with $\text{FFR} > 0.75$ as intermediate and a lesion with diameter reduction > 50% and $\text{FFR} < 0.75$ as severe, respectively.

Results: TTP was not significantly different between the three groups (11 ± 3.4 ; 15 ± 5.7 ; 13 ± 5.1 ; ns). US at rest was comparable (0.08 ± 0.17 ; 0.10 ± 0.035 ; 0.07 ± 0.01 ; n.s.). During stress US increased and was significantly different between normal coronary arteries and severe coronary stenoses (0.28 ± 0.12 vs. 0.08 ± 0.01 ; $p < 0.05$). The ratio US at stress and rest was 3.4 ± 1.5 (2.0-6.3) for normal coronary arteries and 1.7 ± 0.3 (1.2-1.7) and 1.1 ± 0.1 (1.0-1.3) for intermediate and severe coronary lesions ($p < 0.04$ and $p < 0.03$).

Conclusion: MPRI (USStress/USRest) were significantly different between normal and hemodynamically relevant diseased coronary arteries. MR perfusion imaging can give important information about assessment of hemodynamic relevance of coronary artery stenoses.

B-217 14:54

Cine SSFP MR imaging after myocardial infarction: Impact of G-CSF stimulation of peripheral stem cells on cardiac function

B.J. Wintersperger, M.G. Engelmann, H. Theiss, M.F. Reiser, W.M. Franz, S.O. Schönberg; *Munich/DE*

Purpose: Purpose of this study was to monitor global and regional cardiac function in patients after MI treated with granulocyte colony stimulating factor (G-CSF) for peripheral blood stem cell stimulation compared to placebo.

Material and Methods: 12 study patients with ST segment elevation MI (STEMI) were included and underwent cine MR imaging at baseline, 4 and 12 weeks after coronary intervention on a 1.5 T scanner (Magnetom Sonata; Siemens). Cine SSFP was performed in short-axis orientation with a pixel size of 1.5×1.5 mm. LV-EDV, ESV and EF were evaluated as well as regional wall thickening parameters for the main infarct segment based on a 16 segment model. Results of G-CSF and placebo group were compared.

Results: LV-EF of both study groups did not differ significantly, neither at baseline nor at 4 and 12 weeks ($P > 0.05$). LV-EDV and ESV also did not show significant differences when comparing both groups at any time point ($P > 0.05$). LV-EDV of the G-CSF group changed from 158 ± 21 ml at baseline to 143 ± 33 ml at 12 weeks ($P > 0.05$), while within the placebo group it changed from 186 ± 86 ml to 184 ± 15 ml ($P > 0.05$). ESV measurements did not show significant longitudinal changes within both groups ($P > 0.05$). While systolic thickening within the placebo group did not show significant changes from baseline to 4 weeks (0.6 ± 0.4 mm vs. 0.01 ± 0.9 mm; $P > 0.05$), the G-CSF group showed significant improvement ($P < 0.03$).

Conclusion: High-resolution SSFP cine imaging allows monitoring of global and regional cardiac function in MI. Preliminary data shows that the use of G-CSF in patients with STEMI may improve regional wall motion.

B-218 15:03

Single shot and phasesensitive detection for assessment of myocardial infarction within a single breathhold

A.M. Huber, B. Spannagl, C. Hayes, S. Schönberg, M. Reiser; *Munich/DE*

Purpose: The aim of the study was to compare the diagnostic accuracy in viability imaging of the myocardium with a multislice Phasesensitive Inversions Recovery (PSIR) 2 D single shot (SS) TrueFISP sequence and an established IR turboFLASH sequence.

Material and Methods: 21 patients with myocardial infarction were examined at a 1.5 Tesla MR System (Sonata) 10 minutes after administration of contrast material with a single shot 2D multislice technique (IR TrueFISP), that allows imaging of the entire short axis during one breathhold, and with a segmented 2D single slice technique (IR turboFLASH), that requires one breathhold per slice. The inversion time was optimized with a CINE TI-Scout sequence for IR turboFLASH, the PSIR-SS TrueFISP sequence was used with a standard TI of 200 msec. The voxel size was $2.1 \times 1.6 \times 8$ mm 3 for both MR techniques.

Results: The PSIR-SS TrueFISP sequence has a similar contrast/noise ratio (CNR) as the IR turboFLASH sequence (mean values: $11.6.0$ vs. 12.3 , $p > 0.05$, n.s.) for differentiation of viable and non viable myocardium. The assessment of the area of infarction within one slice ($r = 0.96$, $p < 0.003$) and the volume of the entire infarction is possible with excellent correlation of both techniques ($r = 0.97$, $p < 0.002$).

Conclusion: PSIR-SS TrueFISP sequence allows for accurate determination of the area and volume of the infarction with high spatial resolution during data acquisition within a single breathhold without significant loss of CNR.

B-219 15:12

Functional recovery after acute myocardial infarction: Evaluation by MR imaging

L. Natale, A. Bernardini, A. Porcelli, A. Meduri, A. Lombardo, C. Liguori, L. Bonomo; *Rome/IT*

Purpose: To assess the role of contrast enhanced (CE) MR imaging in the prediction of functional recovery after acute myocardial infarction.

Methods and Materials: 43 consecutive patients with first AMI (64 ± 9 yrs., 36 anterior, 7 inferior, 37 primary PTCA, 6 thrombolysis) underwent cine- and CE-MR imaging (GE Signa Horizon Echospeed; GE Signa LX Excite) within the fifth day after onset. Cine-MR imaging was performed in short axis (6-8 slices, Fastcard and FIESTA sequences); first pass imaging (IR-prep FGRE and FGRE-ET with 0.075 mmol/kg Gd-DTPA, 3 mL/s) was obtained on three short axis slices (basal, mid-ventricular and apical); multi-slice short axis (6 slices) delayed T1 imaging (IR-prep FGRE) was obtained 20 min after double dose Gd injection. A total

Scientific Sessions

amount of 731 segments were classified as: 1) normal first-pass, absent or delayed hyperenhancement; 2) hypoenhancement at first-pass, delayed hyperenhancement; 3) hypoenhancement both at first-pass and delayed imaging. Segments from first-pass slices (total amount 774) were classified at delayed imaging as normal (= type 1), hyperenhanced (= type 2) and hypoenhanced (= type 3). Patterns 2 and 3 were considered non viable. At six months MR imaging assessed functional recovery.

Results: Pattern 1 was observed in 1262 segments, with functional recovery appreciated in 1195 (94.7%). Pattern 3 was present in only 31 segments, without recovery (100%). Pattern 2 was observed in 212 segments: of them, 39 showed recovery (18%).

Conclusions: Patterns 1 and 3 respectively identify viable and non viable tissue. Pattern 2 is less specific early after AMI, as it may also represent viable myocardium.

B-220 15:21

MR imaging prediction of β-blocker therapy effect in ischemic cardiomyopathy by assessment of LVEF using dobutamine stress

T.A.M. Kaandorp, H.J. Lamb, J.J. Bax, E. Boersma, E. Viergever, E.E. van der Wall, A. de Roos; Leiden/NL

Purpose: Since left ventricular ejection fraction (LVEF) does not improve in all patients with ischemic cardiomyopathy in response to β-blocker therapy, an investigation to predict the likelihood of a response is desirable. Therefore, we sought to evaluate the feasibility for prediction of β-blocker therapy effect on global LVEF, by measurement of global LVEF during low-dose dobutamine MR imaging, before therapy, in patients with severe ischemic cardiomyopathy.

Methods and Materials: In 20 patients with chronic coronary artery disease, MR imaging was performed at rest and during low-dose dobutamine stress before starting carvedilol therapy and at follow-up to assess global LVEF. Additionally, a NYHA classification was assessed by the patient's cardiologist before and after β-blocker therapy.

Results: Global LVEF at follow-up may be predicted by using the formula: β-blocker induced LVEF improvement = $0.66 \times (\text{LVEF}_{\text{stress}} - \text{LVEF}_{\text{rest}}) + 0.34$ ($R^2 = 0.67$, $P < 0.01$). Thus, an induced improvement in $\text{LVEF} \geq 7\%$ may predict a positive response $\geq 5\%$ at follow-up. This improvement was consistent with the NYHA classification before and after β-blocker therapy.

Conclusion: β-blocker therapy effect may be predicted at baseline by using the formula: β-blocker induced LVEF improvement = $0.66 \times (\text{LVEF}_{\text{stress}} - \text{LVEF}_{\text{rest}}) + 0.34$ ($R^2 = 0.67$, $P < 0.01$). MR imaging can be helpful to select patients who benefit from β-blocker therapy.

Temporal lobe development investigated using fetal MR imaging

G.J. Kasprian, P.C. Brugge, D. Prayer; Vienna/AT

Purpose: The temporal lobe (TL) contains substructures which host main neuropsychological functions. To date fetal TL anatomy has been investigated only *in vitro*. Using fetal magnetic resonance imaging (MRI) we evaluated TL development in healthy and pathological conditions.

Methods and Materials: 60 fetuses with normal brain development, aged between the 18th and 37th gestational weeks (GW), and 35 cases with malformations or acquired conditions known to be associated with hippocampal pathology, underwent MRI. Different substructures of the fetal TL (hippocampus, parahippocampal gyrus, amygdala, temporal gyration) were evaluated at different developmental stages on T2-, T1- and diffusion-weighted sequences in 3 section planes.

Results: The hippocampus and amygdala were recognized by 22 GW, further intrinsic detail became evident with continuing growth. Following the 25th GW temporal sulci begin to appear in an orderly fashion. Occipito-temporal progression of superior temporal sulcus infolding correlated best with GW. Development of the parahippocampal gyrus relates to the inward positioning of the hippocampus. Altered TL morphology was a frequent finding in pathological cases. Hippocampal

malposition was characteristic to corpus callosum agenesis, migrational disorders, and hydrocephalus.

Conclusion: The morphology of the TL can be evaluated quite accurately with fetal MRI after the 24th GW. Hippocampal malposition can be detected from the 24th GW in fetuses with brain anomalies. Further follow-up of the postnatal clinical course of those fetuses will offer more information about the clinical impact of this finding.

B-222 14:09

Incidental findings on brain MR imaging in asymptomatic young adults

M.M.L. de Win, C.B.L.M. Majolie, G.J. den Heeten; Amsterdam/NL

Purpose: When reviewing brain MRIs it is important to know which abnormalities and normal variants can be prevalent in asymptomatic individuals. We determined frequency and nature of incidental findings on brain MR imaging in asymptomatic young adults.

Methods and Materials: Brain MRIs of 237 research volunteers (110 M, 127 F, mean age 22.5 ± 3.6) were reviewed by an experienced neuroradiologist. The scan protocol included axial and coronal PD and T2 weighted images and a high resolution post contrast T1-3D scan. Informed consent stated that relevant findings would be reported to the GP.

Results: 102 incidental findings, both abnormalities and normal variants, were diagnosed in 87 subjects. Multiple findings included pineal gland cyst (N = 15; 6.3%), wide peripheral CSF space (N = 12; 5.1%), wide or asymmetric ventricles (N = 12; 5.1%), white matter hyperintensity on T2 (N = 11; 4.6%), Rathke's cleft cysts (N = 9; 3.8%), wide perivascular spaces (N = 8; 3.4%), mega cisterna magna (N = 7; 3.0%), sinusitis (N = 6; 2.5%), venous angiomas (N = 6; 2.5%), cavum septum pellucidum (N = 4; 1.7%), partial empty sella (N = 2; 0.8%) and low position of the tonsils (N = 2; 0.8%). Findings in single subjects included heterotopic gray matter, choroid plexus cyst, arachnoidal cyst, thalamic lesion and low position of the tonsils. One subject with two contrast-enhanced skull tumors was referred for further examination (diagnosis after CT: fibrous dysplasia).

Conclusion: Incidental findings, most without clinical consequences, were diagnosed in 37% of the asymptomatic subjects. This emphasizes the importance of a protocol for management and reporting of incidental findings when performing brain MR imaging research in healthy volunteers.

B-223 14:18

DTI, perfusion MR imaging and ¹H-MR-spectroscopy of the brain: 'Normal-values' in a population of young healthy adults

M.M.L. de Win, E.J.P. Vlieger, C. Lavini, C.B.L.M. Majolie, E.M. Akkerman, G.J. den Heeten; Amsterdam/NL

Purpose: Use of Diffusion Tensor Imaging (DTI), perfusion imaging (PI) and ¹H-MR-Spectroscopy (¹H-MRS) has increased, but little is known about values and variation in the 'normal population'. We determined 'normal-values' of DTI, PI and ¹H-MRS in young healthy adults.

Methods and Materials: 189 volunteers (84 males, 105 females, 21.9 ± 3.2 yr) were included. MR imaging (1.5 T, Signa, GE) protocol: PD- and T2-weighted images, single voxel ¹H-MRS, DTI (DW-EPI, TE/TR = 90/8000, b = 1000, 12 directions, slice thickness 5 mm), PI (GE-EPI, slice thickness 5 mm), T1-3D scan. ADC, FA and CBV maps were registered to spatially normalized T1-3D scans. The thalamus, putamen, globus pallidus, caudate nucleus, parietal white matter, splenium and genu of corpus callosum, frontal and occipital gray matter were drawn as ROIs onto the normalized brain (both hemispheres) and resized to the original maps. rCBV-values were obtained by dividing mean $\text{CBV}_{(\text{ROI})}$ by mean $\text{CBV}_{(\text{white matter})}$. Spectra were analyzed using LC-Model. NAA, Cho and mI concentrations were calculated using Cr as reference. Mean values and Coefficients of Variation (CV; SD as percentage of the mean) were calculated.

Results: CV varied, depending of the region, between 4 and 18% for ADC, 9 and 22% for FA, 12 and 19% for rCBV and 14 and 22% for spectra.

Conclusion: FA, ADC, rCBV and ¹H-MRS values are dependent of scanner, scan-protocol and analyses. Although these were constant, we found large variations. Possible explanations for the large variations are inter-individual variation, physiological variation, analysis method or partial volume effects and these possibilities should be studied in future research.

Phenylketonuria: Conventional MR imaging and spectroscopic assessment of cerebral PHE concentration with 3 T 1H-MRS

S. Pollici¹, T. Scarabino², V. Leuzzi³, M. Tosetti⁴, F. Carnevale⁵, A. Carriero¹; ¹Novara/IT, ²San Giovanni Rotondo/IT, ³Rome/IT, ⁴Pisa/IT, ⁵Bari/IT

Purpose: Previous research has attested the existence of individual features in the transport of Phe through the blood-brain barrier, as a possible influencing factor of the phenotypic expression of the disease. The objectives of this research were: correlation analysis between Phe emetic value and cerebral tissue concentration; correlation analysis between cerebral Phe value and clinical evolution; correlation analysis between Phe cerebral levels and white matter distortion.

Methods and Materials: We studied thirty-two PKU patients (17M and 15F) between the ages of 7 and 34 years, with no food restriction during the research. The MR imaging sequences used for the white matter examination were: axial FLAIR T1-W, coronal FSE T2-W and sagittal FSPGR T1-W. A score was given in function of the white matter compromise. Phe cerebral concentration was valued with single-voxel method by using a TE PRESS short sequence (TE: 35 ms). VOI was of 8 cc, localized in the peri-ventricular white matter. The morphological and biochemical analysis was made with 3 T MR equipment.

Results: White matter distortion was observed in 93.7% of patients; there was not a great difference in the white matter distortion gravity between early treated patients and late diagnosed and treated subjects; we did not find a significant correlation between white matter distortion grade and Phe cerebral concentration; in patients not being treated there was not a correlation between the cerebral concentration and the I.Q.

Conclusion: Blood and cerebral Phe concentration do not seem to have a direct correlation with clinical state and tissue distortion.

B-225 14:36

Normal ageing compared to alterations in CRPS related regions of the brain: A DTI study

L. Jäger, J. Lutz, R. Stahl, O. Dietrich, G. Schelling, S.O. Schönberg, M.F. Reiser; Munich/DE

Purpose: To compare DTI findings in patients with complex regional pain syndrome (CRPS) to those of normal subjects.

Methods and Materials: 20 healthy volunteers (mean age 28.5 years), 15 healthy volunteers (mean age 61.3 years) and 20 patients with a confirmed diagnosis of CRPS were examined using an 1.5 T MR System with a IPAT DTI EPI-sequence (TE 71 ms, TR 6000 ms, 36 Slices, 1.8x1.8x3.6 mm spatial resolution). Bilaterally the amygdala, hippocampus, anterior cingulate gyrus (AGC) and the superior temporal gyrus (STG) were evaluated with references in the frontal white matter. The fractional anisotropy (FA) and the relative anisotropy (RA) were determined. **Results:** There were no age related changes of RA and FA in the amygdala. A significant decline of RA and FA in the grey and white matter of the STG was found in the elderly control subjects. In the AGC and the hippocampus a decline was lateralized left and right respectively for the elderly healthy controls in comparison to the younger ones. The CRPS patients showed bilaterally increased RA and FA values ($p < 0.001$) in the amygdala, the hippocampus and the AGC in comparison to the younger and older healthy controls.

Conclusion: The results support the hypothesis that the amygdala, the hippocampus and the anterior cingulate gyrus play a major role in mental stress associated disease and second, that CRPS is a mental stress associated disease.

B-226 14:45

Normal ageing compared to alterations in fibromyalgia related regions of the brain: A DTI study

J. Lutz, L. Jäger, R. Stahl, O. Dietrich, G. Schelling, S.O. Schönberg, M.F. Reiser; Munich/DE

Purpose: Aim of the study was to compare DTI findings in patients with fibromyalgia to those of normal subjects.

Methods and Materials: 20 young healthy volunteers (mean age 28.5 years), 15 elderly healthy volunteers (mean age 61.3 years) and 20 patients with a confirmed diagnosis of fibromyalgia were examined using an 1.5 T MR System with an IPAT DTI EPI-sequence (36 slices, 1.8x1.8x3.6 mm spatial resolution). Bilaterally the amygdala, hippocampus, anterior cingulate gyrus (AGC) and the superior temporal gyrus (STG) were evaluated with references in the frontal white matter. The fractional anisotropy (FA) and the relative anisotropy (RA) were determined.

Results: There were no age related changes of RA and FA in the amygdala. A significant decline of RA and FA in the grey and white matter of the STG was found in the elderly control subjects. In the AGC and the hippocampus a decline

was lateralized left and right respectively for the elderly healthy controls in comparison to the younger individuals. The patients with fibromyalgia showed bilaterally increased ($p < 0.001$) RA and FA values in the amygdala, the hippocampus and the AGC in comparison to the younger and elderly healthy controls.

Conclusion: The results support the hypothesis that fibromyalgia is a mental stress associated disease. A decline in anisotropy in the frontal cortex which is associated with normal ageing, confirms the hypothesis that the process of ageing results in bifrontal atrophy. The unevenly distributed anisotropy changes in the hippocampus and the AGC underline their association in the ageing process.

B-227 14:54

A voxel-based morphometric study of Alzheimer's disease

J. Hao, K. Li; Beijing/CN

Purpose: Up till now, the study of regional gray matter atrophy in Alzheimer's disease (AD) has been assessed with regions of interest (ROI), but this method has many shortcomings. In this study we used the fully automated voxel-based morphometry (VBM) approach in order to provide a full-brain assessment of AD morphology.

Methods and Materials: 19 patients with AD and 15 healthy subjects of similar age and gender ratio were included in the study. Magnetic resonance imaging was performed on a 1.5 T Siemens Sonata MR imaging system (Siemens, Erlangen, Germany). Whole brain T1-weighted 3D MPRAGE (magnetization-prepared rapid-acquisition gradient echo) data sets were acquired in the sagittal plane (TR 1900 ms; TE 3.93 ms; slice thickness 1.7 mm; skip 0.85 mm; FOV 250 mm; Matrix 448x512; Flip Angle 15°). Data analysis was performed by Statistical Parametric Mapping software (SPM 99) in conjunction with MATLAB version 6.5 to generate gray matter density map.

Results: Our results confirmed earlier findings with traditional MR imaging measurement, but additionally we demonstrate global asymmetrical cortical atrophy with sparing of the sensorimotor cortex, occipital lobe and cerebellum. Moreover, atrophy of the right caudate head and left medial thalamus was shown.

Conclusion: Our results offer a comprehensive view of atrophy pattern in AD. The consistency of these findings with histopathological descriptions demonstrates the utility of the VBM technique for investigating the neuroanatomy of AD.

B-228 15:03

Visual attention deficits in Alzheimer's disease. A fMR imaging study

J. Hao, K. Li; Beijing/CN

Purpose: To investigate functional activation patterns during two types of visual search tasks in AD patients using fMR imaging.

Materials and Methods: 13 patients with AD and 13 healthy subjects of similar age and gender ratio were measured with functional magnetic resonance imaging (fMRI) while they performed tasks. The time series of fMRI data were acquired with T2*-weighted EPI sequence (TR 4500 ms; TE 40 ms; slice thickness 5 mm; skip 1 mm; FOV 220 mm; Matrix 64x64; Flip Angle 90°) on a 1.5-T Siemens Sonata MR imaging system (Siemens, Erlangen, Germany). Two visual search tasks were used. The first was a "pop-out" single feature task, detecting a vertical target among horizontal distractors. The second was a conjunction task, where the target is defined by a conjunction of features (color and orientation) and the performance depends on some shifting of attention. Data analysis was performed by Statistical Parametric Mapping software (SPM 99) in conjunction with MATLAB version 6.5.

Results: AD patients have a particular impairment in the conjunction task but not in the single-feature task. Although both groups revealed almost overlapping networks engaged in the conjunction tasks including the superior parietal lobule (SPL), frontal and occipito-temporal cortical regions (OTC), primary visual cortex and some subcortical structures. The most pronounced differences between them were found in the SPL (more activity in controls) and OTC (more activity in subjects).

Conclusion: AD particularly affects those mechanisms controlling spatial shifts of attention. Some additional remote activation (ventral visual stream and temporal lobe) can be interpreted as dynamic reallocating of brain functional resource.

B-229 15:12

Brain tissue damage in dementia with Lewy bodies: An in vivo diffusion tensor MR imaging study

M. Bozzali¹, A. Falini¹, F. Baglio¹, M. Cercignani², E. Farina¹, P. Vezzulli¹, G. Scotti¹, R. Nemni¹; ¹Milan/IT, ²London/UK

Purpose: Conventional MR imaging showed uncertain results assessing neuro-radiological features of dementia with Lewy bodies (DLB). In this study, the presence and the distribution of microscopic brain tissue damage from patients

Scientific Sessions

with DLB was assessed in vivo using Diffusion Tensor Imaging (DTI) by Region of Interest (ROI) analysis.

Materials and Method: Fifteen patients with DLB and 10 sex- and age-matched healthy subjects were studied using dual-echo and DTI imaging. After estimation of the diffusion tensor, mean diffusivity (MD) and fractional anisotropy (FA) maps were derived for every voxel. Several anatomical ROIs were selected, and the corresponding MD and FA regional quantities were measured from every subject.

Results: Patients with DLB compared to controls showed statistically significant, (after Bonferroni's correction, $p < 0.005$) higher MD and lower FA values in the white matter (WM) from parietal, frontal and occipital lobes, in the corpus callosum and pericallosal areas. DTI abnormalities were also found in the caudate nucleus, temporal lobe WM, and putamen. Several correlations were found between neuropsychological and regional DTI-derived metrics in DLB patients.

Conclusion: Microstructural abnormalities in regions (corpus callosum, pericallosal areas) with a high prevalence of long connecting fibre tracts suggests the presence of Wallerian degeneration secondary to neuronal loss in the associated cortices. The selective involvement of parietal, frontal and occipital lobes might explain some of the clinical and neuropsychological features of DLB, providing a possible distinctive marker for DLB. The abnormalities in the caudate nucleus and putamen suggest DLB and Parkinson's disease might share a similar nigro-striatal involvement.

B-230 15:21

1H MRS comparative study of cerebral metabolism in patients with mild cognitive impairment (MCI), vascular dementia (VD) and in normal elderly subjects (N)

V.A. Rogozhyn, Z.Z. Rozhkova, N.Y. Bachinskaya; Kiev/UA

Purpose: To characterize the metabolic changes in the brain of patients with MCI and VD in comparison to N using 1H MRS data.

Materials and Method: Three groups of patients were studied by 1H MRS with 1.5 T Magnetom Vision (SIEMENS). The 1st group included 25 patients (56-84 y) with MCI. The 2nd group consisted of 9 patients with VD (52-73 y). The 3rd group (N) consisted of 30 subjects (60-75 y). 1H spectra were recorded in the hippocampus (H), amygdala (A), frontal lobes (FL), in the entothinal cortex (EC) with the SVSSTEAM: TR/TE = 1500/135.30 ms.

Results: From the spectra in all sampled regions of the brain the peak areas of NAA, Cr, Cho and mInos were obtained. For the patients of the 1st versus the 3rd group a significant decrease of NAA and Cr and an increase of Cho peak areas in all regions and also a significant decrease of NAA/Cr, and Cho/Cr in H and FL were observed. In the 1st group (NAA/Cr = 1.01; mInos/Cr = 0.82; Cho/NAA=0.96), in the 2nd group (NAA/Cr = 1.14; mInos/Cr = 0.58; Cho/NAA=0.86), and in the 3rd group (NAA/Cr = 1.25; mInos/Cr = 0.62; Cho/NAA=0.53) were obtained. An increase in mInos/Cr (0.69) ratios in the patients of the 1st compared with the 2nd group (0.52) was noted. The ratios of Cho/NAA, mInos/NAA in H, FL and EC were the most accurate values for differentiation of MCI, VD and N.

Conclusion: 1H MRS data are useful in predicting the progression of MCI and VD and also for identification of cognitively normal subjects at risk for developing MCI.

Using speech recognition reduces time slot between imaging and final report

T. Kauppinen, O. Tolki, P. Korhonen, J. Ahovuo; Helsinki/FI

Purpose: HUS Helsinki Medical Imaging Center (HMIC) is a part of the hospital district of Helsinki and Uusimaa. HMIC products medical imaging services and it is working using infrastructure of PACS. HMIC is formed of the radiological imaging units in ten hospitals around Helsinki and it produces over 500.000 examinations annually. The purpose of this study was to demonstrate the effect of the Finnish radiological speech recognition system for dictation process.

Methods and Materials: Radiological dictation process was examined in two different units of HMIC in different hospitals. Examination period was one week in

both hospitals and all examinations were included except studies of emergency units. Process was evaluated by defining time of the whole dictation procedure and each step starting from request and ending to the final report. The departments in question are mainly doing ultrasound, normal X-ray (e.g. bone and thorax), computed tomography and fluoroscopy examinations.

Results: Procedure turnaround times were defined into following time slots 0-2 h, 2-4 h, 4-6 h, 6-12 h, 12-24 h, 24-48 h, 48-62 h, and over 62 h. Using this classification the distribution of the turnaround were determined. The mean turnaround time of traditional tape based system was 27 h and 23 h in both hospitals when all examinations were included. Respectively, when 5% of minimum and maximum was removed the mean values were 23 h and 21 h.

Conclusion: It was noticed by this study that speech recognition speeds up a dictation process. It will also change a whole workflow increasing the quality of the reports.

B-232 14:09

Improvement of hospital-wide radiology report availability by implementation of a fully PACS/RIS integrated speech recognition system

C.G. Trumm¹, C. Glaser¹, V. Paasche¹, P. Popp², B. Küttner¹, M.F. Reiser¹,

¹Munich/DE, ²Erlangen/DE

Purpose: To quantify the effect of speech recognition on report availability in a university hospital with an integrated PACS/RIS system and digital image and report distribution.

Methods and Materials: Prospectively, time-stamps of image acquisition and first report availability in RIS/HIS were documented for 240 cases of X-ray (CR) and Computed Tomography (CT) each. Time interval between both time-stamps was addressed as report turnaround time (RTT). Reports were created by 12 radiologists with conventional (CD) and speech recognition dictation (SR) respectively. Retrospectively, RTT for 11/02-02/03 (conventional dictation with transcription) and 11/03-02/04 (remote or online SR with transcriptionist (TC) or self correction (SC)) were calculated from the PACS/RIS database. RTT were classified in 3 categories: Reports delivered I) in less than one day, II) in 5 hours or less, III) in less than 1 hour.

Results: Prospectively, mean RTT was 21.1 h /25.1 h /8.9 h for CR with CD/SR (TC/SC) and 23.8 h /29.6 h /7.6 h for CT with CD/SR (TC/SC). In retrospect, 37898/39680 datasets were analysed. The number of reports delivered in less than one day was 3485/11453, in 5 hours or less was 2410/9710 and in less than 1 hour was 352/2050 for 2002-03/2003-04. This corresponds to an increase of reports delivered in less than one day by a factor of 3.1, in 5 hours or less by 3.9, and in less than one hour by 5.6.

Conclusion: The implementation of speech recognition within an existing PACS/RIS environment facilitates a significant improvement of report availability when online speech recognition and radiologist self-correction are used.

B-233 14:18

Hard disk caches in PACS archives: How big is beautiful?

S. Wirth, M. Treitl, J. Rieger, K.-J. Pfeifer, M.F. Reiser; Munich/DE

Purpose: To recommend appropriate sizes of fast image caches for large PACS installations.

Materials and Methods: In a large hospital Radiography, CT and MR imaging studies of in- and outpatients were included consecutively ($n = 1200$). All priors were accessed using AGFA Impax, R4.1 as PACS-System (10 years image coverage). Age, modality, body region as well as relevance for the interpretation of the current examination were analyzed.

Results: Priors existed in 59.7% (CR 62.2%, CT 54.5%, MR imaging 62.3%, inpatients 76.4%, out-patients 46.6%). Number of prior examinations was 7.6 in mean (82% same body region, 71% same modality as well). Age of relevant priors was 203 days in mean, distributed as follows: $56.2 \pm 9.2\%$ within 3 months, $72.0 \pm 4.5\%$ within 6, $84.6 \pm 3.2\%$ within 12, $91.4 \pm 2.5\%$ within 24 and $99.5 \pm 0.2\%$ within 60 months, respectively.

Conclusions: Best workflow requires access to every relevant prior from the fast PACS archive cache. A cache size covering actual images of at least 12 months should be minimum, provided that a working prefetching algorithm can identify the missing 15.4% of priors correctly (8.6% prefetching quota for 24 months coverage). However, falling hard disk prices make prefetching become superfluously since in the near future PACS archiving may be handled by harddisk RAID systems exclusively.

Managing the CT data explosion: Initial experiences of archiving volumetric datasets in a mini-PACS

K. Lee¹, K. Lee¹, H. Lee¹, J. Kim¹, H. Kang¹, H. Hong², H. Lee¹, T. Kim¹; ¹Seongnam-si, Gyeonggi-do/KR, ²Seoul/KR

Purpose: To report our initial experiences of managing increased CT data, using a mini-picture archiving and communication system (PACS).

Methods and Materials: The volumetric dataset from 16-detector-row CT scanners was stored in a mini-PACS with a 271-gigabyte online and 680-gigabyte nearline storages and routed to radiologists' workstations, while another conventional thicker slice dataset was stored in the main PACS. During a sample period of two weeks, the impact on storage need of each dataset type (classified as volumetric, thick axial, standardized three-dimensional (3D) images routinely produced by technologists, 3D images added by radiologists, and scan planning) was assessed by measuring percentage data volume. Storage need of each PACS was analyzed over a five-month period.

Results: For the 867 CT examinations performed during the two-week period, the percentage data volumes of volumetric, thick axial, standardized 3D, additional 3D, and scan planning datasets were 74.4, 15.9, 7.0, 2.3, 0.5%, respectively. Over the five-month period, 278-gigabytes of CT data (8,976 examinations) were stored in the main PACS, and 738-gigabytes of volumetric datasets (6,193 examinations) were stored in the mini-PACS. The volumetric datasets formed 32.8% of total data for all modalities (2.20 terabytes) in the main PACS and mini-PACS. At the end of this period, volumetric datasets of 1,892 and 5,162 examinations were kept online and nearline, respectively.

Conclusion: Using a mini-PACS might be an effective method to archive every volumetric dataset and to deliver it to radiologists.

B-235 14:36

OsiriX: Open-Source 3D/4D DICOM viewer

A. Rosset¹, L. Spadola¹, O. Ratib²; ¹Geneva/CH, ²Los Angeles, CA/US

A multidimensional image navigation and display software was designed for display and interpretation of large sets of multidimensional and multi-modality images such as combined PET-CT studies. The software is developed in Objective-C on a Macintosh platform under MacOS X operating system using GNUstep development environment. It also benefits from the extremely fast and optimized 3D graphic capabilities of OpenGL graphic standard for taking advantage of any hardware graphic accelerator boards available. In the design of the software a special attention was given to adapt the user interface to the specific complex tasks of navigating through large sets of image data. An interactive jog-wheel device widely used in the video and movie industry was implemented to allow the users to navigate in the different dimensions of an image set much faster than with a traditional mouse or on-screen cursors and sliders. The program can easily be adapted for very specific tasks that only require a limited number of functions by adding and removing tools from the program's toolbar and avoiding the users to be overwhelmed by an excessive number of unnecessary tools and functions. The processing and image rendering tools of the software are based on the open source libraries ITK and VTK ensuring that all new developments in image processing that could emerge from other academic institutions using these libraries could be directly ported to the OsiriX program. OsiriX is provided free of charge under the GNU open source licensing agreement at <http://homepage.mac.com/rossetantoine/osirix>.

B-236 14:45

Diagnostic reading of radiology images on a wireless PDA: Fact or fiction?

Futuristic or foolish?

H.E. Gregersen; Aalborg/DK

Hypothesis: The wireless/mobile device that is becoming pervasive today is the PDA. Numerous healthcare sites are adopting large-scale PDA-based IT systems, and emerging technologies are allowing devices to access the full spectrum of radiology data. The hypothesis of this paper is whether PDAs can be used for diagnostic purposes by radiologists, and such use is desirable.

Methods: Aalborg University Hospital is implementing an Image and Data Management (IDM) system that provides RIS and PACS features together with innovative distribution possibilities. Wireless PDAs can be used by clinicians and radiologists to gain full access to radiology data, including all of the analysis tools available on standard workstations. To evaluate the IDM system, examinations were read on PDA as well as on workstations. The findings were compared, with assessment of the radiologists confidence of the diagnosis.

Results: The reading on the PDA matched the reading on the workstation in

most cases. The wireless PDA, together with the IDM software application, provided a diagnostic platform for orthopedic studies that was similar to that for a dedicated workstation.

Discussion: The reason, the combination of the IDM and the PDA technology works, is the unique

- Access to Full-Resolution DICOM Data
- Access to Window Center/Level Operations on Full-Fidelity DICOM Data
- Access to Volume Reconstructions

without sending or processing data on the PDA, but on a central server and send with streaming technology.

Conclusion: We prove the hypothesis that wireless PDAs can be used for primary diagnosis of most radiology data involving orthopedic examinations.

B-237 14:54

Dicom storage into PACS of out-hospital CD-ROMS

P.M.A. van Ooijen, P. ten Bhomer, M. Oudkerk; Groningen/NL

Purpose: With the introduction of digital imaging in radiology, patient studies are increasingly distributed between hospitals using CD ROMs. However, because of different conventions on patient numbers between hospitals digital storage is not easy. We investigated the application of a new software to integrate out hospital data into the local PACS archive for easy storage and reporting.

Materials/Methods: A one month trial was started to import CD ROMs from the radiotherapy and the radiology department. Patients were included into the HIS to obtain a valid patient number and an examination (EXTERNAL DATA or RE-EVALUATION) was entered into the RIS to obtain a valid accession number. All data was read from CD; patient ID and accession number were automatically replaced during transfer to the PACS using a DICOM worklist connection.

Results: 70 CD-ROMs were collected from 19 different hospitals (8 different modality types, 11 different software versions, and 8 different packages from different vendors). All CD-ROMs were successfully transferred into the PACS and could be easily reported. Some CD-ROMs with missing or corrupted DICOM directory files were first transferred to the local hard-disk and then sent to the PACS. This only occurred in older software versions from one vendor.

Conclusion: An easy way of introducing the out-hospital data into the PACS is provided. CD-ROMs can be destroyed after storage and no off-line storage of media is required anymore. Furthermore, all data can now be viewed and reported using the default viewers of the hospital and no additional training of staff is required.

B-238 15:03

Web based system for handling DICOM structured report documents from PACS for educational and research purposes

A. Delistamatis, M. Mantatzis, E. Kaldoudi, D. Ouzounis, P. Prassopoulos; Alexandroupolis/GR

Purpose: The standard DICOM Structured Report (SR) enables constructing and transferring medical reports as well as their storage along with images of each examination in the PACS. The purpose of the study is to develop a web-based system communicating with PACS, for extracting information from stored SR documents for educational and research purposes.

Material / Methods: This system consists of an interface communicating with PACS, made up of web service technologies. The interface extracts data from SR documents stored in the PACS and stores them in a local database of the system. The system database is administrated from an easy to use web user interface which enables viewing and analyzing the data, creating new SR documents for a study and offering full archiving capabilities.

Results: The proposed system gave the opportunity to add medical reports in a study, using web user interface. The stored reports in the system could be transferred towards PACS in the format of DICOM SR and vice versa. Complex queries can be applied by establishing a synchronization between the database of the proposed system and PACS i.e. applying keywords related to specific pathology or imaging findings to reports and analyze results according to time periods, body area and imaging modality, gender, patient's age etc.

Conclusions: Any PACS can use the proposed web-based system for create SR documents, administrate them and analyze data for educational or research purposes.

B-239 15:12

Enterprise information management: Closing the loop for a complete clinical data repository

M.P. Kirk; Genoa/IT

Purpose: Digital information availability is changing the world and Clinical Data Repositories, e.g. Enterprise Information Management, are taking Healthcare to another level of digital information utilization. The incorporation of hardcopy clinical data into a softcopy CDR will offer significant benefits in customer care.

Methods and Materials: The consolidation of clinical data into a widely available data resource, improves the utilization of archive resources and infrastructure. The data availability across multi-functions and multiple locations releases valuable clinical resources for improved patient care.

Results: PACS utilization is increasing and many clinical disciplines have separate hardcopy and softcopy archives resulting in independent 'islands' of clinical data. Healthcare institutions are seeking to unite these 'islands' using enterprise-wide clinical data repositories for softcopy data sources, the innovation of ingesting hardcopy files will create a complete patient record. The integration of document scanners via the ingestion interface of a Enterprise Information Management solution results in a complete Clinical Data Repository of digital information linked to patient identities.

Conclusion: This presentation gives an overview on the integration of document scanners to an intelligent archive and storage solution for a complete CDR available across multiple sites and multiple functions within the enterprise wide clinical information environment. This results in an improved ROI for storage infrastructure supported by the consolidation of the hard and softcopy archives with the hospital and frees valuable clinical support resources for better patient care.

Report of a PACS migration

E. Kotter, D. Jaeger, G. Pache, U. Saueressig, M. Langer; Freiburg/DE

Purpose: Migration from an older model PACS (Philips ARCHIMEDIS) to a modern system (TIANI).

Methods and Materials: *Initial situation:* Old PACS-archive: Philips ARCHIMEDIS. Stored data volume approx. 15 TB, of those approx. 7 TB on RAID, another 9 TB on 12'' WORM. Data production at time of migration 13 GB/day. Connected modalities: 5 CT+5 MR+12 CR+4 RF+4 XA/DS/US. 25 diagnostic workstations (DWS) in Radiology.

Complex system for report and image distribution on the wards via the Electronic Patient Record and a web server using the dynamic access authorization concept developed at Freiburg University Hospital.

Results: With a PACS running routinely and a nearly filmless hospital, the major migration requirement was to ensure undisturbed running of both the DWS in Radiology as well as web based image distribution. To avoid interruption of service, the old and new PACS archive had to run parallel during a transition period. DWS were replaced one by one. The changeover from web based image distribution to the new system by contrary, will be without transitional arrangements. *Status so far:* High Availability PACS server with load balancing is running at two sites. All DWS in Radiology have been replaced. 7 TB of data (2 years) have been imported into the TIANI archive. All clinical presentations have been switched to TIANI software. Tests for the new image distribution are running.

Conclusion: Migration of PACS without interruption of service has been successfully achieved in our hospital. Radiologists' worklist facilitated by the high speed of the new PACS.

Sixteen-row CT angiography for assessment of the aortoiliac and lower extremity arteries in patients with peripheral arterial disease: Prospective comparison with digital subtraction angiography

J.K. Willmann, B. Baumert, T. Schertler, S. Wildermuth, T. Pfammatter, B. Marincek, T. Böhm; Zürich/CH

Purpose: To prospectively compare the accuracy of sixteen-detector row computed tomography angiography (CTA) with digital subtraction angiography (DSA) for assessment of the aortoiliac and lower-extremity arteries in patients with peripheral arterial disease (PAD).

Materials and Methods: Thirty-nine consecutive patients with PAD underwent both DSA and CTA. For data analysis, the arterial vascular system was divided into 35 segments. A total of 1365 arterial segments were analyzed by two independent blinded readers for arterial stenosis using a four-point grading system. A third independent, blinded reader assessed possible reasons for disagreements between CTA and DSA. Effective radiation dose was calculated for both imaging modalities.

Results: CTA and DSA were diagnostic for all 1365 vascular segments. Compared to DSA, the sensitivity and specificity of CTA with regard to detection of hemodynamically significant stenosis of all 35 arterial segments combined were both 96% for reader 1 and both 97% for reader 2. Reader 1 and 2 overestimated arterial stenosis in 42 (3%) and 34 (2.5%) arterial segments, respectively and underestimated arterial stenosis in 13 (1%) and 10 (0.7%) arterial segments, respectively. Interobserver agreement was excellent ($\kappa = 0.84-1.00$). Presence of an anteroposterior located luminal narrowing and extensive vascular wall calcification were considered main reasons for disagreements between both imaging modalities. Effective radiation dose was lower for CTA (1.6-3.9 mSv) compared to DSA (6.4-16 mSv).

Conclusion: Sixteen-detector row CTA is an accurate and reliable, non-invasive alternative to DSA for assessing the aortoiliac and lower-extremity arteries in patients with PAD.

B-242 14:09

Low-dose multidetector row CT (MDCT) angiography of the infrarenal aorta and lower extremity vessels: Comparison of different radiation dosages with standard DSA

F. Fraioli, C. Catalano, F. Venditti, L. Bertoletti, R. Passariello; Rome/IT

Purpose: To compare the effect of different radiation dosages in MDCT-Angiography with DSA in the evaluation of the infrarenal-aorta and lower-extremities vessels.

Materials and Methods: 75 patients, randomly divided into three groups of 25 patients each, were evaluated for atherosclerotic disease with MDCT (4x2.5 mm) and DSA. MDCT scanning parameters were kept constant, except for milliamperage (mAs) and scanning-time. Group A: 50 mAs, scanning time 32 s; group B: 100 mAs, scanning time 40 s; group C: 130 mAs, scanning time: 45 s. Images were analysed by two radiologists in consensus. Diagnostic value of MDCT (comparing with DSA) were evaluated for each data set. Total radiation exposure for each group was also calculated.

Results: The average total weighted CT dose index was 4.7 mGy for 50 mAs, 9.4 mGy for 100 mAs, and 12.21 mGy for 130 mAs. Dose reduction was 62% for group A and 23% for group B. The evaluation of the presence and degree of stenosis revealed a sensitivity of 99.1%, a specificity of 95.5%, an accuracy of 96.3%, a PPV of 86.7%, and a NPV of 99.7% for Group A (50 mAs). Sensitivity, specificity, accuracy, PPV, and NPV of Group B (100 mAs) were 99.2%, 97.2%, 97.7%, 92.2%, and 99.7% respectively. For the standard dose protocol (Group C 130 mAs), we found a sensitivity, specificity, accuracy, PPV, and NPV of 99.2%, 97.4%, 97.9%, 93.2%, and 99.7% respectively for all stenotic lesions.

Conclusion: Low-dose scanning is a feasible and accurate option for 4-channel MDCT angiography of the peripheral vessels. This technique provides substantial reduction of the radiation-dose delivered to the patient while maintaining optimal diagnostic accuracy.

Dynamic time-resolved MRA compared with DSA in patients with limb threatening ischemia

O.A. Meissner¹, J. Rieger¹, C. Weber¹, U. Siebert², M.F. Reiser¹, S.O. Schoenberg¹; ¹Munich/DE, ²Boston, MA/US

Purpose: To compare a time-resolved echoshared MRA technique (TREAT) with DSA in patients with limb threatening ischemia.

Methods and Materials: TREAT (Magnetom Sonata, Siemens Medical Solutions) and DSA studies were obtained in 17 consecutive patients. The MRA protocol consisted of an initial time-resolved acquisition of the lower calf and a four-station bolus-chase MRA of the pelvis, thigh and proximal calf. TREAT with isotropic 1 mm³ voxel size was performed using parallel imaging techniques with in-built auto-calibration of the receiver coils in combination with 3D echo sharing. Each affected limb was divided into 11 segments; 165 (100%) arterial segments were available for comparison. Three blinded readers evaluated the amount of venous contamination (1 = none, 2 = mild, 3 = major - diagnostic evaluation not possible) and identified the target lesion. TREAT was compared with DSA as reference standard. The overall interobserver and intermethod comparison was expressed as percent agreement with 95% confidence intervals (95%CI).

Results: Venous contamination was graded 1 in 162/165 (98%) and 2 in 3/165 (2%) vascular segments, none was graded 3. Interobserver agreement was excellent for TREAT and DSA for identifying the target lesion (89% [61%, 100%] and 94% [73%, 100%] respectively). Intermethod agreement for TREAT and DSA was high (92% [71%, 100%]).

Conclusion: TREAT with dynamic image evaluation has the potential to significantly reduce venous contamination, one major problem inherent to standard MRA. With its high interobserver and intermethod agreement, TREAT is comparable to DSA in planning treatment for patients with limb threatening ischemia.

B-244 14:27

16-slice CT angiography vs gadolinium enhanced MR angiography in the evaluation of peripheral arterial occlusive disease: A work in progress

A. Cina, C. Di Stasi, T. Misciasci, F.M. Martina, R. Manfredi, B. Merlino, L. Natale, L. Bonomo; Rome/IT

Purpose: Multidetector-CT angiography (MDCTA) and gadolinium-enhanced magnetic resonance angiography (MRA) are replacing transcatheter-angiography in the diagnostic imaging of peripheral arterial obliterating disease (PAOD). Several studies have compared MDCTA or MRA to transcatheter-angiography, however no data are available about the comparison MDCTA-MRA in the femoro-popliteal and infrapopliteal regions. The purpose of this paper is the assessment of the accuracy of MDCTA vs MRA.

Materials and Methods: 15 consecutive patients with PAOD (Fontaine II-IV) underwent MDCTA (Lightspeed 16,GE) and (within 30 days) Gadolinium subtracted mobitrac MRA (Signa Echospeed 1.5 T,GE). Thirteen arterial segments per limb were evaluated: from common iliac to pedal. For each segment, the degree of stenosis (< 50%; 50-70%; > 70; 100%) and diagnostic confidence were assessed by a blinded observer. We arbitrarily defined as true-positive and true-negative cases of concordance between MDCTA and MRA, while in discordant segments, false positive and negative where identified by a selective Color-Doppler-US examination performed by an experienced operator.

Results: 152 segments were available for the analysis. Overall accuracy of MDCTA (92%) and MRA (89%) were similar. In the infrapopliteal segments, MDCTA was slightly more accurate (85% vs 79%) giving more confidence for the identification of significant stenosis. In infrapopliteal arteries with extensive calcified lesions (11% in our series), however, MDCTA gave poor results in terms of accuracy (65%) and confidence compared to MRA (78%).

Conclusion: In patients without contraindications to MRA and MDCTA, both techniques are accurate for the identification of significant stenosis. MDCTA, in patients with suspected infrapopliteal lesions, may be considered as first choice if previous examinations (i.e. Color-Doppler) do not reveal extensive calcified lesions.

B-245 14:36

MRA of the pedal arteries with MS-325, a blood pool contrast agent, and comparison with selective intraarterial DSA

K.-F. Kreitner, C. Nieswand, R. Kunz, K. Oberholzer, M. Thelen; Mainz/DE

Purpose: To compare MS-325 enhanced MRA of the pedal vasculature with selective intraarterial DSA.

Patients and Methods: 18 patients with peripheral arterial occlusive disease

and type I or II diabetes were prospectively examined at 1.5 T. For contrast enhancement, 0.03 mmol of MS-325 was administered. MR imaging consisted of dynamic imaging with acquisition of 6 consecutive data sets so as not to miss the bolus arrival, and of high-resolution steady state imaging. Selective DSA was performed within 24 hours and served as a standard of reference. Image analysis was performed by two observers and comprised assessment of image quality as well as the detection of patent segments of the distal calf and pedal vessels.

Results: There were no differences between MRA and DSA regarding overall image quality. MRA detected significantly more patent vessel segments than did DSA ($P < 0.001$, kappa = 0.46). Interobserver agreement of MRA was very good with respect to the detection of patent vessel segments and the assessment of hemodynamically significant stenoses (kappa = 0.97 and kappa = 0.89, respectively). SNR and CNR measurements returned high values during dynamic imaging after contrast arrival and during steady state imaging. Steady state imaging was hampered by venous superimpositions. There were no clinically significant trends in vital signs, laboratory tests or ECGs.

Conclusion: MS-325 enhanced MRA of the pedal vasculature proved to be superior to selective DSA. It demonstrated a long imaging time window, however, due to venous superimpositions, steady state imaging requires dedicated postprocessing techniques.

MDCT angiographic evaluation of radial artery in coronary artery bypass candidates

M. Karcaaltincaba, D. Akata, O.F. Dogan, U. Duman, E. Boke, A. Besim; Ankara/TR

Purpose: The radial artery (RA) is increasingly being used for coronary bypass grafting (CABG). The aim of this study is to demonstrate the usefulness of MDCT angiography for evaluation of RA as an alternative to conventional angiography.

Methods and Materials: Seventeen patients scheduled for CABG entered this study. 4-channel ($n = 13$) and 16-channel ($n = 4$) MDCT angiography was performed in cases with a normal Allen test. There was no selection of patients in relation to patient characteristics. Technical parameters for 4-channel and 16-channel MDCT angiography were: Pitch 1.75 and 1.5; slice thickness, 1.25 mm and 1 mm; detector collimation, 1 mm and 0.75 mm increment, 1 mm and 1 mm; table speed 14 mm/s and 36 mm/s. Contrast dose ranged from 50-140 ml and rate of injection was 4 ml/s.

Results: Bilateral forearm arteries were visualized in all patients. Technical success rate was 100%. Radial artery pathologies were noted in four patients (23.5%). Unilateral radial artery calcification was noted in three of the patients (17.6%) and occlusion was found in one patient with a normal Allen test. Radial arteries with calcification were not used for CABG. Anatomic variations of the upper limb arteries were seen in two of the patients (11.8%), which were: Persistent median artery with absent radial and ulnar arteries, and high bifurcation of radial artery from brachial artery. Patency of the radial arteries were confirmed in patients who underwent surgery.

Conclusion: MDCT angiography can be used for the detection of radial artery calcification and patency, assesment of forearm circulation and its anatomic variations to avoid inadvertent use of a diseased radial artery conduit.

Bilateral contrast-enhanced MR angiography of the hands at 3.0 Tesla versus 1.5 Tesla using parallel imaging: Intraindividual comparison of signal behaviour and image quality with angiological correlation in patients with severe ischemic hand disease

O. Moske-Eick, J.T. Winterer, N. Ghanem, K. Elsner, J. Leupold, R. Strecker, E. Kotter, M. Langer; Freiburg/DE

Purpose: Due to the small-sized target vessels, early venous contamination and variety of possible pathologic conditions, arteriography of the hand vasculature is still a challenge for MR-Angiography. The purpose of this study was to determine the benefits of contrast-enhanced MR angiography (ce-MRA) at 3.0 Tesla to signal-to-noise (SNR), contrast-to-noise (CNR) and diagnostic imaging quality compared with 1.5 Tesla technique in patients with severe ischemic hand disease.

Methods: Following administration of 17 ml Gadobenate Dimeglumine bilateral MRA of the hands was performed on a Sonata 1.5 Tesla and a Trio 3.0 Tesla scanner (Siemens, Erlangen, Germany) in 10 patients with severe ischemic hand disease. MRA was done with a timed ultrafast gradient-spoiled multiphasic elliptically reordered fast low angle shot (FLASH) sequence protocol equipped with parallel imaging (GRAPPA). Postprocessing included image subtraction, overlapping thin-slice MIPs and angulated targeted MIPs. Differences between 1.5 T and 3 T were evaluated intraindividually with a) ROI measurements of vessel

Scientific Sessions

SNR and CNR, b) multi-observer rating of diagnostic image quality c) assessment of artefacts and venous contamination.

Results: Multiphasic centric reordered acquisition provided high-resolution arterial-phase images with sufficient suppression of venous contamination and low incidence of artefacts.

Compared with 1.5 Tesla, SNR and CNR at 3.0 Tesla showed a marked increase of 100% / 121% resulting in a significant improvement of vessel delineation and image quality grading.

Conclusion: 3.0 T parallel MR imaging clearly improves ce-MRA of the hands, providing a twofold increase of SNR/CNR and a better delineation of the small-sized arterial hand vessels in microvascular diseases.

B-248 15:03

Optimisation of imaging parameters of MR angiography of the hand with subsystolic cuff-compression

T. Gluecker, J. Schwarz, G. Bongartz, D. Bilecen; Basle/CH

Purpose: To assess the impact of various injection rates on MR angiography of the hand with and without subsystolic cuff-compression.

Methods and Materials: 10 healthy individuals (mean age 24.4 years, range 20-27 years) underwent MR angiography of both hands. Starting 3 min prior to data acquisition, subsystolic upper arm compression was applied (value 30% below the brachial artery systolic pressure).

Imaging parameters were: 1.5. T whole-body scanner (Magnetom Sonata, Siemens, Erlangen, Germany), 3D GRE sequence (TR 4.45, TE 1.28, flip angle 25°). 7 data sets (20 sec) were obtained consecutively. Intravenous contrast injection of 0.1 mg/kg bodyweight Gadobutrol (Gadovist®, Schering, Berlin, Germany) was done with flow rates of 0.5 ml, 1.0 ml and 1.5 ml /sec. For both hands, quantitative data evaluation was performed with contrast-to-noise ratio (CNR) in the radial, ulnar, palmar and digital arteries. Qualitative assessment of arterial signal and venous contamination was rated by two experienced radiologists.

Results: The lowest amount of venous signal and contamination (CNR and readers' assessment) was observed with a flow rate of 0.5 ml/sec ($p < 0.05$). For the arterial vessels, no significant difference concerning CNR values and readers' assessment of data quality was observed between the 3 flow rates ($p = 0.08$). For all 3 flow rates, compression yielded significantly less venous contamination as compared to the non-compressed side ($p < 0.05$).

Conclusion: For all flow rates, image quality of hand MR angiography was better with cuff-compression. A flow rate of 0.5 ml/sec yielded good CNR ratio and significantly lower venous contamination.

Optimized whole-body cardiovascular magnetic resonance (MR) screening with parallel imaging: Experience in over 100 patients on a 32-channel MR imaging system

H. Kramer, S.O. Schoenberg, K. Nikolaou, A. Struwe, M.F. Reiser; Munich/DE

Purpose: To develop a whole-body cardiovascular MR examination without compromises compared to organ based routine exams and to present experience on a standard and a whole-body scanner in more than 100 individuals.

Material and Methods: We combined recent technical developments such as the whole-body matrix coil system, a scanner with a large range of table movement and the advantages of iPAT. This made it possible to perform MR angiography (MRA) of the entire arterial system together with a complete cardiac examination. 3D-Gd-MRA was performed at a spatial resolution of less than $1.4 \times 1.0 \times 1.5 \text{ mm}^3$. Due to the matrix coils and the large range of table movement, imaging of the entire body including functional and perfusion imaging of the heart, whole-body 3D-Gd-MRA, imaging of CNS, lungs and abdomen was possible within less than 75 minutes. Image quality and pathologic findings were rated by two readers blinded to each other's findings.

Results: Over 100 individuals were examined on two different MR scanners (standard / whole-body). We detected several myocardial (6) and vascular (10) pathologies. Mean scan time on the whole-body scanner (75 min) was significantly shorter than on the standard scanner. Image quality and detection of pathologies showed good to excellent inter-observer agreement ($\kappa 0.67 - 0.91$).

Conclusion: The recent technical improvements in cardiovascular imaging with high temporal and spatial resolution enable a combination of different morphologic and functional techniques in a whole-body scan within less than 75 minutes. The matrix coils together with iPAT offer the possibility of whole-body imaging instead of organ-based imaging.

B-250 15:21

Reduction of contrast agent dose in intraarterial 3D contrast enhanced MR-angiography of the upper and lower leg

C. Hashagen, G. Bongartz, W. Steinbrich, M. Aschwanden, K. Jaeger, R. Hügli, L. Jakob, D. Bilecen; Basle/CH

Purpose: To perform MR-guided interventions, intraarterial repetitive injections of contrast agent are necessary. We focus on a reduction of gadolinium based contrast agent dose, by reducing the injection duration during image acquisition in patients with peripheral arterial occlusive disease (PAOD).

Methods and Materials: Intraarterial gadolinium injection was performed to depict femoropopliteal/infrapopliteal arteries in six patients. Conventional 3D turbo flash sequence was applied on a 1.5 T whole-body MR scanner. Six measurements with an injection duration of 20, 30, 40, 60, 80 and 100% of the total acquisition time (TA = 27 s) were performed. Quantitatively, the intraluminal contrast-to-noise ratio (CNR) was determined. Qualitatively, a consensus reading of image quality was performed.

Results: CNR values comparable to full length injection (100%) were obtained at the femoropopliteal artery at $\geq 40\%$ of injection duration and for the infrapopliteal artery at $\geq 60\%$. In contrast, qualitative analysis demonstrated that injection duration of $\geq 80\%$ is necessary to obtain good diagnostic image quality.

Conclusion: Our data are in accordance with a recently published phantom study, where the CNR value of vessel enhancement is - within a certain range - only moderately affected by reduction of the injection duration (1). In contrast, the image quality itself is strongly affected by the reduction of injection duration and might therefore hamper the diagnostic quality. We conclude that reduction of injection duration is not a valuable method to reduce intraarterial gadolinium dosage. (1.) Hwang,KP, et al., J Magn Reson Imaging, 2002. 15(1):p.55-61.

Detection of osteoporosis-related spine fractures on routine lateral chest radiographs

D. Mueller¹, M. Isbary¹, H. Boehm¹, J. Bauer¹, E.J. Rummey¹, T.M. Link²;
¹Munich/DE, ²San Francisco, CA/US

Purpose: Vertebral fractures are the most common complication of osteoporosis but remain frequently undetected by radiologists on routine lateral chest radiographs. As these fractures lead to important health consequences and further fractures are preventable by appropriate medication, recognition is important. The purpose of this study was to investigate how frequently vertebral fractures were found in lateral chest radiographs, how frequently they were missed in the initial reports and to assess treatment for osteoporosis in the postmenopausal women with fractures.

Methods and Materials: 802 consecutive routine lateral chest radiographs of postmenopausal women (age \geq 50 years) were evaluated. The radiographs were chosen without knowledge of clinical findings and were independently reviewed by two radiologists. A validated semi-quantitative method (spinal fracture index = SFI) was used to assess the radiographs for vertebral fracture. In addition medical record notes and radiology reports were assessed to determine how many fractures were correctly identified and how frequently osteoporosis specific treatment was initiated.

Results: The mean age of the postmenopausal women was 68.2 years ($SD \pm 10.1$ years). Clinically relevant vertebral fractures (SFI > 1) were found in 115 patients (14.3%). Only 36/115 (31.3%) of those fractures were noted in the official radiology reports and in only 22/115 (19.1%) treatment was initiated.

Conclusion: As future osteoporotic fractures can be prevented by appropriate medication and chest radiography has the potential to serve as a tool to diagnose osteoporosis it is of great importance for the radiologist to focus on the spine in these radiographs.

B-252 10:39

Digital X-ray radiogrammetry (DXR-BMD) used in follow-up efficacy of alfacalcidol in postmenopausal osteoporosis

C. Galesanu, R.G. Galesanu, G. Melnic; Iasi/RO

Purpose: To estimate by DXR-BMD, the therapeutic efficacy of alfacalcidol in post-menopausal osteoporosis after two years of treatment. Osteoporosis and fracture risk represent a worldwide public health problem. Estrogen deficiency and declining calcium absorption due to reduced D hormone levels are important factors in the pathogenesis of bone loss. DXR-BMD system has shown to have a good correlation (> 0.90) to DXA.

Material and Methods: 2,475 healthy women addressed to the service of Bone Densitometry using DXR-BMD (Pronosco Xposure System™). From among these 1,741 were in post-menopausal. Using WHO criteria of osteoporosis diagnosis (T-score lower as -2.5), we found 687 women with osteopenia and 303 women with osteoporosis. The other 751 women were represented by the control group. 391 patients with osteopenia received 0.5 mcg alfacalcidol/daily. 165 patients with osteoporosis received 1 mcg alfacalcidol/daily. After 12 and 24 months all patients were evaluated for change in BMD by DXR.

Results: In the group with osteopenia the BMD increased by 3.4% and 2.3% after one and two years respectively. In the group with osteoporosis BMD increased by 1.8% and 2.4% after one and two years respectively. The decrease of BMD in the control group was between 1.8% and 3.4% in the first and second year.

Conclusion: DXR-BMD technology confirmed the therapeutic effect of Alfacalcidol in the abolition of loss of bone mass and the increase of bone mass density (BMD) compared with the control group.

Lumbar spine and hip bone mineral density discordance assessed by dual-energy X-ray absorptiometry (DEXA)

A. Fausto, L. Menicagli, A. Aliprandi, N. Ulgheri, F. Sardanelli; Milan/IT

Purpose: To evaluate concordance and discordance between lumbar spine and hip bone mineral density assessed by dual-energy X-ray absorptiometry (DEXA).

Materials and Methods: Three hundred ninety-seven outpatients (age 62 ± 10 yrs.) with lumbar spine (L1-L4) and hip evaluation of bone mineral density with DEXA (Hologic Delphi) were retrospectively reviewed. We used World Health Organization criteria for the diagnosis of normal, osteopenic, and osteoporotic bone. The information supplied by DEXA, T-score and Z-score of both districts, was compared and scored as follows: same results in both districts = concordance; normal/osteopenia and osteopenia/osteoporosis = grade 1 discordance; normal/osteoporosis = grade 2 discordance.

Results: Analysis showed 215 cases of concordance (54%), 159 grade 1 discordance (40%), and 23 grade 2 discordance (6%). Grade 1 discordances were 23 normal lumbar spine/osteopenic hip (14%), 56 osteopenic lumbar spine/normal hip (35%), 12 osteopenic lumbar spine/osteoporotic hip (8%), 68 osteoporotic lumbar spine/osteopenic hip (43%). Grade 2 discordances were all osteoporotic lumbar spine/normal hip. In all groups, no significant difference for age, menopausal age, weight, and height was observed.

Conclusions: About 46% of DEXA of lumbar spine and hip were discordant. In our series, grade 2 discordance (all osteoporotic lumbar spine/normal hip) suggest a lumbar spine selective involvement by the disease, confirmed by the prevalence (35%) of osteopenic lumbar spine/normal hip in grade 1 discordance. Bone mineral density loss affects the lumbar spine more often, and probably then spreads to other body regions.

B-254 10:57

Potential predictive factors of osteoporosis in young HIV-positive subjects

A. Fausto, M. Bongiovanni, L. Menicagli, P. Cicconi, F. Sardanelli; Milan/IT

Purpose: To evaluate vertebral and hip demineralization with dual-energy X-ray absorptiometry (DEXA) in naive and those treated with highly active antiretroviral therapy (HAART) human immunodeficiency virus (HIV) outpatients.

Materials and Methods: Thirty-one naive HIV patients (20 male, 11 female; age 39 ± 6 years) were age- and sex-matched with a group of HIV outpatients treated with HAART. In both groups, bone mineral density (BMD) was assessed with DEXA in both lumbar spine (L1-L4) and hip. Additional parameters: weight, smoking, risk factors for HIV (intravenous drugs abuse, homosexuality or heterosexuality), HCV sero-status, total treatment duration, CD4 counts, HIV-RNA serum levels, fasting metabolic parameters and biochemical markers of bone metabolism. A Cox multivariable model was used.

Results: Thirty-one patients showed osteopenia and osteoporosis; 20 were on HAART and 11 naive (RR: 1.37, 95% CI: 1.12-2.15, $p = 0.09$). Mean CD4 count and HIV-RNA levels were 471 ± 127 cell/mm 3 and 4.28 ± 2.33 Log10 copies/ml respectively. Osteopenia and osteoporosis affected 22 men (6 naive) and 9 women (5 naive) (RR: 2.70, 95% CI: 0.84-8.68, $p = 0.09$), low weight patients (RR: 0.96, 95% CI: 0.91-1.00, $p = 0.06$ for each kilos more); moreover, the probability of bone demineralization increased with the duration of treatment (RR: 1.02, 95% CI: 1.01-1.03, $p < 0.01$ for each month of treatment more). No significant difference was observed for other parameters. Biochemical markers of bone metabolism were in the normal range for all patients.

Conclusions: Careful surveillance of BMD should be given to HIV infected subjects treated with HAART, particularly if they are women, of low weight, and on long-term treatment.

B-255 11:06

The influence of posterior instrumentation on adjacent and transfixated facet joints in patients with thoracolumbar spinal injuries: A morphological in vivo study using computed tomography osteoabsorptiometry (CT-OAM)

S. Wagner¹, M. Müller-Gerbl¹, A. Weckbach²; ¹Munich/DE, ²Würzburg/DE

Purpose: To examine the influence of posterior instrumentation on content and distribution of subchondral mineralization as a correlate of a long-term load acting on adjacent and transfixated facets.

Materials and Methods: 23 patients with thoraco-lumbar fractures had CTs and received posterior fixation. Patients were divided into group A (second CT on an average of 7.3 days) and group B (second CT on an average of 17 months after implant removal). CT-OAM was performed. Facet joints were separated on each CT-slice and 3D-reconstructed. The subchondral bone plate in each slice was isolated and reconstructed. In the density image summarized HU were represented

Scientific Sessions

by false colors. Finally, the density images were projected onto the 3D images. The resulting pictures were used to evaluate intra-individual changes in mineralization of paired facets joints by visual and quantitative analysis.

Results: There were significant differences between groups A and B with an overall mineralization decrease in group A and an increase in group B. In group A no significant differences between adjacent and transfixated facets were found, in group B the suprarectal joints showed a significantly higher mineralization increase than the transfixated joints.

Conclusion: Decrease in subchondral mineralization indicates reduced load upon the facets. This finding in patients with early follow-up seems to be caused by reduced activity until implant removal. In patients with longer follow-up intervals higher loads are shown which might be caused by unphysiological long-term stress induced by stabilization. Whether these changes lead to spondylarthrosis has to be the subject of further studies.

B-256 11:15

3D structure analysis based on the scaling index method in relationship to DXA in postmenopausal women with osteoporotic spine fractures

D. Mueller¹, R. Monetti², S. Majumdar³, H. Boehm¹, C. Raeth², E.J. Rummel¹, T.M. Link³; ¹Munich/DE, ²Garching/DE, ³San Francisco, CA/US

Purpose: The scaling index method (SIM) is a non-linear technique to extract texture measures for the quantitative characterisation of trabecular bone structure. This new method, which is demonstrated to improve the diagnostic performance in differentiating postmenopausal women with and without osteoporotic spine fractures, was applied to high resolution magnetic resonance (HR-MR) images of the distal radius. The purpose of this study was to investigate the relationship between the SIM and dual energy X-ray absorptiometry (DXA) at different sides of the body of postmenopausal women with osteoporotic spine fractures.

Methods and Materials: Axial HR-MR images of the distal radius were obtained at 1.5 T in 58 women with osteoporotic spine fractures. A 3D-GE sequence was used with a voxel size of 500x195x195 µm³. After segmentation and normalization, trabecular structure analysis was performed using algorithms based on our new local 3D SIM. In addition BMD measurements of the distal radius, spine and proximal femur using dual energy X-ray absorptiometry (DXA) were obtained in all patients.

Results: Linear regression was applied to describe the relationship between the SIM and BMD using DXA at different sides of the body. However, there was no correlation found for any of the BMD values versus the 3D structure measure based on the local scaling index method.

Conclusion: The results of this study suggest that our recently developed algorithm based on a local 3D SIM determines different entities of trabecular bone that are important for the prediction of individual fracture risk and are not reflected by BMD.

B-257 11:24

Multislice-CT-derived trabecular bone structure of the proximal femur.

A comparison with BMD in the assessment of osteoporosis

J.S. Bauer¹, S. Kohlmann², D. Mueller², F. Eckstein³, E.-M. Lochmueller², E.J. Rummel², T.M. Link¹; ¹San Francisco, CA/US, ²Munich/DE, ³Salzburg/AT

Purpose: With the development of Multislice Spiral Computed Tomography (MSCT) the achievable spatial resolution for imaging of trabecular bone at central skeletal sites has increased significantly. The goal of this in-vitro study was to investigate, whether structure parameters measured with MSCT at the proximal femur were able to improve the prediction of osteoporotic vertebral fractures compared to bone mineral density (BMD) as a standard parameter.

Materials and Methods: Ninety-five left femur specimens were harvested from formalin-fixed human cadavers (mean-age 80 ± 10 years). BMD was determined using Dual X-ray Absorptiometry (DXA). Structure parameters were calculated in MSCT-derived images of the proximal femur obtained with three different high resolution reconstruction algorithms (kernels). Additionally, the fracture status of the spine was determined in lateral radiographs of the spine. Receiver-operator-characteristics (ROC)-analysis was performed to determine the diagnostic performance of BMD and structure parameters.

Results: DXA and structure parameters both showed significant differences ($p < 0.01$) between the group of donors with and without fractures. With ROC-analysis AZ-values of up to 0.70 and 0.73 were determined for BMD and structure measures, respectively. The highest AZ-values were found in the trochanteric region with both modalities. No significant differences were found between the different kernels as well as between structure and BMD measurements ($p > 0.05$).

Conclusion: Structure measurements obtained from MSCT images of the proximal femur can be used to separate individuals with and without osteoporotic spine

fractures. However, with the settings used, DXA still remains the preferable method to assess osteoporosis due to better standardization and lower radiation exposure.

B-258 11:33

High-resolution MR imaging of the trabecular bone structure at 3 T:

Comparison between 1.5 T and 3 T

C.M. Phan¹, R. Krug¹, F. Eckstein², D.C. Newitt¹, S. Majumdar¹, T.M. Link¹; ¹San Francisco, CA/US, ²Munich/DE

Purpose: High-resolution magnetic resonance imaging (MRI) is a promising technique to depict trabecular bone (Tb) architecture. However, one drawback is the limited spatial resolution and SNR, which can be improved, in a clinical setting with the advent of 3 T MRI. The purpose of this study was to compare Tb structure parameters obtained from human calcaneus at 1.5 T and at 3 T, and to correlate these measurements with bone mineral density (BMD) data.

Methods: Thirty calcaneus specimens were imaged at 1.5 T and 3 T with a Gradient Echo (SPGR) sequence, using identical parameters (TR/TE/flip angle/bandwidth= 19 ms/4.6 ms/20°/12.5 kHz). Spatial resolution (slice thickness/field of view/matrix= 0.5 mm/80x100 mm/512x384 pixels) was identical at 1.5 T and 3 T. After spatially co-registering images obtained at the two field strengths, structural parameters and SNR in corresponding sections were compared and correlated with BMD measurements.

Results: Qualitative analysis showed a better depiction of the trabecular structure at 3 T than at 1.5 T. Quantitative analysis demonstrated significantly ($p < 0.01$) higher values for apparent trabecular number (1.84 mm⁻¹ vs. 1.538 mm⁻¹), trabecular thickness (0.225 mm vs. 0.186 mm) and bone volume fraction (0.416 vs. 0.287) in the 3 T images. Apparent bone volume fraction at 3 T showed higher correlation with BMD than at 1.5 T ($r = 0.758$ vs. $r = 0.740$). SNR at 3 T was 23% higher than at 1.5 T.

Conclusion: These preliminary results show that consistent high quality MR images of calcaneus can be obtained at 3 T using a sequence similar to that used at 1.5 T. Imaging at 3 T may substantially improve the depiction of trabecular bone micro-architecture though susceptibility artifacts also increase.

B-259 11:42

Variants of the superior labrum and labro-bicipital complex: A comparative study in shoulder specimens using MR arthrography, multi-slice CT arthrography, and anatomic dissection

S. Waldt¹, K. Woertler, S. Metz, E.J. Rummel; Munich/DE

Purpose: To assess the anatomic variability of the superior labrum and to compare the value of MR arthrography and multi-slice CT arthrography in the diagnosis of variants of the labro-bicipital complex.

Material and Methods: 55 human shoulder specimens were examined with the use of MR arthrography and multi-slice CT arthrography prior to joint exploration and macroscopic inspection of the labrum and labro-bicipital complex. Two radiologists evaluated MR and CT arthrograms and the results were compared with macroscopic assessments.

Results: Anatomic dissection of all shoulder specimens revealed a sublabral recess in 39/52 (75%) of cases. The attachment of the superior labrum was categorized as type 1 in 12 (23%) cases, as type 2 in 9 (17%) cases, as type 3 in 12 (23%) cases, and as type 4 in 18 (35%) cases. One lesion was classified as a SLAP type 3 lesion. On MR arthrography and CT arthrography the attachment of the superior labrum at the glenoid was categorized in concordance with macroscopic assessments in 83% and 86% of cases, respectively.

Conclusion: The attachment of the superior glenoid labrum shows great variability. Thus, exact depiction of variants is essential in order to avoid the false positive diagnosis of a superior labral tear (SLAP lesion). MR arthrography and multi-slice CT arthrography both were highly effective in the detection and classification of sublabral recesses.

B-260 11:51

Evaluation of a method for digital definition of bone shapes

P. Peloschek¹, G. Langs², M. Urschler², J. Sailer¹, M. Uffmann¹, T. Schlager¹, F. Kainberger¹, H. Bischof²; ¹Vienna/AT, ²Graz/AT

Purpose: Recent developments in digital radiography raise interest in morphometric analysis as generated data can be used for reproducible and automated quantitative analysis of shape deviations as erosions, osteophytes or fractures. Aim of this study is to evaluate the accuracy of a method allowing almost user independent definition of bone shapes.

Material and Methods: The shape (bone contour) of 10 fifth metacarpal bones (MC) was defined by three radiologists for an estimation of inter- and intra-user

Scientific Sessions

agreement. The time and number of clicks needed per bone was recorded. The annotations of different radiologists were compared by the area between two curves to quantify the inter-user error. On a set of 256 landmarks lying on the bone contour the regional error distribution was analyzed.

Results: The digital definition of a MC shape takes 2-4 (avg. 3.2) minutes per bone, 4-6 (avg. 4, 3) clicks are needed. An average of 92.48% of the bone contour is identical on the manual segmentation of all 3 readers. The mean difference over all landmarks is 0.03 mm. Taking only regions into account where differences occur the mean difference is 0.34 mm. Inter-user differences occur mainly in regions where more control points have to be set manually.

Conclusion: A procedure for digital definition of bone shapes with excellent inter- and intra-user agreement is presented. Future applications include morphometric analysis and training of shapes for advanced computer vision algorithms. The high accuracy of this procedure indicates that consensus reading is not recommendatory in every anatomical region.

Differential diagnosis of up to 10 mm sized breast lesions using morphologic and dynamic features of MR-mammography

M. Dietzel, A. Malich, D.R. Fischer, C. Marx, C. Deicke, C. Reuchsel, F. Taher, W.A. Kaiser; Jena/DE

Purpose: To evaluate the MR-Mammographical differences of dynamic and morphologic patterns in small malignant vs benign lesions of ≤ 10 mm.

Methods and Materials: All histologically verified lesions ≤ 10 mm having had a MR-Mammography (1/2002-3/2004; n = 118; 39 malignant, 79 benign) were retrospectively evaluated by two experienced radiologists in consensus according to standard protocols and study design (2D-FFE sequences, 0.1 mmol/kg bw Gd-DTPA, T2-TSE). The prevalence of the following signs statistically was analyzed (Chi-Square-testing): Dynamic signs - fast initial wash-in (D1), wash out (D2), plateau (D3), fast initial continued signal intensity increase (D4), blooming (D5), segmental enhancement (lesion's surrounding; D6), homogeneity of contrast uptake (D7). Morphologic signs (T1) - hook-sign (M1), root-sign (M2), adjacent vessels (M3), skin thickening (M4), nipple line-sign (M5), inhomogeneity of lesions composition (M6), lesion's shape (round/lobular/linear M7), regular margins (M8), septations (M9). Morphologic signs (T2) - necrosis (M10); perifocal (M11), diffuse edema (M12); hypointensity of vital tumor parts (M13).

Results: Prevalence malignant/benign were: D1s = 49%/34% (n.s.); D2s = 46%/24% ($p = 0.02$); D3s = 31%/36% (n.s.); D4s = 23%/40% (n.s.); D5s = 36%/10% ($p = 0.001$); D6s = 18%/4% ($p = 0.015$); D7s = 36%/57% ($p = 0.03$); M1s = 8%/3% (n.s.); M2s = 69%/19% ($p = 0.001$); M3s = 26%/4% ($p = 0.001$); M4s = 10%/1% ($p = 0.04$); M5s = 3%/4% (n.s.); M6s = 77%/89% (n.s.); M7s = 67%/89% (0.02); M8s = 8%/41% ($p = 0.001$); M9s = 5%/8% (n.s.); M10 = 0%/1% (n.s.); M11 = 15%/3% ($p = 0.015$.); M12 = 3%/5% (n.s.); M13 = 8%/25% ($p = 0.02$).

Conclusion: Whereas there is no significant difference regarding fast initial wash-in, plateau, septations and necrosis, wash out blooming, homogeneity of contrast uptake, root-sign, hypointensity of vital tumor parts, lesion's shape and margins are vital in assessment of small breast lesions.

B-262 10:39

Ductal carcinoma in situ: MR mammographic appearance and pathological correlation

S. Ganau, X. Andreu, E. Sáez, L. Tortajada, A. Massuet, M. Sentís; Sabadell/ES

Purpose: To assess the value of contrast enhancement MR-mammographic (MRM) findings in Ductal Carcinoma in Situ (DCIS).

Methods and Materials: One hundred and twenty-one patients with pure DCIS without micro-infiltration or association to another infiltrating carcinoma (n = 126), selected from the pathology registry, were elected for the present study. MRM was performed on a 1.0 T unit, using T2-weighted SE sequences and dynamic T1-weighted FLASH-3D sequences before and after 0.16 mmol/Kg of Gd-DTPA iv. Normalized signal intensity enhancement, wash-out, speed of enhancement

and morphology was analyzed for all cases. Findings in MRM were compared to histologic and immunohistochemical results.

Results: In 117 lesions enhancement was found (92.86%). In all cases enhancement could be classified as a pathological, despite different curve morphologies. High grade DCIS showed significantly higher enhancement values than lower and intermediate grade, and a more characteristic signal intensity curve. Non-enhancing lesions were predominantly scored 1 point in Van Nuys size evaluation. Significant correlation was found between size in MRM and pathologic size.

Conclusion: MRM is able to visualize the extent of DCIS. Correlation between high-grade DCIS and signal intensity values are found.

B-263 10:48

Correlation of dynamic and morphologic patterns of pure DCIS cases in MR-mammography

M. Facius, A. Malich, S. Wurdinger, H. Neubauer, C. Marx, W.A. Kaiser; Jena/DE

Purpose: To describe characteristic kinetic and morphological patterns of pure DCIS on dynamic MRM.

Methods and Materials: In 74 patients having had a MRM between 1995 to 2001 histopathology revealed a pure DCIS. All patients were performed on a 1.5 T unit (Gyroscan S15 ACS II, Philips) using the same protocol: T1w coronal, TSE prior/post Gd-DTPA (0.1 mmol/kg bw), a dynamic 2D FFE, T2w TSE. Two observers evaluated the features in consensus. Enhancement was: C1 = similar to glandular tissue, C2 = slow-continuous, C3 = strong initial-slowly further, C4 = strong initial-plateau, C5 = strong initial-wash out. Morphological pattern included: M0 = no pattern, M1 = linear/ductal, M2 = segmental/reticular, M3=segmental/homogeneous, M4 = circumscribed.

Results: Grading distribution was as follows: 30/74 (40.5%;G1); 19/74 (25.7%;G2), 18/74 (25.7%;G3), 7/74 (9.5%;no available grading). Dynamic pattern were observed as: C1: 7/74 (9.5%); C2 14/74 (18.9%); C3 15/74 (20.3%); C4: 15/74 (20.3%) and C5: 23/74 (31.1%). Morphological pattern were described as: M0: 8/74 (10.8%); M1: 3/74 (4.1%); M2: 41/74 (55.4%); M3: 9/74 (12.2%); M4: 13/74 (17.6%). Whereas all G3 cases had a morphological pattern in MRM, only 23/30 G1 cases (76.7%) were in any extent visible. 17/18 G3 cases (94.4%) were characterized by M2-4 morphology. 10/18 G3-cases (55.6%) and 11/30 G1-cases (36.7%) were suspicious due to C4 or C5. 6/18 G3-cases (33.3%) and 11/30 G1-cases (36.7%) were characterized by C1 or 2.

Conclusion: There are typical morphological (M2-4) as well as dynamic signs (C4-5), which are especially helpful in the detection of the clinically most relevant G3 cases.

B-264 10:57

What a sensitivity of mammography and dynamic MR for in situ breast cancers if we use the whole breast as a pathologic gold standard? Results from a multicenter trial

F. Sardanelli¹, A. Fausto¹, P. Panizza¹, G.M. Giuseppetti², V. Lattanzio³, A. Del Maschio¹; ¹Milan/IT, ²Ancona/IT, ³Bari/IT

Purpose: To compare mammography and MR in detecting in situ breast cancers (ISBCs).

Methods and Materials: Ninety patients candidate to monolateral (n = 81) or bilateral (n = 9) mastectomy underwent mammography and MR (coronal 3D gradient-echo; 3 mm thickness or less; gadoteridol, Bracco, 0.1 mmol/kg). Pathology: 5 mm slices covering the whole breast. Off-site reading aware of the entry criterion (planned mastectomy).

Results: Out of 99 breasts, pathology revealed 30 ISBCs: Ductal (n = 26), lobular (n = 3), and mixed (n = 1). Diameter at pathology: less than 5 mm (n = 5), between 5 and less than 10 mm (n = 7), between 10 and less than 20 mm (n = 3), greater than 20 mm (n = 2), not assessed (n = 13). Sensitivity was 37% (11/30) for mammography and 40% (12/30) for MR (not significant, McNemar). Mammography recognized 13 lesions, but two of them (opacities) were diagnosed as benign, the remaining 11 as malignant: Opacity (n = 6); opacity and microcalcifications (n = 2); only microcalcifications (n = 2); architectural distortion (n = 1). MR recognized 12 lesions, all as malignant. Mammography and MR were agreeing true positive (TP) in 9 cases (pathological diameter, 20.0 ± 12.9 mm) and agreeing false negative (FN) in 16 (3.5 ± 2.1 mm, $p = 0.017$, Mann-Whitney), disagreeing TP mammography and FN MR in 2, FN mammography and TP MR in 3. Thus, 37% of ISBCs were mammography-detected and only 10% (3/30) mammography-undetected and MR-detected; 40% were MR-detected and only 7% (2/30) MR-undetected and mammography-detected. Only 47% of ISBCs were mammography- or MR-detected, 53% remaining undetected.

Conclusion: If we use the whole breast as a gold standard, both mammography and MR show low sensitivity for ISBCs.

Mammary parenchymal distortions with benign characteristics: Diagnostic accuracy of magnetic resonance

L. Carra, S. Attanasio, F. Crinò, A. Giampietro, F. Bosurgi, A. Carrieri; Novara/IT

Purpose: The aim of this study was to evaluate the diagnostic accuracy of Magnetic Resonance (MR) in patients with a mammographic parenchymal distortion with a radiotransparent core.

Material and Methods: 32 consecutive asymptomatic patients (age range 34-62 years) with parenchymal distortion with a radiotransparent core at the mammographic examination were studied. All patients underwent mammography (craniocaudal and lateral oblique projections with targeted enlargements when necessary), MR and biopsic exams (gold standard). A 1.5 T superconductive magnet with dedicated breast coil was used. The MR images were examined jointly by two experienced radiologists blinded to mammographic results. A multiple choice questionnaire was completed for each patient and the following MR parameters were evaluated: Intensity/time curve (type 1 increasement of 10%, type 2 from 11% to 50%, type 3 over 51%) and vascular pattern.

Results: 10 (31%) out of 32 lesions resulted histologically malignant. Overall sensitivity, specificity and diagnostic accuracy of MR were 100%, 64% and 75%, respectively. A statistically significant correlation between MR enhancement patterns and lesion malignancy was not observed. The absence of enhancement or a "type 2" pattern always corresponded to lesions with a benign characteristic, while "type 3" pattern was aspecific. The enhancement curves observed in patients with sclerosing adenosis were variable and non-specific.

Conclusion: Our results indicate that when a mammographic parenchymal distortion with radiotransparent core do not show any enhancement or the intensity/time curve is "type 1 or 2", the negative predictive value of MR allows the diagnosis of benign epithelial proliferation with a fibro-elastic core. A "type 3" enhancement curve means that mammo-guided surgery should be performed for a conclusive diagnosis.

B-266 11:15

Role of breast MR in the pre-surgical management of invasive breast carcinoma

C. Del Frate, L. Borghese, C. Cedolini, F. Puglisi, C. Zuiani, M. Bazzocchi; Udine/IT

Purpose: Evaluate role of breast-MR in pre-surgical management of invasive breast carcinoma.

Methods and Materials: Two radiologists and one surgeon retrospectively evaluated 121 patients (histological diagnosis of invasive breast carcinoma), who underwent pre-surgical breast-MR. Mammograms, sonograms and histology were re-examined to identify patients theoretically eligible to conservative surgery, from those eligible to radical surgery. Breast-MR and surgery effectively performed were then evaluated to identify cases for which MR determined a change in management. Gold standard was final pathology. Two evaluations, for single patient and for single lesions, were performed.

Results: Breast MR determined an overall change in management in 21/121 patients (26.4%). For patients eligible to conservative surgery, breast-MR determined a change in management in 32/87 (36.8%), 22 T1 (30.6%) and 10 T2 (66.7%), due to size increase in 8/32 cases (25%), to multifocality/multicentricity respectively in 5/32 (15.7%) and in 13/32 (40.7%), to size increase and multifocality/multicentricity in 4/32 (12.6%) cases, to contra-lateral and multicentric foci in 1/32 (3%), and to suspicious pectoral muscle infiltration in 1/32 (3%) case. In the evaluation for single patients RM resulted true positive in 25/32 (78.1%) cases, and false positive in 7/32 cases (21.9%). In the evaluation for single foci RM resulted true positive in 29/39 (74.4%) foci, while MR did not detect 6/35 foci identified in final pathology (17.1%).

Conclusions: Breast MR determines a significant change in management of patients affected by invasive breast carcinoma, particularly in patients eligible to conservative surgery after standard breast examination. Nevertheless, significant over-treatment may be expected.

B-267 11:24

Contrast-enhanced magnetic resonance mammography for screening of the contralateral breast in patients with diagnosed breast cancer

F. Pediconi, C. Catalano, F. Venditti, A. Roselli, S. Padula, R. Passariello; Rome/IT

Purpose: Role of contrast-enhanced Magnetic Resonance Mammography (CE-MRM) for evaluation of contralateral breast in patients with diagnosed breast cancer.

Methods and Materials: Fifty patients with proven unilateral breast cancer and negative contralateral breast at any examination, were evaluated. CE-MRM performed in the axial plane at 1.5 T using a bilateral surface breast coil. CE-MRM protocol comprised a T2-weighted STIR sequence and a dynamic 3D Flash T1-weighted sequence acquired before and at 2, 4, 6, 8 and 10 min after the administration of Gd-BOPTA at 0.1 mmol/Kg. Mammographic parenchymal density evaluated according to the Breast Imaging Reporting and Data System lexicon as class 1 (fatty) to 4 (dense). Level of suspicion was reported on a scale of 0 to 5 according to the BI-RADS classification. Results were compared with histological findings.

Results: 14 of 50 patients (28%) had contralateral lesions identified on CE-MRM. 4 of 14 patients were classified as BI-RADS 4 and underwent lesion biopsy, while 10 patients were classified as BI-RADS 5, and underwent surgery. At histology, 11 lesions were found to be malignant (5 DCIS, 2 LCIS, 3 infiltrating ductal carcinomas and one invasive lobular carcinoma) and considered to be true positive lesions. Conversely 3 lesions were fibroadenomas and were considered to be false positive lesions. No false negative lesions were detected on CE-MRM and none of the patients with fibroadenomas were classified as BI-RADS 5.

Conclusion: Our results demonstrated very good accuracy of CE-MRM for the detection of synchronous contralateral cancer in patients with newly diagnosed breast cancer.

B-268 11:33

Role of breast MR imaging in determining breast as source of unknown metastatic axillary lymphadenopathy

A. Athanasiou, C. Balleguier, C. Dromain, S. Delaloge, R. Sigal; Villejuif/FR

Purpose: To evaluate the role of breast MR imaging in the detection and diagnosis of primary, occult breast tumours in women presenting with isolated axillary lymphadenopathy. Impact of MR imaging in treatment planning.

Methods and Materials: Between 1999 and 2004, 32 women with malignant axillary lymphadenopathy, negative mammography and physical examination underwent a breast MR imaging. Lymph node biopsy revealed in all cases an adenocarcinoma, with hormonal profile indicating a breast tumour. Other imaging and laboratory investigations were negative. Results were compared to surgery and pathology.

Results: In 36.6% (n = 11), breast MR imaging was negative and mastectomy was performed, followed by chemotherapy and radiotherapy. In 63.4% (n = 21) cases, MR imaging detected a suspicious lesion. A focused US examination depicted a corresponding abnormality in 19% (n = 7), confirmed by biopsy. For these patients, lumpectomy followed by chemotherapy and/or radiotherapy was performed. US was normal in 14 patients: A large quadrantectomy was performed in 13 cases and a CT-guided wire localisation lumpectomy in one case. Pathology revealed 18 IDC and 3 ILC. Mean tumour size was 7 mm (4-12). In all mastectomy cases, no primary tumour was found in the specimen.

Conclusion: Breast MR imaging can be very sensitive for the detection and characterization of occult primary breast cancers in patients with isolated axillary lymphadenopathy. In these patients, MR imaging has also a potential role for staging, guiding a focused US examination and allowing a more conservative surgical approach.

B-269 11:42

Feasibility of second look sonography in clarification of incidental enhancing lesions found on preoperative MR imaging for breast cancer

M. Bernathova, G. Bodner, M. Dünser; Innsbruck/AT

Purpose: Incidental enhancing lesions that have no mammographic or palpable correlate, cause potential problems in preoperative breast MR in breast cancer. Post MR imaging second look high resolution sonography directed toward the site of the incidental lesion is introduced as alternative method to MR-guided biopsies.

Methods and Materials: From August 2003 to August 2004, 162 patient (median age 57; age range 33-84) were referred to MR imaging for preoperative staging of breast cancer. In 14 patients, the MR imaging was inconclusive with finding of an additional suspect enhancing lesion, distant from the primary lesion. These patients underwent consecutive high resolution sonography directed toward the site of the incidental finding. The correlation between two imaging modalities was done. The patients with multicentric and multifocal disease diagnosed in mammography and first look sonography were excluded from the study.

Results: In 14 (8.6%) of 162 patients, preoperative MR imaging revealed 20 new suspect foci. In 12 patients a second look sonography found a corresponding lesion. In 3 patients the sonographic guided biopsy and in 2 patients the sonographic guided wire localisation, followed by excisional biopsy disclosed a

Scientific Sessions

malignant lesion. On the basis of second look sonographic findings, a multicentric breast cancer was found in 5 (35%) of 14 patients. The clinical management changed: In 1 patient a wider excision and in 4 patients mastectomy was performed.

Conclusion: Second look direct sonography is a feasible method to clear the incidental finding in preoperative breast MR imaging, if MR-guided biopsy is not available. A skillful operator is indispensable.

B-270 11:51

Value of dynamic breast MR using an open 0.2 T magnet and Gd-BOPTA as a contrast agent: Preliminary results

M. Calabrese¹, L. Bacigalupo¹, A. Fausto², F. Sardanelli²; ¹Genoa/IT, ²Milan/IT

Purpose: To test breast MR using a low field magnet and a high T1-relaxivity contrast agent.

Methods and Materials: Fifteen patients (24-82 yrs, median 43) underwent breast MR using a 0.2 T open permanent magnet (Open, Siemens) and the body coil, in prone ($n = 2$) or supine position ($n = 13$). A coronal ($n = 7$) or axial ($n = 8$) 3D FLASH sequence was used (TR/TE = 23/10 ms, FA 30°; thickness 3 mm; pixel 1.8x1.8 mm) with 0.1 mmol/kg of Gd-BOPTA (MultiHance, Bracco) flushed by 20 ml of saline solution (2 ml/sec). All patients had ultrasound examination with BI-RADS score 5 ($n = 9$), 3 ($n = 1$), or 2 ($n = 5$); 12 patients had mammography with BI-RADS score 5 ($n = 8$), 4 ($n = 1$), or 2 ($n = 3$). Ten patients were operated; 5 MR negative cases had a 1-year or greater negative follow-up.

Results: Pathology: 4 IDCs (mean diameter 22.5 mm, range 15-30 mm); 5 ILCs (33 mm, 10-55 mm); one fibroadenoma (45 mm). At MR imaging, 4/4 IDCs and 3/5 ILCs presented suspicious morphologic and dynamic features and were classified as BI-RADS 5; one ILC presented benign morphology but inhomogeneous enhancement and strong wash-in with wash-out (BI-RADS 4); one ILC presented suspicious morphology, inhomogeneous enhancement and moderate wash-in with plateau (BI-RADS 4). The fibroadenoma presented benign morphology, homogenous enhancement and moderate wash-in with continuous increase (BIRADS 1). No MR false positive or negative case was found in this preliminary series.

Conclusions: Gd-BOPTA allows a reliable detection and characterization of breast tumors at an open magnetic field as low as 0.2 T.

Loudness dependency of the primary auditory cortex: Simultaneous fMR imaging and EEG recording

L. Jäger, C. Mulert, S. Propp, S. Karch, M.F. Reiser; Munich/DE

Purpose: The aim of the study was to compare the loudness dependency of the primary auditory cortex by means of fMR imaging and EEG to study the central serotonergic system.

Methods and Materials: 210 pure tones (1000 Hz, 200 ms duration) were presented to 14 healthy subjects at sound pressure levels of 60, 80 and 100 dB. The acoustic stimulation was performed with simultaneous EEG and fMR imaging recording and with EEG recording outside the MR scanner room. fMR imaging was performed using a 1.5 T MR system and a BOLD-EPI sequence. A multiple regression analysis and a Bonferroni correction was done with the Brain Voyager. 61-channel EEG was recorded with an EEG amplifier designed for the special requirements of the MR environment. Current source density analysis was performed with LORETA software.

Results: For all subjects the N1-amplitude was clearly identified in the EEG recordings performed simultaneously with fMR imaging and outside of the MR scanner room. The amplitude was significantly ($p < 0.05$) larger outside. There was a strong correlation ($p < 0.001$) between the amplitude increase of the N1-potentials and for the LORETA source density of the EEG recorded simultaneously with fMR imaging and the activated fMR imaging volume in Heschl gyrus. The activated fMR imaging volume, the N1-potential and the LORETA source density correlated with the sound pressure level.

Conclusion: The presented results indicate that simultaneous acquisition of event-

related fMR imaging and EEG is useful to study the serotonergic system in the primary auditory cortex.

Aging of the acoustic pathway: A DTI study

L. Jäger, F. Hemminger, J. Lutz, R. Stahl, O. Dietrich, M.J. Hempel, S.O. Schönberg, M.F. Reiser; Munich/DE

Purpose: The aim of the study was to evaluate aging of the acoustic pathway by the means of DTI.

Methods and Materials: 20 young healthy volunteers (mean age 28.5 years) and 15 elderly healthy volunteers (mean age 61.3 years) were examined using a 1.5 T MR System (Magnetom Sonata, Siemens) with a T1-weighted sequence (MPRAGE-Sequence, 1.1x1.1x1.1 mm) and an IPAT DTI EPI-sequence (TE 71 ms, TR 6000 ms, 36 slices, 1.8x1.8x3.6 mm spatial distribution). Ten subjects underwent two examinations, the second one two days later. Lateral lemniscus, inferior colliculus, medial geniculate body, auditory radiation, superficial temporal gyrus and transverse temporal gyrus were evaluated. The fractional anisotropy (FA) and the relative anisotropy (RA) were studied.

Results: There were no significant differences in FA and RA in the lateral lemniscus and medial geniculate body. However, FA and RA were reduced significantly ($p < 0.05$) in the inferior colliculus, the auditory radiation, the superficial temporal gyrus and the transverse temporal gyrus in the elderly subjects in comparison to the younger ones. There were no significant differences in anisotropy in the follow-up examinations.

Conclusion: Normal aging of the acoustic pathway is associated with a decline in anisotropy mainly in the cortical grey and white matter rather than in the subcortical regions. The normal aging process may be responsible for a reduced plasticity of the associated cortical regions and the involvement of the inferior colliculus in the pathogenesis of tinnitus. DTI results of the acoustic pathway are reproducible.

B-273 10:48

CT-MR fusion image guidance for navigated neurosurgery of temporal bone tumors

S.F. Nemec; Vienna/AT

Purpose: Presentation of CT and MR image data fusion for computer assisted navigated neurosurgery of tumors of the temporal bone.

Materials and Methods: 16 patients with temporal bone tumors underwent computed tomography (CT) and magnetic resonance imaging (MRI). CT was performed with a multi-detector CT (MDCT) using 4x 0.75 mm thick slices in high resolution bone window level setting in axial plane without inclination. MRI was performed in axial and coronal planes with T2-weighted turbo spin-echo sequences, unenhanced and contrast-enhanced T1-weighted spin-echo (SE) sequences, and coronal T1-weighted SE sequences with fat suppression and 3D T1-weighted gradient-echo (GE) contrast-enhanced sequences. The 3D T1-weighted GE sequence had a slice thickness of 1 mm in axial plane without inclination. Image data sets of CT and 3D T1-weighted GE sequences were merged on a workstation for interventional planning and intra-operative image guidance. MDCT and MR images were used to depict and to characterize lesions, the accuracy of the navigation unit and the intervention time were measured.

Results: Tumorous lesions of bone and soft tissue were excellently depicted and characterized by CT and MR images and image fusion. The images had a high diagnostic value and great impact on the surgical procedure as lesions could be differentiated into benign and malignant pathologies. The accuracy of the navigation unit was under 1 mm. The neuro-navigation reduced the surgical intervention time for 30% on average.

Conclusion: Computer assisted navigated surgery with CT-MR image data fusion helps the surgeon in planning and performing surgery and decreases intervention time.

B-274 10:57

Comparison of multislice CT (MSCT) cross-sectional source images with multiplanar 2D-, 3D- reconstructions and virtual endoscopy in the assessment of middle ear diseases

A. Trojanowska, E. Czekajska-Chehab, P. Trojanowski, W. Olszanski, W. Golabek, A. Drop; Lublin/PL

Purpose: Evaluation of cross-sectional images, multiplanar 2D- reformations, 3D- reconstructions and virtual endoscopy in the assessment of the middle ear in inflammatory diseases, trauma, otosclerosis and tumours. Comparison of each method and correlation with surgical findings.

Scientific Sessions

Material and Methods: Investigations were carried out in 150 patients with middle ear pathology. MSCT of the petrous bone was performed (GE Light Speed Ultra Advantage 8-row scanner). Additionally to cross-sectional axial scans, frontal and sagittal images were created using MPR reconstructions. 3D volume rendering (VR) and virtual endoscopy (VE) images were generated. Value of axial scans information, 2D, 3D reconstructions and virtual endoscopic views was assessed in comparison to intra-operative findings.

Results: MPR reconstructions achieved higher scores for diagnostic value ($p < 0.001$, t-test), but not for the image quality with regard to both 2D and 3D reconstructions in the assessment of skull base trauma, skull base tumors and in cases of chronic otitis media. Axial images proved to be the best for direct interpretation in case of otosclerosis. In case of stapes prosthesis assessment the most useful were 3D reconstructions. 3D- and virtual reconstructions indicated an improved representation and spatial orientation of the ossicular chain, therefore were a method of choice in the assessment of stapes prosthesis. These reconstructions also provided additional important information in some tumors regards invasion of the skull base or vascularity.

Conclusions: MSCT virtual endoscopy proved to be useful in evaluating post-traumatic and post-operative changes. In the majority of diseases axial images and MPR reformations were most useful.

CT diagnosis of otosclerosis: A review of 31 cases

E. Neri, S. Berrettini, F. Ravecca, C. Bartolozzi; Pisa/IT

Purpose: To review the CT criteria for the diagnosis of otosclerosis and to evaluate the sensitivity of high resolution spiral CT in the detection of signs of fenestral and cochlear otosclerosis.

Methods and Materials: The spiral CT data sets (13 single-row and 18 multi-row CT) of the petrous bone of 31 patients (62 ears) with otosclerosis were reviewed. A thickening of the stapes (crus anterior or posterior, or involving the footplate), or a focus in the fissula antefenestrata were considered signs of fenestral otosclerosis; the focus in the fissula antefenestrata was also divided in otospongiotic or otosclerotic. The extension of bone demineralization in the perilabyrinthine region was classified as unifocal, multifocal and diffuse; the location was classified as anterior (peri-cochlear) and posterior (peri-vestibular). Other signs of otosclerosis were considered the obliteration of the round window and cochlear ossification.

Results: Signs of otosclerosis were found in 31/62 ears (sensitivity 50%). Perilabyrinthine foci of otosclerosis were found in 18 ears; anterior foci in 18 ears, posterior in 2 (but associated with anterior); these were single in 5, multiple in 3, and diffuse in 10 cases. Foci in the fissula antefenestrata were found in 28 ears. Obliteration of the round window was detected in 2 ears and cochlear ossification in 4.

Conclusions: Our study has shown a low sensitivity of CT in the detection of otosclerosis, but identifies for CT an important role in demonstrating the extension of the disease.

B-276 11:15

Flat-panel based volume-CT could overcome current limitations of CT in cochlea implant imaging

S.H. Bartling¹, T. Stoever¹, T. Rodt¹, R. Gupta², T. Lenarz¹, H. Becker¹;

¹Hannover/DE, ²Boston, MA/US

Purpose: Current imaging methods are challenged by cochlea implant imaging. The limited resolution and metal artifact behavior of current CT scanners make it impossible to assess single implant electrodes in relation to the cochlea - information highly desirable for advanced post-implantation evaluations. Due to its high resolution and excellent metal artifact behavior flat-panel based Volume-CT could overcome these limitations.

Materials and Methods: Two ex-vivo temporal bones were implanted and were scanned in a 4-slice CT (GE Lightspeed Qx/i) (MSCT) using a standard temporal bone protocol. Furthermore, a scan in an experimental gantry and flat-panel based Volume-CT (Siemens VCT) (VCT) was performed (250 μm^3 big voxels at Nyquist's limit). To acquire a ground truth, the ears were fine grinded. The data sets were compared regarding the information about the implant, the inner ear and their relationship.

Results: A rough assessment of the insertion depth was possible using both CT. No single electrodes were circumscribable in the MSCT, but they were in VCT. The surrounding cochlea was much less compromised by metal artifacts in VCT than in MSCT. Actually, the spiral osseous lamina was visible in some slices. The comparison with fine grinds confirmed the conclusions that were drawn from the VCT images regarding the implant position within the cochlea.

Conclusion: VCT has the potential to give exact measurements of electrode positions within the cochlea and its relationship to the spiral osseous lamina. Further experiments, need to show how scanning of whole skull base changes the image quality of VCT.

B-277 11:24

Delineation of temporal bone anatomy: A comparison between low-dose 64-slice CT and conventional 4-slice CT technique

J. Lutz¹, L. Jäger¹, M.J. Hempel¹, S. Srivastav², M.F. Reiser¹; ¹Munich/DE, ²New Orleans, LA/US

Purpose: The aim of the study was to evaluate the depiction of anatomical landmarks of the temporal bone using a 64-slice and a 4-slice computed tomography (CT).

Methods and Materials: In 100 patients HRCT of the temporal bone was performed; in 50 using a 64-slice CT (Sensation 64, Siemens) with low-dose technique (0.6 mm collimation, 120 kV, 140 mAs, 250 μSv) and in 50 using a 4-slice CT (Sensation 4, Siemens) with conventional technique (0.5 mm collimation, 120 kV, 180 mAs, 600 μSv). Axial images were acquired and reformatted coronal images (1 mm slice thickness) were calculated. Two radiologists performed the evaluation in consensus. The visibility of 30 anatomical landmarks was scored using a five-point quality rating scale. The Fisher exact test and the Mann-Whitney U test were performed to statistically evaluate the visibility of anatomical landmarks with both imaging techniques.

Results: In delineating anatomical landmarks on the primarily acquired axial images as well as on the reformatted coronal images there was no significant difference in image quality between the low-dose 64-slice CT technique and the conventional 4-slice CT technique. This was particularly true for the delineation of the ossicles, the tegmen tympani, the labyrinth, the oval window and the canal of the cochlear nerve, vestibular nerve and facial nerve.

Conclusion: The new scan geometry of the 64-slice CT scanner facilitates imaging of the temporal bone in a low-dose technique; a good image quality can be obtained and radiation exposure can be reduced by approximately 60%.

B-278 11:33

True-FISP for inner ear imaging: Delineation of anatomical structures and pathologies

G.A. Krombach, L. Pani, B. Jung, E. DiMartino, E. Spuentrup, R.W. Günther, A. Buecker; Aachen/DE

Purpose: To compare true-FISP images with standard T2-weighted turbo spin-echo (TSE) images for delineation of anatomical details and pathologies of the inner ear.

Materials and Methods: In 58 patients (mean age 50 years, range 1-73 years) true-FISP (TR/TE 9.8/4.2 ms, 80°, matrix 512 x 512, FOV 230 mm², imaging time 4.19 min) and TSE images (TR/TE 2000/500 ms, matrix 128x128, FOV 90 mm², imaging time 5.46 min) were obtained. Two radiologists evaluated visualization of anatomical structures and pathologies using a 4-point non-parametric scale. In addition SNR and CNR were calculated and compared.

Results: Small structures such as modiolus, osseous spiral laminal, facial, vestibulocochlear, cochlear, superior and inferior vestibular nerve were significantly better delineated on true-FISP images ($p < 0.001$). There was no difference for delineation of large structures with high signal intensity (vestibule, semicircular canals). Pathological findings were encountered in 28 cases. Delineation of pathologies did not differ between both types of images. CNR was higher for bone/brain on true-FISP images.

Conclusions: True-FISP can be used for imaging of the inner ear. Compared to TSE images more anatomical details can be delineated, due to differences in the point-spread function. Signal characteristics due to T2/T1 weighting of the true-FISP images contribute to better CNR between brain and bone. This may help in the assessment of pathologies.

B-279 11:42

CT and MR imaging of lesions involving the pterygopalatine fossa

D. Haba, C.C. Aldescu; Iasi/RO

Purpose: To present a wide spectrum of usual and unusual lesions involving the pterygopalatine fossa (PPF) and to evaluate the efficacy of CT and MR imaging in the assessment and management of these lesions.

Methods and Materials: The CT and MR imaging examinations of 41 patients, 22 females and 19 men, aged between 12 and 72 years, were retrospectively reviewed considering the site, bony walls, fatty contents and intracranial extension.

Results: The PPF was involved in 40 cases by lesions located in paranasal sinuses

Scientific Sessions

(squamous cell carcinoma n = 19, lymphoma n = 5, fibromyxoma n = 2, fibrosarcoma n = 2, adenoid cystic carcinoma n = 1), nasopharynx (squamous cell carcinoma n = 6, juvenile angiomyxoma n = 2), masticator space (lymphoma n = 2) and middle cranial fossa (meningioma n = 1). Only one lesion (pleomorphic adenoma) originated in the pterygopalatine fossa. The fatty content of the pterygopalatine fossa disappeared in all patients in association with enlargement of the PPF (n = 9), erosion of bony walls (n = 31) and hyperostosis (n = 1). MR imaging was superior to the CT in delineating the lesion involving the PPF with secondary intracranial extension.

Conclusion: The lesions involving the PPF are commonly depicted on CT and MR imaging. MR imaging seems to be better than CT for any residual or recurrent lesion involving the PPF.

B-280 11:51

Influence of different mAs-products on image quality in MSCT of the head and neck region

U. Baum, M. Lell, K. Anders, H. Greess, W.A. Bautz; Erlangen/DE

Purpose: To determine the influence of tube current-time products on image quality and noise in MSCT of the head and neck region.

Methods: 20 patients suffering from head and neck malignancies were examined by MSCT using a high resolution protocol (4 x 1 mm). Image reconstruction was performed by means of a dedicated reconstruction software (Syngo Explorer, VAMP GmbH, Germany) consisting of a standard reconstruction algorithm with additional adaptive filtering. Surplus image noise was added to existing raw data sets in order to simulate different effective mAs values, and raw data sets were reconstructed with a slice width of 3 mm at 160, 120, 80 and 40 mAs at three pre-defined anatomical positions. Image noise was measured in all reconstructions, and image quality was rated on a five-point scale.

Results: The coronal diameter varied from 100 to 181 mm in the neck region and 362 to 500 mm at the thoracic inlet. In order to reach sufficient image quality, 80, 40 and 160 mAs were required at the hypopharynx, larynx and the thoracic inlet, respectively. Taking into account the varying body diameter at the thoracic inlet, a dose reduction down to 120 mAs should be possible in slim patients with a coronal diameter of 410 mm and less at the thoracic inlet.

Conclusion: This study demonstrates the feasibility of considerable dose reduction in CT scans of the head and neck region. The collected data may provide a basis for mAs adjustments.

Pre-procedural MR based decision of needle tip placement in vertebroplasty

C.W. Ryu, S.J. Kim, D.H. Lee, C.G. Choi, D.C. Suh; Seoul/KR

Purpose: To investigate the effectiveness of vertebroplasty according to the target of needle tip base on pre-procedural MR.

Materials and Methods: Retrospective reviews were conducted in 162 sites of 81 vertebral compression fracture (VCF) performed vertebroplasty. All cases were undergone pre-procedural MR. We classified the MR finding of VCF into three types: type1, VCF with fracture cleft near endplate; type2, VCF with fracture cleft around mid-body; type3, VCF without fracture cleft. The location of needle tip was identified on the X-ray radiography taken during the procedure and matched on the sagittal MR images. Location of needle tip was classified as follow: into cleft, abnormal marrow, borderline between abnormal and normal marrow, and normal marrow. On post-procedural X-ray radiography, result of vertebroplasty was assessed as good, if bone cement was filled over 70% of total body height combined with cleft and trabecular opacification (if fracture cleft is present), and assessed as incomplete, if bone cement was filled under 70% of total body height. VCF type and needle tip location was correlated with the result of vertebroplasty.

Results: In type1(48%) groups, when needle tip was placed into cleft, the result was significantly incomplete compared to other placement of needle tip ($p < 0.05$). In type2 groups (21%), and type3 groups (31%), the difference between each needle tip placement was not statistically significant.

Conclusion: According to presence or location of the fracture cleft and the

placement of needle tip, the result of vertebroplasty was varied. MR based decision of needle tip placement would be helpful for effective treatment of vertebroplasty.

B-282 10:39

Vertebroplasty in patients with osteoporosis-related osteonecrotic intravertebral clefts

M. Krauss, H. Hirschfelder, D. Losert, I. Bär; Nürnberg/DE

Purpose: To assess the results of vertebroplasty in patients with intravertebral clefts compared to patients with normal osteoporotic fractures.

Material and Methods: Between March 2002 and September 2004 we performed 140 vertebroplasties in 84 patients with osteoporotic fractures. Prior to intervention all patients underwent physical examination, conventional X-rays and MR imaging of the spine. Preoperative pain was classified using VAS-Scoring. All vertebroplasties were performed with a biplane angiography system using a monopolar approach. Conventional X-rays and VAS-Scoring were repeated before discharge and at regular follow-ups.

Results: 28 vertebrae showed intravertebral clefts, in some cases mobility of the fragments was visible under fluoroscopy. All clefts were filled with PMMA (average amount 3.2 ml) no matter where the needle tip was placed in the vertebra, showing a typical filling pattern. Due to prone position of the patient during vertebroplasty a significant reduction of kyphosis angle was achieved in some patients. Cement leakage occurred in 17.8% of clefts and 52.3% of regular osteoporotic fractures. No cement-dependant complications were observed. Average VAS-Score was 9.2 preoperatively, 4.5 before discharge and 3.5 at follow-ups showing no significant difference between both groups.

Conclusion: Patients with intravertebral clefts have a significantly lower risk of cement leakage during vertebroplasty. Clefts are easy to fill with bone cement, sometimes with a good reduction of kyphosis angle. Pain reduction is comparable to patients with normal osteoporotic fractures.

B-283 10:48

Percutaneous vertebroplasty: A multicenter Italian experience in over 1000 patients

G.C. Anselmetti¹, F. Baruzzi², G. Bonaldi³, P. Carpegiani⁴, L. Manfré⁵, M. Muto⁶, S. Vallone⁷, D. Regge¹; ¹Candiolo/IT, ²Varese/IT, ³Bergamo/IT, ⁴Pisa/IT, ⁵Catania/IT, ⁶Naples/IT, ⁷Imperia/IT

Purpose: To retrospectively evaluate the results and complications of percutaneous vertebroplasty performed in a large series of patients in seven different Italian centers.

Method and Materials: Since August 2000, 1118 patients underwent percutaneous vertebroplasty (PV) in 7 Italian Centers for a total of 2191 procedures. 826 (73.8%) patients had osteoporotic vertebral fracture, 259 (23.1%) had neoplastic disease, 27 (2.4%) suffered from symptomatic angioma and the remaining 6 (0.5%) had a recent traumatic fracture. A monolateral approach, under fluoroscopic (lower dorsal and lumbar levels) or combined CT-fluoroscopic guidance (cervical and upper dorsal levels), was mostly employed. All procedures were performed in local anesthesia.

Results: 1035/1118 (92.5%) patients had significant pain relief within 48 hours: 98% of cases with osteoporosis patients, 70% with cancer, 100% in the angioma and the recent traumatic fracture groups. 86 patients (7.6%) were retreated for a new fracture, 32 (2.8%) patients in the contiguous vertebra. No major neurological complications were reported. 12/1118 (1%) had asymptomatic cement pulmonary embolism while in 438 patients (39.1%) a venous and disk leakage was observed. In 6/1118 (0.5%) a subcutaneous haematoma was reported, and 10/1118 (0.8%) referred symptomatic radiculopathy successfully treated with steroid local injection.

Conclusions: This large series of patients confirms that Percutaneous Vertebroplasty is a safe procedure especially if combined CT-fluoroscopic guidance is employed for the upper spine. Percutaneous Vertebroplasty is effective in the treatment of backpain due to osteoporosis, angioma and traumatic vertebral fracture while the rate of pain relief is lower in patients suffering from neoplastic vertebral lesions.

B-284 10:57

New vertebroplastic procedures: Besides the vertebral body

L. Manfré¹, M. Bonetti², L. Tomarchio¹, C. Cristaudo¹; ¹Catania/IT, ²Brescia/IT

Objective: We investigate the use of vertebroplastic procedures in the treatment of sacral neoplastic and osteoporotic fracture, in case of neoplastic involvement of the vertebral pedicles, and in patients affected by severe spinal cord compression and paresis.

Method: From October 2001 to August 2004, 184 patients underwent vertebroplastic procedures in our department. In 5 patients, neoplastic involvement

Scientific Sessions

of the pedicle occurred, with destruction of the lateral wall of the spinal canal. 8 patients had sacral neoplastic involvement and one patient suffered from osteoporotic sacral fracture. Two patients had paraparesis related to severe collapse of the 7th thoracic vertebral body. Both pedicle and sacral involvement were cementified using a CT-guided & PMMA microinjection technique. The two patients affected by paraparesis underwent intraoperative vertebroplasty in the operating theatre.

Results: After vertebroplasty, all the patients with sacral and pedicle involvement had reconstruction of the pedicle and the sacral bone, maintaining regular neural foraminal shape. No foraminal PMMA leakage was observed. They became painless in 24 h. In patients undergone to combination of surgery & vertebroplasty, reduction of severe kyphosis and restorage of the spinal curve was obtained, with pain resolution and reduction of spinal cord compression.

Conclusion: Using a CT-guided vertebroplastic technique and PMMA micro-injection, vertebroplasty procedure can be performed in pedicle and sacral reconstruction. In combination with spinal surgery, vertebroplasty can be useful in restoring a regular shape in case of vertebral body collapse and spinal cord symptomatic compression.

B-285 11:06

Risk of secondary fractures after percutaneous vertebroplasty.

A retrospective analysis and a review of the literature

J. Hierholzer¹, H. Fuchs¹, K. Westphalen¹, G. Anselmetti², ¹Potsdam/DE, ²Candiolo/IT

Background: The potential risk of secondary fractures after vertebroplasty (VTP) is discussed in the literature. We report about our experience and review the pertinent literature.

Materials and Methods: Since 1999, VTP was performed on 414 vertebral bodies in 270 patients for severe back pain. In 229/270 pts. malignancy was excluded and osteoporosis identified as the cause of fracture and pain in 364 further treated vertebral bodies. Results were compared and added to those published in the literature.

Results: 27/229 pts. returned for 46 secondary vertebral body fractures. Time interval ranged from 7-400 days (mean 105 days). 21 symptomatic fractures were found adjacent to and 25 distant to previously treated levels. Together with our date, the literature offers data on 451 pts. treated, with 48 patient returning with 78 secondary fractures. 44/78 were adjacent and 34/78 distant to pre-treated levels. Baseline risk for new fractures after initial fractures ranges around 20% per year for untreated osteoporosis.

Conclusion: Although retrospective and un-controlled, our data and data published do not suggest an increased risk for secondary fractures after VTP for osteoporotic vertebral fractures.

B-286 11:15

Percutaneous kyphoplasty: Preliminary results with the SKy-Bone

Expander a new polymer device

G.C. Anselmetti¹, G. Bonaldi², M. Muto³, P. Carpegnani⁴, L. Manfrè⁵, D. Regge¹; ¹Candiolo/IT, ²Bergamo/IT, ³Naples/IT, ⁴Pisa/IT, ⁵Catania/IT

Purpose: To evaluate feasibility and effectiveness of kyphoplasty in old vertebral fractures by means of a new device: The SKy-Bone Expander.

Method and Materials: 20 percutaneous kyphoplasty were performed in 19 patients (17 female, 2 male - mean age 64 years) using the SKy-Bone Expander (Disc-O-Tech Medical Technologies Ltd, Herzliya, Israel), a new polymer device. All the patients had osteoporotic vertebral fractures aged more than 3 months (from 4 months to 8 years). All the procedures were performed in local anesthesia under fluoroscopic or combined CT and fluoroscopic guidance.

Results: In all patients percutaneous kyphoplasty with SKy-Bone Expander was feasible. Even if the procedure was performed with local anesthesia no pain have been reported during procedures. Mean vertebral height increase was 4.1 mm and mean difference between the anterior and the posterior vertebral wall height was 55% before and 78% after the procedure. In five cases a small cement leakage in the disk space was reported. No neurological injury were observed. All the patients referred complete back pain regression.

Conclusions: These preliminary results show that percutaneous kyphoplasty is also feasible in old vertebral fractures with the new polymer device SKy-Bone Expander and a reduction of kyphosis can be achieved. The procedure, performed with local anesthesia, was painless and well accepted by the patients. This new device, if compared with balloon kyphoplasty, seems to have the advantages of a pre-defined expanded configuration creating a defined void even in old vertebral fractures, a directional mechanical expansion, a safe and complete device retraction.

B-287 11:24

Intradiscal O2-O3 vs. corticosteroid injection in the treatment of sciatica

N. Limbucci, S. Carducci, C. Fiumara, M. Di Bartolomeo, C. Masciocchi, M. Gallucci; L'Aquila/IT

Purpose: To assess the clinical efficiency of O2-O3 periganglionic and intradiscal injection (chemiodiscolysis) vs periganglionic and intradiscal injection of corticosteroids in the management of acute pain following root compression from acute disk herniation.

Methods and Materials: 96 patients with sciatic nerve root compression due to disk herniation (level L3-S1) entered the study. 49 patients (group A) underwent intradiscal and periganglionic injection of 80 mg of Triamcinolone-acetonide and Ropivacaine 2%, 2-4 cc. 47 patients (group B) underwent intradiscal and periganglionic injection of 5-7 ml of O2-O3 (concentration 0.28 ig) and Ropivacaine 2%, 2-4 cc. Patients were assigned randomly to group A or B. All procedures were performed under CT guide (axial scans, 3 mm thickness), in prone position, with 22G spinal needle. We always performed clinical evaluation and administered pain questionnaire (McNaab) before treatment and after 7-14 days (mid time 11 days) and 6 months. Patients and clinicians who tested them before and after treatment were unaware about the kind of therapy performed.

Results: Group A: after 3 months remission of symptoms was registered in 35 patients (72%), after 6 months good results were registered in 23 (48%). Group B: after 3 months symptoms remission was registered in 36 (78%) of patients, while at 6 months in 34 (72%). Clinical controls correlate to data obtained by pain questionnaire.

Conclusion: O2-O3 periganglionic injection and chemiodiscolysis is most effective than periganglionic injection of corticosteroids in the treatment of acute lumbar pain and sciatica caused by acute disk herniation, resulting a valid alternative to other treatments.

B-288 11:33

Lumbar disk nucleolysis by oxygen-ozone injection: Midterm results in 244 patients

B. Oder, M. Loewe, G. Gruber, W. Ilias, W. Lang, S. Thurnher; Vienna/AT

Purpose: To assess the potential benefit of oxygen-ozone injection for disc nucleolysis in patients with chronic low back pain due to disk disease.

Materials and Methods: 710 patients were treated with an intradiscal (4 mL) and periganglionic (6 mL) injection of a oxygen-ozone mixture at an ozone concentration of 30 µg/mL, followed by a periganglionic injection of long lasting corticosteroid and anesthetic. All patients suffered from chronic low back pain and showed degenerative disorders of the lumbar spine visualized by MR imaging. Exclusion criteria was a motoric deficit. Patients were divided into 5 groups according to morphological changes: group 1 bulging disc, group 2 protruding disk, group 3 postoperative disk, group 4 osteochondrosis, group 5 various findings. Questionnaires regarding the Oswestry disability score (ODS) and a visual pain scale were sent to the patients 2 and 6 months after treatment, respectively.

Results: Questionairs of 244 patients could be evaluated for a 6 months follow-up: Improvement was stastically significant, especially in group 2, concerning the ODS before (mean value, 48.35%) and after treatment (mean value, 33.1% - Wilcoxon Test p < 0.0001). Improvement was also stastistically significant (p < 0.0001) comparing the visual pain scale before (mean value 85%) and 6 months after therapy (mean value 52%). 62% of the patients were generally content and 69% would accept the procedure again.

Conclusion: Disk nucleolysis by ozone injection is an effective minimal invasive treatment in patients with chronic low back pain with failing response to noninvasive means especially with MR imaging proven protruding disk disorder.

B-289 11:42

Percutaneous nucleoplasty in the treatment of lumbar pain

S. Masala, A. Ursone, R. Fiori, F. Massari, G. Simonetti; Rome/IT

Purpose: To assess the effectiveness of Percutaneous Nucleoplasty in the treatment of lumbar pain due to contained discal herniation.

Methods and Materials: Fifty Patients with positive Visual Analogue Scale (mean score: 7.5) and lumbar pain were selected for treatment. In all patients lumbar MR imaging revealed a contained discal herniation (8 pts: L2-L3; 15 pts: L3-L4; 27 pts: L4-L5). All patients were refractory to medical and rehabilitative therapy for more than three months. The main physical principle of this procedure is a bipolar radiofrequency energy emitted by an electrode-needle, with consequent volumetric reduction of the nucleus polposus and elastic return of the anulus fibrosus. The treatment is performed under fluoroscopic visualisation in the AP and LL projections.

Scientific Sessions

Results: Postprocedural evaluation confirmed reduction of the VAS (mean score: 3.5). MR imaging performed 6 and 12 months after the procedure demonstrated complete resolution of the treated discal pathology in all patients. No post-procedural complications or recurrences of the disease were observed.

Conclusion: In our experience Percutaneous Nucleoplasty demonstrated to be an effective and feasible technique. This minimally invasive procedure is ideal for treatment of patients with pain refractory to conservative medical therapy and contained discal herniation, not suitable for surgical treatment.

B-290 11:51

Percutaneous radiofrequency thermoablation with cool-tip probe of osteoid osteoma

E. Mazza, L. Sali, C. Vannini, D. Beccani, F. Toccafondi, M. Zini, M. Acquafresca; *Florence/IT*

Purpose: To evaluate the efficacy of CT-guided percutaneous RadioFrequency (RF) thermoablation with cool-tip probe in the treatment of osteoid osteoma.

Methods and Materials: From June 1998 to February 2004, 72 RF thermoablation procedures were performed in 71 patients (range of age, 3-70; mean age, 28) with osteoid osteoma located in the inferior or superior limbs, pelvic bones, vertebrae and, in one case, in a rib. Percutaneous thermoablation was performed with Radionics Cool-tip RF Ablation System by using probes with 1 or 2 cm unprotected tip applied for 4 minutes in the centre of the lesion. At the beginning the osteoid osteoma was localized on CT images. Thereafter a Kirschner wire was inserted within the lesion, rigged on a hand-drill device. Once the nidus was engaged the Kirschner wire was exchanged for a RF probe and radio waves were emitted.

Results: At a mean follow-up of 41 months the treatment was considered effective in 94% of the cases. In four patients pain had recurred; one of these cases was treated for a second time with success. In two cases procedural complications of minor degree (limited cutaneous burns) have occurred.

Conclusion: In our experience CT-guided percutaneous RF thermoablation of osteoid osteoma proved to be effective in the large majority of the cases. Deprived of severe complications, it may represent a minimally invasive, rapidly effective procedure, alternative to the surgical treatment.

Intra-abdominal pressure influences endotension following endoluminal grafting of AAA: Experimental findings

M. Gawenda, S. Winter, G. Jaschke, G. Wassmer, J. Brunkwall; *Cologne/DE*

Purpose: It has been postulated that the intra-abdominal pressure (IAP) produce pressurization inside the aneurysm sac. The present study was designed to investigate whether, and to what extent, aneurysm sac pressure after ELG is influenced by the IAP.

Methods and Material: Experimental study, *in vitro*. Compliant Latex aneurysms (aneurysm diameter: 60 mm) were inserted into an circulation model. The systemic mean pressure (SP_{mean}) was varied from 50 to 120 mm Hg with pulse pressure of 40 mm Hg. The aneurysms were excluded by a latex sealed woven polyethylene graft. The systemic and aneurysm sac pressures (ASP) were measured simultaneously. The aneurysm models were placed inside a closed chamber, which was pressurized stepwise (0, 20, and 40 cm H₂O), simulating an increasing intra-abdominal pressure.

Results: In the *in vitro* model ELG created a closed cavity without any endoleak, but showed a relevant aneurysm sac pressure. At a systemic mean pressure of 80 mm Hg, the aneurysm sac mean pressure (ASP_{mean}) was 24 mm Hg at median. By simulating an increasing IAP, the aneurysm sac pressure increased as well. At an IAP of 20 cm H₂O the ASP_{mean} was 29 mm Hg, at 40 mm H₂O IAP the ASP_{mean} was 34 mmHg.

Conclusions: The presented *in vitro* model demonstrated that the aneurysm sac mean pressure is influenced by the intra-abdominal pressure; increasing intra-abdominal pressure resulted in increasing aneurysm sac pressures as well. These data need to be considered when studying endotension.

B-292 10:39

CT angiography evaluation of patients with abdominal aortic aneurysms:

How many are candidates for endovascular repair?

R. Iezzi, F. Quinto, A. Pierro, F. Spigonardo, A. Cotroneo, C. Colosimo; *Chieti/IT*

Purpose: To determinate how many patients with abdominal aortic aneurysms (AAA) are candidates for endovascular repair (EVAR) on the basis of clinical and CT findings.

Method and Materials: From January 2002 to June 2003, 182 patients with suspected abdominal aortic aneurysm underwent MSCT angiography (MSCTA) (4x1-mm collimation, pitch 6, 1.25-mm slice width). The number of patients who met inclusion criteria for EVAR were recorded as were the anatomical characteristics of each aneurysm. All patients treated with EVAR underwent MSCTA follow-up at 1, 6 and 12 months.

Results: Among 182 patients, 130 patients were jumped to be candidates for treatment: EVAR in 51 patients (39.3%) and surgical repair in 79 patients (60.7%). The primary anatomical reason for ineligibility for EVAR was a short or extremely tortuous or calcified infrarenal neck in 41 patients (51.9%), abdominal aortic aneurysm diameter > 7 cm in 13 patients (16.4%), extremely tortuous iliac arteries in 6 patients (7.6%). 17 patients (21.5%) were classified as non-candidates due to age (< 65 years). 2 patients (2.5%) refused EVAR. CTA follow-up showed a low rate of midterm complications.

Conclusions: In our experience unfavourable infrarenal neck anatomy was the primary exclusion criteria of endovascular repair. EVAR is a safe and reliable procedure for the treatment of abdominal aortic aneurysm.

B-293 10:48

Outcome of endovascular repair in patients with difficult aortic necks

G.J. Munneke, E. Choke, T. Loosemore, M. Thompson, A. Belli, R. Morgan; *London/UK*

Purpose: The principle anatomical contra-indication to endovascular aneurysm repair (EVAR) is an unfavourable proximal aortic neck. The aim of this study is to illustrate how aneurysms with unfavourable anatomic morphology may be treated with stent-grafts.

Materials and Methods: 100 patients who underwent EVAR were studied. Unfavourable morphological features in the aortic neck were defined as neck diameter more than 25 mm, neck length less than 15 mm, angulation more than 60° and circumferential thrombus exceeding 50%. Endoleak and mortality rates were determined for patients with 0, 1 and ≥ 2 adverse features, groups 1 (55 patients) 2 (37 patients) and 3 (8 patients) respectively.

Results: After initial graft implantation the incidence of intra-operative attachment site endoleak requiring re-intervention was 9.1%, 24.3%, and 25% in groups 1-3 (The re-intervention rate for patients with favourable anatomy is 13% in the EUROSTAR registry). The incidence of Type I endoleaks at 30 days was 3.6%, 2.7% and 25% for Groups 1-3. Both patients in Group 3 underwent placement of Palmaz stents to abolish the leak. 30 day mortality was 7.2%, 2.7% and 0% in the three groups. The number of patients with AAA sac regression or stable sac was 44 (98.2%), 34 (91.9%) and 6 (75%) in groups 1-3 respectively.

Conclusions: Patients with unfavourable neck anatomy who are unsuitable for open surgery may be treated with EVAR, although many patients require additional procedures. Early outcomes are encouraging in this group of patients. These data suggest that the indications for EVAR may be expanded.

B-294 10:57

Haemodynamic differentiation of type II lumbar endoleaks by contrast-enhanced ultrasound

V. Napoli, I. Bargellini, A. Pratali, P. Petrucci, S. Sardella, C. Bartolozzi; *Pisa/IT*

Purpose: To differentiate type II lumbar endoleaks (ELs) through dynamic features identified by contrast-enhanced ultrasound (CUS), and to identify its relationship with aneurysm enlargement rate ≥ 1 mL/month.

Materials and Methods: Eighteen patients (mean age 71.8 years) with type II lumbar EL underwent Computed Tomography Angiography (CTA), CUS and Digital Subtraction Angiography (DSA). On CTA, AAA volumes were calculated, and EL visualization and volume were assessed. At CUS, detection of contrast enhancement within the aneurismal sac (EL) was assessed, together with the time of EL wash-in and wash-out from the beginning of contrast injection, the visualization of inflow and outflow vessels, and the presence of cavity filling.

Results: All patients showed an EL at CUS. Median wash-in and wash-out times were 84 and 320.5 sec, respectively, and were significantly associated ($P < .01$). By Youden plots, the ELs were classified as hyperdynamic when wash-in was < 100 sec ($n = 10, 55.5\%$) and/or wash-out was < 520 sec ($n = 13, 72.2\%$). Slower wash-out was associated with non-visualized outflow and/or inflow arteries

Scientific Sessions

($P < .05$). Eight ELs were missed at CTA; it occurred in hypodynamic ELs, no detectable inflow or outflow vessels and absence of cavity filling ($P < .05$). Mean aneurysm volume increase was 1.1 ± 1.7 mL/month. Aneurysm enlargement ≥ 1 mL/month ($n = 8$, 44.4%) was significantly associated with hypodynamic ELs. Sensitivity, specificity, PPV, NPV and accuracy in identifying enlarging AAA were 62.5%, 100%, 100%, 76.9% and 83.3% for wash-out time ≥ 520 sec.

Conclusion: Type II lumbar ELs show different haemodynamic features at CUS, that might influence aneurysm enlargement, addressing the need for treatment.

B-295 11:06

Endoleakdetection after endovascular aneurysm treatment

M.B. Pitten, H. Schweitzer, S. Herber, W. Schmiedt, A. Neufang, P. Kalden, J. Schneider, M. Thelen; Mainz/DE

Purpose: To investigate the diagnostic accuracy of MR imaging and spiral CT for endoleak detection.

Material and Methods: 52 patients, 48 men and 4 women (age 71.1 ± 6.9) underwent endovascular aneurysm repair with nitinol stent grafts. Follow-up data sets included spiral CT (slice thickness of 3 mm, reconstruction interval 2 mm, unenhanced and biphasic contrast enhanced) and MR imaging (1.5 Tesla MR scanner, axial T2w-TSE, T1w-Flash 2D unenhanced, Flash 3D angio and T1w-Flash 2D contrast enhanced) within 48 hours postinterventionally, at 3, 6, and 12 months and every year. Consensus reading of CT and MR imaging was defined as the standard of reference.

Results: 141 of 252 data sets demonstrated evidence for endoleaks. The incidence of Type I, II, III endoleaks, and complex endoleaks was 3.2%, 40.1%, 8.7%, and 4.0%, respectively. Sensitivity for endoleak detection was 92.9%, 43.3%, 34.0%, and 37.6% for MR imaging, biphasic CT, uniphasic arterial CT, and uniphasic late CT, respectively. The corresponding negative predictive values were 91.7%, 58.1%, 54.4%, and 55.8%. Cases without endoleaks in CT and MR imaging showed better aneurysm shrinkage compared to those with positive MR imaging but negative CT (-4.3, -7.9, -7.6, -9.4 mm versus -3.1, -5.8, -5.9, -7.3 mm at 1, 2, 3, and 4 years). In 2 of 15 cases with reinterventions, the positive MR imaging findings alone demonstrated the source of endoleak and enabled reintervention.

Conclusion: MR imaging is significantly superior to biphasic CT for endoleak detection and rating of endoleak size and can help to clarify endotension. Endoleak rates reported after endovascular aneurysm repair substantially depend on the imaging modalities used.

B-296 11:15

Modalities of treatment of type II endoleaks after abdominal aorta endoprostheses deployment

R. Marcello, M. Castrucci, G. Assegnati, P. Costa, E. Serrao, N. Mangialardi; Rome/IT

Purpose: To evaluate the treatment modalities of type II endoleaks.

Method and Materials: From January 1998 to July 2004, 520 patients received endoprostheses treatment of abdominal aorta aneurysms. Over this number, 11 subjects aged from 66 to 87 (mean 77 yrs, 10 men and 1 woman) with type II endoleaks were treated with percutaneous coil embolization of IMA (3 cases), ileolumbar artery coil embolization (2 cases), laparoscopic clipping (3 cases) and aneurysm sac needle injection of clotting drugs (3 cases). The procedure was selected on the basis of imaging appearances. Follow-up was carried out with c.e. spiral CT in 30 days and six months following the procedure.

Results: All cases turned out successful. The two patients treated with translumbar needle injection of glue and coils had impossible endovascular approach due to inconsistent vessels network. Laparoscopy clipping was the treatment of choice when endoleak perfusion was provided only by IMA but its endovascular navigation was unfavourable.

Conclusions: Type II endoleaks management should be performed on the basis of endovascular procedure in all cases of a feasible vascular pattern. Alternative fluoro guided needle injection technique may be advocated in those cases with unclear vascular mapping.

B-297 11:24

Treatment of type II endoleaks by CT-guided translumbar puncture and injection of N-butyl-2-cyanoacrylate glue into the aneurysm sac

R. Cioni, I. Bargellini, M. Femia, C. Cappelli, F. Fontana, S. Sardella, C. Bartolozzi; Pisa/IT

Purpose: To evaluate the results of CT-guided translumbar N-butyl-2-cyanoacrylate surgical glue (Glubran 2) injection in the treatment of type II endoleaks after endovascular repair of abdominal aortic aneurysm (EVAR).

Materials and Methods: From March 2003 to April 2004, nine patients (all male,

mean age 76.2 years) with type II endoleak and increasing aneurysm diameter, underwent translumbar puncture of the aneurysm sac 1-3 years after EVAR, using a 20-22- Gauge needle under CT-guidance. A mixture of N-butyl-2-cyanoacrylate glue (Glubran 2, 1-2 cc) and Lipiodol (2:1 ratio) was slowly injected under fluoroscopic guidance. Patients were discharged 24 hours after treatment. CT angiography was performed at 1, 6 and 12 months follow-up.

Results: The procedure was technically successful in all cases, with no major complications. In one patient an abscess along the psoas muscle was detected and solved completely 1 month later. One patient required a second procedure two months after the initial treatment, whereas in 2 patients the procedure was repeated three times. On follow-up (range, 3-18 months), the endoleak reduced in 1 patient, whereas in the remaining 8 cases it completely disappeared. CT examinations showed progressive aneurysm diameter reduction in all cases.

Conclusion: Translumbar intrasac glue injection represents a safe and effective procedure to treat selected cases of type II endoleak after EVAR.

B-298 11:33

Emergency endovascular treatment of ruptured abdominal aortic aneurysms

D. Laganà, G. Carrafiello, R. Caronno, P. Castelli, F. Fontana, M. Mangini, C. Fugazzola; Varese/IT

Purpose: To verify the feasibility and effectiveness of endovascular treatment of ruptured abdominal aortic aneurysms (RAAA).

Materials and Methods: In the last 36 months we have treated, in emergency, with endovascular exclusion, 27 symptomatic RAAA. In 19 haemodynamically stable patients a pre-operative angio-TC was performed to confirm the diagnosis and to plan the treatment; 8 patients, with hemorrhagic shock, were evaluated with pre-treatment aortography performed in operating room. 19 Excluder/Gore® and 5 Zenith/Cook® stent-grafts (22 bifurcated devices and 5 aorto-uni-iliac were used). The follow-up was performed with angio-CT at 1, 3, 6 and 12 months.

Results: We have obtained 100% technical success with 11% mortality rate (1 cardiac failure and 2 MOF). The follow-up (mean 8 months, range 1-24) has showed: the complete exclusion of AAA in 22/27 cases; 1 iliac leg occlusion (treated with femoro-femoral bypass), 3 type II endoleaks with spontaneous thrombosis and 1 patient with type I and III endoleak. We observed a reduction of aneurismal sac in 6/27 patients and stability of the same one in the other patients.

Conclusion: In conclusion we can affirm that EVAR is a good option for treatment of RAAA, with a lower mortality rate than surgery. The team's experience allows a correct planning of the procedure also in emergency with immediate and late results comparable with elective repair. In our experience the bifurcated stent-graft is the chosen device in patients with suitable anatomy because the procedure is less time consuming than aorto-uni-iliac stent-grafting with surgical cross-over, allowing faster aneurysm exclusion.

B-299 11:42

Six-year experience in the percutaneous treatment of abdominal aortic aneurysms

M. Corona, F. Fanelli, F. Salvatori, A. Bruni, V. Dominelli, L. Di Rezze, A. Pucci, P. Rossi, R. Passariello; Rome/IT

Purpose: To report our six-year experience using a bifurcated endoprosthesis in the treatment of abdominal aortic aneurysms (AAA).

Methods and Materials: From September 1998, 133 patients with AAA (mean 50.2 mm) were treated using different type of stent-grafts: 25 Vanguard II (Boston-Scientific), 89 Excluder (WL-Gore), 9 Talent (World-Medical), 2 Anaconda (Sulzer-Medical), 1 Quantum (Cordis), 2 Endologix (Endologix), and 5 Zenith (Cook). Procedures were performed in angio-suite (51) and operating room (82) with patients under general, epidural or local anesthesia.

Results: Technical success with complete exclusion of the aneurysm was achieved in 132/133 patients, while in 1 case an immediate conversion was necessary. After a follow-up ranging from 1 to 69 months, 125 patients (94.6%) are alive while 7 dead. A progressive reduction of the aneurysmatic sac (mean value 2.3 mm) was observed in 42 patients (31.8%). The sac diameter remained stable in 67 patients (50.7%), and increased in 23 patients (17.4%). Endoleak was detected in 21 patients (15.9%): 3 type I, 15 type II, 1 type III, 2 type IV. Two late conversion were performed after 22 and 31 months respectively for multiple fractures of the stent-graft and for a persistent type II endoleak. In one case (0.7%) an occlusion of the right renal artery was observed after 4 months for stent-graft migration. Limb obstruction occurred in 5 patients (3.7%) successfully solved with a fem-fem by-pass.

Conclusions: Percutaneous treatment of AAA seems to be a feasible technique only in selective patients. However an accurate follow-up is mandatory to prevent and manage complications.

Fenestrated abdominal stent-grafts: Preliminary results

M.J. Fischer, G. Maselli, P. Pozzilli, S. Mosca, T. Lupattelli, G. Scalera, L. Lupattelli; Perugia/IT

Purpose: To report the preliminary experience in the endovascular treatment of abdominal aorta aneurysm (AAA) with proximal neck less than 10 mm using fenestrated stent-grafts.

Methods and Materials: In 6 patients with suprarenal AAA an aortic-biiliac fenestrated endoprostheses (COOK, Australia) was positioned. Multidetector CT angiography provided to produce a custom-design endovascular stent-graft for each patient.

Results: in 6 patients (mean age, 81 years; range, 66-81 years) classified as ASA III (n = 5), and ASA IV (n = 1), the exclusion of the aneurysm sac and a good representation of the renal arteries (n = 4) was obtained. Stent-graft prosthesis was converted and implanted in infrarenal site and covered by extensive fenestrated stent-graft because a selective catheterism of the renal artery was impossible. 1 patient had renal acute transitory insufficiency with fatal hemoperitoneum after 2 months. The death rate was 33% (two patients) and occurred within 30 days.

Conclusion: An adequate choice of a device allows treating the patients with limited options for treatment as well as the patients noneligible for placement of infrarenal prosthesis. An accurate patient selection, an appropriate CT assessment and a high skill in endovascular procedure is needed.

Coronary plaque imaging

Moderators:

R. Rienmüller; Graz/AT

P.M.A. van Ooijen; Groningen/NL

B-301 10:30

Coronary plaque imaging with MSCT: The characterisation of lipid and fibrous plaques is affected by intracoronary attenuation

F. Cademartiri, N.R. Mollet, G. Runza, M. Midiri, R. Hamers, N. Bruining; Rotterdam/NL

Purpose: To define the effects of intracoronary contrast on the density values of coronary plaques.

Material and Methods: MSCT protocol (Sensation 16, Siemens, Germany): slice/collimation 16/0.75 mm, rotation time 375 ms retrospective ECG-gating mode. MSCT was performed in 7 ex-vivo left coronary artery specimens set in oil and filled with 5 solutions with decreasing dilutions of contrast material: 1/∞, 1/200, 1/80, 1/50 and 1/20. In-vivo assessment was performed in 12 patients (males 9; mean age 59 ± 10) who underwent two subsequent scans (arterial and delayed) (MSCT-CA) after intravenous administration of a single bolus of contrast material (100 ml of iomeprol 400 mg/ml at 4 ml/s). The attenuation (HU) value of atherosclerotic plaques was measured in each solution at: lumen, plaque (non calcified thickening of the vessel wall), calcium and oil. The results were compared with one-way ANOVA-test and correlated with Pearson's test.

Results: The mean attenuation of the 5 solutions in the lumen (45 ± 38 HU; 85 ± 38 HU; 121 ± 38 HU; 322 ± 104 HU; 669 ± 151 HU) and plaque (11 ± 35 HU; 20 ± 38 HU; 34 ± 43 HU; 61 ± 65 HU; 101 ± 72 HU) was significantly different ($p < 0.001$). The attenuation of lumen and plaque of coronary plaques showed moderate correlation ($r = 0.54$; $p < 0.001$). The mean attenuation value in-vivo arterial/delayed for lumen (325 ± 70 HU; 174 ± 46 HU) and non-calcified plaque (138 ± 71 HU; 100 ± 52 HU) was significantly different ($p < 0.001$). The attenuation of calcium and oil was not effected by differences in lumen contrast both in ex-vivo and in-vivo measurements.

Conclusion: Non-calcific coronary plaque attenuation values are significantly modified by differences in lumen contrast densities.

B-302 10:39

Imaging and classification of atherosclerotic plaques in Watanabe heritable hyperlipidemic rabbits using 16-row multidetector-CT

C. Herzog, S. Zangos, D.N. Krug, K. Eichler, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To assess whether multidetector-row CT (MDCT) allows for a reliable

differentiation between different types of non-calcified atherosclerotic plaques (AHA types I-Va).

Methods: Six Watanabe heritable-hyperlipidemic rabbits underwent contrast-enhanced 16-row MDCT of the entire aorta. Scanning / image reconstruction parameters were: 16x0.75 mm collimation, LTF = 20 lp/cm, 9 mm feed/rotation, 500 ms TI, 120 kV and 300 mAs, 1.0 mm slice-thickness, 0.5 mm increment and a 50 mm FOV. Maximum in-plane resolution was 0.3 mm². After subdividing of the aorta into equal stacks of 5 mm, each atherosclerotic lesions was assessed for their tissue attenuation. For histopathological correlation each rabbit's aorta was dissected en-bloc, likewise cut into 5 mm pieces and analyzed by an experienced pathologist.

Results: Correlation to the histological results was possible in 237 plaques. Mean CT attenuation values for plaque types AHA I-Va were: -3.1 ± 49.0 HU; -17.6 ± 45.1 HU, 9.9 ± 58.9 HU; 39.9 ± 49.8 and 66.4 ± 45.2 HU. Correlation coefficients for the subdivision into groups AHA I-VI were $r = 0.42$ ($p = 10^{-6}$) and $r = 0.34$ ($p < 10^{-4}$) for observers 1. and 2. Mean CT attenuation values for plaques types ≤ AHA III (preatheroma) were -0.33 ± 57.4 HU, for plaque types ≥ AHA IV (atheroma) 49.3 ± 43.7 HU. Sensitivity of CTA for the detection of plaques types ≥ AHA IV was 67.3 (54.81%, 76.45%), specificity 76.21% (70.13%, 81.60%), NPV 33.75% (23.55%, 45.19%) and PPV 23.79% (18.40%, 29.87%).

Conclusion: High resolution CTA was neither able to adequately differentiate between varying stages of atherosclerosis nor between atheromas and preatheromas. A large variability in tissue attenuation as observed for either plaque type, prevented from any reliable assessment of the predominant component.

10:48

The association of low-dose sex hormone replacement therapy and coronary artery disease as determined by multi-slice spiral computed tomography

Y. Wang, Z. Jin, L. Kong, J. Jiang, H. Xue, Z. Zhang, Q. Ge; Beijing/CN

Purpose: To investigate whether longtime low-dose sex hormone replacement therapy (HRT) has an effect on coronary calcifications and stenoses.

Methods and Materials: 122 postmenopausal women (PMW) were studied by ECG-gated MSCT (0.42 s-rotation time, 16 × 0.75 mm collimation), 54 of them (aged 68 ± 8) who took low-dose HRT for more than five years composed HRT group, the other 75 (aged 69 ± 8) who never took HRT composed contrast group. Patients with a heart rate above 65/min received β-blockers before the scan. Plain scans were performed for calcium scoring (three people with coronary stents didn't have calcium scores). Contrast-enhanced scan (100 mL contrast agent IV at 4 mL/s) was performed during an approximately 20 s breath hold for screening over 70% stenoses. The calcium scores and incidence rate of over 70% stenoses of HRT group were compared with contrast group.

Results: In the analysis of calcium scores, the mean score of HRT group was 29.6 ± 81.3, which of contrast group was 125.8 ± 305.8; a significant difference was found between two groups ($Z = -2.025$, $P < 0.05$). The incidence rate of over 70% stenoses of HRT group was 9.6% (5/52), while that of the contrast group was 24.3% (17/70); a significant difference was found between these two groups ($\chi^2 = 4.344$, $P < 0.05$). Logistic regression found that HRT had a significant effect on coronary over 70% stenoses, the regression coefficient beta being -1.104 ($P < 0.05$).

Conclusion: These findings suggest that longtime low-dose HRT may decrease coronary calcifications and significant stenoses in PMW.

B-304

10:57

Coronary calcinosis and statin therapy

M.B. Belkind, V.E. Sinitsyn, A.A. Lyakishev, V.G. Naumov, S.K. Ternovoy; Moscow/RU

Purpose: The purpose of our study was to estimate the dynamics of coronary calcium score measured by electron-beam computed tomography (EBCT) in hypercholesterolemic patients treated with inhibitors of HMG-CoA reductase.

Materials and Methods: 119 patients with hypercholesterolemia (total serum cholesterol (TC) > 5.2 mmol/L) and positive calcium score were included in the study. 69 patients took statins, 50 without statin therapy - made the control group. EBCT (3-mm slices, acquisition time 100 ms, threshold definition of coronary calcification at 130 HU in an area > 1 mm², Agatston calcium score) and TC assessment were performed prior and after 25 ± 11 months of statin treatment.

Results: The average decrease of TC in the statin group was 24.4%, in the control group - 0.5% ($p < 0.0001$). Absolute increase of calcium score in the statin group was 63 ± 84 units, in control group - 122 ± 180 units ($p = 0.044$). We discovered inverse correlation between range of lowering TC and increase of coronary calcium ($r = -0.243$; $p = 0.008$).

Scientific Sessions

Conclusion: Therapy with HMG-CoA reductase inhibitors slows down the process of coronary calcification. EBCT may be used for follow-up of lipid-lowering therapy.

B-305 11:06

Electron beam CT measurement of coronary artery calcium allows individual risk assessment of CHD in UK diabetic patients

S.J. Howling, C. Hare, C. Harvey, T. McArthur, M. Tighe, C. Salek, P.J. Jenkins; London/UK

Purpose: Statins have been advocated for all patients with diabetes for primary prevention of CHD. Measurement of coronary artery calcium score (CACS) in diabetic patients is reported to offer a superior prognostic assessment of an individual's risk of cardiovascular disease than the Framingham Risk assessment. To date, there have been no studies of CACS in the UK diabetic population.

Methods and Materials: CACS was assessed in 1571 male subjects who had no cardiovascular symptoms, of whom 84 had diabetes. CACS was performed on a GE C300 Electron Beam CT (EBCT) scanner using Agatston's method, and categorised as Group 1 = 0; 2 = 1-10; 3 = 11-100; 4 = 101-400; 5 ≥ 400.

Results: Overall, the prevalence of elevated CACS was significantly greater in diabetic subjects than non-diabetic subjects: Group 4 - 34.5% vs 13.1%, p < 0.0001; Group 5 - 28.6% vs 11.6%, p < 0.0001. However, 23.9% of diabetics were in Group 1 or 2, indicative of no or very mild cardiovascular disease. Categorizing by total cholesterol levels revealed that of diabetic subjects with a level < 5.2 mmol/l, 20.9% were in Group 1 or 2, 16.7% in Group 3, and 62.5% in Groups 4 or 5.

Conclusion: Asymptomatic UK male diabetics have a high prevalence of significant coronary atherosclerosis. However, the significant proportion of subjects with no or mild CHD suggests that statin therapy may not be appropriate for all patients but reserved for those in whom EBCT has demonstrated an increased individual cardiovascular risk.

B-306 11:15

Analysis of the atherosclerotic plaque and cross-sectional surface of coronary arteries by MSCT (Vessel View software) and ICUS (reference method)

M. Pasowicz, P. Klimeczek, A. Gackowski, T. Przewlocki, R. Banys, K. Zmudka, W. Tracz; Krakow/PL

Aim: The purpose of this blinded study was to compare ICUS and MSCT in the assessment of the plaque, diameter and internal surface of coronary arteries.

Methods: 14 pts (3F, 11M, mean age 46(SD8)) were included in the study. Overall, 19 proximal segments of coronary arteries were assessed: LM-6, LAD-6, Cx-2, RCA-5. Only the segments with luminal diameter > 2 mm were analyzed. MSCT was performed using 16-slice device (Sensation 16 Cardiac, Siemens). All patients were pretreated with a beta blocker, mean heart rate during the study was 51 (SD9) bpm. The slice thickness was 0.75 mm. Intracoronary examination was performed using the Jomed In Vision Plus V4.8.2 device. Avanar F/X probes were pulled back from coronary arteries with a constant speed of 1 mm/s. Side branches or large calcifications were used as the landmarks to orient the ICUS and MSCT images. Overall, we analyzed 119 coronary arterial cross-sections (MSCT vs IVUS).

Results: ICUS revealed atherosclerotic lesions in 86 cross-sections (overall 20 plaques); soft-46, intermediate-24, calcified-16. MSCT revealed and correctly identified the morphology of the plaque in 71 cross-sections: soft-36, intermediate-19, calcified-16. The correlation between MSCT and ICUS in the assessment of the internal area was 0.86, the least internal diameter 0.72. Internal area ICUS vs. MSCT (11.1 (SD4.5) vs. 9.2 (SD4.67)), least diameter ICUS vs. MSCT (3, 1 (SD0.98) vs. 3.9 (SD1.3)).

Conclusions: MSCT was found to be consistent with ICUS in the detection and assessment of plaque morphology, especially calcified. There was a high correlation between ICUS and MSCT in the measurements of luminal area and least diameter.

B-307 11:24

Noninvasive coronary artery plaque visualization and differentiation by contrast enhanced black blood MR imaging

D. Maintz¹, M. Ozgun¹, A. Hoffmeier¹, W. Heindel¹, R. Fischbach¹, R. Botnar²; ¹Münster/DE, ²Boston, MA/US

Purpose: To evaluate contrast enhanced black-blood coronary MR imaging for selective visualization and non-invasive differentiation of atherosclerotic coronary plaque in humans.

Method and Materials: Eight patients with coronary artery disease (CAD) as

confirmed by X-ray angiography and multi-detector CT (MDCT) were studied by T1-weighted black-blood-inversion-recovery coronary MR imaging before (N-IR) and after administration of Gd-DTPA (CE-IR). Plaques were categorized as calcified, non-calcified, and mixed based on their Hounsfield number derived from MDCT.

Results: With MDCT, 27 plaques could be identified, 6 of which were calcified (calcified nodules were not evaluated), 5 non-calcified and 16 mixed calcified/non-calcified. On N-IR, 6/6(100%) calcified plaques appeared dark, 3/5(60%) non-calcified plaques were dark and the remaining 2/5(40%) were bright. 2/16(13%) mixed plaques were bright and 14/16(87%) were dark. On CE-IR, all calcified plaques appeared dark, 2/5(40%) non-calcified plaques were dark and 3/5(60%) were bright; 10/16(63%) mixed plaques were bright and 5/16(31%) were dark. Of the 16 non-calcified and mixed plaques that appeared dark on N-IR, 1 non-calcified and 10 mixed plaques appeared bright on CE-IR (contrast uptake). There were no plaques with bright appearance on N-IR and dark appearance on CE-IR MR imaging.

Conclusions: We demonstrate the use of black-blood CE-IR coronary MR imaging for the detection of selective contrast uptake in non-calcified and mixed coronary plaque in patients with CAD. The observed contrast uptake may be associated with neovascularization, inflammation, endothelial dysfunction and/or markers for plaque vulnerability. We conclude that this method may have potential for noninvasive characterization of coronary plaque in patients with subclinical and advanced CAD.

B-308 11:33

Coronary artery atherosclerotic plaque burden evaluated with MSCT

coronary angiography: Stable vs. unstable angina with ICUS validation

F. Cademartiri, N.R. Mollet, C. van Mieghem, G. Runza, T. Baks, P.J. de Feyter, G.P. Krestin; Rotterdam/NL

Purpose: Evaluate the differences in coronary plaque burden between patients with stable and unstable angina using 16-row Multislice CT (MSCT).

Materials and Methods: Twenty-one patients with stable (17 male, mean age 59 ± 9 yrs) and twenty patients with unstable angina pectoris (15 male, mean age 60 ± 11 yrs) underwent MSCT coronary angiography (Sensation 16, Siemens) prior to diagnostic conventional coronary angiography (CCA). A subset of 15 patients underwent intra-coronary ultrasound (ICUS) of a vessel not targeted for intervention. To determine the MSCT coronary plaque burden, we assessed the extent (number of diseased segments), size (small or large), type (calcific, non-calcific, or mixed) of plaque and its anatomic distribution in all ≥ 2 mm coronary segments.

Results: The sensitivity and specificity of MSCT in the detection of significant coronary plaques (≥ 50% plaque area on ICUS) was 83% (25/30) and 87% (54/62). A total of 473 ≥ 2 mm coronary segments were included for the assessment of MSCT plaque burden. Plaques were present in 62% (292/473) of all segments. Plaques were classified as small in 53% (155/292) and large in 47% (137/292) of diseased segments. Thirty-two percent (93/292) were non-calcific, 25% (73/292) calcific, and 43% (126/292) mixed. Plaques were predominantly located in the proximal and mid-segments of the main coronary vessels. Plaque was found in one third of segments classified as normal on CCA. Patients with unstable angina had significantly more non-calcific plaques when compared to stable patients.

Conclusions: MSCT coronary angiography provides in-vivo information regarding the presence, extent, severity, and distribution of coronary atherosclerosis.

B-309 11:42

Coronary calcification characteristics on multidetector CT and accompanying stenosis severity

J.B. Houwers, J. Dorgelo, T.P. Willems, F. Zijlstra, M. Oudkerk; Groningen/NL

Purpose: Coronary calcifications often complicate the differentiation between significant and non-significant stenoses in coronary multidetector CT (MDCT) due to blurring artifacts. This often leads to false positive cases of coronary stenoses, compared to coronary catheter angiography (CAG). A study was performed to determine whether certain characteristics of calcified lesions on MDCT are related to the severity of an accompanying lumen reduction.

Material and Methods: Fifty-eight patients (44 male, mean age 62.0 ± 8.7) scheduled for coronary intervention, were examined with 16-slice MDCT. The latest CAG on which the PCI indication was made was used as reference standard. The mean time between CAG and MDCT was 28.0 ± 11.0 days. Of all segments, calcified lesions were described by shape and presence or absence of accompanying soft plaque. The characteristics were compared to the lumen reduction on CAG.

Results: A total of 211 calcified lesions were found. The majority, 149 (71%), was

Scientific Sessions

accompanied by soft plaque. Of the 62 purely calcified lesions, in only eight cases (13%) was there a true stenosis, whereas 42 out of 149 mixed lesions (28%) were related to true stenosis. This difference was significant ($p < 0.02$).

When looking at the shape of the eight pure calcified stenotic lesions, seven of these were of the spotty type.

Conclusion: A significantly lower occurrence of $\geq 50\%$ stenosis was found in purely calcified lesions, compared to mixed lesions. Only in cases of spotty pure calcified lesions one has to be aware of possible underlying stenosis of the coronary lumen.

B-310 11:51

Is coronary plaque morphology a useful predictive tool for the detection of severe coronary lesions? Analysis of 469 plaques as assessed by 16-slice computed tomography

A. Kuettner, A. Feyer, J. Rothfuss, M. Heuschmid, A.F. Kopp, S. Schroeder, C.D. Claussen; Tübingen/DE

Background: MDCT systems with retrospective ECG-gating permit visualization of the coronaries. Also, plaque composition of atherosclerotic lesions can be assessed. The purpose of this study was to investigate whether plaque composition can be a tool to identify or rule out severe coronary lesions.

Methods and Results: 60 patients (pts) underwent conventional coronary angiography (CCA). All patients were also studied by 16-slice-MDCT. All coronary plaques as assessed by MDCT were compared to CCA regarding degree of luminal obstruction $> 70\%$ and also classified as having one of the following 11 characteristics: 1: calcified nodule, 2: small wall adherent calcified plaque (cp), 3: cp at vessel bifurcations, 4: "obstructive" cp, 5: cp conglomerate, 6: small non-calcified plaque (ncp), 7: larger ncp, 8: "twin" ncp, 9: vascular occlusion by ncp, 10: mixed plaque, 11: mixed plaque with predominant calcifications.

Results: 469 plaques were detected in $n = 60$ pts. The distribution was as follows (number of severe lesions): 1: $n = 33(0)$, 2: $n = 85(1)$, 3: $n = 12(0)$, 4: $n = 11(1)$, 5: $n = 33(6)$, 6: $n = 89(0)$, 7: $n = 47(1)$, 8: $n = 45(9)$, 9: $n = 30(10)$, 10: $n = 74(29)$, 11: $n = 18(12)$. For groups 1, 2, 3, 4, 6 and 7 a predictive value to exclude severe coronary lesion was ≥ 0.98 , for groups 6, 8, 9, 10, 11 and 12 the predictive value was < 0.91 .

Conclusions: Our data suggest that the postulated plaque groups allow for reliable exclusion of severe coronary artery lesions independent of luminal assessment of a given plaque type. Prospective studies have to show whether these findings can be used in clinical routine practice to exclude significant CAD.

Prediction of the extent of cerebral infarction and assessment of the clinical condition using functional CT perfusion and diffusion-weighted MR imaging in hyperacute ischemic stroke

S. Bisdas¹, F. Donnerstag², K. Weissenborn², C. Herzog¹, M. Harth¹, B. Ahl², I. Bohrer², H. Becker², T. Vogl¹; ¹Frankfurt a. Main/DE, ²Hannover/DE

Purpose: To determine the accuracy of CT perfusion (CTP) and diffusion-weighted MR imaging (DWI) in assessing the admission and follow-up clinical condition and predicting the follow-up infarction in hyperacute stroke.

Methods and Materials: CTP and DWI were obtained in 27 patients untreated with thrombolysis within 4 hours of stroke onset. On the CTP-delivered cerebral blood flow (CBF) images 3 CBF cut-off values were used to discriminate between infarcted, non-infarcted, and penumbra areas. On the DWI areas of acute infarction were delineated on the base of apparent diffusion coefficient (ADC) values. The measured areas on CTP and DWI were correlated with the admission and follow-up (mean interval time 5 days) National Institutes of Health Stroke Scale (NIHSS) scores as well as with the areas of infarction on follow-up imaging.

Results: The volumes of the infarcted and ischemic (infarction and penumbra) tissue on admission CTP correlated with the NIHSS score ($p < 0.005$). At the time of follow-up imaging the infarcted tissue volume correlated with the initial CTP ischemic and infarcted tissue volumes ($r = 0.63$, $p < 0.01$ and $r = 0.71$, $p < 0.01$). A correlation was shown between the initial diffusion abnormality volume

and the follow-up infarcted tissue ($r = 0.74$, $p < 0.01$). The follow-up NIHSS score correlated only with the ischemic and infarcted lesion area on CTP ($p = 0.001$). **Conclusion:** Admission CTP and DWI in hyperacute stroke can accurately predict the short-term follow-up infarct size. Areas of ischemic and infarcted tissue on the CTP correlate with the admission clinical condition and allow the evaluation of clinical prognosis.

B-312 10:39

Role of MR perfusion-weighted images for predicting severe lesion growth in the hyperacute stage infarction

S.H.J. Seon, K.S.J. Kim; Seoul/KR

Purpose: To evaluate the diagnostic performance of each perfusion map of MR perfusion-weighted images (PWI) for predicting severe lesion growth in stroke patients.

Methods and Materials: We examined 43 patients with acute middle cerebral artery territory infarction in whom diffusion-weighted images (DWI) and PWI were obtained within 6 hours after symptom onset and follow-up MR imaging including DWI within 5 days. Infarct volume was measured on initial and follow-up DWI by using threshold technique in the workstation. Enlargement of the lesion more than 1.5 times on follow-up was defined as severe progression. Perfusion maps (relative cerebral blood volume; rCBV, mean time to enhancement; MTE, and relative cerebral blood flow; rCBF map) were created by using a commercial software program. We regarded the presence of mismatch in each map as an indicator for predicting lesion growth. We analyzed the sensitivities, specificities, positive predictive value, negative predictive value, and diagnostic accuracy of each perfusion map for predicting severe lesion growth.

Results: rCBV map showed the highest diagnostic accuracy (65.1%) and specificity (77.4%), but low sensitivity (33.3%). rCBF and rMTE map showed the highest sensitivity (75.0%), but low specificity (48.4% and 22.6%). All maps showed relatively high negative predictive value (rCBV: 75%, rCBF: 83.3%, and rMTE: 70%), but low positive predictive value (36.4%, 36.0%, and 27.3%).

Conclusions: Perfusion images provide important clues for predicting severe lesion growth in acute stage infarction, but also have limitations in applying to individual cases and should be used as a complementary tool.

B-313 10:48

CT perfusion in the acute stage of SAH: Relationship to the development of delayed cerebral ischemia

I. van der Schaaf, R. Hoff, G. Rinkel, G. van Dijk, B. Velthuis; Utrecht/NL

Purpose: To study the relationship between quantitative perfusion parameters and perfusion asymmetries of both hemispheres in the acute stage of SAH with the development of DCI.

Methods and Materials: CTP scans were performed in 32 patients within 48 hour after SAH. Regions of interest were drawn in the peripheral (cortical) and deep (basal ganglia) flow territories of the anterior cerebral artery and middle cerebral artery by two observers. Ratios of CBF and CBV values and differences of MTT and TTP values were calculated between hemispheres. The differences of quantitative perfusion values, in patients and locations with and without DCI were compared by means of the T-test statistics.

Results: Eight of 32 patients developed DCI (25%). Patients with DCI had significantly lower quantitative CBV and CBF values, lower CBV and CBF ratios and higher MTT and TTP differences between the left and right hemisphere (both ratios and differences indicating more asymmetry between hemispheres). Significantly lower quantitative CBV and CBF values, higher MTT values and lower CBV and CBF ratios between both hemispheres were present for locations with DCI. The lowest CBF and CBV and the highest MTT were always on the side of DCI.

Conclusion: Lower CBF and CBV values are present in the acute stage after SAH in patients who develop DCI. More asymmetry of perfusion values between hemispheres is present for all four perfusion parameters. This information might help in the development of a predictive model for patients with a higher risk of developing DCI.

Diffusion and perfusion weighted magnetic resonance imaging in patients with acute ischemic stroke: Can diffusion/perfusion mismatch predict outcome?

J. Ma, R. Bruening, D. Morhard, G.F. Hamann, H. Brueckmann; Munich/DE

Purpose: To investigate whether perfusion MR imaging hemodynamic parameters in mismatched regions were correlated with stroke severity and if they were useful for prediction of outcome.

Scientific Sessions

Saturday

Methods and Materials: Routine MR imaging, diffusion and perfusion weighted imaging was performed in 35 acute stroke patients, and the stroke severity assessment (National Institutes of Health Stroke Scale Score, NIHSS) at admission and the functional outcome (modified Rankin scale, MRS) at discharge was recorded. The perfusion maps were processed and the parameters were obtained by identifying regions of interest on both ischemic core and mismatched regions, and on the normal mirror region.

Results: *Hemodynamic parameters in relation to MRS outcome score:* In the mismatched region, relative cerebral blood flow (rCBF) change and time to peak (TTP) delay showed statistically significant regression to MRS ($p < 0.05$). The more the rCBF decreased and the longer the TTP delay, the higher the MRS (poor outcome) was. In ischemic core, rCBF change and mean transit time (MTT) delay was significantly related to MRS ($p < 0.05$). *Hemodynamic parameters in relation to NIHSS:* Only TTP delay in the mismatched region was related to NIHSS significantly ($p < 0.05$). No other hemodynamic parameters were found to correlate with NIHSS. No statistical significance was found in cerebral blood volume (rCBV) and bolus arrival time (T0) in relation to NIHSS or MRS.

Conclusions: The hemodynamic parameters derived from perfusion MR imaging may be a helpful adjunct to predict the outcome and severity in acute stroke patients. In the mismatched region, the rCBF reduction and TTP delay are statistically correlated to stroke outcome (MRS).

B-315 11:06 ♀

Voxel-based CT analysis for improved detection of early CT signs in cerebral infarction

C. Grimm¹, A. Hochmuth², H.-J. Huppertz²; ¹Basle/CH, ²Freiburg/DE

Purpose: In acute cerebral infarction early CT signs (e.g., attenuation of involved structures due to edema, loss of gray-white matter differentiation) may be difficult to detect within the first hours after symptom onset. Here, we present a novel technique for post-processing of CT scans to enhance these signs.

Methods and Materials: A cranial CT scan with 512x512 matrix and axial cuts of 5 mm through infra- and supratentorial space is interpolated to a volume data set and normalized to a customized CT template using standard algorithms of SPM2 (Statistical Parametric Mapping Software, Wellcome Department of Imaging Neuroscience, London). The distribution of gray and white matter is analyzed on a voxelwise basis and compared with a normal database consisting of the normalized CT scans of 30 healthy subjects. Based on this analysis, a 3-dimensional map is created which characterizes density loss of brain tissue as compared to the normal database.

Results: In a preliminary study this technique was applied to the CT scans of 12 patients with acute cerebral infarction (CT within 1-6 hours after symptom onset). The resulting feature maps displayed the infarction much more clearly than the original CT scans, even in 3 cases in which the lesion was initially not detected in the CT.

Conclusion: The novel technique for CT post-processing presented here may facilitate the interpretation of CT scans in acute cerebral infarction.

B-316 11:15

Treatment of stroke in rats with microplasmin: Magnetic resonance imaging evaluation

F. Chen¹, Y. Suzuki¹, N. Nagai¹, P. Peeters¹, X. Sun², W. Coudyzer¹, G. Marchal¹, Y. Ni¹; ¹Leuven/BE, ²Weifang/CN

Purpose: To evaluate Microplasmin (μ Pli) in a rat thrombotic stroke model with magnetic resonance imaging.

Methods and Materials: Rats ($n = 24$) were subjected to photochemical thrombosis of the middle cerebral artery (MCA) and randomized to 3 groups: controls (solvent, $n = 8$), low dose (7.5 mg/kg, $n = 8$) or high dose (10 mg/kg, $n = 8$) μ Pli, administered as an intravenous bolus 90 min after MCA occlusion. Cerebral ischemic damage was evaluated at 1 and 24 h after MCA occlusion by diffusion weighted imaging (DWI), and susceptibility contrast enhanced perfusion weighted imaging (PWI), and correlated with 2, 3, 5-triphenyl tetrazolium chloride (TTC) staining. The relative lesion size (RLS), PWI-DWI derived growth rate of RLS, relative cerebral blood volume (rCBV) and neurological signs were evaluated.

Results: The RLS measured with TTC staining at 24 h was $19 \pm 5.0\%$ in controls, and $12.1 \pm 2.5\%$ and $13.1 \pm 4.7\%$ in rats with 7.5 and 10 mg/kg μ Pli. The growth rate of RLS from 1 to 24 h was reduced from $18.1 \pm 7.1\%$ in controls to $2.5 \pm 9.5\%$ and $3.4 \pm 10.9\%$ with 7.5 and 10 mg/kg μ Pli respectively. The rCBV of ischemic areas at 24 h increased from $37 \pm 14\%$ in controls to $54\% \pm 15$ and $46\% \pm 16$ with 7.5 and 10 mg/kg μ Pli respectively. The neurological deficits improved from a Bederson score of 7(6-9) in controls to 4.5(3-8) and 4(3-6) with 7.5 and 10 mg/kg μ Pli respectively ($p < 0.05$ for each dose vs controls for all parameters).

Conclusion: As monitored with MR imaging and histomorphology, μ Pli reduced stroke size with improved neurological function in rats.

B-317 11:24 ♀

Metabolite profile in pyramidal tracts after ischemic brain stroke - 1H MRS study.

B. Kubas, J. Walecki, W. Kulak, J. Kochanowicz, E. Tarasow, W. Dzienis, J. Janica; Bialystok/PL

Purpose: To assess the role of 1H MRS in the detection of changes in cerebral metabolite levels in pyramidal tracts after cortical/ subcortical infarction and to compare metabolite alterations to clinical outcome (Barthel index, Scandinavian Stroke Scale).

Materials and Methods: 21 patients with supratentorial cortical/ subcortical infarction were studied, 1 month after the onset of clinical symptoms of ischemic stroke. The MR studies were performed on 1.5 T system. The results of spectra approximation (presented as metabolite ratios: NAA/Cr, Cho/Cr, lac/Cr, lip/Cr) were subjected to statistical analysis. MR spectra were recorded from normal appearing brain regions: contra and ipsilateral internal capsule and cerebral peduncles. Spectra from stroke patients were compared with a control group of 32 healthy volunteers.

Results: The statistical analysis revealed significant differences between data obtained from the various regions in the same patients who had undergone ischemic stroke and between the infarcted and control groups. Proton MR spectroscopy detects changes in cerebral metabolite levels in also apparently normal regions. In contralateral brain regions, as well as in the internal capsule we have noticed significant reduction of NAA and increase of Cho and lac; we found correlation between NAA level and Barthel Index and between lac/Cr and SSS.

Conclusions: Proton MRS is a very useful tool for evaluating major changes in metabolite levels in pyramidal tracts after brain stroke. Our preliminary results of 1H MRS, MR imaging and clinical data support the idea that metabolic lesions distant from the infarcted tissue can be responsible for the clinical course and have predictive value.

B-318 11:33

Cerebral vasospasm after subarachnoid haemorrhage: Multislice computerized tomography (MSCTA): A comparison with digital subtraction angiography (DSA) and contribution of perfusion CT in vasospasm management

M. Colleoni, A. Uské, R. Meuli, P. Maeder, L. Regli, P. Schnyder, S. Binaghi; Lausanne/CH

Purpose: To assess the diagnostic accuracy of MSCTA in detecting vasospasm following subarachnoid haemorrhage, on several intracranial arterial segments. To discuss the combination of MSCTA and perfusion CT in the management of vasospasm.

Methods: Twenty-six patients with clinical cerebral vasospasm underwent simultaneously DSA, MSCTA and perfusion CT. MSCTA consisted of 125-mm slice, reconstructed every 0.8 mm, pitch 0.75 and timing determined by a test bolus. Vasospasm was analysed by MSCTA and DSA on seven intracranial arterial locations and was categorized as none, mild, moderate or severe. Sensitivity, specificity, and accuracy of MSCTA in detection of vasospasm were calculated for each segment. Perfusion CT maps were performed in 17 patients, from which regional cerebral blood volume (rCBV), regional cerebral blood flow (rCBF) and mean transit time (MTT) values were calculated in 5 regions of interest on each hemisphere.

Results: 63 vasospasms were identified by means of MSCTA and DSA on 261 arterial segments. Accuracy of MSCTA was greatest for the A2 segment of the anterior cerebral artery (100%) and M2 segment of the middle cerebral artery (100%), whereas it was lowest for distal carotid siphon (45%). On perfusion CT, overall mean CBF values were significantly lower in segments with moderate to severe vasospasm ($P < 0.001$).

Conclusion: MSCTA can identify vasospasms even if located distally. MSCTA coupled with perfusion CT is a fast, accurate and non-invasive strategy to detect and evaluate intracranial vasospasms and their consequences on cerebral perfusion, allowing a time-saving selection of patients that will undergo endovascular treatment.

MR digital subtraction angiography using parallel imaging in the diagnosis of vasospasm after subarachnoid hemorrhage

K. Tsuchiya, A. Fujikawa, K. Honya, M. Nakajima, T. Nitatori, S. Takemoto; Tokyo/JP

Purpose: MR digital subtraction angiography (DSA) visualizes vessels employing a rapid T1-weighted sequence in combination with a bolus injection of gadolinium. We assessed whether MR DSA using parallel imaging is effective in the diagnosis of vasospasm after subarachnoid hemorrhage.

Methods and Materials: On a 1.5-T imager, we used a three-dimensional fast field-echo sequence using parallel imaging (TR/TE/excitations = 3.1/0.9/1, flip angle = 20 deg, matrix = 128x256, field of view = 26x28 cm, reduction factor = 2) with intravenous injection of 7 ml of ProHance at a rate of 3 ml/sec. In 28 patients examined 5-20 days after clipping of a ruptured cerebral aneurysm, we reviewed MR DSA images comparing with images of diffusion-weighted imaging, dynamic susceptibility contrast (DSC) perfusion imaging, and 3D time-of-flight (TOF) MR angiography (MRA).

Results: Temporal resolution was as short as 0.8 sec. Vasospasm was noted in a total of 48 arterial segments on MR DSA and/or 3D-TOF MRA. In 19 of the 48 segments (40%), MR DSA was able to detect vasospasms but 3D-TOF MRA was not due to artifacts from a clip. In other 26 segments (54%), MR DSA and 3D-TOF MRA showed concordant findings. In 16 of the 28 patients, diffusion-weighted images showed new ischemic lesions. MR DSA was able to depict vasospasm leading to ischemia in 10 of the 16 patients (63%). Abnormalities on DSC perfusion imaging noted in eight patients were consistent with areas with vasospasm on MR DSA.

Conclusion: MR DSA using parallel imaging can be a tool to sensitively visualize vasospasm after subarachnoid hemorrhage.

B-320 11:51

Diffusion-weighted MR imaging in MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis and stroke-like episode) syndrome

M. Lim¹, J. Kim², C. Suh¹; ¹Incheon/KR, ²Seoul/KR

Purpose: To investigate the nature of the infarct-like lesions on MR images during acute stroke-like episodes of the MELAS syndrome.

Materials and Method: We reviewed 11 MR images (including 10 diffusion-weighted images (DWI)), obtained within a week of the acute neurological event, and the medical records of 4 patients with MELAS syndrome to identify new edematous brain lesions. Visual assessment of the conventional MR images, DWI, and apparent diffusion coefficient (ADC) maps were performed for each lesion. In addition, the ADCs in normal and abnormal appearing areas were compared. The temporal evolution of the lesions on follow-up MR images was also analyzed.

Results: A total of 13 lesions during six acute episodes were identified. They appeared as acute infarct-like swelling in the cortex and subcortical white matter of the cerebral hemispheres. All 13 lesions gave a variable degree of high signal on DWIs, and among them, 7 lesions exhibited lower signal on ADC maps and decreased ADCs compared to those of the normal appearing white matter. The remaining 6 lesions produced ADCs that were not significantly different from or slightly higher than those of the normal regions on ADC maps. Five of 8 followed lesions evolved to localized tissue loss (hemorrhage occurred in 2 of them) corresponding to initial ADC decrease. The remaining 3 lesions resolved with or without small areas of residual abnormal signal.

Conclusion: Cytotoxic edema may occur either from vasculopathy or energy production failure during the acute stroke-like episodes of MELAS syndrome and they evolve to progressive tissue loss.

Machine learning for computer-aided diagnosis in dynamic breast MR imaging: Can neural network analysis improve the diagnostic accuracy in suspicious lesions?

A. Wismueler¹, G. Leinsinger¹, A. Meyer-Baese², R. Wiegard¹, O. Lange¹, T. Schlossbauer¹, M.F. Reiser¹; ¹Munich/DE, ²Tallahassee, FL/US

Purpose: To develop, test, and evaluate a neural network machine learning approach for characterization of diagnostically challenging breast lesions in MR imaging.

Methods and Materials: 88 women with 92 indeterminate mammographic lesions (BIRADS III-IV, 41/51 benign/malignant lesions confirmed by histopathology) were examined by standardized dynamic contrast-enhanced breast MR imaging on a 1.5 T system. The machine learning approach is based on a 3-layer radial basis functions (RBF) neural network for automatic classification of 6-dimensional lesion-specific signal intensity time course vectors. For reference, interactive visual classification was performed by human experts using a standardized semi-quantitative evaluation score (Kuhl et al., Radiology 211:101-110). In addition, morphological criteria were included by a clinically approved scoring system. Classification performance was evaluated by a meticulous 25-run multiple leave-out cross-validation setup for test and training data. For quantitative assessment of diagnostic accuracy, areas under ROC curves (AUC) were computed for both machine learning and human expert classification.

Results: Neural network machine learning increased both sensitivity and specificity for classification between benign and malignant lesions, as confirmed by quantitative analysis of diagnostic accuracy: Neural network results (AUC=80 ± 4%) clearly outperformed human expert evaluation of SI time-series with (AUC=64 ± 5%) and without (AUC=59 ± 6%) consideration of lesion morphology. The increase in diagnostic accuracy for neural network classification proved to be statistically significant (Wilcoxon matched-pairs, two-sided, p < 0.05).

Conclusion: Automatic lesion classification in breast MR imaging by RBF neural networks is a powerful method for computer-aided diagnosis in suspicious lesions leading to a substantial improvement of diagnostic accuracy beyond the visual interactive classification by human experts.

B-322 10:39

Performance of an adaptive wavelet contrast enhancement method in interpretation of microcalcification clusters on dense parenchyma

L. Costaridou, S. Skiadopoulos, P. Sakellaropoulos, C. Kalogeropoulou, E. Likaki, G. Panayiotakis; Patras/GR

Purpose: To assess performance of a locally adaptive-wavelet (AW) contrast enhancement method in interpretation of microcalcification (MC) clusters on dense breast parenchyma. The method was compared to the manual intensity-windowing (IW) method, considered as the current standard.

Methods and Materials: The sample consists of 86 mammographic images corresponding to dense breasts, originating from the DDSM database. Specifically, it consists of 43 images containing MC clusters (29 malignant and 14 benign) and 43 images without abnormalities. The sample has been processed with the AW and the IW enhancement methods and reviewed by two experienced qualified radiologists, using two high-resolution display monitors. Comparative evaluation was performed between original plus AW-processed and original plus IW-processed images with respect to the detection (five-point rating scale), morphology characterization (four categories) and pathology classification (five levels of confidence) of MC clusters, according to BIRADS lexicon.

Results: Detection accuracy of the method based on original plus AW-processed images is higher according to ROC analysis (area under the ROC curve, $A_z = 0.98$), than those of the method based on original plus IW-processed images ($A_z = 0.94$). Morphology characterization accuracy of the method based on original plus AW-processed images is better (18.6% increase). For pathology classification accuracy, high performance (~70%) is achieved for both enhancement methods as compared to radiologists' assessments of DDSM database (~63%), according to Wilcoxon signed ranks test.

Scientific Sessions

Saturday

Conclusion: The AW contrast enhancement method demonstrates improved performance for detection, morphology characterization and pathology classification of MC clusters on dense breast parenchyma, as compared to IW contrast enhancement method.

Computer-aided diagnosis as a second reader for nodule detection in chest radiographs versus single and double reading

A.M.R. Schilham, B. van Ginneken; Utrecht/NL

Purpose: Instead of using Computer-Aided Diagnosis (CAD) only for generating prompts at suspicious areas, we assess the potential of a CAD system as an independent second reader for lung nodule detection in chest radiographs, compared to single and double reading.

Method and Materials: The public JSRT database was used, containing 154 chest radiographs with a single proven lung nodule and 93 normal cases. Five experienced radiologists and one resident participated. All cases were read by one radiologist and by the resident. A CAD system developed by the authors was used as an independent second reader, operating at 7 markers on average per case (marking 68% of the nodules). Observers marked regions suspect of being a nodule, and assigned a suspicion score, using a low threshold on confidence. Scores were scaled to make observers comparable. Independent double reading was simulated by averaging probabilities of matching regions, with zero probability for missing regions. Performance was assessed with localized ROC curves. Results are given as sensitivities at a clinically important, low false positive referral rate of 0.02.

Results: Single reading sensitivities of radiologists and resident were similar: 0.13. The JSRT database contains many subtle nodules which may explain these low sensitivities. With double reading, the sensitivity increased to 0.40. Using CAD as a second reader gave a sensitivity of 0.27.

Conclusions: Using CAD as an independent double reader outperforms single reading. The sensitivity at low false positive referral rate is doubled. Human double reading is superior to CAD double reading.

Clinical evaluation of the sensitivity and specificity of a software for automated detection of lung nodules in preliminary CT examinations

J. Gurung, A. Wetter, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To evaluate the efficacy (sensitivity/specificity) of a software for automated detection of intrapulmonary nodules in multidetector CT examinations.

Materials and Methods: The "Nodule Enhanced Viewing" (NEV) algorithm of Siemens LungCare was applied to 16-row multidetector CT (MDCT) examinations in 20 patients [Somatom Sensation, Software VB10A; tube-voltage 140 kVp; tube-current 120 mAs ($n = 11$) and 80 mAs ($n = 9$); 5 mm slice thickness; 1.5 mm reconstruction increment; lung kernel B60f] with a total of 510 intrapulmonary nodules. The nodules were first evaluated by 2 experienced radiologists and taken as control. The nodules detected by NEV were evaluated and compared by the radiologists for their genuinity and specificity. A nodule was considered correctly detected when both radiologists agreed in concordance. Factors influencing detectability were evaluated like diameter, location, density and overlapping of intrapulmonary blood vessels.

Results: Of 539 nodules detected by NEV, 166 co-related with nodules detected by the radiologists with sensitivity rate of 66.13% and specificity rate of 30.77%. Detection was not affected by location or density of the nodules. Detection was however affected by diameter (nodules with diameter > 1 cm were not detected). Over detection by NEV was attributed to localisation of overlapping blood vessels as nodules. NEV detected 7 additional nodules that were missed by the radiologists. Via NEV, nodules were detected that were shadowed by partial volume effect from bones and soft tissues.

Conclusion: NEV as sole algorithm for detection of lung nodules is not a dependable instrument but it has its advantage in detecting nodules usually shadowed by soft tissues and bones.

A visualization-based method for pulmonary emboli identification within high-resolution CT images

A.P. Kiraly¹, D.P. Naidich², C.L. Novak¹; ¹Princeton, NJ/US, ²New York, NY/US

Purpose: Contrast-enhanced high-resolution CT provides an effective means for detecting pulmonary emboli (PE). However these large datasets require tedious evaluation. We propose and evaluate a visualization method for rapid PE detection with high sensitivity and acceptable false positive (FP) rates.

Methods and Materials: Interactive 3D visualization of pulmonary vessel trees with Hounsfield unit (HU) values determining rendering color is utilized. Preprocessing consists of vessel segmentation and path-based labeling. Each element of the vessel tree is rendered with the color determined by HU values along a path to the vessel centerline. As a result, the entire vessel tree may be visualized simultaneously, with dark regions pointing to potential PE inside specific arteries. Classification is further applied to reduce false positives. Evaluation was performed on 13 patients, including 10 positive cases containing 128 emboli. Each visualization was examined and dark regions were marked, requiring about 5 minutes per patient. These markings were compared against ground truth to evaluate sensitivity and FP rates.

Results: Sensitivity equaled 72% of 114 emboli within the vessel segmentation or 64% for all emboli. The segmentation occasionally missed the main and lobar pulmonary arteries and hence missed 14 (11%) emboli. However, radiologists are unlikely to miss centrally located emboli. The average FP rate was 9.2/patient. Many FPs stemmed from segmentation errors and could be trivially dismissed.

Conclusion: Our method demonstrated good sensitivity for segmental and sub-segmental emboli with an acceptable FP rate. This visualization may provide a powerful tool, specifically in the identification of smaller peripheral PE.

Large evaluation of fully automatic colon tracker for CT colonoscopy

R. Tryoen¹, M. Medved², G.A.F. Schoonenberg³, R.E. van Gelder⁴; ¹Best/NL, ²Ljubljana/SI, ³Eindhoven/NL, ⁴Amsterdam/NL

Purpose: To evaluate the performance of a fully automatic colon tracker on a large set of CT colon cases. This automated preprocessing is intended to further facilitate primary 3D inspection of CT colon exams.

Method and Materials: CT scans of 185 patients (prone + supine) were retrospectively identified out of a larger colon study (1). After patient preparation multi-detector CT scans were performed (Mx8000 Philips Medical Systems) with parameters: 120 kV; 25-100 mAs; collimation 4x2.5 mm; slice thickness 3.2 mm. Scans were automatically processed by using a prototype based on EasyVision/ViewForum functionality (Philips Medical Systems). After background and lung removal, all air-filled parts were tracked and connected using anatomical knowledge. After comparison to a centerline defined by an expert the sensitivity (percentage of expert centerline found) and positive predictive value (percentage of tracked parts that were colon) were calculated before and after anatomy-based connection.

Results: The colon had no obstructions in 33% of the cases, few in 56% and many (3 or more) obstructions in the remaining 11%. Before applying anatomy-based connection 94% of the expert centerline was found (sensitivity) while 71% of the found parts were colon (positive predictive value). Anatomy-based connection increased the positive predictive value to 95%, at the cost of a reduced sensitivity (88%) caused by few cases where the anatomy-based connection fails.

Conclusion: Without anatomy-based connections the full colon centerline was found.

Automatic connection is feasible and dramatically reduces overdetection, but can fail in some cases. (1) Van Gelder RE et al. Gastroenterology 2004;127:41-48.

Evaluation of an automated polyp measurements tool compared with experienced observers: A comparative study

A. Jerebko¹, S. Lakare¹, T. Mang², C. Mueller², D. Salovic³, W. Schima², J. Weßling⁴, L. Bogoni¹; ¹Malvern, PA/US, ²Vienna/AT, ³Tournai/BE, ⁴Münster/DE

Purpose: Polyp size assessment could be critical for decision on a patient management. This comparative study was performed to assess the quality of 3D automatic segmentation, reliability and accuracy of automatic polyp measurement versus experienced radiologists.

Methods and Materials: An automatic polyp measurement tool was designed to allow the measurement of a polyp, along largest axial slice across the polyp (given fixed window-level). 44 polyps ranging in size from small (< 6 mm, $n = 18$), medium (6-9.9 mm, $n = 20$) and large (> 10 mm, $n = 6$) were measured and segmented by five radiologists (each performing VC on regular basis).

Results: The median difference of automatic and median manual measurements across all radiologists was 0.4285 mm (less than the average voxel size in the participating studies). Accuracy of automatic measurement was found to be highest in polyps in the 4 to 8 mm range. Two polyps out of 44 were automatically measured smaller by more than 1 mm than any of participant measurements. One small polyp located on a very thin fold was over measured by 4 mm since portion of the fold was erroneously included in the automatic segmentation of the polyp.

Conclusion: 3D automatic segmentation provided accurate measurements within expert inter-observer variability boundaries in 93% of polyps.

Automatic registration of multiphase dynamic contrast multidetector CT (MDCT) studies for the diagnosis of small hepatocellular carcinoma (HCC)
G.-Q. Wei¹, F. Yan², P. Xu², W. Cheng², X. Zeng¹, J.-Z. Qian¹, L. Fan¹, C.-C. Liang¹; ¹Princeton Junction, NJ/US, ²Shanghai/CN

Purpose: Automated accurate localization of the same HCC across multiphase MDCT scans is desirable for efficient evaluation of its enhancement pattern and for diagnosis. This work is to develop and evaluate an automatic method for accurately registering multiple phase CT liver images.

Methods and Materials: 35 contrast-enhanced MDCT studies were acquired at pre-contrast, arterial and portal venous phases. Three physicians marked suspicious small HCCs (< 30 mm) by consensus in each scan, resulting a total of 41 lesions (9-27 mm) to be used as reference. The liver volume is first extracted using a fuzzy-segmentation technique in each phase. An intensity weighting method is then applied to suppress non-liver anatomies. A cross-correlation method is employed to find corresponding slices among different phases. A correspondence is defined as 'hit' if the error in registered position falls within the nodule radius.

Results: The hit rate for all 41 small HCCs was 82.9% between pre-contrast and arterial phases, and 90.2% between arterial and portal venous phases. The hit rate for simultaneous hit across all 3 phases was 78%. The mean registration error was 0.4 slices (maximum 2 slices). The higher hit rate between arterial and portal venous phases was attributed to a more accurate segmentation of the contrast enhanced liver area than at the pre-contrast phase.

Conclusion: The proposed intensity-weighted cross-correlation method effectively achieves accurate registration of small HCCs across multiphase MDCT liver scans. This method offers a base on which efficient tools may be developed to aid physicians in the detection and diagnosis of small HCCs.

A 3D CAD tool for body fat identification

D. Illea¹, O. Ghita², K. Robinson², M. Lynch², P.F. Whelan²; ¹Brasov/RO, ²Dublin/IE

In recent years non-invasive medical diagnostic techniques have been used widely in medical investigations. The distribution of fat tissue in the body is an important measure of health and overall fitness and is not well quantified by the body mass index (BMI) which is currently the measure most widely used to quantify body fat content. The aim of this work is to present the development of a fully automatic CAD tool that can be applied to identify the actual fat mass in MR data. The MR acquisition protocol currently in use involves imaging the patient in a number of successive coronal sections in order to achieve a full body scan. As the grayscale in-homogeneities between adjacent sections are quite significant, to make this data suitable for automated CAD we have been forced to devise a procedure to alleviate as much as possible the discontinuities in the unprocessed data. The devised unsupervised segmentation algorithm that is applied to segment the fatty tissues has three main steps. The first step pre-processes the data using a feature preserving diffusion-based technique to improve the local homogeneity and reduce the level of image noise. The second step extracts the image areas representing fat tissues by using an unsupervised clustering algorithm. Finally, image refinements are applied to reclassify the pixels adjacent to the initial fat estimate and to eliminate outliers. The devised CAD tool has been tested on a database of 42 patients and the experimental data indicates that the proposed tool returns accurate results.

Development of white matter tractography using 3D density field in diffusion tensor (DT) MR imaging

S. Kumazawa, T. Yoshiura, F. Mihara, H. Honda, Y. Higashida, F. Toyofuku; Fukuoka/JP

Purpose: Conventional tractography algorithms fail to trace the path at the crossing or branching of the fiber tracts. Our goal was to develop a new white matter tractography algorithm in DT-MR imaging which permits fiber tracts crossing and branching.

Method and Materials: To express the distribution of tract density based on the geometric nature of the DT within a voxel, we defined a polarized metaball which had a 3D Gaussian distribution of positive or negative density. Using a self-organizing map, voxels in DT-MR imaging were classified into three clusters according to the geometric measures of DT as follows: 1) linear diffusion (LD) cluster, 2) planar diffusion (PD) cluster, and 3) spherical diffusion (SD) cluster. Positive and negative metaballs were generated on each voxel of LD cluster and SD cluster, respectively. No metaball was assigned to the PD cluster. By summat-

ing effects of all metaballs in the voxel space, a map of density field of tracts was generated. In this tract density field, our algorithm tracked voxels with a density larger than a certain threshold value. We tested the algorithm on human brain DT-MR imaging datasets. The human brain data consisted of 6 diffusion-weighted image volumes ($b = 800 \text{ s/mm}^2$) and an unweighted image volume ($b = 0 \text{ s/mm}^2$) with a 128x128 in-plane resolution.

Results: Our algorithm could track major white matter tracts beyond the fiber crossing in the human brain datasets.

Conclusion: We developed a new tractography algorithm which permits tracking through crossing and branching. Efficacy of our new method was demonstrated in human brain data.

MR assessment of collateral blood flow and cardiac function in acute experimental aortic coarctation before and after self-expandable stent placement

C.B. Henk, M. Saeed, O. Weber, A. Martin, M. Wilson, C.B. Higgins; San Francisco, CA/US

Purpose: The purpose of this study was to determine the acute effect of aortic coarctation on collateral flow and LV function in a dog model before and after endovascular repair.

Methods: In seven dogs, the descending aorta (DAO) was dissected distal to the left subclavian artery and looped with a plastic band which was tightened to reduce distal pressure to 40-50 mmHg. Imaging / intervention was done in an XMR suite containing two systems; MR (1.5 T Intera) and X-ray fluoroscopy system (Integris V5000) (Philips Medical Systems) connected by a movable tabletop. The retrospectively-gated FFE (VEC-MR, TR/TE/flip = 8.3/5.1 ms/15°, 16/RR, VENC = 50-200 cm/s) and B-TFE (TR/TE/flip = 4/2 ms/70°, 18/RR) were used for flow measurement / cardiac function. Aortic flow measurements were obtained proximal and 1 cm distal to the coarctation and at the diaphragm level. A self-expandable nitinol stent was placed across the coarctation.

Results: DAO flow changed after creation of the coarctation (proximal = 0.84 l/min, distal = 0.28 l/min, diaphragm = 0.83 l/min) compared to baseline (at subclavian artery = 1.46 l/min, diaphragm = 1.29 l/min). The greater flow at the diaphragm suggests that development of collateral flow is a rapid process. Stent deployment increased aortic flow distal to the stent (0.76 l/min). Cine MR imaging showed increase in LV volumes with coarctation. Coarctation reduced mean blood pressure from 110 ± 10 to 45 ± 8 mmHg. Stenting restored phasic and mean pressure.

Conclusions: The left ventricle and major vessels adjust rapidly to acute aortic coarctation. MR imaging provides quantitative assessment of aortic blood flow and cardiac function as well as immediately demonstrating the success of the intervention.

Arteries arising from the aneurysmal sac as a cause of type 2 endoleak after endovascular treatment of abdominal aortic aneurysms: Study of 115 patients

M. Gola, R. Pacho, L. Bakoñ, L. Grabowska, P. Palczewski; Warsaw/PL

Purpose: To evaluate the role of arteries arising from the AAA sac in the development of type 2 endoleak in patients treated endovascularly with stentgrafts for AAAs.

Methods and Materials: 115 patients were treated endovascularly for AAAs. All patients had a CT examination prior to the endovascular treatment and follow-up CTs performed at 6 month intervals (max. time of follow-up: 3 yrs).

Results: On the CT examination prior to endovascular treatment, patent inferior mesenteric artery, lumbar arteries or medial sacral artery were visualized in 72 patients. On follow-up CTs, patent arteries arising from the AAA sac were found in 43 patients; in 9 patients type 2 endoleak was observed. In 1 case the endoleak resolved spontaneously. In 1 case the endoleak was increasing and embolization

Scientific Sessions

of the IMA was necessary. In the remaining 7 cases, symptoms of endoleak and diameter of AAA did not increase.

Conclusion: Prophylactic embolization of arteries arising from the AAA sac is not needed prior to endovascular treatment. We suggest that intervention should be carried out when there is an increase in the symptoms of endoleak and/or in the diameter of AAA.

B-333 10:48

Evaluation of experimental implanted occlusions in a stent-tube-model with a cone-beam flat-panel volumetric-CT (FP-VCT)

G. Heidrich, F. Melderis, C. Dullin, K.-P. Hermann, E. Grabbe, M. Funke; Göttingen/DE

Purpose: The aim of this experimental study was stenosis evaluation and plaque quality assessment in a stent-tube-phantom using a cone-beam flat-panel volumetric CT (FP-VCT).

Methods and Materials: Balloon catheters from 2 to 5 mm filled with substances of different densities and X-ray attenuations were implanted in a 7 mm stent-tube-phantom to simulate occlusions with air embolism, soft or hard plaques. This phantom was scanned in a FP-VCT with an isotropic spatial resolution of 200 imx200 im. Volume-rendered images, being postprocessed on a workstation, were analysed with respect to the visibility of the stenosis diameter, the plaque quality and the residual lumen. Data analysis was performed based on a five or seven point evaluation scale.

Results: An excellent assessment of the intraluminal conditions was demonstrated. Independent from the balloon position the residual lumen could be reliably visualised up to 100 im. Concerning the assessment of the media in axial reformations, 71% of the simulated soft and hard plaques and 100% of the simulated air emboli reached the highest level of the evaluation scale, in sagittal reformations 86% of the hard plaques. 86% of the soft plaques and 71% of the air emboli showed a good identification of the residual lumen, 57% of the hard plaques showed a good identification. 19% of the balloon catheters showed the claimed size by the company, 81% a deviation between 0.1 and 0.3 mm.

Conclusion: In experimental preclinical use FP-VCT is an excellent diagnostic modality for evaluation of vessel reocclusions after stent implantation. In addition the quality of the plaque material could be exactly determined.

B-334 10:57

Active bleeding in a physiological phantom: Detectability on digital subtraction angiography (DSA) versus multislice CT (MCT)

S.H. Roy-Choudhury, D. Gallacher, J. Pilmer, P. Woodburn, G. Fowler, J. Steers, P. Morales, S. Rankin, A. Adam; London/UK

Purpose: To establish the lower threshold of bleeding detectable with DSA and MCT and the relative sensitivity of these two imaging modalities.

Methods: A closed pulsatile cardio-pulmonary bypass circuit was connected to tubing that ran through a water bath. Three smaller interconnecting 4 mm perspex tubes (no holes, 100 µm hole and 250 µm hole) were used to mimic bleeding arteries. Leak rates were predetermined with a cardiac output of 4.0 l and 2.5 l and with mean arterial pressure (MAP) of 10 to 100 mm of Hg for each hole size. 16-slice-CT was performed using bolus tracking after 35 ml of intravenous contrast was injected into the venous limb. DSA was performed with a 4F straight catheter placed at the holes and with the catheter 10 cm proximal to the holes. Cine-loops of MCT and DSA were read by 2 blinded observers.

Results: The lower limit of MCT was 0.30 ml/min while that of DSA with the catheter 10 cm proximal to the holes was 0.78 ml/min. Detection improved with increasing MAP with CT failing to detect leaks below MAP of 30 mm Hg. DSA with the catheter at the site of the holes was more sensitive (0.25 ml/min or less) and was independent of MAP.

Conclusion: In vitro, MCT is more sensitive than DSA in detecting active haemorrhage unless catheter position is highly super-selective, especially in presence of a MAP of 40 mm Hg and above. Time permitting, CT should be used as initial modality in diagnosis of active haemorrhage.

B-335 11:06

Value of high resistance index - HRI calculated from Doppler spectrum of popliteal arteries in patients with systemic lupus erythematosus (SLE)

A. Walecka, M. Sawicki, M. Brzosko, L. Ostanek, K. Fischer, J. Kordowski; Szczecin/PL

Purpose: HRI is a new Doppler index calculated as a ratio between S - maximal systolic flow and D - maximal early diastolic reversed flow - HRI=D/S. The aim of the study is to evaluate the diagnostic significance of HRI calculated from the Doppler spectrum of popliteal arteries in patients with systemic lupus

erythematosus (SLE), with and without secondary antiphospholipid syndrome (SAPS), compared with healthy controls.

Methods and Materials: During a 9-month period (May 2003 - January 2004), 93 patients (81 women and 12 men) with SLE (including 24 patients with SAPS) and 30 healthy controls (24 women and 6 men) underwent bilateral duplex Doppler examinations of lower limb arteries. The examinations were performed using HDI 3500 (ATL) with 5-12 MHz linear transducer under standardized conditions: correct insonation angle and sample volume size, with the patient in a supine position, after 10 minutes rest.

Results: Mean HRI value obtained in the control group was 0.415 (range 0.305-0.555; median 0.402). In the group of SLE patients without SAPS, mean HRI value was decreased to 0.320 (range 0-0.584; median 0.334) and even lower - 0.283 in SLE patients with SAPS (range 0.106-0.545; median 0.291).

Conclusion: Small arteries, arterioles and capillaries are the main affected vessels in SLE. This chronic process probably stimulates circulation through lower resistance collaterals, decreasing HRI value. The Doppler HRI calculation can be valuable in early diagnosis and monitoring of lower extremity vascular changes in patients suffering from SLE with and without SAPS.

B-336 11:15

Alterations in ocular artery blood flow in patients with type II diabetes mellitus

S. Mylona, A. Kokkinaki, E. Gamvroula, L. Thanos, E. Karaxaliou, N. Mpatakis; Athens/GR

Purpose: To study blood flow alterations in the ocular arteries in patients with diabetes mellitus type II, with or without retinopathy, according to the duration of diabetes, using color Doppler ultrasound.

Material and Method: During a 6-month period we performed color Doppler ultrasound in 50 type II diabetic patients and compared them with a control group of 50 healthy individuals of similar age range. We measured peak systolic and end diastolic velocity in the ophthalmic artery (OA), the central retinal artery (CRA) and the common carotid artery (CCA). We classified patients according to the duration of diabetes (which ranged from 5 to 40 years), and whether retinopathy (of different grades) was present. The presence of systemic hypertension was noted. Patients with other ophthalmic diseases were excluded. In addition we measured glycosylated hemoglobin and serum ferritin, which are elevated in diabetic retinopathy.

Results: A decrease was observed in flow velocity in patients with sub clinical, initial, moderate, proliferative or severe retinopathy, whereas no decrease was observed in diabetics without retinopathy and in the control group. The mean velocity ratio of CRA/CCA was lower in diabetics with severe retinopathy. Ocular blood flow was significantly lower in diabetics without systemic hypertension than in controls.

Conclusion: In diabetic eyes, decreased ocular blood flow velocity and high levels of glycosylated hemoglobin and serum ferritin may indicate risk of progression of diabetic retinopathy.

B-337 11:24

Ultrasound assessment of endothelial dysfunction in obstructive sleep apnea hypopnea syndrome (OSAHS) before and after continuous positive airway pressure (CPAP) therapy

K. Pagonidis, I. Lambiri, D. Tsetis, S. Schiza, S. Yarmenitis, N. Siafakas, N. Gourtsoyannis; Iraklion/GR

Purpose: Epidemiological studies have implicated OSAHS as an independent comorbid factor in cardiovascular and cerebrovascular disease. We discuss the induction of endothelial dysfunction as a possible mechanism. We evaluated endothelial function by high-resolution ultrasonography in patients with OSAHS before and after CPAP therapy by measuring endothelium-dependent (flow-mediated dilatation, FMD) and endothelium-independent (nitroglycerin mediated dilatation, NMD) vasodilator function of the brachial artery.

Materials and Methods: We evaluated 13 pts with OSAHS and 12 control subjects with a mean age 50.08 ± 8.94 years and 39.17 ± 5.69 years respectively and BMI 36.39 ± 7.3 and 33.02 ± 4.87 respectively. FMD and NMD of the brachial artery were measured by high-resolution ultrasonography. In the patient group, measurements were repeated 24 hours and one month after CPAP therapy. The average of 5 consecutive cardiac cycles was used for all measurements. FMD and NMD were expressed as the percent increase in vessel diameter from baseline.

Results: Patients before treatment, compared with control subjects had lower brachial FMD ($4.39 \pm 1.61\%$ vs. $13.04 \pm 1.23\%$; $p < 0.0001$) and comparable NMD (14.04 ± 6.4 vs. $16.4 \pm 2.1\%$; $p = 0.1427$). After CPAP treatment the FMD

Scientific Sessions

increased and was significantly higher compared with FMD before treatment ($4.39 \pm 1.61\%$ vs. $6.23 \pm 2.28\%$; $p = 0.0017$ after 24 hours and $4.39 \pm 1.61\%$ vs. $9.52 \pm 1.5\%$; $p = 0.0002$ after one month). In contrast, the NMD was not significantly altered 24 hours and one month after treatment ($15.37 \pm 6.02\%$; $p = 0.583$ and $15.68 \pm 4.84\%$; $p = 0.326$, respectively).

Conclusion: Obstructive Sleep Apnea Hypopnea Syndrome is associated with an impairment of endothelial function, as assessed by high-resolution ultrasonography, which improves promptly even 24 h after CPAP therapy.

B-338 11:33

Dynamic contrast-enhanced MR imaging or diffusion-weighted MR imaging for monitoring the effect of a vascular targeting agent on rodent tumors?

H.C. Thoeny¹, F. De Keyzer², V. Vandecaveye², F. Chen², C. Boesch¹, Y. Ni², W. Landuyt², G. Marchal², R. Hermans²; ¹Berne/CH, ²Leuven/BE

Purpose: To compare dynamic contrast-enhanced MR imaging (DCE-MRI) and diffusion-weighted MR imaging (DW-MRI) for noninvasive evaluation of early and late effects of a vascular targeting agent in a rat tumor model.

Material and Methods: Thirteen rats with rhabdomyosarcomas in both flanks underwent DCE-MRI and DW-MRI in a 1.5 T MR unit, before and early (1 and 6 hours) as well as later (2 and 9 days) after intraperitoneal injection of Combretastatin A-4 phosphate (CA-4-P). Histopathologic correlation was obtained at each time point. To differentiate the influence of perfusion and diffusion, the ADC was calculated for low ($b = 0, 50, 100 \text{ sec/mm}^2$; ADC_{low}) and high b values ($b = 500, 750, 1000 \text{ sec/mm}^2$; ADC_{high}). An indicator for the influence of perfusion was arbitrarily defined as the difference between these two values (ADC_{perf}). DCE-MRI was quantified by the volume transfer constant k and the initial slope of the contrast-time-curve.

Results: Early after CA-4-P administration, k , initial slope as well as ADC_{perf} decreased significantly ($p < 0.001$), while ADC_{high} remained essentially unchanged; histology showed still viable tumor tissue. At two days the necrotic tumor fraction increased markedly, whereas at nine days regrowth at the tumor periphery was histologically confirmed. ADC_{high} increased at two days and decreased at nine days. In turn, k , initial slope and ADC_{perf} increased at nine days. Changes in ADC_{perf} correlated with changes in k ($R^2 = 0.46$) and in initial slope ($R^2 = 0.67$).

Conclusion: Both DCE-MRI and DW-MRI allow monitoring of tumor perfusion changes by vascular targeting agents and correlate directly. DW-MRI provides additional information regarding cell viability versus necrosis.

B-339 11:42

Multiphase multidetector-row CT in abdominal aortic aneurysm treated with endovascular repair (EVAR): Are unenhanced and delayed phase enhanced images really effective for the detection of endoleaks?

R. Iezzi, F. Quinto, A. Pierro, F. Di Fabio, A. Filippone, A.R. Cotroneo; Chieti/IT

Purpose: To determine the true usefulness of performing unenhanced (UNE) and delayed phase enhanced (DEP) in addition to arterial phase enhanced (HAP) Multidetector-Row CT (MDCT) images for detecting endoleaks after EVAR.

Method and Materials: Fifty patients with abdominal aortic aneurysms treated with EVAR underwent long-term follow-up MDCT (at 1, 6 and 12 months). Unenhanced CT-images were obtained with a 2.5-mm collimation and a 5-mm slice thickness; arterial and delayed CT-images were obtained using a 1-mm collimation and a 1.25-mm slice thickness. Two independent readers were asked to assess the presence of endoleak, according to a five-point confidence scale. At 1 month, CT images were evaluated in four reading sessions, as follows: A) HAP; B) UNE + HAP; C) HAP + DEP; D) UNE + HAP + DEP. At 6- and 12-month follow-up a fifth reading session was added, including pUNE (1-month unenhanced phase CT-images) + HAP (E). Sensitivity, specificity and diagnostic accuracy of each reading session were compared.

Results: Sensitivity, specificity and diagnostic accuracy of session B were significantly higher ($p > 0.05$) than those obtained with A and C reading sessions. No statistically significant differences were found between values obtained with session B and session D. At 6 and 12-months follow-up session E showed similar values than session B.

Conclusions: The addition of UNE to HAP is truly effective for detection of endoleaks only at 1-month follow-up. Delayed phase does not statistically increase diagnostic accuracy in detecting endoleak.

Peripheral artery stent visualization and in-stent re-stenosis analysis in 16-row computed tomography: An in-vitro evaluation

C. Herzog, J.O. Balzer, M.G. Mack, T. Lehnert, W. Schwarz, S. Zangos, K. Eichler, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To assess the accuracy of 16-row multidetector CT in the visualization of different peripheral artery stents and the appraisal of in-stent re-stenosis.

Methods: Twenty-seven stents, made of different material (steel, nitinol) and size (6-10 mm) were analyzed in a barrel-shaped (130 HU) vascular model. Low-grade ($\leq 40\%$) and high-grade ($\geq 60\%$) in-stent re-stenosis was simulated by polyurethane sticks (70 HU) with a defined length and diameter (2-6 mm) placed inside each stent. Imaging was performed parallel and perpendicular to the stent axis (scanning parameters: $16 \times 0.75 \text{ mm}$ detector collimation, 130 mAs , 120 kV , 12 mm table feed/rotation, 1.0 mm slice thickness and 0.5 mm increment). Stent diameter, strut thickness, intraluminal attenuation values, degree and length of in-stent re-stenosis were evaluated.

Results: Nitinol stents showed significantly less stent lumen narrowing ($27.4\% \pm 8.9\%$ vs. $32.3\% \pm 6.5\%$; $p < 10^{-6}$) and artificial strut thickening ($1.48 \text{ mm} \pm 0.14$ vs. $1.58 \text{ mm} \pm 0.13$; $p < 10^{-4}$) than stainless steel stents, distinctly less in-stent attenuation changes, less underestimation of the degree and less overestimation of the length of the in-stent stenosis. Stent lumen narrowing and in-stent attenuation values were significantly lower in 10 mm stents than in 8 mm ($p < 10^{-4}$) or 6 mm ($p < 10^{-6}$) stents; artificial strut thickening and overestimation of in-stent re-stenosis was significantly lower in 10 mm ($p < 10^{-6}$) and 8 mm ($p < 0.04$) stents than in 6 mm stents. High-grade in-stent re-stenosis was significantly ($p = 0.01$) more overestimated than low-grade stenosis.

Conclusions: 16-row MDCT allows for the reliable detection of in-stent re-stenosis and the differentiation between low- and high-grade re-stenosis under in-vitro conditions. The effective degree of re-stenosis is still significantly overestimated, preventing an accurate distinction particularly between total stent occlusion and high-grade re-stenosis.

64-slice coronary CT angiography: Heart rate dependency of image quality at 0.33 s/360° gantry rotation

B.J. Wintersperger¹, K. Nikolaou¹, C.R. Becker¹, F. Ziegler¹, T. Johnson¹, T. Flohr², C. Rist¹, A. Knez¹, M.F. Reiser¹; ¹Munich/DE, ²Forchheim/DE

Purpose: The purpose of this study was to evaluate the impact of a $0.33/360^\circ$ rotation on image quality of coronary CTA in relationship to the patients' heart rate (HR) using a 64-slice scanner.

Material and Methods: Coronary CTA data sets of 32 patients (HR 53-92) examined on a 64-slice scanner system (Sensation 64, Siemens) with a $0.33 \text{ s}/360^\circ$ gantry rotation were evaluated. A standardized protocol with $64 \times 0.6 \text{ mm}$ collimation and automated contrast injection (Spectris, Medrad) of iopromide (Ultravist 300, Schering) was implemented. Data was reconstructed in 50 ms intervals throughout the RR-Interval and reviewed by 2 observers. At $\text{HR} > 65$, single- and dual-sector reconstruction was performed and image quality rated using a 3-point scale from excellent (1) to non-diagnostic (3) for coronary segments. Quality was correlated to the HR and the benefit of multi-sector reconstruction evaluated.

Results: Diagnostic quality was achieved in all patients. Mean image quality for $\text{HR} \leq 65 \text{ bpm}$ was 1.16 compared to 1.57 in $\text{HR} > 66 \text{ bpm}$ ($P = 0.01$). Dual-sector reconstruction did not significantly improve quality in $\text{HR} > 66 \text{ bpm}$ (1.71 ± 0.43 vs. 1.65 ± 0.30 ; $P = 0.62$). While in $\text{HR} \leq 70 \text{ bpm}$ best quality was consistently found in diastole, in $\text{HR} > 75 \text{ bpm}$ best quality was achieved in systole. Overall, image quality did not significantly correlate with HR ($R = 0.22$; $P = \text{NS}$).

Conclusion: Improved temporal resolution at 0.33 s rotation allows for diagnostic image quality within a wide range of HR even when using single-segment algorithm. However, with increasing HR the time point of best image quality shifts from mid-diastole to systole. Further studies are required to evaluate whether coronary imaging within systole affects the diagnostic value.

Diagnostic accuracy of non-invasive 64-slice CT coronary angiography

F. Cademartiri, N.R. Mollet, C. van Mieghem, G. Runza, M. Belgrano, T. Baks, P.J. de Feyter, G.P. Krestin; *Rotterdam/NL*

Purpose: Evaluate diagnostic accuracy for the detection of significant obstructive coronary artery stenosis with a new 64-slice CT scanner.

Materials and Methods: We studied 30 patients (18 men, mean age 57.5 ± 6.7 years) with stable angina or an acute coronary syndrome prior to diagnostic conventional angiography. Only patients in sinus rhythm, who had never undergone angioplasty or bypass surgery and were able to breath-hold for 15 s, were included. Patients with pre-scan heart rates ≥ 70 bpm received oral β-blockade. The heart was scanned after intravenous injection of 100 ml contrast material (Iomeprol 400 mg/ml) at 5 ml/s with a 64-slice CT scanner (Sensation 64, Siemens, Germany) with the following parameters: slices/width 64/0.6 mm, gantry rotation time 330 ms, 700-900 mAs, 120 kV. Images were retrospectively reconstructed at 350 ms prior to the next R wave. The CT datasets were analysed by 2 observers unaware of the results of invasive angiography and all main coronary arteries and ≥ 1.5 mm branches were included for comparison with quantitative coronary angiography.

Results: Eighty-seven percent of the included patients received a β-blocker. The mean heart rate was 58 ± 7 bpm and the total scan-time was 13 ± 1 s. There were 47 significantly obstructed vessels. Sensitivity, specificity, positive and negative predictive value for detection of significantly obstructed vessels were 96% (47/49, 95% CI 86-97), 89% (63/71, 95% CI 79-95), 85% (47/55, 95% CI 73-95), and 97% (63/65, 95% CI 89-99) respectively.

Conclusions: 64-slice CT coronary angiography reliably detects significant coronary stenoses in patients with stable angina pectoris or an acute coronary syndrome.

B-343 14:18

High-resolution ex vivo imaging of coronary artery stents using 64-detector-row computed tomography with a z-axis flying focal spot technology. Initial experience

C. Rist¹, K. Nikolaou¹, T. Flohr², B.J. Wintersperger¹, M.F. Reiser¹, C.R. Becker¹; ¹Munich/DE, ²Forchheim/DE

Purpose: To test the potential of the new 64DCT scanner for the depiction of coronary artery stents in an ex-vivo setting.

Method and Materials: Three ex-vivo porcine hearts have been examined. Coronary artery stents of 3.0 and 2.5 mm diameter were implanted in the proximal right coronary artery. Ex-vivo hearts were scanned with a 16DCT (Somatom Sensation16, Siemens Medical Solutions; minimal slice-thickness 0.75 mm), and a new-generation 64DCT (Somatom Sensation64), applying a z-axis flying focal spot technology (minimal slice-thickness 0.6 mm). In all ex vivo hearts, lumen enhancement (HU) has been measured outside the stent lumen and within the stent lumen, using a region-of-interest of 2 mm diameter, on both the 16DCT and 64DCT images. Additionally, stent diameters have been measured.

Results: Assessing the vessel lumen enhancement, no significant differences between the 16DCT and 64DCT data was found outside the stent lumen (258 ± 20 HU vs. 245 ± 17 HU, respectively). CT densities derived from the 64DCT images were significantly lower as compared to densities measured on the 16DCT images (345 ± 35 HU vs. 398 ± 43 HU, respectively). Also, stent diameters could be assessed more exactly on the 64DCT images. With a known stent diameter of 3.0 and 2.5, measured diameters were 3.1 and 2.6 for the 64DCT scanner, and 3.3/2.8 using the 16DCT system, respectively.

Conclusions: With the new 64DCT using a z-axis flying focal spot technology, assessment of vessel lumen opacification within a coronary artery stent and the true stent diameter can be assessed more accurately as compared to a 16DCT system, due to a significantly higher spatial resolution.

B-344 14:27

Evaluation of coronary artery by-pass: Multi-slice CT assessment of artery and venous surgery graft

M. Sperandio, A. Romagnoli, M. Tomassini, M. Di Roma, L. Pellegrino, G. Simonetti; *Rome/IT*

Purpose: Our aim was to investigate the accuracy of the multislice spiral computed tomography (MSCT) in the detection of significant obstruction in the artery and venous grafts in symptomatic patients, who have undergone coronary artery bypass grafting.

Methods and Materials: In 126 patients (105 male, mean age 58 ± 5 years) with suspected graft anastomosis obstruction or a possible coronary artery stenosis,

a MSCT (GE Light Speed-16, collimation: 16 x 0.625 mm) was performed 20 days before the coronary angiography (CAG) that was regarded as the standard of reference. In total we studied 350 by-passes (90 internal mammary artery grafts and 260 aortocoronary saphena grafts).

Results: In all patients the MSCT was carried out without complications. Of 350 by-passes we could analyze completely 320 grafts, the other grafts were excluded for the presence of artefacts due to rapid heart rate during the contrast scan. Considering only the segments judged evaluable, we calculated a sensitivity of 97% and specificity 100%.

Conclusion: Using a scanner with a collimation of 16 x 0.625 mm, our study confirms the potential role of MSCT in the detection of artery and venous graft disease with an important value of sensitivity and a very high specificity (100%), in particular in the detection of occlusions of the proximal anastomosis of venous grafts.

B-345 14:36

Multidetector-row cardiac CT before minimal invasive bypass surgery

C. Herzog, W. Schwarz, S. Zangos, J.O. Balzer, K. Eichler, M.G. Mack, T.J. Vogl; *Frankfurt a. Main/DE*

Objective: To evaluate the benefit of multidetector-row cardiac CT (MDCT) before totally endoscopic coronary bypass (TECAB) procedures.

Material and Methods: 72 patients preoperatively underwent MDCT and quantitative coronary angiography (QCA). 38 patients were examined on a 4-row MDCT and 38 on a 16-row MDCT. Scanning parameters were: 4x1 mm / 12x0.75 mm collimation, 500 mm / 420 ms TI, 1.25 mm / 1.0 mm SD, increment 0.6/0.5 mm). Assesment criteria were: myocardial course of the coronary arteries, localization/degree of stenoses and localization/quality of atherosclerotic plaques. Finally the most suitable region for distal bypass touchdown was recommended. All findings were correlated to QCA and surgery.

Results: 4-row MDCT allowed evaluation of 79.4% of all segments of surgical relevance and 80.4% of all coronary segments. Values for 16-row MDCT amounted to 87.2% and 89.2%, for QCA to 91.7% and 96.3%. Calcified plaques were detected by 4- and 16 row MDCT in 100%, in QCA in 81.6%. Stenoses > 75% were detected by 4-row MDCT in 76.4%, by 16-row MDCT in 85.1% and by QCA in 100%. Intramyocardial coronary segments were identified by 4-row MDCT in 75%, by 16-row MDCT in 100% und by QCA in 20%. The site of distal bypass touchdown was predicted correctly by 4-row MDCT in 75.1%, by 16-row MDCT in 87.3% and by QCA in 80.1%.

Conclusion: 4 and 16-row MDCT were able to provide extended information on the coronary target site and therefore should be regarded as valuable planning tools before complex minimally invasive procedures such as TECAB or MIDCAB.

B-346 14:45

64-detector-row computed tomography of the coronary arteries: Initial experience

K. Nikolaou¹, C. Rist¹, B.J. Wintersperger¹, T. Flohr², T. Johnson¹, F. von Ziegler¹, A. Knez¹, M.F. Reiser¹, C.R. Becker¹; ¹Munich/DE, ²Forchheim/DE

Purpose: To compare the diagnostic value of a 64-detector-row CT system (64DCT) with that of invasive coronary angiography in the diagnosis of coronary artery disease (CAD).

Materials and Methods: 33 patients with known or suspected CAD underwent both 64DCT of the coronary arteries and invasive coronary angiography. For coronary CT angiography, a recently introduced 64DCT system (SOMATOM Sensation 64, Siemens Medical Solutions, Forchheim, Germany) was employed, using the following parameters: 64x0.6 mm slices; spatial resolution, 0.75x0.6x0.6 mm; gantry rotation time, 330 ms; temporal resolution, 83-165 ms; contrast agent, 80 ml; flow rate, 5 ml/s; retrospective ECG-gating. The MDCT-scans were analysed for signs of significant CAD (stenoses > 75%) on a per-patient basis, blinded to results from invasive angiography. Sensitivity, specificity and diagnostic accuracy in the detection or exclusion of significant CAD were evaluated.

Results: 31 of 33 (94%) coronary CT angiograms were of diagnostic image quality (image quality: 6% non assessable, 30% sufficient, 64% excellent). In the 31 patients available for comparison, invasive coronary angiography demonstrated significant CAD in 71% (22/31) and non-significant disease or normal coronary angiograms in 29% (9/31). Sensitivity, specificity, and diagnostic accuracy of 64DCT for the correct detection or exclusion of significant CAD on a per-patient basis were 95%, 89% and 94%, respectively.

Conclusion: 64DCT coronary angiography provides an increased spatial resolution with an isotropic sub-millimeter voxel size and an improved temporal

Scientific Sessions

resolution of 83-165 ms. These benefits hold great promise for the reliable diagnosis or exclusion of significant CAD.

B-347 14:54 ♀

Coronary angiography with 16-slice spiral computed tomography: Results in 180 patients

Y. Wang, Z. Jin, L. Kong, Z. Zhang, S. Zhang, S. Lin; Beijing/CN

Purpose: To evaluate the image quality of coronary CT angiography (CTA) and to determine the diagnostic accuracy of CTA for the assessment of coronary artery stenosis.

Methods and Materials: 180 patients (95 male, aged 63 ± 12) with suspected coronary artery disease were studied by a 16-slice spiral CT scanner: 0.42 s-rotation time, 16×0.75 mm collimation.; 47 of them underwent conventional coronary angiography (CAG). Contrast-enhanced scan (100 mL contrast agent IV at 4 mL/s) was performed during an approximately 20 s breath hold. The left main, left anterior descending, left circumflex and right coronary artery were evaluated for image quality which was divided into three classes, and screened for the presence of over 50% stenosis.

Results: In the evaluation of image quality with VRT images, there were 610 branches (85%) in the first class, 81 branches (11%) in the second class, and 29 branches (4%) in the third class. Logistic regression found that both heart rate and CT density in the root of the aorta had significant effect on image quality, regression coefficient beta was 0.296 and -0.010, respectively, $P < 0.05$. In comparison with CAG, the sensitivity, specificity, positive and negative predictive values of CTA to identify over 50% stenosis was 93% (50/54), 92% (123/134), 82% (50/61), and 97% (123/127), respectively.

Conclusion: 16-slice spiral CT coronary angiography permits reliable non-invasive detection of coronary artery stenosis with high image quality which is affected by heart rate and CT density in the root of the aorta.

B-348 15:03

A new way of looking at cardiac CT - polar maps of the coronary arteries

F. Schoth, G. Mühlensbruch, A.H. Mahnken, G.A. Krombach, R.W. Günther; Aachen/DE

Purpose: Contrast enhanced cardiac computed tomography (CT) opens up non-invasive evaluation of the coronary arteries. Yet the visualization of the coronary arteries requires curved MPR images or VRT, which are time-consuming to produce. In this study we applied polar maps of the coronary arteries to visualize the information of the complete coronary artery system on one single image.

Methods and Materials: 10 subjects (9 male, mean age 62.2 years) underwent contrast enhanced retrospectively ECG-gated cardiac MSCT (Sensation 16; Siemens, Erlangen, Germany) applying a standardized examination protocol (120 kV, 550 mAs/eff). Image reconstruction was performed at 60% of the RR-interval providing a voxel resolution of $0.35 \times 0.35 \times 1$ mm. Using a newly-developed algorithm the polar maps then provided a maximum intensity projection of the myocardium including the coronary arteries in polar coordinates. Unfold to two dimensions as planar projection, the polar maps were provided for evaluation. Visibility of the coronary arteries was rated on a scale from 0 (not visible) to 3 (good visibility).

Results: The visibility was rated as follows: LAD proximal 2.4 ± 0.7 , medial 2.2 ± 0.6 , distal 1.4 ± 0.9 ; RCA proximal 2.1 ± 0.7 , medial 1.9 ± 0.8 , distal 1.3 ± 0.8 ; RCX proximal 2.4 ± 0.6 , medial 1.8 ± 0.6 , distal 1.3 ± 0.7 . Stents and coronary calcifications were displayed accurately.

Conclusion: Polar maps of the coronary arteries provide information regarding morphology and patency of the coronary arteries in a single image. Therefore using this technique may speed up evaluation of contrast enhanced cardiac CT examinations.

B-349 15:12

Flat-panel detector CT for assessment of coronary artery stents:

Comparison with 16-slice spiral CT

A.H. Mahnken¹, T. Seyfarth², T. Flohr², C. Herzog³, S. Stanzel¹, R.W. Günther¹, J.E. Wildberger¹; ¹Aachen/DE, ²Forchheim/DE, ³Frankfurt a. Main/DE

Purpose: Evaluation of coronary artery stents is a major limitation of cardiac multislice spiral CT (MSCT). Development of flat-panel detector computed tomography (FPCT) with truly isotropic spatial resolution may overcome this limitation. Thus, we evaluated the use of FPCT in comparison to MSCT for the assessment of coronary artery stents.

Material and Methods: Eight different coronary artery stents with a diameter of 3 mm each were placed in a static chest phantom. The phantom was positioned

in the CT gantry at an angle of 0° , 45° and 90° towards the z-axis and examined with the prototype of a FPCT (Siemens, Forchheim, Germany) and a commercially available 16-slice spiral CT scanner (Sensation 16, Siemens). Slice thickness was 0.25 mm with FPCT while for MSCT an effective slice thickness of 1 mm with a reconstruction increment of 0.5 mm was used. Image quality was assessed visually using a five point grading scale. Stent diameters were measured and compared using a repeated measure ANOVA.

Results: When compared to MSCT artificial lumen reduction was significantly less using FPCT. On average the visible stent lumen was reduced by 16.1% with FPCT, whereas the mean of the lumen reduction was 47.2% with 16-slice spiral CT. Visible lumen diameter significantly increased using FPCT ($p < 0.001$). Even delineation of the different stent struts became possible.

Conclusion: FPCT proved to be superior when compared to 16-slice spiral CT for the in-vitro assessment of coronary artery stents. Improved spatial resolution allows for a superior assessment of the coronary artery stent lumen.

B-350 15:21

Cardiac imaging: Coronary artery bypass grafting imaging of the proximal anastomoses created by nitinol implants. A retrospective two observer evaluation

M. Khan, C. Herzog, K. Landenberger, S. Martens, A. Maataoui, M. Dietrich, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To investigate the proximal anastomosis of CABG grafts using an automated aortic connector with nitinol implants in a 1 year follow-up by using different reformations.

Methods: To evaluate graft patency 33 patients after receiving CABG underwent CT examination of the heart. On the same patients CT was performed on postoperative day 5 (4- row CT, group A) and again as a follow-up examination 1 year thereafter (16- row CT, group B). 23 ACVB to RCX and 27 ACVB to RCA grafts were included. Every automated anastomosis was reviewed under different reformations such as thin slab MIP, multiplanar reformation and volume rendering technique (VRT). Interobserver correlation was determined.

Results: 5 days postop 48 anastomoses were classified as patent, 2 not patent. 1 year postop 42 anastomoses were classified as patent, 8 not patent. In both groups the aortic connector could be visualized in good quality: 1.82 ± 1.10 (group A) and 1.93 ± 1.22 (group B) for ACVB to RCA and 1.86 ± 1.10 (group A) and 1.77 ± 1.23 (group B) for ACVB to RCX grafts (MPR). Image quality at the aortic connector site did not display a significant difference for any reformation between groups ($p > 0.05$). Within groups MPR displayed better visualization as compared to MIP and VRT ($p < 0.05$).

Conclusion: In the presence of metal implants CT provides reliable data in evaluation of the proximal anastomosis; but 16- row CT does not bring a significant benefit to image quality. MPR displayed the best visualization within both groups.

The magic angle phenomenon in MR imaging of ankle tendons: Prevalence and site in asymptomatic subjects and cadaveric specimens with histologic correlation

B. Mengiardi, C.W.A. Pfirrmann, P.B. Schöttle, B. Bode, J. Hodler, P. Vienne, M. Zanetti; Zürich/CH

Purpose: To evaluate the prevalence and site of the magic angle phenomenon (MAP) of ankle tendons in MR examinations.

Materials and Methods: MR imaging of the ankle in 30 asymptomatic volunteers (mean age 42.8 years) and in five cadaveric feet was performed both in standard supine body position (with neutral position of the foot) and in prone position (with plantar flexion of the ankle). MR images were evaluated separately by two radiologists in consensus for the site and the extent of increased T1-weighted signal of the ankle tendons. Histological evaluation of the posterior tibialis tendon (PTT) was performed by a pathologist unaware of the MR findings.

Results: MAP was noted in 6 (20%) vs. 1 (3%) (supine vs. prone body position)

Scientific Sessions

anterior tibialis tendons (ATT), in 30 (100%) vs. 0 extensor hallucis longus tendons, in 29 (97%) vs. 0 PTT, in 30 (100%) vs. 1 (3%) peroneus brevis tendons and in 24 (80%) vs. 1 (3%) peroneus longus tendons. In the cadaveric study in 19 of 25 sites of the PTT an increased signal was observed in the supine body position. Signal abnormalities in both body positions were seen in 9 of 25 sites corresponding to degeneration (4/9) and to the presence of fibrocartilage or a chondroid sesamoid (3/9) within the tendon substance.

Conclusion: In the standard supine position, the prevalence of MAP in all ankle tendons is high (80-100%) except in the ATT (20%). Contrarily, MAP is almost never observed in prone position with plantar flexion of the ankle.

B-352 14:09

Histological correlation of MR imaging cartilage imaging in the knee joint before total replacement

A. Cavallaro¹, W. Horger¹, B. Swoboda¹, W. Bautz¹, B. von Rechenberg², T.C. Mamisch³, ¹Erlangen/DE, ²Zürich/CH, ³Bochum/DE

Purpose: To determine the diagnostic quality of different standard cartilage sequences in MR imaging in correlation with histological data in patients for total knee replacement.

Methods and Materials: 6 patients with severe osteoarthritis of the knee joint and who had an indication for total knee replacement underwent 3D-Flash, 2D TSE, 3d-Medic and 3D-Dess MR imaging (resolution 0.5x0.5x0.5, Siemens 1.5 T Symphony). After intra-operative macroscopic evaluation and grading, the resected surface of the condyles was marked with pins and imaged with the same protocol. The sections were then fixed and semi-thick slices of 0.25 mm were made with Toluidin Blue staining. The histological data was staged by Mankin histopathological scale and registered by the pin location to the MR imaging data. The MR imaging images were analysed by Noyes classification and compared.

Results: There were comparable results for grade 3 and 4 osteoarthritis for all four sequences with the histological data. For grade 2 lesions with loss of cartilage volume 3D-Flash and 3D-Medic were more comparable, for lesions without loss 3D-Dess. For grade 1 lesions with superficial loss of staining, the 2D TSE sequence was most sensitive, for grade 1 lesions with loss of cartilage structure and increase of chondrocytes all sequences were highly false negative.

Conclusion: Our preliminary results show still a lack of diagnostic efficiency for early stages of osteoarthritis. Also it shows the limits of thickness measurement techniques, especially in detection of structural defects with intact surface.

B-353 14:18

Contrast enhanced high resolution MR imaging of autologous cartilage implants of the knee joint

C.M. Plank, K. Kubin, K. Friedrich, M. Weber, S. Marlovits, S. Trattnig; Vienna/AT

Purpose: To investigate if the enhancement of synovial fluid by intravenous administration of contrast agent improves the magnetic resonance (MR) evaluation of cartilage repair in the knee joint.

Methods and Materials: Eleven patients after matrix-based autologous cartilage transplantation in the knee joint were examined by proton-density fast spin echo sequence (PD-FSE) without and after intravenous administration of gadodiamide (indirect MR-arthrography). High-resolution MR imaging could be achieved by the use of a surface coil placed over the implant site. Implant thickness, surface and integration of implant to the adjacent native cartilage and subchondral bone were evaluated.

Results: Contrast enhanced MR imaging of matrix-based autologous chondrocyte implants was superior to non-enhanced cartilage imaging. In particular, incomplete integration of the cartilage implant to adjacent normal hyaline cartilage was better delineated with indirect MR arthrography. Implant thickness and surface abnormalities such as fibrillations and fissures were better visualized by filling of defects with contrast-enhanced synovial fluid. Each of these properties could be distinguished significantly better with contrast enhanced imaging ($p < 0.001$ for all 3 parameters).

Conclusion: Indirect MR arthrography is a promising technique for the evaluation of cartilage repair, since it allows one to combine the advantage of high-resolution PD-FSE imaging for subtle intrachondral abnormalities with a better delineation of cartilage implant surface and integration defects.

B-354 14:27

Patellar osteochondral autograft transplantation: Assessment with high-resolution MR imaging at 1.5 T

K. Woertler, M. Settles, V. Martinek, J. Stollfuss, E.J. Rummeny; Munich/DE

Purpose: To evaluate high-resolution MR imaging at 1.5 T in the assessment of osteochondral autografts of the patella in correlation with clinical outcome.

Materials and Methods: 24 patients (16-59 years) were examined by high-resolution MR imaging at 12-64 (mean 31.4) months after patellar osteochondral autograft transplantation. Examinations were performed on a 1.5 T system (loop-coil) with use of an "arthrographic" T1-weighted FSE sequence and a fat-suppressed PD-weighted FSE sequence, both combined with DRIVen Equilibrium pulses and obtained with a resolution of 0.2 x 0.4 x 2 mm. MR images were evaluated with regard to alterations of the transplants and their adjacent structures using a 20-point score system. MR-score values were correlated with Lysholm-Score and Visual-Analogue-Scale (VAS = pain score) values.

Results: MR-score values of 5-20 were assigned. Improvement of Lysholm-Scores and decrease of VAS values between pre- and post-operative clinical examinations ranged from -18 to 71 (mean 32.1) and from -2 to 7 (mean 3.5), respectively. The best correlations were observed between overall MR-score values and differences in clinical scores (0.79-0.81). Pathologic alterations of adjacent structures showed a higher correlation with poor clinical outcome (0.79-0.82) than suboptimal fit (0.70) or alterations of the transplants themselves (0.64-0.65).

Conclusions: In patients with patellar osteochondral transplants, findings at high-resolution MR imaging correlate well with clinical outcome. However, mid-term results appear more closely related to the status of adjacent joint structures than to that of the transplants themselves. Long-term studies have to be awaited to assess the prognostic significance of fit and integrity of the osteochondral plugs.

B-355 14:36

Quantitative relationship of normal cartilage in the hip joint based on isotropic 1.5 T MR imaging

H. Mestan¹, A. Cavallaro¹, J. Kordelle², R. Forst¹, W. Bautz¹, T.C. Mamisch¹; ¹Erlangen/DE, ²Gießen/DE

Purpose: To determine the variability of cartilage thickness and pattern in the hip joint of healthy volunteers in correlation to sex, body weight, height and side of the standing leg based upon MR imaging.

Methods and Materials: We examined 30 healthy volunteers (15 male and 15 female) with an age range from 21 to 29 years with a 3D-DESS sequence (resolution 0.84x0.84x0.84, Siemens Symphony 1.5 T). The cartilage thickness was analysed in a Carthesian view based on the centre of rotation corrected by the femoral anteversion in five radial areas coronal and sagittal. The grade of acetabular coverage was assessed and compared to cartilage distribution.

Results: The acetabular coverage was 159.5 degrees (std.1.39) for the coronal and 158.2 degrees (std.1.07) for sagittal view. There was a thinning in the mid ventral portion of 17.81 mm (std. 2.14) to a maximum thickness of 25.54 mm (std. 4.84) in the mid anterior-superior portion. For the other contact areas we found a cartilage thickness of 23.45 (std. 7.82) with wide variation but no significant changes. There were also no significant changes of cartilage thickness side or sex differences.

Conclusion: The results of our ongoing study shows wide variation of cartilage thickness in the different contact pressure areas of the hip joint. It is possible to assess cartilage in the hip joint and correlate it to the centre of rotation and the femoral anteversion. This leads to biomechanical analysis of cartilage pathology in patients with osteoarthritis.

B-356 14:45

In vivo correlation of gross pathology in osteoarthritis of the hip to MR imaging cartilage imaging

T.C. Mamisch¹, G.C. Welsch², A. Cavallaro², W. Horger², M. Menzel², F.F. Hennig², G. Muhr¹; ¹Bochum/DE, ²Erlangen/DE

Purpose: To determine the quality of articular cartilage detection in the hip joint of MR imaging by comparison of these findings with the resected femoral head.

Methods and Materials: 12 patients with advanced osteoarthritis of the hip before total hip replacement underwent 3 T MR imaging of both hips (resolution 0.5x0.5x0.5 mm). A cartilage quality assessment based on the Noyes classification was performed after resection of the femoral head. For the macroscopic classification the femoral head was divided into 8 anatomical portions correlating to the femoral neck position. Identical MR imaging was performed for the femoral head. The results of MR imaging classification were compared to the macroscopic findings and histology in the mid-sagittal plane. The analysis of the histology was based on the Mankin criteria.

Scientific Sessions

Results: It was possible to analyse the femoral and acetabular cartilage separately in 86% of the observed areas. The detection of moderate and severe osteoarthritis corresponded significantly with the macroscopic findings. There were false positive findings in contact pressure areas without macroscopic changes and false negative to early stages of macroscopic changes with cartilage fibrillation. False findings in MR imaging compared to all stages of histological changes in the mid sagittal plane.

Conclusion: MR imaging is useful for non-invasive detection of cartilage lesions in the hip. There are still limitations to detection of early stages of osteoarthritis, especially without cartilage thinning in MR imaging for diagnosis.

B-357 14:54

3 T MR imaging cartilage imaging of the hip: Cartilage pattern, lesions, biomechanical analysis and comparison to 1.5 T

T.C. Mamisch¹, A. Cavallaro², W. Horger², G. Muhr¹, R. Forst², W. Bautz²,
¹Bochum/DE, ²Erlangen/DE

Purpose: To evaluate the possibility of 3 T imaging in the hip joint for cartilage thickness measurement, cartilage quality analysis, separation of femoral and acetabular cartilage for diagnosis of early lesions and imaging of both hips for biomechanical analysis using isotropic resolution in MR imaging.

Methods and Materials: 18 volunteers and 7 patients with X-ray signs of moderate osteoarthritis underwent MR imaging on 1.5 T and 3 T systems. On the 1.5 T system both hips were imaged separately (3D-MEDIC, resolution 0.84x0.84x0.84, Siemens Symphony). On the 3 T system both hips were imaged in one slab (3D-Medic, 0.7x0.7x0.7, Siemens TRIO). Radial images based on the centre of rotation in the axis of the femoral neck, each of 30 degrees, were reconstructed and analysed for separation of femoral and acetabular cartilage, assessment of cartilage quality and inter-observer reproducibility for cartilage thickness measurement of three observers. Perpendicular reconstructions in the acetabular opening were used to determine the acetabular labrum.

Results: There was a significant improvement in the separation of acetabular and femoral cartilage, especially in the lateral portions of the hip joint. Positioning of the femoral anteversion was more reliable; also the inter-observer correlation was significantly higher for cartilage thickness on the 3 T system. Classification of cartilage quality by Noyes was improved by division between losses of cartilage less and more than 50%.

Conclusion: By using a 3 T system we found an improvement for all diagnostic criteria of early osteoarthritis. Histological and macroscopic comparison is necessary in future work to show the clinical importance.

B-358 15:03

Morphology of the acetabular labrum on MR imaging in comparison to the quality of corresponding cartilage

G. Welsch¹, A. Cavallaro¹, W. Horger¹, M. Menzel¹, W. Bautz¹, T.C. Mamisch²,
¹Erlangen/DE, ²Bochum/DE

Purpose: To assess the cartilage quality in comparison to the morphology of the acetabular labrum and correlate it with the portion of the labrum based on radial MR imaging.

Methods and Materials: 20 healthy volunteers with an age range from 21 to 36 and 12 patients with a minimum of 15 years after prophylactic pin treatment of Slipped Capital Femoral Epiphysiolysis underwent MR imaging and clinical hip examination. For MR imaging a DESS-3D Sequence (resolution 0.7x0.7x0.7, Siemens Avanto 1.5 T) and a radially sectioned PD-TSE sequence (resolution 0.4 x 0.4 x 5 mm) perpendicular to the acetabular labrum were performed. For planning of the radial sections the acetabular opening was used from the isotropic images. The acetabular labrum morphology was compared to the corresponding femoral and acetabular cartilage quality in the radial portions.

Results: In healthy volunteers a triangular shape was detected in 78%, a round shape in 18% and an irregular round shape in 4% not correlated with cartilage lesions in the corresponding contact area. For 7 patients we found in the anterior-superior portion an increase of signal intensity with irregular labrum and corresponding cartilage thinning. These were correlated with femoral neck remodelling.

Conclusion: It was possible to compare cartilage morphology to acetabular abnormalities by using an isotropic cartilage sequence for positioning of the acetabular opening and the radial section. We found in our ongoing study variations of the labrum without cartilage defects and defects with cartilage lesions based of femoral neck impingement.

B-359 15:12

MR imaging in sports related groin pain - prevalence of adductor dysfunction versus osteitis pubis

C.J. Johnston, P. Cunningham, D. Brennan, J. Moriarty, S.J. Eustace; Dublin/IE

Purpose: To identify the mechanism and cause of sports related groin pain using MR imaging.

Methods: 70 sportsmen with groin pain referred for MR imaging and 70 age- and sex- matched asymptomatic sportsmen undergoing MR imaging pelvis as part of an unrelated study were included as controls. In each case images were reviewed to determine the presence or absence of an adductor tear at the tendo-osseous junction on the basis of hemorrhage and oedema at the attachment with local bone oedema, and assessed to determine the presence or absence of osteitis pubis on the basis of symphyseal articular surface irregularity, disc herniation and para-articular bone oedema.

Results: Isolated adductor dysfunction was identified in 32 patients, both adductor dysfunction and osteitis pubis were identified in the same patients in 13 cases, whilst isolated osteitis pubis was identified in 7 patients. No significant abnormality was identified in 18 cases. Features of osteitis pubis were identified in 3 of the asymptomatic controls; the remainder of the images of the controls were normal.

Conclusion: Adductor dysfunction appears to be the commonest cause of groin pain in affected sportsmen. Its presence appears to precede the development of osteitis pubis in most patients. Isolated osteitis pubis is uncommon.

B-360 15:21

MR imaging of wrist cartilage: Comparison between imaging at 1.5 T, 3 T and anatomical section

N. Saupe, C.W.A. Pfirrmann, M.R. Schmid, T. Schertler, S. Wildermuth, M. Manestar, B. Marincek, D. Weishaupt; Zürich/CH

Purpose: To compare MR imaging of the wrist cartilage at 3 T and at 1.5 T in cadaveric wrists using the same imaging protocol and similar imaging parameters for both magnetic field strengths with gross pathology as standard of reference.

Materials and Methods: Coronal proton density (PD)-w, intermediate-w (TSE) and 3D FFE-weighted sequences were obtained in 10 cadaveric wrists (7 left, 3 right, age range: 46-99 years) at both 1.5 T and 3 T MR systems (Signa GE Medical Systems 1.5 T and Intera 3.0, Philips Medical Systems). All MR imaging at 3 T as well as at 1.5 T was performed with similar imaging parameters, using a surface coil at 3 T and a dedicated wrist coil at 1.5 T. Two observers analyzed and graded the cartilage defects on the distal carpal row, proximal carpal row and STT joint using a 4-point grading scale. The results were compared between images obtained at 3 T, 1.5 T and gross pathology, respectively.

Results: Sensitivity ranged from 20-43% (specificity 83-91%, accuracy 52-59%) for the proximal and distal carpal rows and 66-74% (specificity 65-66%, accuracy 65-66%) for STT joint. There was no significant difference in diagnostic performance between 3 T and 1.5 T in assessing cartilage abnormalities compared to the gold standard ($p = 0.12$). No significant inter-rater differences were noted ($p = 0.14-0.57$).

Conclusion: MR imaging in detection of articular cartilage abnormalities at the wrist depends on the location but there is no difference in diagnostic performance between 3 T and 1.5 T assessing cartilage abnormalities, however no dedicated wrist coil was used at 3 T.

Imaging in appendicitis: Ultrasound, CT or neither?

R. Ananthasivan, S. Fataar, A. Derweesh; Muscat/OM

Purpose: To assess whether ultrasound and CT has reduced negative appendectomy rates in our institution.

Methods and Materials: The results of ultrasound (145 patients) and CT (57 patients) referred with a suspected clinical diagnosis of appendicitis over an eight month period 1/1/2004-31/08/2004 were reviewed. The results were compared to the operative findings and the histopathological report of the resected specimen

Scientific Sessions

or to the clinical outcome. All patients had an ultrasound of the abdomen and pelvis with graded compression sonography of the right iliac fossa as the first investigation. Patients with an inconclusive study (57/145) alone proceeded to a limited CT for appendicitis. Negative appendectomy rates during the period of study were compared to the rates in a similar period prior to the regular use of ultrasound and CT for appendicitis in our institute. (1/1/1995-31/08/1995). Negative appendectomy rates during the period of study were compared between patients who had surgery on clinical grounds alone to those who had surgery after radiological assessment.

Results: CT had a negative predictive value of 96% and a specificity of 91.6% both higher than ultrasound. There was a significant reduction in negative appendectomy rates in patients who had imaging compared to those who had surgery on clinical assessment alone.

Conclusion: Ultrasound should be the first radiological investigation in suspected appendicitis followed by CT in inconclusive studies. Radiological assessment reduces negative appendectomy rates. Further reduction in negative appendectomy rates can be achieved by referring more patients for imaging.

B-362 14:09 ♀

Thickness and features of the normal appendix at MDCT: Are diameter and appendicoliths misleading tools?

L. Huwart, M. El Khoury, B. Bessoud, A.-S. Rangheard, Y. Menu;
Le Kremlin-Bicêtre/FR

Purpose: To evaluate the features of the normal appendix with MDCT.

Methods and Materials: MDCT of 57 consecutive adult patients without symptoms suggesting appendicitis were prospectively studied. Most patients (41/47) had IV iodine injection, but no intraluminal contrast. Thick (5 mm) and thin (1 mm) slices were analyzed on a workstation. MPR were available. Localization of the appendix, overall diameter, wall thickness, intraluminal gas and appendicoliths were recorded.

Results: The appendix was visualized in 47/57 (82%). The location was retrocaecal (28%), mediocaecal (21%), subcaecal (19%) or pelvic (32%). The overall diameter of the normal appendix varied between 5.0 and 11 mm (mean 6.7 mm ± 1.2) and was larger than 6 mm in 70%. The overall wall thickness varied between 2.6 and 6.4 mm (mean 4.8 mm ± 1). Intraluminal gas was identified in 87%. An appendicolith was found in 13%.

Conclusion: Despite MDCT, 18% of normal appendices were not detected. The overall diameter of normal appendix may overlap the currently accepted threshold for appendicitis at CT. Appendicolith was found in a significant number of normal patients and may not represent a reliable sign for appendicitis.

B-363 14:18

Slivers of free fluid detected by screening abdominal sonography after blunt trauma: What does it mean?

M. Scaglione, A. Pinto, S. Romano, R. Farina, R. Grassi, L. Romano; Naples/IT

Purpose: To assess the clinical implication of small amounts of free fluid detected on screening abdominal sonography (US) after blunt abdominal trauma (BAT).

Methods and Materials: 5142 consecutive patients with BAT were evaluated with abdominal US performed by radiologists in the emergency room. Those patients in whom US showed a sliver of free fluid < 15 mm thick were selected, recorded and compared to the findings on computed tomography (CT), repeat US, angiography, laparotomy and clinical follow-up.

Results: of 5142 patients screened with abdominal US, 127 patients were found to have a sliver of fluid < 15 mm. 109/127 patients were subjected to subsequent CT, 11/127 had repeat US, 7/127 were followed clinically and underwent CT before discharge. 7 patients had angiographic embolization, 4 went on to laparotomy with repair of injuries. Injured organs included the spleen (n = 21), liver (n = 16), bowel/mesentery (n = 15), kidneys (n = 12), adrenal glands (n = 7) and 9 patients were found to have retroperitoneal hemorrhage.

Conclusions: Our data suggest that small amounts of fluid can be related to minor injuries that heal non-operatively in most cases. Nevertheless, in the appropriate clinical context, this finding warrants further investigation to exclude significant injury and to be managed appropriately.

B-364 14:27

MSCT with combined CT-angiography for diagnosis of suspected mesenteric ischemia or intestinal bleeding in patients presenting with acute abdominal symptoms

M. Dobritz, W. Weiss, J. Stollfuss, E.J. Rummeny; Munich/DE

Purpose: To evaluate the diagnostic performance of Multislice-Computed-

Tomography (MSCT), including CT-angiography, in patients with suspected gastrointestinal bleeding or mesenteric ischemia.

Materials and Methods: 43 consecutive patients presenting with symptoms suggestive for intestinal bleeding (n = 15) or mesenteric ischemia (n = 28) were investigated. MSCT was acquired including an arterial and porto-venous phase (120 ml iodinated contrast media, 4-5 ml/sec flow, 16×0.75 mm collimation, 0.7 cm reconstruction increment, 0.75 mm slice thickness). In conjunction to standard image reading image interpretation was done with respect to vessel structures using a 3D workstation. Intraoperative findings and/or conventional fluoroscopic angiography was used as the standard of reference in patients with suspected bleeding. Intraoperative findings were available in 14/28 patients with suspected ischemia.

Results: 5/6 patients with confirmed mesenteric ischemia were correctly diagnosed by MSCT (Sensitivity 83%). MSCT was able to demonstrate other potential causes for abdominal pain in 15 of the remaining 22 patients with suspected ischemia including mesenteric vein thrombosis, inguinal herniation, bowel perforation, pneumonia and tumors. 9/9 patients with confirmed gastrointestinal bleeding were correctly identified by MSCT (Sensitivity 100%). Other findings that were likely to explain bleeding were found in 5 of the remaining 6 cases (GIST 3, NHL 1, Hematoma 1).

Conclusion: MSCT in conjunction with CT-angiography is highly reliable in the diagnosis of patients presenting with suspected bleeding or mesenteric ischemia. MSCT also shows important other causes of abdominal pain without evidence of bleeding or ischemia and, thus, should be used as the primary diagnostic technique in the management of these patients.

B-365 14:36 ♀

Frequency of visualization of normal appendix at MDCT: Junior versus senior radiologist performance

L. Huwart, M. El Khoury, B. Bessoud, A.-S. Rangheard, Y. Menu;
Le Kremlin-Bicêtre/FR

Purpose: To evaluate the detection rate of the normal appendix by a junior and a senior radiologist at MDCT.

Methods and Materials: A junior (< 6 months training) and a senior radiologist (specialized in abdominal radiology), blinded to patient history, prospectively and independently reviewed abdominopelvic MDCT scans in 85 consecutive adult patients without symptoms suggesting appendicitis. 70/85 patients had iodine injection. No contrast material was orally or rectally administered. All slices (1 and 5 mm) and MPR were available on the workstation. Interobserver agreement and effect of adequacy of intraperitoneal fat in identification of the appendix were assessed.

Results: The prevalence of appendectomy was 32.9% (28 of 85 patients). The means for the sensitivity, specificity, positive and negative predictive values of visualization of normal appendix were 79%, 82%, 90% and 66% for the junior and 82%, 93%, 96% and 72% for the senior radiologist. For the two reviewers, the detection rate did not increase with amount of intraperitoneal fat ($p > 0.05$, Chi² test). The nonweighted κ value for interobserver agreement for normal appendix visualization was 0.78, which indicated excellent agreement.

Conclusion: There was no significant difference between a junior or a senior radiologist for the detection of normal appendix at MDCT. No relationship between the detection rate and the amount of abdominal fat was found.

B-366 14:45 ♀

CT or plain abdominal X-rays as primary examination of patients with acute abdomen?

J.G. Andersen, Å. Torvund, T. Tofte; Oslo/NO

Purpose: To assess the total time used in the diagnostic process if CT is used as the primary evaluation of patients with acute abdomen compared to plain X-ray.

Methods and Materials: Sixty-nine consecutive patients with suspected ileus or subileus admitted to the Radiology department of Ulleval University Hospital were included. The patients were above 40 years old, none had known contrast agent allergy or kidney failure. For the first 23 of these patients the primary examination was plain abdominal X-ray, as opposed to CT for the remaining 46 patients. Effect measure was the total duration of the diagnostic process (TDP), defined as the time from entrance into the hospital until the final diagnostic examination was performed. TDP was analysed by using Statistical Process Control.

Results: TDP varied markedly from above 1 hour to 60 hours in both groups. Further, TDP appeared to be fairly stable over time in both periods. Average TDP was 16.5 hours when plain abdominal X-ray was first choice, as opposed to 9 hours when CT was first choice (45% reduction). The prevalence of patients with TDP above 24 hours was 26% when X-ray was the first choice, as opposed to 6.5% when CT was first choice.

Scientific Sessions

Conclusion: This study indicates that the prevalence of a long TDP is markedly reduced if CT is used compared to plain abdominal X-ray as the primary examination of patients with acute abdomen. However, the results must be interpreted with care because of the low sample size.

B-367 14:54

Comparison between the site of multislice spiral computed tomographic signs of gastrointestinal perforation and the site of perforation detected at surgery in fifty perforated patients

A. Pinto, M. Scaglione, N. Gagliardi, R. Grassi, F. Lassandro, L. Romano; Naples/IT

Purpose: To compare the site of MSCT signs of gastrointestinal perforation and the site of perforation at surgery in fifty perforated patients.

Materials and Methods: Fifty patients (32 men and 18 women, age ranging from 21 to 86 years old) underwent surgery for gastrointestinal perforation. In all cases, plain abdominal film was integrated by MSCT. The following MSCT findings were evaluated: free air, free fluid and bowel wall discontinuity. The site of these MSCT findings were compared with the site of perforation at surgery.

Results: Free air was detected in 72% of cases, free intraperitoneal fluid in 94% of cases and bowel wall discontinuity in no cases. In 15/50 patients with gastroduodenal perforation, free air and free fluid were detected together and free air was observed in supramesocolic compartments in all cases; in 4/50 cases of ileal perforation, free air was observed in one patient and fluid in three (in two of them in inframesocolic compartment). In 8/50 patients with acute perforated appendicitis free fluid was always observed in inframesocolic compartments; in 6/50 patients with sigmoid perforation free air was observed in four cases (all in supramesocolic compartments) while free fluid was detected in both compartments.

Conclusions: In gastroduodenal perforations free air and free fluid are present together and free air is localized in supramesocolic compartments. In acute perforated appendicitis free fluid is present in inframesocolic compartments and in sigmoid perforations free air, when present, is detected in supramesocolic compartments, while free fluid is observed in both compartments.

B-368 15:03

Multislice-CT findings in patients with colonic-diverticulitis: Do they correlate with intraoperative and postoperative immunohistological findings

S. Bitschnau, S.M. Maksan, F. Bittinger, P. Mildenberger; Mainz/DE

Purpose: The diagnosis of diverticulitis is often accompanied by controversies between CT-findings, macroscopic intraoperative findings and histological findings. The expression of intercellular-cell-adhesion-molecule-1 (ICAM-1) has been shown to have potential significance in the diagnosis of the stages of appendicitis. This study is designed to correlate the expression of ICAM-1 in diverticulitis with intraoperative-findings and preoperative CT-findings.

Material and Method: MSCT-datasets of 79 patients with clinically suspected colonic-diverticulitis were analyzed retrospectively. All patients had rectal-filling with positive iodine contrast-media. Extent of diverticula, signs of inflammation (e.g. thickening of fascia, fatty stranding) and complications like perforation, abscess were evaluated. Correlation to results of intraoperative and histomorphological and immunohistological findings (ICAM-1).

Results: 56 of 79 patients went to operation. 51 of the 56 operated patients had signs of diverticulitis in MSCT, which was proven intraoperatively. 1 patient did not have diverticula but had signs of inflammatory-bowel-disease. 4 pts were proven to have diverticulosis without inflammation. 23 pts without signs of inflammation in MSCT had consequently not been operated on (CT showed diverticulosis 11 patients and neither diverticulosis nor -itis in 12 patients). No relevant complication was missed by MSCT. Perforation (contained/ free) was detected in 36 pts (28/8).

Conclusion: MSCT can readily detect presence and extent of inflammation in patients with colonic diverticulitis. MSCT therefore has a high impact on the choice of therapy and can precisely give the indication for operation.

B-369 15:12

Importance of attending scientific paper sessions in international radiology meetings

S.M.R. Rizzo¹, M.K. Kalra¹, M.M. Maher¹, S. Saini², M. Bellomi³, G. Cornalba³; ¹Boston, MA/US, ²Atlanta, GA/US, ³Milan/IT

Purpose: To determine proportion of scientific papers presented at the annual RSNA meeting, which are subsequently published in peer-reviewed medical journals and factors that impact their publication.

Materials and Methods: We evaluated abstracts of scientific papers (n = 217) presented in the gastrointestinal sessions of the 2000 RSNA Annual Meeting. This meeting was chosen to allow a four-year period (April 2000-April 2004) for subsequent publication in peer-reviewed journals. Name and number of imaging modalities, number of authors, continent, grant support, research subjects (human, animal or phantom), number of patients, presentation date and study outcome were recorded for all abstracts. A Medline search was performed to find scientific papers published in indexed journals over a period of 4 years. For each published paper, journal name, study outcome result (positive/negative) and date of publication were recorded. Statistical analysis was performed to determine proportion of published papers and to assess factors impacting their publication.

Results: 29.9%(65/217) of scientific papers were published in indexed journals over a 4 years-period with most publications in Radiology (8.7%;19/217) and with an average presentation-to-publication time of 547 ± 32 days. Interestingly, there was no significant difference between number of imaging modalities, continent of origin, type of research subjects, number of recruited subjects and study outcome for published and unpublished papers ($p > 0.1$).

Conclusions: Less than one-third of scientific papers presented in the gastrointestinal sessions of 2000 RSNA Annual meeting were published within 4 years. Contrary to general expectation, type of study, country of origin, number of research subjects and research modalities did not predict publication of scientific papers.

B-370 15:21

Path to publication of original research articles in major peer-reviewed radiology journals: An audit of time from initial submission to publication

S.M.R. Rizzo¹, M.K. Kalra¹, M.M. Maher¹, T. Roberts¹, S. Saini², M. Bellomi³;

¹Boston, MA/US, ²Atlanta, GA/US, ³Milan/IT

Purpose: To compare time to publication of original research articles from submission-date to date of publication, and to assess if subjective and Evidence Based Medicine (EBM) grading of validity and strength of articles affect time to publication in radiology journals.

Materials and Methods: Twenty-five consecutive original research articles were selected from 8 peer-reviewed, monthly radiology journals from North America (Radiology, AJR, Academic Radiology, Investigative Radiology) and Europe (European Radiology, European Journal of Radiology, BJR, Clinical Radiology) (n = 200 articles). Dates of initial receipt, acceptance and print publication were recorded along with number of authors, institution and country. Average duration of receipt-to-acceptance, receipt-to-print publication, and acceptance-to-print publication were calculated. Two radiologists blinded to journal, author and affiliation graded validity and strength of articles using Oxford Center for EBM scoring system based on levels of evidence (1a-5). Each article was also graded based on likelihood to change current practice, cost to society, need for immediate research and safety concerns (1-5). Statistical analysis was performed using appropriate tests.

Results: Significant difference in receipt-to-print publication and acceptance-to-print publication was found between journals ($p < 0.0001$). North American authors had longer time-to-acceptance and to-publication in European journals and vice-versa ($p < 0.005$). No significant correlation was found between EBM scores ($p > 0.2$) and subjective grading scores ($p > 0.3$) and publication times in the journals.

Conclusions: Time-to-acceptance and to-publication of original research articles in major radiology journals are not affected by likelihood to change practice or cost to society and safety concerns. These disturbing trends may be explained on low EBM levels (3b-5) for validity and strength of most radiology research articles (78%;156/200).

Comparison of dynamic and morphologic MR features of small vs large breast cancer cases

M. Dietzel, A. Malich, D.R. Fischer, C. Marx, C. Reuchsel, C. Deicke, F. Taher, W.A. Kaiser; Jena/DE

Purpose: To evaluate the clinical relevance of dynamic and morphologic pattern of breast cancer in MR-Mammography depending on the tumor size.

Methods and Materials: All histologically verified breast cancer cases having had a MR-Mammography (1/2002-3/2004; n = 188) were retrospectively evaluated by two experienced radiologists in consensus according to standard protocols and study design (2D-FFE sequences, 0.1 mmol/kgbw Gd-DTPA, T2-TSE). Two groups were created related: Up to 10 mm largest diameter=group 1 (n = 39); > 11 mm=group 2 (n = 149). The prevalence of the following signs were statistically analysed (Chi-Square-testing): Dynamic signs - fast initial wash-in (D1), wash out (D2), plateau (D3), blooming (D4), segmental enhancement (lesion's surrounding; D5), homogeneity of lesion's contrast uptake (D6). Morphologic signs (T1) - hook-sign (M1), root-sign (M2), adjacent vessels (M3), skin thickening (M4), nipple line-sign (M5), inhomogeneity of lesions composition (M6), lesion's shape (irregular; M7), irregular margins (M8). Morphologic signs (T2) - necrosis (M9), perifocal edema (M10), diffuse edema (M11), iso/hyperintensity of vital tumor parts (M12).

Results: Prevalence were: D1=49%/62% (n.s.); D2=46%/57% (n.s.); D3=31/28% (n.s.); D4=36%/47% (n.s.); D5=18%/56% (p = 0.001); D6=36%/ 8% (p = 0.001). M1=8%/32% (p = 0.003); M2=69%/83% (p = 0.038); M3=26%/45% (p = 0.03); M4=10%/21% (n.s.); M5=3%/10% (n.s.); M6=77%/89% (p = 0.06); M7=18%/44% (p = 0.003); M8=70%/83% (n.s.); M9=0%/14% (n.s.); M10=15%/37% (p = 0.01); M11=3%/9% (n.s.); M12=92%/97% (n.s.).

Conclusion: Whereas no significant differences regarding dynamic features could be obtained, hook-sign, root-sign, perifocal edema and adjacent vessels are significantly more often associated with larger breast cancers and less typical for small lesions.

B-372 14:09

Clinical potential of various MR signs to discriminate malignant from benign breast lesions in MR-mammography

A. Malich, D.R. Fischer, S. Wurdinger, J. Boettcher, A. Hansch, W.A. Kaiser; Jena/DE

Purpose: To increase objectivity of MR-mammography use of rating points for MR-signs, which are weighted according to their discriminatory power was tested.

Methods and Materials: From 3583 MR-mammographies, 641 cases were evaluated by two radiologists in consensus retrospectively. In extension to already published MR-signs the following were rated according to their prevalences in malignant and benign lesions: T2 intensity (vital tumor), blooming-sign, hook-sign, lymph nodes, septations, nipple line interruption, edema, skin thickening. In a prospective double-blinded study, 3 radiologists evaluated all histologically verified 132 cases of MR-mammographies (6-12/03). Mean sum of rating points was calculated in order to define cut off values for benignity and malignancy of lesions.

Results: In 10 cases the extended rating did not yield a clarification due to an intermediate sum (6 pt.) (PPV and NPV 50%). In total 10 pure CIS cases were analyzed, having a value of at least 7 points in 6/10 (Sens.60%). Within the remaining 112 lesions, 63/66 invasive malignancies and 6/46 benign lesions had 7 or more rating points, 3/66 invasive malignancies and 40/46 benign had 5 or less points (S = 95.5%; Sp = 87.0%, Acc=91.2%, PPV=91.3%; NPV=93.0%).

Conclusion: The use of rating points for MR-features is helpful to accurately discriminate benign and invasive malignant findings using cut off values of 5 (benignity) and 7 (malignancy). Further studies on pure CIS cases are required for a better detection rate. Lesions having a sum of 6 are recommended to be histologically verified (high ratio of malignancies in this subgroup).

Observer variability and applicability of BI-RADS terminology for breast MR imaging

G. Marcelli, F. Pediconi, R. Occhiato, F. Venditti, G. Nardis, R. Passariello; Rome/IT

Purpose: To assess the validity of the terminology and categories of the Breast Imaging Report and Data System for breast lesions detected with MR imaging and to assess the inter- and intraobserver variabilities in the use of the descriptors and final assessment categories.

Methods and Materials: In 122 patients, 150 were evaluated independently by three radiologists and described by BI-RADS classification with respect to lesion morphology (mass, shape, margin and enhancement pattern), signal intensity parameters (time to peak enhancement, maximum slope of enhancement curve, washout) and BI-RADS final assessment categories. Two radiologists interpreted each case twice to evaluate intraobserver variability.

Results: The final assessment category was BI-RADS category 5 in 52 lesions (34.6%), category 4 in 26 lesions (16%), category 3 in 21 lesions (14%) and category 2 in 51 lesions (34%). Histo-pathologic results, obtained in BI-RADS categories 3, 4 and 5, revealed 67 invasive carcinomas, 24 in situ carcinomas and 8 benign lesions. The interobserver agreement was moderate ($k = 0.40-0.60$), while the intraobserver agreement was good ($k = 0.55-0.75$).

Conclusions: The BI-RADS lexicon has a positive impact value to describe features of breast lesions detected on MR imaging.

B-374 14:27

Cluster analysis of signal-intensity time course in dynamic breast MR imaging: Does neural network clustering help to find the correct diagnosis in unclear small lesions?

T. Schlossbauer¹, A. Wismueller¹, G. Leinsinger¹, O. Lange¹, M. Scherr¹, A. Meyer-Baese², M.F. Reiser¹, ¹Munich/DE, ²Tallahassee, FL/US

Purpose: To examine whether neural network clustering could support the characterization of diagnostically challenging breast lesions in MR imaging.

Methods and Materials: We examined 88 women with 92 breast lesions (detected by mammography and classified BIRADS III - IV, median diameter 12 mm) using dynamic contrast-enhanced MR imaging. The diagnoses (51 malignant, 41 benign) were confirmed by histology. Conventional analysis included initial signal increase and post-initial signal intensity (SI) time-course. Morphological criteria were evaluated according to a clinically approved score system. For neural network analysis, all pixels within lesions were divided into four clusters. For clustering we used minimal-free-energy vector quantization which assigns pixels presenting similar SI-time-courses to prototypical clusters. The cluster with signal-characteristics most typical of malignancy was used for lesion characterization.

Results: All lesions with initial signal increase > 50% and plateau or wash-out of post-initial SI-time-course were classified as malignant. Sensitivity increased from 70.5% (conventional method) to 82.3% (vector quantization); specificity was 68.3% with both methods. Accuracy increased from 70.0% to 76.1%. When including morphological criteria, maximum accuracy was 66.3% (conventional method) compared to 69.6% (vector quantization). SI-dynamics proved to be more relevant than morphology for lesion characterization. In addition, vector quantization improved the inter-observer agreement for classification of lesion dignity from 80% to 85%. All results proved to be statistically significant ($p < 0.05$).

Conclusion: Vector quantization proved to be a useful tool for the characterization of unclear breast lesions and could provide valuable contributions to computer-aided diagnosis in MR imaging mammography.

B-375 14:36

Color-coded automated signal intensity-curve for detection and characterization of breast lesion: Preliminary evaluation of a new software for MR based breast imaging

F. Pediconi, C. Catalano, F. Venditti, M. Ercolani, L. Carotenuto, A. Roselli, R. Passariello; Rome/IT

Purpose: To investigate the value of a new color-coded automated signal intensity-curve software package for CE Magnetic Resonance Mammography in patients with breast cancer and correlate results with histo-pathologic specimens.

Methods and Materials: Fifty women with proven breast cancer at pathology who preoperatively underwent CE-MRM were included in the evaluation. CE-MRM was performed with a 1.5 T magnet using a bilateral surface coil. T2-weighted STIR and dynamic 2D Flash Dynamic T1-weighted sequences in axial plane acquired pre and 2, 4, 6, 8 and 10 min post-contrast media administration were performed. 0.1 mmol/Kg of Gd-BOPTA was administered at a flow rate of 2 ml/s

Saturday

Scientific Sessions

followed by 10 ml of saline. Criteria for lesion evaluation included morphological enhancement patterns and signal intensity-time curves. Images were analysed both with a new software using a user-friendly interactive mechanism and separately with a standard display method. Bi-RADS scores of lesions obtained with and without software analysis were compared and correlated to histopathological results.

Results: At pathology, 11 DCIS, 6 LCIS, 16 invasive ductal, 12 invasive lobular, 2 medullar carcinoma, 3 intra-ductal papilloma, 3 ductal hyperplasia, 2 lobular hyperplasia and 6 fibroadenoma were evaluated. Perfect agreement was seen between Bi-RADS scores obtained with and without software evaluation. Good correlation between CE-MRM findings and histo-pathological specimens was obtained with both methods.

Conclusion: Novel color-coded signal intensity-curve software allows visualization of lesions with corresponding signal intensity-time curves in a false-color map and provides quickly and easily interpretable images for detection and characterization of breast lesions.

B-376 14:45

CADM RM: A prototype software for automatic computer aided detection and classification of lesions in contrast-enhanced MR-mammography

T.W. Vomweg¹, M. Buscema², E. Grossi³, D. Mayer¹, H. Faber¹, C. Hintze¹, M. Mattiuzzi³, S. Terzi², M. Intraligi², ¹Mainz/DE, ²Rome/IT, ³Milan/IT

Purpose: Further improvement and widespread availability of MR scanners increase the number of performed MR investigations of the female breast. Assessing the likelihood of malignancy of a contrast enhancing lesion is more difficult than in any other organ. Therefore evaluating MRM is a demanding task for any physician and shows a high inter-observer variability. A fully automatic software functioning as independent second opinion should improve the situation.

Methods and Materials: A software prototype evaluating MRM investigations fully automatically was programmed using C++. At first a non-rigid image registration algorithm reduces motion artefacts to improve overall image quality. Next, a threshold based algorithm detects contrast enhancing lesions followed by several algorithms assessing morphological as well as dynamic features. Lastly, an Artificial Neural Networks analyses all information and estimates the likelihood of malignancy of each detected lesion. The results of 54 lesions were compared with histology. Performance of the whole prototype was evaluated by ROC-statistics.

Results: The prototype functions without any user interaction. Registration improves image quality by motion correction without compromising contrast enhancing lesions. Sensitivity and specificity for detection and classification of malignant lesions were 81% / 80% and for benign lesions were 82%/79%.

Conclusion: A software prototype for Computer Aided Detection and Classification was successfully applied to MR-Mammography. The performance of the system must be improved by larger sample sets. Cooperation of Semeion Research Centre and University of Mainz is financed by Bracco Imaging, Milan, Italy.

B-377 14:54

Impact of different measurements techniques in the prediction of histological response, in patients with locally advanced breast cancer treated by primary chemotherapy

L. Martincich, F. Montemurro, D. Campanella, S. Debernardi, F. Russo, D. Regge; Candiolo/IT

Purpose: To compare different measurement techniques (unidimensional, bi-dimensional and volumetric) in the prediction of response, in patients with locally advanced breast cancer (LABC), undergoing primary chemotherapy (PCT) and monitored by Dynamic Contrast-enhanced MR imaging (DCE-MRI).

Methods and Materials: 30 patients underwent PCT and were monitored by DCE-MRI (1.5 T; 3DSPPGR sequence) performed at baseline, after 2 and 4 cycles of PCT. MIP reconstructions were used to define unidimensional (greatest diameter) and bidimesional (product of 2 major diameters) measurements, while dedicated software was used to define the tumoral volume. Histological response was assessed using a grade system; grade 4 (small cluster of dispersed cancer cells) and grade 5 (absence of invasive cells) were defined as major histopathological response (MHR). The tumor reduction during PCT (defined with different measurement criteria) was correlated with the histological response.

Results: Baseline DCE-MRI identified 30 lesions (mean major diameter 51 mm; mean product of the two major diameters 2193 mm²; mean volume 31 cc). MHR was achieved in 11 patients. After 2 cycles of PCT, using unidimensional criteria, tumor reduction > 30% was identified in 14 cases; 9 were MHR (sensitivity 82%, specificity 73%, PPV 64% NPV 87%). Using bidimensional criteria tumor reduction > 50% was detected in 16 cases; 10 were MHR (sensitivity 91%, specificity 72%,

PPV 63%, NPV 76%). Using volumetric criteria tumor reduction > 65% was identified in 13 cases; 10 were MHR (sensitivity 91%, specificity 88%, PPV 77%, NPV 94%).

Conclusion: In our series, the reduction assessed using volumetric criteria showed the highest specificity and NPV values, providing a possible early identification of non responder patients.

B-378 15:03

Accuracy of breast MR in the evaluation of the response to chemotherapy in 70 patients and accuracy of parametric images in a subgroup of 46 patients

J. Camps Herrero¹, M. Sentís Crivellé², L. Tortajada Giménez², V. Ricart Selma¹, C. Martínez Rubio¹, M. Ferrer Puchol¹, M. Lloret Martí¹, ¹Alzira/ES, ²Sabadell/ES

Purpose: To assess the accuracy of breast MR imaging in the evaluation of the response to neoadjuvant chemotherapy in 70 patients. In a subgroup of 46 patients we also compared the accuracy of parametric maximum enhancement speed (MES) images and parametric maximum enhancement (ME) images in the evaluation of the response to neoadjuvant chemotherapy and in the differentiation between ductal carcinoma in situ (DCIS) and infiltrating ductal carcinoma (IDC).

Methods and Materials: Seventy patients with core biopsy proven breast cancer underwent breast MR imaging prior to and 3-4 weeks after completion of chemotherapy. T1-weighted FLASH 3D pre- and post-contrast images were obtained. Morphologic and semi-quantitative analysis was done in all patients. Analysis of MES and ME parametric images in a subgroup of 46 patients was done with a dedicated software for breast MR imaging (Asymed®). UICC criteria for response were followed. Maximum diameters (MD) were compared in breast MR imaging exams after chemotherapy and in the final histopathological exams and a linear regression model was obtained. We also compared maximum diameter of MES and ME parametric images and obtained a Pearson correlation coefficient.

Results: The Pearson correlation between breast MR and pathology was $r = 0.75$. For pathologic complete response, breast MR sensitivity and specificity were 73% and 96%. In the subgroup of 46 patients the best correlation was obtained with ME images. ME parametric images were more accurate in all DCIS cases, with a correlation coefficient of 0.85 and MES images enabled differentiation between DCIS and IDC.

Conclusion: Breast MR can accurately predict response after neoadjuvant chemotherapy.

B-379 15:12

Monitoring response to neoadjuvant chemotherapy in locally advanced breast cancer: Efficacy of contrast-enhanced MR imaging to predict presence of residual disease

C.E. Loo, A.T.E.F. Schijf, E.E. Deurloo, S.M. Muller, M. vd Vijver, K.G.A. Gilhuijs; Amsterdam/NL

Purpose: To assess the efficacy of contrast-enhanced (CE) MR imaging to predict presence of residual tumor during and after completion of neoadjuvant chemotherapy in patients with locally advanced breast cancer.

Method and Materials: 53 patients (24-66 years) with locally advanced breast cancer were consecutively included between September 2000 and August 2004. Tumors (44 IDC, 9 ILC) were examined with 3 CE MR imaging scans: 1st before, 2nd during (two courses) and 3rd after completion (6 courses) of neoadjuvant chemotherapy. A combined MR imaging protocol was employed: Fast dynamic imaging in the first 45 s after contrast injection (Turbo-FLASH) followed by dynamic imaging in 5 consecutive series at 90 s intervals (FLASH-3D). MR imaging findings were correlated with postoperative pathology findings. Multivariate logistic regression with double cross-validation and ROC analysis was employed to identify MR imaging features that are predictive of tumor response after the second and after the sixth course of chemotherapy.

Results: Pathology revealed residual disease in 37(70%) of 53 patients (pCR17; 30%). During chemotherapy (2 courses), prediction of tumor response was best indicated by the change of largest washout diameter on scan 2 relative to scan 1(double-validated Az = 0.76). After completion of chemotherapy, the best predictor of tumor response is the initial enhancement combined with the change of largest washout diameter on scan 2 relative to scan 1(double-validated Az = 0.84).

Conclusions: MR imaging is accurate in predicting the presence of residual tumor after completion of neoadjuvant chemotherapy in both early as well as late stages of the treatment.

B-380 15:21

Locally advanced infiltrating lobular carcinoma (LALIC): A histological subtype with poor correlation when MRM is used to monitor primary chemotherapy (PCT)

M. Sentís¹, E. Saez Artacho¹, F. Andreu Navarro¹, L. Tortajada Jimenez¹, S. Ganau Macias¹, J. Camps², M. Seguí Palmer¹; ¹Sabadell/ES, ²Alzira/ES

Purpose: To describe the differential behaviour of LALIC during primary chemotherapy and the limitations of MRM to monitor the tumor changes.

Methods and Materials: A prospective study of 50 consecutive patients diagnosed with LABC between 2002 and 2003 by large needle core biopsy (LNCB) (38 (76%) ductal 12 (24%) lobular. 4 cycles of epirubicina-cyclophosphamide, followed by 8-12 weekly doses of docetaxel. Surgery after PCT. Pathological assessment using Miller & Payne histological grading with five grades of local response and four grades of lymph node response. The MR studies were performed before, after the first cycle and after chemotherapy. Protocol including T2-w and dynamic FLASH ·3D sequences with 0.16 mmols/bwKg. Measurements: Tumor size, volumetry, distribution and multifocality. Normalization of signal intensity values. Signal intensity variation. Saturation and wash-in rate was calculated before and after treatment in order to stratify the responses. Parametric images for correlation with pathological response and immunohistochemical markers.

Results: Local response in the breast directly correlates with axillary response. Good correlations exists in ductal carcinoma between MR and pathology. Good correlation in 35 cases (68%), underestimation in 8 cases (16%) and overestimation in 7 cases (14%). LALIC has a poor response and MR overestimates the level of response. Good correlation on 3 (25%) and overestimation in 9 (75%).

Conclusions: MR imaging results for monitoring PCT in LALIC should be interpreted with caution due to the difficulties in exactly depicting the extent of residual disease. Good categorization of the histological type before PCT is mandatory to better evaluate the MR imaging findings.

Trial design and first screening results from the Dutch-Belgian trial on lung cancer screening by spiral CT (NELSON study)

R. Vliegenthart¹, C. van Iersele², D. Xu¹, Y. Wang¹, R.J. van Klaveren², H.J. de Koning², M. Prokop³, W.P.T.M. Mali³, M. Oudkerk¹, ¹Groningen/NL, ²Rotterdam/NL, ³Utrecht/NL

Purpose: The NELSON study is a randomized screening trial in current and former smokers, aimed at early detection of lung cancer by spiral CT, and designed to be large enough to show a 20% reduction in lung cancer mortality.

Materials and Methods: In the Netherlands and Belgium 16.000 male current or ex-smokers aged 50-75 with a history of at least 20 cigarette pack-years were randomised 1:1 to spiral CT screening versus usual care in a randomised controlled trial. In the four screening sites 16-detector multi-slice CT scanners and Siemens Lungcare® workstations were used. Automated measurement of solid lesions and manual measurement of non-solid lesions was performed. Nodules were divided into 3 categories: solid, non-solid and part-solid. Solid nodules with a volume between 50 and 500 mm³, and non-solid nodules larger than 8 mm in diameter were called significant nodules. In these cases, a follow-up scan was performed after 3 months. Larger solid nodules were referred to the pulmonologist without delay.

Results: Of the first 806 patients screened, 651 (72%) had no significant pulmonary nodules. In 239 cases (26%), significant nodules were found. Sixteen patients (2%) were referred to the pulmonologist with a strong suspicion of lung cancer. Up-to-date screening results will be presented.

Conclusion: In an elderly population of male current and ex-smokers, only a low percentage (2%) showed pulmonary lesions very suspicious of lung cancer on a baseline low-dose CT scan.

B-382 14:09

Lung cancer screening in asbestos-exposed high risk patients with low dose MDCT: Results of baseline screening and first year follow-up

M. Das¹, G. Mühlenbruch¹, A.H. Mahnken¹, M.K. Felten¹, T.G. Flohr², T. Kraus¹, R.W. Günther¹, J.E. Wildberger¹; ¹Aachen/DE, ²Forchheim/DE

Purpose: To assess the risk of lung cancer in a high-risk cohort with low-dose MDCT baseline screening and first year follow-up.

Methods and Material: 174 former power plant workers (mean age 66.6 y; range 55-77 y) who were characterized as high risk individuals for lung cancer according to the risk model of Doll and Peto [(age/50) 3 x asbestos exposure time x smoking habits] were entered into a prospective trial. Average asbestos exposure time was 29.65 y (range 16-45 y); 87% were smokers, 12% ex-smokers and 1% non-smokers. CT-screening was performed on a 16-slice MDCT (Somatom Sensation 16, Siemens), using a low dose technique (120 kV, 10/20 mAs_{eff}, dependent on patients weight, collimation: 16 x 0.75 mm, rotation time: 0.5 s, table feed/rotation: 18 mm). Images were reconstructed as 1 mm thick sections with reconstruction increment: 0.5 mm. As well as visual analysis on a workstation, a dedicated CAD-software was used for data analysis (LungCARE; Siemens).

Results: Diagnostic workup with CT-guided biopsy was performed in eight patients showing bronchial cancer in six patients. 353 additional small lung nodules ranging between 1.2 mm to 13.1 mm were found (mean 5.36 mm). 133 were between 5-10 mm and were followed with CT. Asbestos related changes (plaques, fibrosis) were visible in 48 patients. Within the first year of follow-up no additional lung cancer was found.

Conclusion: Lung cancer screening in this high-risk cohort revealed a malignancy rate of 3.4% at baseline screening. Within the first year of follow-up no additional lung cancer has been found to date.

B-383 14:18

Comprehensive pulmonary MR imaging in patients with bronchial carcinoma using parallel acquisition techniques

S.O. Schoenberg, O. Dietrich, K.A. Herrmann, T. Strauss, R. Hatz, M.F. Reiser; Munich/DE

Purpose: To assess the value of a morphologic and functional MR imaging protocol for staging of bronchial carcinoma including high-resolution 3D-Gd-MRA, perfusion and oxygen imaging and whole-body tumor staging using integrated parallel acquisition techniques (iPAT).

Material and Methods: 20 patients with stage III a bronchial carcinoma were imaged on a 32 channel whole-body MR imaging scanner (Magnetom Avanto). The protocol consisted of pulmonary 3D-Gd-MRA with isotropic spatial resolution of 0.9 mm using iPAT with an acceleration factor of 3. Oxygen-enhanced imaging of the lungs was carried out with a gated IR-HASTE sequence and iPAT. Time-resolved perfusion was performed with a fast 3D FLASH sequence during injection of 0.1 mmol/kg BW of gadobutrol (Gadovist). Assessment of tumor invasion into the heart and mediastinum was detected by time-resolved TrueFISP imaging. For detection of metastases, whole-body STIR images were obtained with iPAT within 12 minutes. The results are compared to scintigraphy, CT and intraoperative findings.

Results: The entire protocol was completed in under 60 minutes. In the case of arterial or bronchial invasion by the tumor, perfusion or ventilation defects were well visualized using oxygen and perfusion MR imaging. In cases of isolated arterial occlusion, a ventilation/perfusion mismatch was observed. Bone metastases were well seen on the whole-body STIR images. Assessment of tumor invasion into the mediastinum by MR imaging correlated well with intraoperative findings.

Conclusion: Using whole-body MR imaging scanners, comprehensive morphologic and functional staging of bronchial carcinoma by MR imaging is feasible. High-resolution MRA, perfusion and oxygen imaging benefit greatly from the acceleration of image acquisition using iPAT.

B-384 14:27

Presurgical staging of non-small cell lung cancer: A performance comparison between PET, hardware PET/CT and software image fusion

B.S. Halpern, C. Schiepers, W.A. Weber, T. Crawford, B.J. Fueger, O. Ratib, M.E. Phelps, J. Czernin; Los Angeles, CA/US

Purpose: ¹⁸F-FDG PET stages Non-Small Cell Lung Cancer (NSCLC) with high accuracy. The purpose of our study was to assess whether hardware PET/CT and software PET and CT image fusion raise the diagnostic accuracy.

Materials and Methods: Thirty-six patients (17 males and 19 females) with NSCLC underwent staging with a hardware PET/CT followed by mediastinal lymph

Scientific Sessions

node dissection and tumor resection in 30 patients. 25 of the 36 patients (69%) had separate CT studies within a maximum of 6 six weeks of the hardware PET/CT study. With these images, fully automated image fusion was performed, by using commercially available software. Two blinded reviewers in consensus analyzed all PET images and an experienced radiologist was subsequently added to assess hardware and software fused PET/CT images.

Results: Reviewers examining PET and hardware PET/CT classified T-stage accurately in 67% (20/30) and 97% (29/30) of patients, respectively ($p < 0.05$) and tended to be more accurate than PET alone for N-staging (78% vs. 69%). Interpretations based on hardware PET/CT correctly staged 83% (25/30), overstaged 3 (10%) and under-staged 2 patients (7%). The overall staging accuracy of PET/CT was significantly higher than that of PET ($p < 0.05$). Automatic software fusion of separately obtained PET and CT studies failed in 32% of the patients, most frequently in those with extensive and intense glucose metabolic abnormalities.

Conclusion: Hardware PET/CT compared with PET alone was associated with 26% greater overall diagnostic accuracy. The software fusion method failed to provide acceptable co-registration in 32% of the patients.

B-385 14:36

Value of integrated PET-CT versus CT and PET alone in the detection of lung metastases in patients with a known primary tumor: A retrospective study

W.F.M. De Wever, L. Meylaerts, L. De Ceuninck, J.A. Verschakelen; Leuven/BE

Purpose: The purpose of this study was to retrospectively evaluate the additional value of integrated PET-CT in comparison with CT or PET alone to detect lung metastases in patients with a known primary tumor.

Material and Methods: Fifty-six lung nodules were detected in 24 patients with a known primary tumor who underwent a PET-CT examination for staging of their primary tumor. The benign or malignant character of these nodules was determined by either an anatomical-pathological examination or a follow-up during at least 6 months. The CT scan was evaluated by a radiologist, the PET-scan by a specialist in nuclear medicine and the integrated PET-CT images by a different radiologist and specialist in nuclear medicine in consensus. The investigators were asked to search for lung nodules and to determine whether these nodules were metastatic or not. The specificity, sensitivity, PPV, NPV and accuracy were calculated for PET-CT, CT and PET.

Results: With PET-CT 53 nodules were detected, while CT and PET detected respectively 55 and 20 nodules.

Specificity, sensitivity, PPV, NPV and accuracy are respectively:

- PETCT: 92%, 93%, 93%, 92%, 93%
- CT: 22%, 100%, 58%, 100%, 62%
- PET: 48%, 88%, 61%, 82%, 68%

Conclusion: PET-CT has a higher specificity, sensitivity, PPV, NPV and accuracy in the detection and characterisation of lung nodules in comparison with CT and PET alone and seems to be the most adequate examination for evaluation of lung metastases.

B-386 14:45

Clinical value of CT-based, software-assisted preoperative prediction of postoperative pulmonary function after lung surgery

D. Wormanns¹, F. Beyer¹, P. Hoffknecht¹, J.-M. Kuhnigk², V. Dicken², T. Lange¹, M. Thomas¹, W. Heindel¹; ¹Münster/DE, ²Bremen/DE

Purpose: To evaluate a morphology-based approach for prediction of post-operative forced expiratory volume in one second (FEV₁) after lung resection from preoperative CT scans.

Material and Methods: Fifteen patients with surgically treated (lobectomy or pneumonectomy) bronchogenic carcinoma were enrolled. A preoperative chest CT (slice thickness ≤ 5 mm) and pulmonary function tests (PFT) before and after surgery were performed. CT scans were analyzed by prototype software: Automated segmentation and volumetry of lung lobes was performed with minimal user interaction. Determined volumes of different lung lobes were used to predict postoperative FEV₁ as a percentage of the preoperative values. Predicted FEV₁ values were compared to the observed postoperative values as the standard of reference.

Results: Patients underwent lobectomy in twelve cases (6 upper lobes; 1 middle lobe; 5 lower lobes; 6 right side; 6 left side) and pneumonectomy in three cases. Automated calculation of predicted postoperative lung function was successful in all cases. Predicted FEV₁ ranged from 54% to 95% (mean $75\% \pm 11\%$) of the preoperative values. Two cases with obviously erroneous PFT were excluded from analysis. Mean error of predicted FEV₁ was 7.5 ± 250 ml, indicating absence of systematic error; mean absolute error was $11.1 \pm 5.3\%$ respective 204 ± 130 ml/s.

The 200 ml reproducibility criterion for FEV₁ was met in 10 of 13 cases (77%).

Conclusion: Software-assisted prediction of postoperative lung function yielded a clinically acceptable agreement with the observed postoperative values. This method might add useful information for evaluation of functional operability of patients with lung cancer.

B-387 14:54

Oxygen-enhanced MR imaging: Correlation with postoperative lung function in lung cancer patients

Y. Ohno¹, M. Nogami¹, T. Higashino¹, D. Takenaka², H. Hatabu³, K. Sugimura¹; ¹Kobe/JP, ²Kasai/JP, ³Boston, MA/US

Purpose: To prospectively determine if oxygen-enhanced MR imaging correlates with post-operative lung function in patients with lung cancer, as compared with quantitative and qualitative CT and scintigraphy.

Materials and Methods: Thirty consecutive patients (16 men, 14 women; aged 44 to 81 years; mean age 65 years) considered candidates for lung resection underwent oxygen-enhanced MR imaging, CT, perfusion scintigraphy, and measurement of forced expiratory volume in 1 second (FEV1). A respiratory-synchronized inversion recovery half-Fourier single shot turbo spin echo sequence (TR 3200-5000 ms; TE 4 ms; TI 900 ms; ETS 4 ms) was used for data acquisition. Correlation of post-operative lung function (post-operative FEV1) as determined by oxygen-enhanced MR imaging (poFEV1_{MR}), quantitative assessment by CT (poFEV1_{Quantitative CT}), qualitative assessment by CT (poFEV1_{Qualitative CT}), and perfusion scintigraphy (poFEV1_{Perfusion scintigraphy}) was made with actual post-operative FEV1, and the limits of agreement of each was also determined by Bland-Altman analysis.

Results: Correlation between poFEV1_{MR} and actual post-operative FEV1 was excellent ($r^2=0.81$, $p < 0.0001$); better than that of poFEV1_{Qualitative CT} ($r^2=0.76$) and poFEV1_{Perfusion scintigraphy} ($r^2=0.77$), and similar to that of poFEV1_{Quantitative CT} ($r^2=0.81$). The limits of agreement of poFEV1_{MR} were between -9.9% and 10.9%.

Conclusion: Oxygen-enhanced MR imaging correlates with post-operative lung function in lung cancer patients, similar to quantitative CT.

B-388 15:03

Accuracy of multislice CT with multiplanar reformations in staging malignant pleural mesothelioma

B. Feragalli, M.L. Storto, A.G. D'Agostino, R. Sacco, M. Mereu, C. Colosimo; Chieti/IT

Purpose: To assess the value of Multislice CT (MSCT) with multiplanar reformations in staging Malignant Pleural Mesothelioma (MPM) and in predicting resectability of tumor for radical surgery.

Methods and Materials: Twenty-four patients with biopsy-proved MPM underwent MSCT of the thorax before surgery. MSCT was performed with the following protocol: 1 mm-collimation, 1 mm-slice width, 0.8 mm-reconstruction increment. Two radiologists assessed tumor resectability by consensus, focusing on local invasion of three separate regions: the mediastinum, diaphragm and chest wall. Results of all CT examinations were carefully correlated with intraoperative pathologic findings.

Results: 14 patients underwent extrapleural pneumonectomy and 10 had pleural decortication because the tumor was unresectable. The sensitivity and specificity of MSCT in predicting resectability were 93% and 90% at the mediastinum, 94% and 100% at the diaphragm and 94% and 86% at the chest wall. Accuracy was 92%, 96% and 92% at the mediastinum, diaphragm and chest wall respectively.

Conclusion: MSCT with multiplanar reformations has high diagnostic accuracy in predicting tumor resectability, and also in the assessment of diaphragmatic involvement. It is likely that MSCT can replace Magnetic Resonance in the preoperative assessment of patients with MPM.

B-389 15:12

Evaluation of the diaphragm in malignant pleural mesothelioma: Role of US L.L. Ciarpaglini, S. Pascoli, P. Regimonti, L. Portalone, G. Pedicelli; Rome/IT

Purpose: To evaluate the sensitivity and diagnostic accuracy of contrast echo in diaphragmatic invasion in malignant pleural mesothelioma.

Materials and Methods: From January 2003 to August 2004 we observed 14 patients with the diagnosis of malignant pleural mesothelioma. 7 patients that did not present invasion of pericardium or chest wall were evaluated with CT, MR and US with contrast media for the detection of diaphragmatic involvement.

Results: There was full agreement of CT, MR and US: 3 patients had infiltration of the diaphragm, and in 4 patients there was no involvement of this structure.

Conclusion: This study has showed that US with contrast media, revealing the

Scientific Sessions

neoangiogenesis of neoplastic foci, has a very high diagnostic accuracy and sensitivity in the diagnosis of diaphragmatic invasion.

B-390 15:21

Interobserver variability in the CT assessment of suspected mesothelioma without final histologic diagnosis

I. Moraschi, D. Farina, P. Maculotti, G. Battaglia, P. Barbieri; *Brescia/IT*

Purpose: To identify CT findings statistically correlated to mesothelioma (M1). To assess interobserver variability in defining, based on CT, the probability of mesothelioma in pleural lesions without histologic diagnosis (M2: possible; M3: probable).

Methods and Materials: Retrospective analysis of CT examinations of 40 patients (11 M1, 7 M2, 13 M3, 9 non-mesothelioma) included in Malignant Mesothelioma Register of Brescia performed by three blinded radiologists. Several CT parameters were assessed (pleural effusion, hemithorax retraction, mediastinal shift, calcified/solid pleural plaques, thickening of fissures, parenchymal consolidation/nodules/masses, infiltration of mediastinum/diaphragm/thoracic wall, lymphadenopathy, pericardial effusion, distant metastases). Each patient was finally assigned a score designating the probability of mesothelioma, ranging from 0 (slight) to 5 (elevated). Statistical correlation between each of CT parameters and M1 class was assessed.

Results: In 70% of patient the reviewers completely agreed on the score assigned to the patients. In 30% of cases, minor inconsistencies occurred, as one reviewer assigned a score in all cases just one figure different from the others. Classification in Malignant Mesothelioma Register of Brescia was retrospectively changed in 2/20(10%) of M2 and M3 patients. Statistically significant correlation was found between M1 class and the following CT parameters: hemithorax retraction ($p = 0.0005$); solid pleural plaques ($p = 0.004$) with circumferential distribution ($p = 0.01$) or involving either the mediastinal ($p = 0.0001$) or diaphragmatic pleura ($p = 0.0003$); infiltration of mediastinum ($p = 0.01$) or diaphragm ($p = 0.008$).

Conclusion: CT findings allow us to define the probability of mesothelioma in suspected cases lacking a final diagnosis. This may have crucial legal implications.

Functional radiogenomic identification of alterations in global gene expression in human solid renal tumors with conventional cross sectional imaging

M.D. Kuo¹, B. Chan¹, J. Buckley², B. Gooding³; ¹*San Diego, CA/US*, ²*Palo Alto, CA/US*, ³*San Francisco, CA/US*

Purpose: Genomics, the study of genome-wide gene expression, has led to important discoveries about cancer but requires cells to be obtained invasively. We sought to show proof of concept that computed tomography (CT) and magnetic resonance imaging (MRI) has potential for non-invasively identifying functionally relevant alterations in global gene expression in solid renal neoplasms.

Methods: 27 renal tumors in 27 patients imaged with contrast enhanced CT ($n = 20$) or MRI ($n = 9$) were reviewed by 2 radiologists in consensus. 4 independent imaging parameters were defined a priori (pattern of enhancement, necrosis, hemorrhage, tumor borders), and then evaluated and scored without knowledge of the genomic information. Imaging parameters were then evaluated across matched tumor cDNA microarray data representing ~17,000 genes. Supervised and unsupervised statistical and bioinformatic analyses were then performed to identify imaging-genomic correlations.

Results: 2/4 imaging parameters (pattern of enhancement and necrosis) showed statistically significant correlation ($P < 0.01$) with the corresponding gene expression data and revealed plausible insights into tumor biology based on the imaging. These genes were largely grouped into several well defined co-expressed gene clusters representing: immune infiltration (e.g. T cell and B cell), hypoxia/angiogenesis (e.g. VEGF, HIF, CD34, THY-1), extracellular matrix remodeling, and metabolic and cell signaling gene expression clusters.

Conclusions: We show preliminary evidence that conventional cross sectional imaging has potential to non-invasively characterize components of large-scale gene regulation in renal neoplasms into co-regulated functional gene clusters

representing biological processes based on imaging traits alone. Further study into this emerging area of functional radiogenomics is warranted.

B-392 14:09

Renal lesions too small to classify by CT; outcome study based on follow-up for 18-62 months (38 mean) by multiphasic helical CT or laparoscopy

E.K. Lang¹, B. Gayle², R. Macchia², R. Charafeddine¹, L. Meyers¹; ¹*New Orleans, LA/US*, ²*Brooklyn, NY/US*

Purpose: Establish significance and possibly, etiology of "renal lesions too small to classify by CT" by follow-up multiphasic helical CT, laparoscopy, biopsy or surgery.

Materials and Methods: 465 "renal lesions too small to classify by CT" and with follow-up studies for 18 - 62 months (38 mean) at three university medical centers were analyzed in this retrospective study. 72 lesions featured a lower than parenchymal density on pre-enhancement CT, 393 lack of enhancement on post-enhancement CTs. The lesions ranged in size from 0.4 to 1.0 cm (7 mm mean), were hypovascular and lacked enhancement. Outcome is based on multiphasic helical CT ($N = 440$), laparoscopy ($N = 19$), biopsy ($N = 4$) and surgery ($N = 2$).

Results: 335 of these lesions were no longer identifiable on follow-up examinations. However, 58 of these had been treated for urinary tract infections. 69 lesions had increased to greater than 1 cm in diameter and exhibited CT criteria of cysts. 51 had increased in size with CT findings consistent with medullary necrosis, renal abscess, or calyceal diverticula. Follow-up CTs suggested renal infarcts in 4. Four enlarging lesions proved to be metastatic neoplasms; 2 others angiomyolipomas.

Conclusion: Less than 1% of the lesions were malignant neoplasms, however, 51 (11%) were caused by inflammatory disease prone to progress to medullary necrosis, renal abscesses or calyceal diverticula if left untreated. 58 (12.5%) of the lesions were no longer identifiable possibly due to treatment of coexisting urinary infections. 277 lesions (60%) disappeared without treatment, likely due to normalization of a temporary ischemic process.

B-393 14:18

Tuberous sclerosis complex: Prevalence of minimal fat-containing angiomyolipoma (AML) and renal cell carcinoma

E. Simpson, U. Patel; *London/UK*

Purpose: Define prevalence of the various types of renal masses in Tuberous Sclerosis Complex (TSC).

Materials and Methods: A study group of 12 patients with TSC (ages 17-66 years) evaluated. All patients underwent two dedicated renal Computerised Tomography (CT) scans, 2 years apart. The prevalence of solid and cystic renal masses was defined. The solid masses were further divided into typical AML's [definition: region of interest (ROI) density < -10 units] and indeterminate masses [ROI density > -10 units].

Results: 200 masses identified (mean diameter 3.6 cm, range 8 mm -16 cm). 12 were simple (Bosniak type 1) cysts. Of the rest, 136/188 were typical AML with a ROI density < -10 units. The remainder (52/188 or 27% of all solid masses) could not be accurately categorised by CT as being minimal fat containing AML or renal cell carcinoma. Over a two-year follow-up period, 7/52 masses have undergone biopsy because of suspected renal cell carcinoma. 1/7 proved to be carcinoma. The rest were minimal fat AML's. The remainder (45/52) have not shown any substantial interval growth and are presumed to represent minimal fat AML's as well.

Conclusion: In TSC, over a quarter (27%) of renal masses will be diagnostically indeterminate on renal CT and indistinguishable from renal cell carcinoma. But on two year follow-up only 1 case of renal cell carcinoma was found (overall incidence = 0.5%).

B-394 14:27

Renal angiomyolipoma with no discernible fat on CT and chemical shift MR imaging

J. Lee, S. Lee, S. Kim, T. Moon; *Pusan/KR*

Purpose: To evaluate the imaging findings of renal angiomyolipoma with no discernible fat on CT and chemical shift MR imaging.

Materials and Methods: Five patients with 16 proved angiomyolipoma after partial nephrectomy were retrospectively reviewed. The main CT features analyzed are the presence of fat component, homogeneity, enhancement of mass. Qualitative analysis of the MR images was done on the basis of signal loss on out-of-phase images and signal intensity of mass on T2-weighted images. Quantitative analysis

Scientific Sessions

of MR images was performed by calculating the difference in signal intensity between in-phase and out-of-phase by use of regions of interest (signal intensity index and mass-spleen ratio) and signal intensity ratio between renal mass and parenchyma on T2-weighted images.

Results: Renal masses were ranged from 3 mm to 3 cm in size. All of masses showed no fat component, homogenous density, and good enhancement and washout on CT images. All of masses showed no loss of signal intensity on out-of phase images and lower signal intensity compared to that of renal parenchyma on T2-weighted images. Quantitatively, there were no discernible fat components in the mass (mean signal intensity index, 24.7; mean mass-spleen ratio, 1). Mean signal intensity ratio between renal mass and parenchyma was 67.3 on T2-weighted images.

Conclusion: In case of renal mass with no discernible fat component on CT and chemical shift MR imaging, MR image may have value in demonstrating abundant muscle and vessel tissue, which leads to the diagnosis of angiomyolipoma.

B-395 14:36

The angular interface sign: New sign for differentiation of renal cell carcinoma and angiomyolipoma on MR imaging of small renal masses

H. Sherif, A.E. Mahfouz; Doha/QA

Purpose: To assess the shape of the interface between renal masses and normal renal parenchyma as differentiating sign between renal cell carcinoma and angiomyolipoma.

Methods and Materials: Sixty eight patients with small solid renal masses (< 3 cm) have been examined at 1.5 T by T2-weighted half-Fourier turbo spin echo (HASTE), and T1-weighted gradient-echo (GRE) images of the kidney before and after fat saturation in transverse, coronal, and sagittal orientations during breathhold. Additionally, breathhold gadolinium-enhanced fat-saturated T1-weighted GRE images were obtained in the three orthogonal orientations. To avoid bias caused by signal intensity of fat in angiomyolipoma, only fat saturated images were evaluated collectively in the three orthogonal planes by blinded reader for the angularity or roundness of the lesion-kidney interface.

Results: The lesion-kidney interface was round in 44 out of 50 renal cell carcinomas (88%) and angular in the remaining 6 lesions (12%). On the other hand, the lesion-kidney interface was angular in 16 out of 18 angiomyolipomas (89%), and round in 2 lesions (11%). Difference between renal cell carcinoma and angiomyolipoma was statistically significant ($p < 0.001$).

Conclusion: Angiomyolipoma has angular configuration of the interface with the normal renal parenchyma more frequently than malignant renal neoplasm. This newly described sign may be used, in conjunction with other imaging features, for differentiation between small angiomyolipoma and renal cell carcinoma on MR imaging.

B-396 14:45

Morphologic characterization of subtypes of renal cell carcinoma by multislice CT

M. El-Azab, A. Mosbah, M. El-Baz, K. Shoier; Mansoura/EG

Purpose: The purpose of our study to differentiate subtypes of renal cell carcinoma on multislice CT scans.

Materials and Methods: We reviewed CT scans of three subtypes of renal cell carcinoma: 37 conventional (clear cell), 26 papillary and 24 chromophobe. Biphasic CT scans (unenhanced, cortico-medullary, excretory phase scans) were obtained in all patients. We compared patient age and sex; tumor size; degree and pattern (homogeneous, heterogeneous, predominantly peripheral) of enhancement; presence or absence of calcification; and tumor-spreading patterns including perinephric change, venous invasion and lymphadenopathy in three subtypes.

Results: Conventional renal carcinoma showed stronger enhancement than the other subtypes ($p < 0.05$): 138 ± 38 H (mean \pm SD) in the corticomедullary phase. No statistically significant difference between papillary and chromophobe renal carcinomas was detected in attenuation value or degree of enhancement in either the corticomedullary phase or the excretory phase ($p > 0.05$). Conventional (70.3%) and papillary (69.2%) renal carcinomas tended to show heterogeneous or predominantly peripheral enhancement, whereas chromophobe renal carcinoma (75%) usually showed homogeneous enhancement. Calcification was noted in conventional (21.6%), papillary (23.1%) and chromophobe (25%) renal carcinomas without statistically significant difference ($p > 0.05$).

Conclusion: For the differentiation of the subtypes of renal cell carcinoma, pattern and degree of enhancement is the most valuable parameter.

B-397 14:54

Correlation between radiologic and pathologic TNM using MDCT in staging of renal masses

F. Toso, M. Vergendo, G. Ciccarese, G. Como, C. Del Frate, M. Bazzocchi; Udine/IT

Purpose: To evaluate role of MDCT in renal masses staging and to correlate pre-surgical staging, with pathologic staging.

Material and Methods: 48 patients with renal mass detected by US or CT underwent MDCT (Aquilion-TOSHIBA), using a multiphase protocol after iodine-contrast media (400 gml/ml) injection (flow-rate: 4 ml/s) using Sure Start® software for bolus-tracking. Acquired data were processed to obtain coronal MPR and three-dimensional MIP and VR for angiographic, nephrographic, urographic assessment. Each renal mass was evaluated for location, size, relationship with surrounding structures, urinary-tract invasion, loco-regional lymphadenopathy, and vascular invasion. Each mass was classified following radiologic-TNM and correlated with pathologic-TNM after surgery.

Results: 45 suspicious renal masses were detected in 40/48 patients who underwent MDCT, while in 8 patients renal findings resulted to be benign. Considering TNM staging system we identified 34/45 masses with major diameter smaller than 7 mm (T1). Comparing radiologic staging with pathologic one in patients who underwent surgery we found two discordant cases (MDCT overstaged both, for renal fascia invasion in one and of renal capsule in second). Seven masses were classified by MDCT as T3a, due to invasion of peri-renal fat tissue (in one case involvement of adrenal gland was found) and 4 masses as T4, due to invasion of renal fascia. No masses were classified as T2, and we never found involvement of renal vein in our cases.

Conclusions: In our experience, MDCT seems to be gold-standard examination in staging of renal masses, thanks to high correlation found between radiologic and pathologic-TNM.

B-398 15:03

Preoperative staging of renal cell carcinoma with inferior vena cava thrombus using multi-detector CT and MR imaging: Prospective study with histopathological correlation

P.J. Hallscheidt, C. Fink, A. Haferkamp, G. Kauffmann; Heidelberg/DE

Purpose: To evaluate accuracy of multi-detector computed tomography and magnetic resonance imaging in staging and estimating renal carcinomas with caval thrombus.

Materials and Methods: Initially 23 patients with suspected caval thrombi were admitted into this prospective study. Triphasic CT imaging was performed using a multi-detector CT with a reconstructed slice thickness of 2 mm. 3D CT reconstructions were used. MR imaging protocol included: a transverse T1-weighted GE sequence with and without Gd-DTPA, a transverse T2-weighted respiratory-gated TSE and a coronal T1-weighted GE sequence with Gd-DTPA and fat saturation. In addition, multi-phase 3D angiography was performed after Gd-DTPA injection. Patients were divided into three groups: caval thrombus below the insertion of the hepatic veins, within the intrahepatic vena cava, and intra-atrial extension. The results of tumor thrombus extension and staging results by two independent readers were correlated with surgical and histopathological staging.

Results: Of the 23 patients admitted, CT and MR scans of 14/13 patients respectively were correlated with histopathological workup. CT thrombus detection sensitivity and specificity for both readers was 0.93 and 0.8 respectively. MR imaging sensitivity and specificity for both readers was 1.0/0.85 and 0.75. Readers I and II evaluated the uppermost extension of the tumor thrombus by both CT and MR imaging. CT and MR accuracy was 78% and 72%, 88% and 76% respectively.

Conclusion: In cases of a suspected tumor thrombus, MR imaging and multi-detector CT imaging showed similar staging results. Consequently, these staging modalities can be used to assess the extension of the tumor thrombus.

B-399 15:12

Multiphase multidetector CT (MDCT) in diagnosis and staging of transitional cell carcinoma of the renal pelvis and the ureter

G.A. Fritz, H. Schoellnast, B. Unger, H.A. Deutschmann, U. Stessel, M. Tillich; Graz/AT

Purpose: To evaluate the potential of MDCT in the diagnosis and staging of transitional cell carcinoma of the renal pelvis and ureter.

Methods and Materials: CT scans of 30 patients with transitional cell carcinoma (9 renal pelvic, 21 ureteral) were evaluated. In all patients the urinary tract was examined using MDCT performing unenhanced and contrast enhanced scans

Scientific Sessions

during the corticomedullary phase (scan delay 30 s) and the excretory phase (scan delay 180 s). All scans were obtained with 2.5 mm collimation, pitch 1.5, and reconstruction interval of 2 mm. The attenuation of the tumors was documented in Hounsfield units (HU) using ROI measurements. Tumor staging was performed according to the TNM classification. CT and histopathologic findings were correlated.

Results: All transitional cell carcinomas were visible on corticomedullary and excretory phase scans, mean attenuation was 73 ± 10 HU in the corticomedullary and 77 ± 16 HU in the excretory phase. There was no statistically significant difference in the attenuation of the tumor between both contrast enhanced phases ($p = 0.23$). CT correctly diagnosed a transitional cell carcinoma confined to the organ in 19/20 cases (95%). In the one false positive case chronic inflammatory changes of the renal pelvis and proximal ureter were found at histopathological examination. A differentiation between T1 and T2 stages was not possible with MDCT. A stage T3 was correctly diagnosed in 7/8 patients (87.5%), in one patient histological examination revealed a stage T4. In 2/2 patients (100%) T4 was correctly diagnosed. CT was accurate in predicting pathologic TNM stage in 27/30 patients (90%).

Conclusion: MDCT with its high spatial resolution is an accurate tool for diagnosis and staging of transitional cell carcinoma. However, a reliable differentiation of neoplastic and chronic inflammatory lesions is not possible.

B-400 15:21

Characterization of adrenal masses with MDCT and MR imaging

B.M. Happel¹, T. Mang, W. Matzek, D. Latzke, B. Niederle, K. Kaserer, G. Heinz-Peer; Vienna/AT

Purpose: To compare the diagnostic performance of MDCT and MR imaging in characterization of adrenal masses and to correlate imaging findings with histopathologic results.

Material and Methods: 38 patients (25 female, 13 male, median age 51 y) underwent MDCT and MR imaging for evaluation of adrenal masses. CT was performed on either a 4 or 16 row scanner (Siemens). CT protocol included an unenhanced scan, 1 min post contrast and 15 min delayed contrast series. All MR examinations were performed on a 1.5 T unit (Siemens). MR protocol included chemical shift and Gd-enhanced dynamic imaging with delayed contrast series. CT- and MR images were independently reviewed by two radiologists, experienced in adrenal gland imaging, and blinded to patients' history. CT and MR imaging findings were compared to histologic results in all cases.

Results: 39 adrenal masses (1 bilateral) were detected on MDCT and MR imaging (mean size 32 mm, range 8-86 mm). Histology revealed 17 adenomas, 10 pheochromocytomas, and 12 further lesions (4 metastases, 1 carcinoma, 1 primary lymphoma, 1 borderline tumor, 1 haematoma,...). On MR imaging 15/17 adenomas, 9/10 pheochromocytomas and 11/12 further lesions were correctly diagnosed. In two atypical adenomas MR imaging findings were indicative for malignant lesions. Overall sensitivity for MR imaging was 90%.

On MDCT 17/17 adenomas, 9/10 pheochromocytomas and 11/12 further lesions were correctly diagnosed. Overall sensitivity was 95%.

Conclusion: Both MDCT and MR imaging have high sensitivity in characterization of adrenal masses. MDCT seems to be more reliable in evaluation of atypical adenomas compared to MR imaging.

A new cordless coil for MR-guided percutaneous biopsies in a low field system: First clinical experiences

S. Zangos¹, M.G. Mack¹, K. Eichler¹, C. Herzog¹, M. Heller¹, T. Vetter², T. Lehnert¹, T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Erlangen/DE

Purpose: To evaluate the safety and precision of MR-guided biopsies with a new cordless coil in an open low field system for different regions.

Materials and Methods: In 8 patients with uncertain tumors MR-guided biopsies were performed in a low field system (0.2 T, Magnetom Concerto, Siemens) with a new cordless coil (Siemens). The biopsies were performed in different organ

systems (5 liver, 2 abdomen and 1 hip). For the monitoring of the biopsy procedures T1-weighted FLASH sequences were used. The lesions were biopsied repeatedly through a G15 pencil tip with a G16 biopsy-handy. The visibility of the anatomy, the tumor and the needles as well as the handling of the coils were evaluated.

Results: The cordless coil can be easily handled for the biopsies with sufficient image quality for interventional procedures. Via MR-guidance the needle position could be easily visualized during the biopsy of soft tissue lesions using T1-weighted sequences.

The biopsy procedures could be performed successfully in all cases without any side effects or complications. The use of the cordless coil allows an increased patients comfort during the biopsy procedure.

Conclusion: MR-guided biopsies of soft tissue lesions with cordless coils can be performed safely and precisely with easy handling of the coil resulting in an reducing of the procedure time.

B-402 14:09

Cryotherapy of breast cancer under ultrasound-guidance

S.O.R. Pfeiferer, C. Marx, A. Malich, O. Camara, W.A. Kaiser; Jena/DE

Purpose: Cryosurgery has been used in the treatment of tumours of the liver and prostate for more than 25 years. The potential and feasibility of cryotherapy in breast cancer was evaluated.

Methods and Materials: 48 female patients (median age 61 years; range 38-81 years) with breast cancers (median tumor diameter 12 mm; range 5-37 mm) underwent argon-based cryotherapy. 32 patients had tumors which were smaller than 16 mm. After local anaesthesia the tip of a 3 mm cryoprobe was placed into the tumor under ultrasound guidance. Two freeze/thawing were performed. The size of the iceballs was measured sonographically in one-minute intervals. The patients underwent open surgery within 3 weeks and the specimens were evaluated histologically.

Results: During cryosurgery iceballs could be well delineated using ultrasound. The mean diameter of the iceball was 31 ± 4.5 mm after the second freezing cycle. No severe side effects were observed. In all 32 patients with tumours of smaller than 16 mm histological evaluation of the specimens removed by open surgery did not reveal remnant invasive tissue. 4 of these had ductal carcinoma *in situ* (DCIS) in the surrounding area. In 16 patients cryotherapy of tumours reaching diameters of more than 15 mm resulted in incomplete necrosis.

Conclusions: Tumours of less than 16 mm diameter are completely destroyed by cryotherapy with a 13% risk of leaving DCIS in the surrounding tissue. In tumors of more than 15 mm diameter the technique of cryotherapy must be locally extended.

B-403 14:18

MR-guided large core breast biopsy inside the bore of a 1.5 Tesla scanner using a robotic system (ROBITOM)

S.O.R. Pfeiferer¹, C. Marx¹, J.R. Reichenbach¹, J. Vagner², H. Fischer², W.A. Kaiser¹; ¹Jena/DE, ²Karlsruhe/DE

Purpose: The aim of this study was to investigate the feasibility of MR-guided large core breast biopsy (LCBB) using a robotic system (ROBITOM) which helps to localize lesions and operates at the isocentre of a 1.5 Tesla scanner.

Methods and Materials: 16 patients with MR-detectable breast lesions were biopsied by using the first prototype ROBITOM I to position the trocar, which was subsequently inserted into the breast in front of the lesion. Specimens were taken in coaxial technique using a 14 G core needle biopsy gun. In case of malignant histology open surgery was performed afterwards. In vitro experiments using the second prototype (ROBITOM II) which contains a high-velocity device to insert the trocar and a phantom containing vitamine E capsules (7 x 3 mm in size) serving as artificial lesions were performed.

Results: Evaluating ROBITOM I in 5 cases biopsy findings were confirmed by open surgery. In 3 cases two invasive cancers were missed and one invasive cancer was underestimated. 8 patients with benign findings are still in the follow-up period. Investigating ROBITOM II under in-vitro conditions capsule material in the specimen cylinders were detected in all 13 experiments. First clinical results of LCBB using the second prototype will be presented.

Conclusions: The patient study demonstrated the feasibility of manipulator assisted LCBB inside a whole body scanner using ROBITOM I. The missed cases are most likely due to lesion shifts. Implementing a high-velocity trocar setting unit in the second prototype shifting the lesion could be avoided in-vitro.

Scientific Sessions

Interventional MR angiography with no strings attached: Wireless active catheter visualization

H.H. Quick¹, M.O. Zenge¹, H. Kuehl¹, G.M. Kaiser¹, S. Aker¹, S. Massing¹, S. Bosk², M.E. Ladd¹; ¹Essen/DE, ²Erlangen/DE

Purpose: To develop and evaluate a wireless active catheter visualization strategy for interventional MRA that 1) provides high contrast instrument visualization; 2) avoids electrical conducting wire connections to eliminate the risk of RF heating; and 3) offers unhampered instrument handling through obviating any wire connection.

Materials and Methods: 6F catheters were designed containing 120-mm-long self-resonant RF single-loop coils to enable wireless active instrument visualization. Surface coils were employed for simultaneous visualization of the anatomy and inductive signal coupling of the instrument coils. Imaging was performed on a 1.5 T Siemens Sonata using real-time TrueFISP sequences. Instrument-to-background contrast-to-noise vs. the excitation flip angle was systematically investigated in phantom experiments. In vivo evaluation of the concept was performed on five pigs. Instruments were guided through the vasculature under real-time MR imaging. Following selective catheterization, time-resolved 3D contrast-enhanced (CE) angiograms were acquired.

Results: The distal curvature of wireless active catheters could successfully be visualized with robust signal. TrueFISP sequences allowed for simultaneous depiction of the instrument outline and morphology with up to 9 frames/second. Instrument-to-background contrast could be adjusted by varying the excitation flip angle. Best contrast was achieved with flip angles about 15°. Time-resolved CE selective angiograms were successfully acquired in the abdominal aorta, the renal, splenic, mesenteric, and hepatic arteries of the pigs.

Conclusion: Wireless active visualization of catheters with resonant loop RF coils enables reliable visualization of the instrument curvature to the very tip. Additionally, due to inductive signal coupling, no wire connection compromises instrument handling. Instrument RF heating is not expected.

B-405 14:36

MR-guided laser induced thermotherapy (LITT) of colorectal carcinoma metastases in the liver

M.G. Mack, K. Eichler, R. Straub, T. Lehnert, J.O. Balzer, S. Zangos, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To evaluate MR-guided LITT for the treatment of colorectal liver metastases in a long-term follow-up study and to demonstrate why ablation is superior to resection under certain circumstances.

Material and Methods: MR-guided LITT was performed in 803 patients (mean age 61.2 years) with 2376 liver metastases of colorectal cancer between 1993 and 2004. Survival rates were calculated using the Kaplan-Meier method.

Results: The local hepatic tumor control rate at 6-month follow-up was 2.2% for metastases up to 2 cm diameter, 2.9% for metastases between 2 and 3 cm diameter, 0.4% for metastases between 3 and 4 cm diameter and 2.6% for metastases larger than 4 cm in diameter. The mean survival rate for all treated patients, starting the calculation at the date of diagnosis of the metastases which was treated with LITT, was 3.9 years (95% confidence interval: 3.6 - 4.2 years, 1 year survival 93%, 2 year survival 72%, 3 year survival 49%, 5 year survival 25%). The mean survival of patients who refused resection and were treated with LITT was 5.2 years, which is superior to data published for surgical resection. The mean survival of patients who had already partial liver resection before was 3.8 years, in patients with bilobar liver metastases the mean survival was 3.6 years. **Conclusion:** MR-guided LITT yields high local tumor control and survival rates in patients with liver metastases of colorectal carcinoma. LITT appears in surgical candidates to be superior to resection.

B-406 14:45

MR-guided percutaneous sclerotherapy of low-flow vascular malformations: Final qualitative and quantitative assessment of therapy and outcome

D.T. Boll¹, E.M. Merkle², J.S. Lewin³; ¹Ulm/DE, ²Durham, NC/US, ³Baltimore, MD/US

Purpose: To prospectively assess the therapeutic procedure and outcome of magnetic resonance (MR)-guided percutaneous sclerotherapy in low-flow vascular malformations.

Material and Methods: 76 percutaneous sclerotherapy treatments were performed under real-time MR guidance on 15 patients with vascular malformations in the head and neck (n = 64), spine (n = 5), and extremities (n = 7). Qualitative assessment analyzed success of the therapy and occurrence of complications. Quantitative evaluation assessed length of time of minimally

invasive MR-guided sclerotherapy in a regression analysis, the ability of MR imaging to depict post-interventional perfusion changes by calculating changes in the Contrast to Noise Ratios (CNR), and the detection of volume changes on follow-up examinations.

Results: All sclerotherapy procedures were successfully performed without complications. Induced vascular sclerosis successfully treated the individual predominant symptoms, such as hemorrhage, pain, cosmetic disfigurement, and functional impairment. Quantitative analysis focusing on the actual interventional length of time presented a significant acceleration over the investigated five-year time period, matching a cubic function in the regression curve fit, and taking 31.50 ± 14 min. Induced vascular thrombosis was identified in all treated portions on post-interventional studies by the statistically significant changes in CNR ($p < 0.05$) compared to pre-interventional imaging. On follow-up examinations (after 12 ± 6 weeks), a significant shrinkage was observed in the targeted portions ($67.2 \pm 18.9\%$).

Conclusion: MR imaging allows the safe guidance and monitoring of minimally invasive sclerotherapy and also permits the verification of therapeutic success post-interventionally and during follow-up examinations.

B-407 14:54

MR guided focussed ultrasound surgery (MRgFUS) in the treatment of uterine fibroids. Are there any predictors for treatment success

S.A. Hengst, T. Ehrenstein, A. Beck, I. Utz-Billing, H. Herzog, R. Felix, J. Riecke; Berlin/DE

Purpose: MRgFUS represents a new, non-invasive thermoablative treatment procedure for uterine fibroids. Aim of this study was to evaluate the shortterm influence of MRgFUS in symptom relief and size of fibroids.

Method: As part of a prospective multicentric study 19 patients suffering from uterine fibroid related symptoms where included. Pretreatment MR imaging scans were performed and evaluated regarding size, location and characteristics of the fibroids. Additionally the symptom-severity-score was assessed prior to and 3, 6 and 12 month after MRgFUS. MR follow-up was performed after 6 and 12 month. For statistical analysis Students t-test, Mann-Whitney-test and Wilcoxon test were performed.

Results: 19 patients were included in the intention to treat analysis, for 15 patients the treatment was performed technically successful. None of the patients experienced severe adverse effects. The symptom severity score decreased from $70.6 (\pm 10)$ to $52.5 (\pm 13.1)$; $p = 0.003$, $n = 13$ after 3, to $58.7 (\pm 14.9)$; $p = 0.014$, $n = 13$ after 6 and eventually to $51.9 (\pm 22.7$, n.s.; $n = 9$) points after 12 month. Whereas there was no significant shrinkage in the size of the uterine fibroids for all patients after 6 and 12 month a subgroup analysis for patients with homogenous and dark myomas (T2w-images) revealed an average decrease in size of 28.6% (± 24 ; $p = 0.02$) after 6 and 51.0% (± 11.9 ; $p = 0.02$) after 12 month.

Conclusion: MRgFUS is a safe and effective procedure for short term symptom relief in patients suffering from uterine fibroids. Patients with homogenous and dark myomas are more likely to profit from this treatment.

B-408 15:03

MR-guided laser induced thermotherapy (LITT) for retroperitoneal lymph nodal metastases

T.J. Vogl, J. Li, M. Mack, T. Lehnert, K. Eichler, H. Ghazy, Y. Wang; Frankfurt a. Main/DE

Objective: The aim this study was to evaluate the experience with percutaneous MR image guided laser induced thermotherapy (LITT) for retroperitoneal lymph nodal metastases.

Materials and Methods: Twenty-two retroperitoneal lymph nodal metastases underwent MR-guided laser induced thermotherapy (LITT) using a 0.5 T MR unit. There were 15 men, and 7 women (average age 72.3 years). MR-guided LITT was performed with a cooled power laser system (Nd:YAG-Laser). A fast low-angle shot 2D sequence for MR thermometry was used for monitoring of the treatment tumors. The average metastases diameter was 3.6 cm (range, 1.5-5.6 cm). The follow-up was with MR imaging at 1.5 T MR unit at 3 months then 6 months interval after laser treatment. Lack of enhancement with contrast material in ablated tumors on MR images was considered coagulation necrosis.

Results: No complications occurred during laser treatment in 22 patients. A total of 28 laser applicators were performed. The mean laser power was 28.2 W; Average laser treatment time was 10.7 minutes. Follow-up was in average 9.2 months (range, 3-24 months) after procedure. Follow-up with gadolinium enhanced Min 20 treated tumors, In two lesions (diameter > 5 cm), enhancement of residual tissue was demonstrated; No patient had recurrent tumor at the treated site, 18 tumors size did no change, 4 lesions decreased in size about 60%-80%.

Conclusion: MR-guided laser induced thermotherapy (LITT) is a safe, feasible

Scientific Sessions

for treatment of retroperitoneal lymph nodal metastases, and can produce total destruction or large areas of necrosis within tumors.

B-409 15:12

Use of multidetector-row CT for the evaluation of E-PTFE covered stent in tips

M. De Rubeis, F. Fanelli, M. Bezzi, M. Corona, A. Bruni, L. Petrucci, A. Pucci, V. Dominelli, R. Passariello; Rome/IT

Purpose: Assess the efficacy of multidetector-row CT (MDCT) in the detection of TIPS malfunction, performed with e-PTFE stent-graft, to avoid the difficulties of Ultrasound-Color-Doppler (USCD) in stent-graft evaluation.

Materials and Methods: Eighty-five patients underwent a TIPS procedure with a stent-graft (Viatorr-Gore). Patients were followed-up with USCD and MDCT at 3-6-12 months; in case of abnormal findings a portogram and intravascular ultrasound (IVUS) were performed. MDCT was done using a multidetector scan (Somatom Volume Zoom-Siemens) at the level of the upper abdomen with 5 mm slice thickness (2.5 mm collimation, 5 mm reconstruction interval); after intravenous administration of 150 ml of iodinated contrast media at 4 ml/s, arterial (30 sec-3 mm slice thickness-2.5 mm collimation-1 mm reconstruction interval) and venous (60 sec-1.25 mm slice thickness-1 mm collimation-1 mm reconstruction interval) phases were acquired.

Results: MDCT was successfully performed in all cases, analysing stent-graft position, shunt patency, hepatic veins and portal vein. Correlation of shunt patency or malfunction between MDCT and USCD was observed in 80/85 patients (94.2%). In 5 cases (5.8%) MDCT indicated the completely shunt patency, not correlate with USCD that showed a mild stenosis of the shunt. Conventional venography and IVUS were then performed confirming the patency of the stent-graft according to the MDCT. Stenosis of the hepatic vein ($n = 8$) and of the portal vein ($n = 4$) were correctly diagnosed and MDCT demonstrated the complete patency of the shunt in 66 patients and shunt occlusion in 2 cases; these data were also evidenced by USCD and venography.

Conclusions: MDCT seems to be a safe and accurate method in the evaluation of stent-graft patency.

B-410 15:21

"Lesions in necrosis phenomenon" in patients with liver metastases of neuroendocrine tumor after thermal ablation

K. Eichler, M.G. Mack, T. Lehnhert, S. Zangos, O. Söllner, C. Herzog, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To analyze the imaging characteristics of the "lesions in necrosis phenomenon" in patients with liver metastases of neuroendocrine carcinoma post treatment via thermal ablation.

Materials and Methods: 28 patients with 102 lesions of neuroendocrine carcinoma were treated with the MR-guided laser-induced thermotherapy (LITT) using a Nd-YAG laser device, liquid irrigated power laser applicators and multiapplicator technique. Local control of tumor was evaluated by unenhanced and contrast-enhanced MR imaging follow-up using T1 and T2 weighted SE and GRE sequences at 3-month intervals following treatment.

Results: Post interventional T1-weighted SE sequence images revealed in 51 lesions an intralesional hypointense area with corresponded exactly to the preinterventional morphology of the liver metastases pre interventional regarding size, shape and morphology within the coagulated necrosis.

Contrast-enhanced T1 weighted image 3 months after laser intervention demonstrated a reduction in the volume of necrosis. Follow-up studies revealed no local recurrence in all treated lesions.

Conclusion: The phenomenon of lesions in necrosis after MR-guided laser-induced thermotherapy (LITT) in patients with liver metastases of neuroendocrine carcinoma should be not misinterpreted as a local recurrence.

Liver metastases on serial contrast-enhanced MDCT examinations.

Retrospective analysis of the previous examination: Were they detectable?

S. Tresoldi, I. Borzani, C. Valsecchi, M. Midulla, N. Flor, F. Sardanelli, G.P. Cornalba; Milan/IT

Purpose: To verify the detectability of liver metastases on serial contrast-enhanced multidetector CT examinations.

Material and Methods: A series of 12 (age 63.8 ± 7.7 years) patients with known diagnoses of a primary cancer (colon=5; lung=2; pancreas=1; stomach=1; melanoma=1; small bowel=1; non-Hodgkin lymphoma=1) who had undergone at least 4 contrast-enhanced 4-detector MDCT examinations (100-130 ml of non-ionic iodined contrast agent at 3 ml/sec, precontrast and portal venous phases) entered a retrospective study. When a metastasis was prospectively first reported, a retrospective evaluation of the previous MDCT examination was done by two readers by consensus in order to define whether the lesion was detectable, detectable only for minimal signs, undetectable or misdiagnosed as benign lesion.

Results: A total of 88 hypovascular metastases (diameter 13.7 ± 8 mm) were analyzed. Evaluating the previous exam (performed 1-14 months before, mean 3.7 ± 1.8), we defined that the metastases were; detectable ($n = 8$); detectable only for minimal signs, ($n = 5$); undetectable ($n = 74$) or misdiagnosed as a benign lesion ($n = 1$). The minimal signs group was comprised of 4 small (< 5 mm in diameter) hypodense foci and 1 calcification. The benign misdiagnosis was a hemangioma.

Conclusions: An important fraction (13/88 = 15%) of liver metastases were prospectively not reported but retrospectively detectable (8/88 = 9%) or visible as minimal signs (5/88 = 6%), while only less than 1% (1/88) were misdiagnosed as a benign lesion. In patients with known primary cancer, attention should be paid not to miss lesions which are judged as detectable metastases at a retrospective analysis.

B-412 14:09

Prospective evaluation of multi-detector CT (MDCT) for treatment decision making in pancreatic adenocarcinoma

H. Furukawa, K. Uesaka, N. Boku; Shizuoka/JP

Purpose: The usefulness of multi-detector computed tomography (MDCT) in selecting the treatment for patients with pancreatic carcinoma was prospectively evaluated.

Methods and Materials: When a patient with a suspicion of pancreatic carcinoma was referred to our hospital, MDCT and laboratory tests were the first examinations to be done, followed by the "pancreatic disease conference" held by surgeons, medical oncologists, endoscopists, and diagnostic radiologists to discuss the treatment plan. When the tumor was classified stage III or higher it was considered "certainly unresectable". When the tumor classification was stage IIB or lower it was deemed "probably resectable". When the tumor included equivocal unresectable findings it was considered as "probably unresectable". When additional information was required at the conference, further examinations were performed. We verified whether the intended treatment was completed or not.

Results: Among 111 patients with pancreatic carcinoma who were enrolled between September 2002 and March 2004, 41 cases were classified as "probably resectable", 67 as "certainly unresectable" and 3 as "probably unresectable". Thirty-eight of 41 "probably resectable" tumors turned out to be resectable. Among 3 cases that were deemed "probably unresectable" unresectable findings were found during surgery. Nonsurgical treatment was selected for the 67 cases classified as "certainly unresectable". MRCP was recommended for the 53 cases for gathering additional diagnostic information. Both EUS and ERCP were performed in 10 cases and angiography in 1.

Conclusion: MDCT provides reliable information for staging of pancreatic carcinoma. This noninvasive technique will replace other staging methods that are more invasive.

Heidelberg score of vascular invasion for pancreatic cancer

T. Marinelli¹, A. Filippone¹, L. Grenacher², G. Kauffmann², G.M. Richter²,
¹Chieti/IT, ²Heidelberg/DE

Purpose: To create a new score for venous invasion in patients with potentially resectable pancreas adenocarcinoma using Computed Tomography (CT) for better assessment of potential outcome.

Materials and Methods: 56 patients with pancreatic adenocarcinoma who underwent surgical therapy were included. All patients underwent CT-scan according to a standard protocol. Resection was curative (R0) in 37 patients (66%). Tumour involvement of the portal and superior mesenteric veins was retrospectively graded on a new four-point scale based on the following CT-criteria: length of venous tumour contact; circumferential venous involvement; degree of venous stenosis and tumour convexity towards the vessel. The four-point scale was divided as following: 1-definite absence of invasion; 2-probable absence of invasion; 3-probable presence of invasion; 4-definite presence of invasion.

Results: Our score achieved a sensitivity of 80%, specificity of 96% and an accuracy of 93% in the evaluation of portal vein and a sensitivity of 100%, a specificity of 94% and an accuracy of 95% in the evaluation of the superior mesenteric vein. Considering surgical results for the parameter of portal vein infiltration 76% of patients with score 1-2 underwent a curative R0-resection meanwhile only 21% of patients with score 3-4 had a curative operation. Similar data were obtained for superior mesenteric vein infiltration: 76% of R0-resections in patients with a score 1-2 and 40% of curative resections for patients with a score 3-4.

Conclusions: Our Heidelberg score can predict a high risk of invasion in potentially resectable pancreatic cancer and achieve a high probability of determining resectability vs. non-resectability.

B-414 14:27

Prospective comparison of multislice-CT versus MR imaging in the diagnosis and staging of pancreatic carcinoma

M. Klauß, L. Dukic, S. Delorme, H.-P. Knaebel, H.-U. Kauczor, M.W. Büchler, G.W. Kauffmann, G.M. Richter, L. Grenacher; Heidelberg/DE

Purpose: To investigate the value of multislice-CT versus MR imaging in diagnosis and staging (resectability) of pancreatic carcinoma in a prospective multireader-analysis.

Material and Methods: 50 patients suspected of having a pancreatic carcinoma underwent both multislice-CT (4-row, hydro-technique) and MR imaging (1.5 T). For both modalities examination times were recorded. Examinations were evaluated by two reader pairs for 1. Diagnostic quality, 2. Lesion detection, 3. Resectability in positive findings and 4. Diagnostic reliability. A Kappa analysis was made to determine the observer variations. The gold standard was either postsurgical histopathological findings or clinical follow-up (6 months).

Results: In a total of 28 patients a pancreatic lesion was detected. Group 1 achieved 100% sensitivity for lesion detection by CT (specificity 77%) versus 73% at MR imaging (specificity 77%). Group 2 achieved 89% sensitivity at both modalities (specificity 77% at CT, 73% at MRI). For the subgroup of pancreatic adenocarcinomas (n = 17) we found an overall sensitivity of 100% (specificity 67%) at CT versus a sensitivity of 82% (group1)/94% (group 2) at MR imaging (specificity 67%/61%). In determining resectability CT achieved a sensitivity of 91%/82% versus 90%/82% in MR imaging. The Kappa analysis showed a good correlation in CT (0.71) and a moderate correlation in MR imaging (0.49). The average examination time for CT was 15 minutes and for MR imaging 45 minutes respectively ($p < 0.001$).

Conclusion: MR imaging and multislice-CT performed equally well for lesion detection and in the assessment of resectability. Therefore, the preference of CT for patients suspected of having pancreatic cancer is supported because of its lower costs and shorter examination time.

B-415 14:36

Multidetector CT in the assessment of pancreatic malignant masses

C. Cappelli, S. Mazzeo, D. Caramella, A. Belcari, G. Caproni, D. Campani, U. Boggi, C. Bartolozzi; Pisa/IT

Purpose: To evaluate the role of multidetector CT in the assessment of pancreatic malignant masses.

Methods and Materials: The study includes 86 patients submitted to surgical resection or biopsy for pancreatic malignant mass. We retrospectively analysed the multidetector CT images to evaluate the enhancement of the pancreatic masses compared to normal pancreatic parenchyma. Results were correlated

with the histopathological finding. CT studies were done before and after 120 ml of highly concentrated contrast medium in pancreatic (35") and venous phases (70"). The post-contrast enhancement of the lesions was evaluated in the pancreatic phase and four CT patterns were identified: hypodense, hyperdense, isodense and mixed.

Results: The histopathological results demonstrated: 65 ductal adenocarcinomas, 5 neuroendocrine lesions, 6 mucinous carcinomas, 6 metastases (2 breast, 4 kidney) and 4 other lesions. The hypodense pattern was observed in 60/65 (92%) ductal adenocarcinomas, 2/6 (33%) mucinous carcinomas and 2/5 (40%) neuroendocrine lesions. Hyperdensity was present in 1/65 (1.5%) ductal adenocarcinomas, 3/5 (60%) neuroendocrine carcinomas and 5/6 (83%) metastases. Only 2 cholangiocarcinomas and 1 metastasis appeared isodense. The mixed appearance was demonstrated in 4/65 (6%) ductal adenocarcinomas, 4/6 (67%) mucinous carcinomas and 1 case of pseudopapillary solid carcinoma.

Conclusion: In our experience multidetector CT is accurate in characterizing pancreatic malignant masses, and the CT enhancement pattern can be related to the histopathological type. The hypodense pattern is not only observed in ductal adenocarcinomas. When a hyperdense appearance is observed, a neuroendocrine or metastatic lesion must be suspected, while the mixed presentation suggests a mucinous lesion.

B-416 14:45

Value of single-phase multidetector CT in patients with suspected pancreatic tumor

M. Imbriacò, S. Maurea, C. Mollica, S. Bortone, M. Volpe, G. Buono, M. Salvatore; Naples/IT

Purpose: To assess the diagnostic value of single-phase multidetector CT (MDCT) in patients with suspected pancreatic tumor (PT).

Materials and Methods: Seventy-one patients suspected of having PT underwent MDCT scanning. Scans were performed on a MDCT scanner with 0.5 sec gantry rotation and acquisition of 4 slices per rotation. The unenhanced scan was followed by one set of scans in the caudo-cranial direction from the inferior hepatic margin to the diaphragm with a scan delay of 60 sec after I.V. injection of 150 ml of contrast material delivered at 3 ml/sec. Two readers scored images in a blinded fashion for the presence of tumor and assessment of resectability. ROC analysis was performed.

Results: Final diagnosis was PT in 40 cases and chronic pancreatitis in 31. A_z values for the assessment of tumor detection were 0.97 for reader 1 and 0.95 for reader 2 ($p = n.s.$). A_z values for tumor resectability were 0.90 for reader 1 and 0.89 for reader 2 ($p = n.s.$). No statistically significant differences were observed between superior mesenteric artery and vein opacification with the hepatic parenchyma enhancing at a time closer to the peak hepatic enhancement optimizing the detection of hepatic lesion.

Conclusion: Single-phase MDCT is an accurate technique for the diagnosis and assessment of resectability of patients with suspected PT. This technique provides optimal tumor-to-pancreas contrast, maximal pancreatic parenchymal and peripancreatic vascular enhancement and allows us to explore the entire liver and the whole upper abdomen during the portal-phase for accurate identification of liver metastases and peritoneal seeding.

B-417 14:54

The role of FDG PET and PET/CT in differential diagnostics of pancreatic lesions

J. Votruba, O. Belohlavek; Prague/CZ

Purpose: The aim of our study was to evaluate the usefulness of fluorodeoxyglucose (FDG) PET and PET/CT in the differential diagnosis of pancreatic lesions.

Materials and Methods: Forty-one patients (14 men and 17 women) with a clinical suspicion of pancreatic carcinoma with/without history of chronic pancreatitis underwent FDG PET (21 patients) or PET/CT (10 patients) examinations.

Results: A series of 41 patients was examined in a retrospective study. Twenty-nine patients were confirmed histologically, the others by follow-up (USG, CT and MRI). In the group of patients, who underwent FDG PET examination three cancers showed no pathological FDG uptake and they were considered to be false negative. Two of them were proven as tubular adenocarcinoma by histology and one as non-differentiated carcinoma. There were no false negative findings by PET/CT. FDG uptake was present in 24 of 27 cancers in total (sensitivity 88.9%). In 14 patients with benign lesions no false positive FDG uptake was found by PET or PET/CT (specificity 100%). The overall accuracy of FDG PET and PET/CT was 92.7%. In the subgroup of 10 patients investigated by PET/CT neither false positive nor false negative finding were found.

Scientific Sessions

Conclusion: Our results indicate that FDG PET and PET/CT are both excellent in the differential diagnosis of benign vs. malignant pancreatic lesions. In agreement with previously published data, we registered some limitations of PET alone in detecting FDG non-avid pancreatic tumours. Due to the additional morphological information provided by CT the hybrid PET/CT imaging seems to be even more promising.

B-418 15:03

TNM staging for ampullary carcinoma using thin-section helical CT:

Pathologic correlation with dual-phase CT images

S. Lee, W. Lee, Y. Yim, J. Choi, D. Choi, H. Lim, J. Lim; Seoul/KR

Purpose: To analyze thin-section helical CT findings of ampullary carcinoma (AC) and correlating with pathologic findings for assessing its TNM staging.

Materials and Methods: During 6-years, we collected 50 patients with surgically proven AC who had preoperative dual-phase (arterial (AP) and portal (PP)) thin-section helical CT (M:F=26:24, age range; 35-80 years, mean age; 60 years). All CT images were analyzed retrospectively for the following parameters: the tumor size and shape, the T stage [T2; duodenal invasion, T3; pancreatic invasion, T4; peripancreatic invasion] and the N stage [N1; regional lymph node (LN) metastasis]. Diagnostic values of all parameters were obtained by correlating pathologic results, and overall TNM staging was assessed by using these parameters.

Results: All tumors except six (88%) were detected that ranged from 9.4-40.0 mm (mean, 17 mm) and 80%(40/50) were round in shape. The sensitivity (Se), specificity (Sp) and accuracy (Ac) were 86%, 33% and 58% at AP, and 84%, 31% and 53% at PP for duodenal invasion ($p > 0.05$), were 65%, 74% and 71% at AP, and 64%, 68%, and 67% at PP for pancreatic invasion ($p > 0.05$), and were 38%, 95% 86% at AP and 38%, 95% and 86% at PP for peripancreatic invasion ($p = 0.024$). There was no significant difference between AP and PP for all parameters. A total of 233 LNs [short-axis diameter (< 5 mm; n = 36, 5-10 mm; n = 150, ≥ 10 mm; n = 47)] were detected at CT and 51 LNs (22%) (< 5 mm; n = 1, 5-10 mm; n = 26, ≥ 10 mm; n = 24) have metastasis respectively ($p < 0.001$).

Conclusion: Thin-section helical CT is useful in detecting the primary tumor but has limitations in precisely depicting the pathological TNM stage for AC.

B-419 15:12

Two-phase CT findings of mass-forming intrahepatic peripheral cholangiocarcinoma in cirrhotic patients: Comparison with those in non-cirrhotic patients

S. Yoon, J. Byun, S. Park, H. Won, A. Kim, Y. Shin, P. Kim, H. Ha, M.-G. Lee; Seoul/KR

Purpose: To compare the two-phase CT findings of mass-forming intrahepatic peripheral cholangiocarcinoma (MIPCC) in cirrhotic patients with those in non-cirrhotic patients.

Methods and Materials: We reviewed the two-phase CT findings of MIPCC proven pathologically in 33 cirrhotic patients (range, 27-67 years) and compared with those in 35 non-cirrhotic patients (range, 44-75 years). We evaluated the morphology of the tumors (size, margin and satellite nodules), enhancement patterns and other ancillary findings (capsular retraction, bile duct dilatation, portal vein invasion, lymphadenopathy and extrahepatic metastasis). The enhancement patterns of the tumor were classified as follows: Type 1 - peripheral enhancement during hepatic arterial phase (HAP) and delayed enhancement during portal venous phase (PVP), Type 2 - no enhancement during HAP and PVP, Type 3 - homogeneous enhancement during HAP and wash-out during PVP. We statistically evaluated the difference of the CT findings between two groups using χ^2 test.

Results: There was no statistically significant difference ($p > .05$) between the morphology and ancillary findings in cirrhosis and those in non-cirrhosis. Also, there was no statistical difference ($p = .236$) in the enhancement patterns between cirrhosis (type 1 in 25 patients [75.8%], type 2 in four [12.1%], type 3 in four [12.1%], respectively) and non-cirrhosis cases (type 1 in 22 patients [62.9%], type 2 in 10 [28.6%], type 3 in three [8.6%], respectively).

Conclusion: MIPCC in cirrhotic patients represents the same features as those in non-cirrhotic patients and therefore typical CT features of MIPCC are helpful when we distinguish MIPCC from hepatomas in cirrhotic patients.

Assessment of left ventricular volume and mass in endurance athlete's heart: A cardiac-MR (CMR) and 3D ultrasound study (D-US)

I. Carbone, M. Francone, S. Visconti, A. Ascarelli, S. De Castro, R. Passariello; Rome/IT

Purpose: Extensive endurance training leads to cardiac hypertrophy. The aim of this study was to evaluate the left ventricular masses (LVMs) and volumes (LVVs) of endurance athletes and healthy volunteers and to compare CMR results with 3D-US.

Materials and Methods: Sixteen trained rowers underwent CMR and 3D US within the same day. A control group of 10 healthy untrained volunteers was enrolled in the study. CMR was performed with a 1.5-T system. Nine to 14 short axis on CINE-GRE images, with a sl.thickness of 10 mm and without any interslice gap were acquired for the evaluation LVMs and LVVs. Quantitative analysis including end-diastolic and end-systolic volume (EDS, ESV), ejection fraction (EF), and LVM, was performed off-line using a dedicated software by two blinded radiologist. 3D-US LV measurements were assessed on short axis, and quantitative analysis was blindly performed by 2 cardiologists. The interobserver agreement and results of either CMR and 3D-US were compared.

Results: LV masses and volumes were increased in endurance athletes compared with the healthy volunteers ($40 \pm 6\%$ and $34 \pm 9\%$ respectively). The average athlete's cardiac mass and volumes assessed by MR and 3D-US were respectively: LVM 204.7 g (MR), 210.1 g (3D-US); EDV 209.9 ml (MR), 232.7 ml (3D-US); ESV 85.8 ml (MR), 91.6 ml (3D-US). The interobserver agreement was almost perfect for either MR ($K=0.92$) and 3D-US ($K=0.86$).

Conclusions: CMR have shown that endurance athlete's heart has increased volumes and masses, compared with an healthy volunteer. 3D-US seems to be an interesting modality in the evaluation of LVVs and LVMs.

B-421 14:09

Comparison of contraction pattern of the normal right ventricle using cine magnetic resonance imaging in transaxial plane versus long axis plane

J. Fritz¹, M. Solaiyappan¹, C. Bomma¹, H. Tandri¹, J.A.C. Lima¹, C.D. Claussen², D.A. Bluemke¹; ¹Baltimore, MD/US, ²Tübingen/DE

Purpose: Transaxial images of the right ventricle (RV) may be difficult to interpret due to the double oblique orientation of the heart. Differences and description of RV contraction pattern as visualized in transaxial plane versus horizontal long axis (HLA) plane, which is orientated to the heart axis are introduced.

Material and Methods: 30 normal volunteers (13 females, 27 ± 7 years) were imaged using cine MR imaging in axial and HLA plane. Contraction patterns of the RV were qualitatively assessed in cine mode by two observers and compared to the calculated subtended angle between corresponding axial and HLA planes. Multiplanar reformation was used to directly visualize detected differences between corresponding planes by continuous rotating transition.

Results: On axial images, focal outpouching in the apical third of the anterior RV free wall during systole (bulging) was seen in 17/30 (57%) cases compared to 3/30 (10%) on HLA images. In volunteers with subtended angles between 30° - 40° , bulging was diagnosed in 9/18 (50%) cases on axial images whereas HLA views were normal. In volunteers with subtended angle $> 40^\circ$, bulging was always identified on axial images. Multiplanar reformation revealed that the appearance of bulging were due to increased portions of the right ventricular outflow tract, that were increasingly visualized with increasing subtended angle on axial images compared to HLA images.

Conclusions: Contraction pattern of the normal RV is substantially different on axial compared to HLA view. HLA view can add valuable information in order to avoid misdiagnosis of functional RV variations as abnormalities by axial MR imaging only.

Functional and metabolic evaluation of the left ventricle of sprinters, middle distance and endurance elite track runners in the resting state by magnetic resonance imaging (MRI) and ^{31}P -MR spectroscopy (^{31}P -MRS)

A. Esposito, F. De Cobelli, G. Perseghin, P. Scifo, T. Canu, A. La Torre, L. Luzi, G. Alberti, A. Del Maschio; Milan/IT

Purpose: Our aim was to test whether different exercise training habits may influence the functional and metabolic status of the left ventricle (LV) of elite track runners.

Methods and Materials: 7 sprinters (SR:100-200 m), 7 middle distance runners (MDR:400-800 m), 11 endurance runners (ER:marathon) and 13 normal control subjects (NCS) underwent cardiac-MRI and ^{31}P -MRS with a 1.5 T-magnet (Gyroscan Intera; Philips Medical System). LV mass, volume and systolic function were determined by cine-balanced-FFE sequence. The parameters of LV diastolic function were obtained by analysing the trans-mitral flow with 2D-cine Phase-Contrast sequence. Phosphocreatine (PCr) to ATP myocardial ratio (PCr/ATP) was calculated by ^{31}P -MRS, performed by means of 10 cm-diameter surface coil. PCr/ATP was normalized for LV mass.

Results: The LV mass (SR:157 \pm 17, MDR:159 \pm 28, ER:167 \pm 31 vs NCS:129 \pm 16 g; $P < 0.01$) and the end-diastolic volume (SR:158 \pm 24, MDR:157 \pm 12, ER:161 \pm 33 vs NCS:137 \pm 22 ml; $P < 0.05$) were significantly higher in the athletes compared to normal subjects. There were no differences between the four groups regarding the LV mass to volume ratio (SR:0.99 \pm 0.13, MDR:1.02 \pm 0.16, ER:1.07 \pm 0.26, NCS:0.95 \pm 0.12) and the LV ejection-fraction (SR:63 \pm 6, MDR:59 \pm 8, ER:60 \pm 8, NCS:64 \pm 5%).

Early-to-Atrial peak filling rate ratio (E/A) was apparently higher in sprinters compared to normal subjects and middle distance runners but not compared to endurance runners (SR:3.7 \pm 1.0, MDR:2.6 \pm 0.4, ER:2.9 \pm 0.9, NCS:2.6 \pm 0.7; $P = 0.05$). Deceleration time was not different among study groups (SR:176 \pm 34, MDR:173 \pm 25, ER:192 \pm 28, NCS:177 \pm 36 ms). PCr/ATP corrected for LV mass did not differ among groups (SR:1.48 \pm 0.42, MDR:1.24 \pm 0.14, ER:1.46 \pm 0.28, NCS:1.47 \pm 0.30).

Conclusions: Despite different exercise training programs and increased LV wall mass, elite track runners showed normal LV function and normal high-energy phosphates metabolism.

B-423 14:27

Evaluation of parameters that effect QRS duration in patients after surgical repair of fallot determined by magnetic resonance imaging (MRI)

M. Grothoff, B. Spors, H. Abdul-Khalil, R. Felix, M. Gutberlet, M. Gutberlet; Berlin/DE

Purpose: To evaluate those right and left ventricular parameters which have the greatest effect on genesis of cardiac arrhythmias in patients after surgical repair of tetralogy of fallot (TOF).

Methods: 67 pts. were studied using a 1.5 T Gyroscan (Philips). Mean age at surgical repair was 6.8 years. Valveless repair with patch was performed in 34 patients, in 33 patients a conduit was used. Volumetry was performed with a SSFP-sequence with breathhold or respiratory gating. We obtained left and right ventricular volumes, ejection fractions and myocardial masses. To quantify regurgitation fraction (RF) we performed a phase contrast measurement in the main pulmonary artery in a transverse section. Acquired data was evaluated in an univariate and multivariate regression analysis.

Results: Flow-measurement showed 42 mild to moderate and 12 severe cases of regurgitation. Significant correlation was found between RF and QRS duration ($r = 0.49$; $p < 0.01$). RV end-diastolic volume index was correlated to RF ($r = 0.46$; $p < 0.001$) and QRS-duration ($r = 0.29$; $p < 0.05$). A further correlation was found between right- and left-ventricular EF ($r = 0.54$; $p < 0.01$). In the multivariate data analysis QRS-duration showed close relation to: 1. RF, 2. time since surgical repair 3. left ventricular end diastolic volume index and 4. a negative correlation to age at first surgical repair.

Conclusion: Pulmonary regurgitation has a great effect on QRS-prolongation. MRI flow-measurement can quantify regurgitation fraction exactly and is therefore an ideal method for follow-up examinations. In addition to right ventricular parameters also secondary impairment of left ventricular function seems to affect prognosis after correction of TOF.

B-424 14:36

MR evaluation of cardiac function in one breath hold with real-time true fast imaging with steady-state precession and parallel acquisition techniques

X. Zhao, K. Li, Y. Li; Beijing/CN

Purpose: To evaluate cardiac function using a real-time cine technique with parallel imaging algorithms.

Methods: Ten healthy volunteers and ten patients with cardiac diseases were enrolled in the study group. The subjects underwent cardiac cine MR imaging using real-time multislice cine trueFISP with iPAT. Data acquisition was performed in a single breath-hold along the short axis. Evaluation of end-diastolic volume (EDV), end-systolic volume (ESV), stroke volume (SV), ejection fraction (EF) and myocardial mass was performed and results were compared to a standard segmented single-slice cine trueFISP. Combination of real-time cine trueFISP and iPAT provided a temporal resolution of 52.8 ms. Data acquisition of a 192 x 72 matrix was completed in 6.4-7.2 s. Ventricular volume and mass were evaluated by two observers independently with manual tracing.

Results: Real-time True-FISP cine quality was sufficient for contour detection in all 20 subjects. Measurements based on real-time True-FISP cine with iPAT correlated well with those based on single-slice cine True-FISP [left ventricular (LV) EDV: $r = 0.996$; LV ESV: $r = 0.918$; LV SV: $r = 0.970$; LV EF: $r = 0.929$; LV mass: $r = 0.999$. No significant differences could be found. The use of parallel acquisition techniques (iPAT) allow for a substantial improvement of temporal resolution in real-time cine MR imaging. Intra- and interobserver variability were sufficiently small in real-time True-FISP cine with iPAT.

Conclusion: Real-time True-FISP cine with iPAT techniques in one breath-hold has high reproducibility and is applicable to patients with severe cardiac dysfunction and/or arrhythmias.

B-425 14:45

Contribution of early systole to total forward flow volume in breath-hold phase-contrast flow measurements

R.P. Kunz, F. Oellig, F. Krummenauer, K. Oberholzer, M. Thelen, K.-F. Kreitner; Mainz/DE

Purpose: To evaluate the contribution of early systole in the assessment of antegrade aortic flow volume by breath-hold velocity-encoded MR flow measurements.

Materials and Methods: Expiratory breath-hold fast low-angle shot phase-contrast flow measurements (temporal resolution tRes 61 msec, shared phases) perpendicular to the proximal ascending aorta and short-axis true fast imaging with steady-state precession (TrueFISP) cine MR ventriculometry (tRes 34.5 msec) were performed in ten healthy male volunteers on a 1.5 T MR system. Antegrade aortic flow volume (AFV) and left ventricular stroke volume (LV-SV) were evaluated using Argus MR 2002B software (Siemens Medical Solutions). A beta release of Argus MR 2004A allowed interpolation of the flow up-slope during early systole to the preceding R-wave trigger. The respective intraindividual median differences between AFV of each flow evaluation and LV-SV and between both AFV measurements were calculated and compared using the sign test for paired samples.

Results: Non-interpolated AFV significantly deviated from LV-SV ($p = 0.002$) underestimating the latter by 13.1 mL. Interpolating aortic flow during early systole significantly increased AFV by 10.8 mL compared to the flow evaluation that did not take early systole into account ($p = 0.002$). AFV with interpolation of early systolic flow agreed well with LV-SV (median difference -3.0 mL), and no significant difference between these measurements was found ($p = 0.344$).

Conclusion: Flow during early systole contributes tremendously to total forward flow volume in the ascending aorta. Interpolation of the early systolic up-slope is therefore recommended for the evaluation of breath-hold phase-contrast flow measurements.

B-426 14:54

Automatic determination of quiescent cardiac motion phases for CT imaging: Initial experience

M.H.K. Hoffmann¹, J. Lessick², M. Robert³, F. Schmid¹, A. Aschoff¹, M. Grass³; ¹Ulm/DE, ²Haifa/IL, ³Hamburg/DE

Purpose: Temporal resolution of cardiac multi-detector row CT is limited. Therefore quiescent motion phases of the cardiac cycle have to be detected to succeed with artifact-free imaging. Currently, low-motion phases are detected manually in a time consuming user-dependent selection process. This study reports initial experience with a semi-automatic tool ("motion-map") to provide guidance for the selection process.

Scientific Sessions

Method and Materials: 20 consecutive patients were included in the study. Low motion phases of the coronary tree were determined by usual user-dependent selection. 20 phases equally distributed over the cardiac cycle were reconstructed. Manually determined phase selections were compared to semi-automatic phase selection on the basis of a motion map. The motion map is derived from similarity measures calculated on 50 different phases of low spatial resolution reconstructions. Low motion phases of the cardiac cycle can be detected with a minima search applied. Manual and semi-automatic selection were compared. A quantitative comparison was conducted with a Bland-Altman analysis. A qualitative comparison relied on a side-by-side analysis of images generated with the two methods. Images were assessed for accurate delineation of the coronary vessel lumen. Interobserver variability was evaluated by simple Kappa analysis.

Results: A high level of agreement was found for percentage phase selection achieved with the two methods (mean difference 1.07%; 95%CI: -3.6-5.8%). Side-by-side comparison of image quality showed matching results of the two methods in 85%(17/20) of the cases. Interobserver agreement was good (kappa = 0.8).

Conclusions: Similarity measures and derived motion maps allow semi-automated quiescent phase detection of the cardiac cycle.

B-427 15:03

Determination of right ventricular volumes and function using multidetector row CT. Comparison with MR imaging

A. Lembcke, C. Klessen, M. Dewey, T. Elgeti, B. Hamm, D. Kivelitz; Berlin/DE

Purpose: To validate right ventricular (RV) measurements obtained from multidetector row CT (MDCT) in comparison with MR imaging.

Methods and Materials: Prior to cardiac surgery, 25 patients (among them 12 subjects with compromised RV function) underwent standardized contrast-enhanced, electrocardiogram-gated 16-detector row CT (Aquilion, Toshiba; maximum rotation speed 400 msec, effective acquisition time per cardiac cycle 123.8 ± 37.4 msec using multisegmental reconstruction) and MR imaging (Magnetom Vision, Siemens, repetition time 80-100 msec resulting in an effective acquisition time of 40-50 msec) RV end-diastolic, end-systolic and stroke volume (EDV, ESV, SV), ejection fraction (EF), and mass were calculated using 5 mm axial slices according to the slice summation method. Measurements were compared using Pearson's correlation coefficient, paired Student's t-test, and Bland-Altman analysis.

Results: The RV was completely visualized with invariably acceptable image quality on all MDCT and MR images. For all parameters a close correlation between MSCT and MR imaging was found (EDV: $r = 0.93$; ESV: $r = 0.95$; SV: $r = 0.91$; EF: $r = 0.96$; mass: $r = 0.94$; $p < 0.05$ each) and limits of agreement were in an acceptable range (EDV: -30.6 to 32.2 ml; ESV: -17.5 to 22.5 ml; SV: -19.8 to 15.8 ml; EF: -9.6 to 6.8%; mass: -16.8 to 12.0 g). Mean SV and EF obtained from MDCT were slightly lower compared to MR imaging, however these differences were not statistically significant ($p > 0.05$ each).

Conclusions: Despite its lower temporal resolution, MDCT seems to be an adequate technique for evaluating RV parameters, when compared with MR imaging.

B-428 15:12

Validation of right ventricular systolic function using multislice CT

H. Dogan, L.J.M. Kroft, J.J. Bax, J.D. Schuijf, A. de Roos; Leiden/NL

Materials and Methods: Data from 15 patients (13 male, 2 female; mean age, standard deviation: 61 year, ± 11) with suspected coronary artery disease were evaluated. These patients had no signs of valvular disease or intra-cardiac shunting on 2D-echocardiography. All patients had undergone contrast-enhanced ECG-triggered cardiac CT by using a 16-slice MSCT scanner (Aquilion 16, Toshiba), without β -blocker preparation. Twenty cardiac phases were reconstructed retrospectively for each investigation. The end-diastolic and end-systolic endocardial ventricular border contours of the right and left ventricles were drawn on axial slices covering the entire right and left ventricles. Ventricular stroke volumes (SV) and the ejection fractions (EF) were calculated. The Pearson correlation coefficient was assessed between the right and left ventricular SV, and between the left ventricular EFs as assessed by MSCT and 2D-echocardiography.

Results: An excellent correlation was found between the right and left ventricular SV as determined by MSCT (Pearson correlation coefficient, $r^2: 0.95$; 2-tailed $p < 0.0001$). In addition, MSCT and echocardiographically derived left ventricular EF showed a good correlation (Pearson correlation coefficient, $r^2: 0.79$; 2-tailed $p < 0.0001$).

Conclusion: Right ventricular systolic function can be accurately assessed by multiphase MSCT.

B-429 15:21

High-resolution multi-slice evaluation of cardiac function with cine SSFP using a dedicated 32-element array-coil and parallel acquisition techniques (PAT)

B.J. Wintersperger¹, S.B. Reeder², S.O. Schoenberg¹, T. Lanz³, O. Dietrich¹, A. Huber¹, M. Nitka⁴, C. Hayes⁴, M.F. Reiser¹; ¹Munich/DE, ²Palo Alto, CA/US, ³Würzburg/DE, ⁴Erlangen/DE

Purpose: The purpose of this study was to implement a high-resolution multi-slice cine SSFP technique with PAT using a newly developed dedicated 32-element cardiac array coil on a 32 receiver channel MR scanner system.

Material and Methods: 6 volunteers and 12 patients underwent cardiac imaging on a 32-channel 1.5 T scanner (Magnetom Avanto; Siemens) using a dedicated 32-element array-coil (RAPID Biomedical). Retro-gated Cine SSFP (2.2/1.2; 75°) was performed in multiple axis acquiring 5 slices in a single breath-hold. Data sampling (PAT) used GRAPPA (Factor 4) and allowed a temporal resolution of 48 ms and a spatial resolution of 2.2x1.8 mm (matrix 192). For comparison, identical slice orientations at identical parameters were acquired using a single-slice retro-gated cine SSFP without PAT (nonPAT) in consecutive breath-holds. Image data was compared regarding SNR and CNR as well as data acquisition length.

Results: Acquisition time per slice was significantly shorter for PAT compared to nonPAT (3 vs. 7 hb; $P < 0.001$). Myocardial SNR (11.5 ± 3.0 vs. 16.2 ± 1.8 ; $P = 0.005$) and SNR of the LV cavity (49.7 ± 18.8 vs. 75.9 ± 21.2 ; $P = 0.001$) were significantly lower for PAT. Myocardium/cavity CNR was 38.2 ± 17.4 for PAT and 59.7 ± 21.6 for nonPAT ($P = 0.0015$). Visual evaluation of PAT images did not reveal significant artifacts.

Conclusion: PAT using a dedicated 32-element coil system allows for significant speed up of data acquisition in cine imaging using high acceleration factors. Although with high acceleration factors a significant decrease in SNR and CNR comes along, based on the intrinsic high SNR in SSFP techniques, image quality remains acceptable for evaluation of cardiac function.

Interictal patterns of perfusion MR imaging in temporal lobe epilepsy

I. Huynh¹, V. Bouilleret¹, P. Masnou¹, P. Charlier², P. Lajaunesse¹, D. Ducreux¹; ¹Le Kremlin-Bicêtre/FR, ²Lille/FR

Purpose: To evaluate interictal MR Perfusion Weighted Imaging (PWI) patterns in patients with refractory temporal lobe epilepsy.

Materials and Methods: We prospectively studied on a 1.5 T MR scanner 13 patients with refractory temporal lobe epilepsy and 10 healthy volunteers using conventional T2-weighted sequences and T2* EPI sequences with Gadolinium bolus injection. Maps of Cerebral Blood Volume (CBV) and Cerebral Blood Flow (CBF) were calculated in volunteers and patients on which Region of Interest (ROI) were drawn on the Centra Oval, Thalamus, Hippocampal grey and white matter. Statistical correlations were performed using Z score analysis between volunteers and patients ($|Z| > 2$, $p < 0.02$), and PWI results were correlated with the clinical and electronic data.

Results: CBV and CBF measurements in volunteers were similar to those previously reported in normal grey and white matters. All patients had abnormal perfusion areas of hypo (decreased CBV and CBF) and/or hyperperfusion (increased CBV and CBF) and/or stasis (increased CBV, normal or decreased CBF). Eleven patients (85%) had PWI abnormalities correlated to the clinical and electronic data. All these patients had ipsilateral hippocampal PWI abnormalities, either on the grey ($n = 7$) or white ($n = 10$) or both ($n = 5$) matters, and also on the contralateral hippocampus. Eight patients (73%) had stasis remote from the temporal lobe in centra ovale ($n = 8$) and in the thalamus ($n = 1$).

Conclusion: PWI highlighted interictal brain perfusion remodelling in refractory temporal lobe epilepsy that not only involves the hippocampal areas but also affects remote grey and white matter structures.

Improved detection and localization of focal cortical dysplasia by voxel-based 3D MR imaging analysis

H.-J. Huppertz¹, C. Grimm², S. Fauser¹, J. Kassubek³, J. Spreer¹, A. Schulze-Bonhage¹; ¹Freiburg/DE, ²Basle/CH, ³Ulm/DE

Purpose: Focal cortical dysplasia (FCD), i.e. neuronal derangement due to developmental malformation, is a frequent cause of pharmaco-resistant epilepsy and can be difficult to detect in MR imaging. We present three novel post-processing techniques which improve lesion detection by enhancing image properties not readily accessible by visual analysis.

Methods and Materials: Following the principles of voxel-based morphometry, a T1-weighted MR imaging volume data set is normalized and segmented using algorithms of SPM99 (Statistical Parametric Mapping Software). The distribution of gray and white matter is analyzed on a voxelwise basis and compared with a normal database. Based on this analysis, 3-dimensional maps are created which characterize different features of FCD, i.e. abnormal thickness of the cortical ribbon, abnormal extension of gray matter into white matter, and blurring of the gray - white matter junction. These methods were applied to the MR imaging data of 25 epilepsy patients with histologically proven FCD. In each feature map the locations of the maximum deviations from the normal database were automatically determined and compared with the sites of the lesions or - in case of cryptogenic epilepsy - with the subsequent resections in the conventional MR imaging.

Results: With all feature maps combined, this approach was able to identify 23 out of 25 dysplastic lesions, four of which had totally or partly not been recognized in conventional MR imaging despite acquisition and assessment in a tertiary epilepsy center.

Conclusion: The automated post-processing of MR imaging presented here facilitates the detection of FCD and increases the sensitivity of MR imaging.

B-433 14:18

Temporal lobe epilepsy - correlation analysis of MR imaging volumetry, ¹H MRS and PET

H. He, T. Shen, X. Feng; Shanghai/CN

Purpose: To discuss the etiology of temporal lobe epilepsy (TLE) and the mechanism of ¹H MRS and PET abnormality by correlation analysis of MR imaging volumetry, ¹H MRS and PET results of 20 patients.

Materials and Methods: 20 patients with hippocampal sclerosis verified by operation and pathology were studied. MR imaging volumetry, ¹H MRS and PET were performed before surgery. The asymmetry index (AI) of hippocampal volume of both sides, AI of NAA/(Cr+Cho) ratio and AI of glucose metabolism of both temporal lobes were calculated. Correlation analysis of them was made respectively.

Results: The AI of hippocampal volume of 20 patients was $-27.14\% \pm 24\%$ ($-77.81\% \text{--} 7.63\%$). The AI of NAA/(Cr+Cho) ratio was $-19.45\% \pm 10.37\%$ ($-41.86\% \text{--} 3.08\%$). The AI of glucose metabolism of the medial temporal region was $-6.39\% \pm 8.61\%$ ($-21.76\% \text{--} 7.65\%$). The AI of glucose metabolism of the medial temporal region was found to be statistically related to the AI of NAA/(Cr+Cho) ratio and the AI of hippocampal volume, respectively ($r = 0.50, p = 0.029; r = 0.56, p = 0.011$).

Conclusions: MR imaging volumetry, ¹H MRS and PET are different methods to evaluate TLE. They reflect the structural abnormality, pathophysiology and metabolic changes of the brain, respectively. The correlation of them helps to understand the etiology of TLE and the mechanism of ¹H MRS and PET abnormality.

B-434 14:27

MR imaging segmentation in diagnosis and clinical correlations of temporal lobe epilepsy

H. He, T. Shen, X. Feng; Shanghai/CN

Purpose: To study the different patterns of hippocampal atrophy by MR imaging segmental analysis and to investigate the etiology and pathogenesis of temporal lobe epilepsy.

Methods and Materials: Oblique coronal T1W images were obtained perpendicular to the long axis of the hippocampus. The mesial temporal structures are divided into four parts: the amygdala and the hippocampal head, body and tail. We investigated the MR imaging patterns of atrophy in 50 hippocampal

sclerosis patients by MR imaging volumetric measurement and segmental analysis and compared the clinical features and surgical outcomes of different groups.

Results: Diffuse hippocampal atrophy was found in 22 of 50 patients (44%), 5 of the 50 patients showed diffuse atrophy involving both the amygdala and hippocampus. 20 of 50 patients (40%) had hippocampal focal atrophy and 8 of 50 patients (16%) had no obvious atrophy. 76% of those with hippocampal sclerosis had atrophy in the hippocampal body, 58% had hippocampal head atrophy, 48% had hippocampal tail atrophy and the least involved part was the amygdala (16%). 10 patients who had normal hippocampal volume showed focal hippocampal atrophy by segmental analysis. Various patterns of hippocampal atrophy were found to be statistically related to the duration of epilepsy, the frequency of seizure and the outcome of surgery respectively ($P < 0.05$), but not related to the history of febrile convulsions, age of onset and the history of secondary generalized tonic-clonic seizures ($P > 0.05$).

Conclusion: MR imaging segmental analysis can improve the diagnostic sensitivity of temporal lobe epilepsy and help to investigate its etiology and pathogenesis.

Supratentorial intra-axial brain tumors: Physiological MR imaging in diagnosis and preoperative planning

C.-V. Salvan, J.L. Ulmer, W.M. Mueller, K.M. Schmainda, R.W. Prost; Milwaukee, WI/US

Purpose: To present the potential of physiological MR imaging techniques in the diagnosis and preoperative planning of supratentorial intra-axial brain tumors.

Methods and Materials: Physiological MR Imaging techniques; BOLD functional MR imaging (fMRI), Diffusion Tensor Imaging (DTI), Fractional anisotropy (FA), Perfusion MR imaging and MR Spectroscopy were used in addition to standard MR imaging in the diagnosis and preoperative planning of 15 patients with supratentorial intra-axial brain tumors. Cortex and white matter tracts as part of eloquent networks, tumor angiogenesis, normal and pathological metabolites were assessed and integrated in the diagnosis and the impact on preoperative planning was defined. Contingent surgical risks and postoperative neurological deficits were suggested as well.

Results: Functional MRI established the relationship between brain tumor and sensori-motor, language and/or visual cortex. The displacement, involvement or destruction of white matter tracts was specified by Fractional anisotropy and color-coded maps. Total and microvascular regional cerebral blood volume was predictive for tumor grade and intraoperative complications. MR Spectroscopy confirmed the distribution of high mitotic activity. At least one of the physiological characteristics was important in the preoperative planning and risk assessment in each case.

Conclusion: Physiological MR imaging data is complementary and integrative in the diagnosis and preoperative planning of supratentorial intra-axial brain tumors, yielding powerful information to neurosurgeons and optimizing postoperative outcomes.

B-436 14:45

Perfusion MR imaging of cerebral gliomas: Which contrast media and dosage to use

M. Essig¹, S.O. Schönberg², W. Reith³, M. Le-Huu¹, N. Dannenberg¹, K.-P. Lodemann⁴; ¹Heidelberg/DE, ²Munich/DE, ³Homburg a.d. Saar/DE, ⁴Konstanz/DE

Purpose: To compare image quality and signal characteristics of two new generation contrast media for perfusion measurements of cerebral gliomas.

Methods and Materials: 30 patients with histologically confirmed cerebral gliomas (grade II - IV) were examined in a randomized exploratory intraindividual comparative study with dosages of 0.1 mmol/kgbw of MultiHance (Bracco) and Gadovist (Schering). For perfusion MR imaging a multislice gradient-echo EPI sequence was found to be best suited. Imaging parameters, slice positioning and contrast media application were standardized. For the quantitative assessment rCBV and rCBF measurements of tumor, normal gray and white matter were performed. The T2* effect of the contrast agents and dosages was assessed in a ROI analysis. The percentage of signal drop, and the full width half maximum of the signal time curves were quantified. The qualitative assessment focused on the quality of rCBV and rCBF maps.

Results: All perfusion measurements were of good to excellent image quality. The quantitative assessment of the T2* effect presented no significant difference between the two agents. The percentage of signal drop and the FWHM was not different between the contrast agents. For both agents the single dose measurements were sufficient to achieve high quality perfusion maps and yield to good tumor delineation and additional clinical information.

Scientific Sessions

Conclusion: MultiHance proved to be a safe and valuable contrast agent for perfusion imaging in CNS pathologies. It achieved a comparable T2* effect as the higher concentration Gadovist and produces high quality perfusion maps at a cost effective 0.1 dosage.

B-437 14:54

How much can a negative FDG-PET be trusted?

S. Wang¹, K. Ericson², B. Jorgen²; ¹Guangzhou/CN, ²Stockholm/SE

Purpose: To investigate the factors that may affect FDG accumulation in irradiated brain tumour.

Materials and Methods: 10 patients with an initial negative positron emission tomography (PET) finding whose subsequent PET study after a very short time was positive (group I) and 6 surgically confirmed false-negative PET (group II) were traced in a ten year retrospective review. Tumour size, histological types, irradiation parameters and steroid effect were analysed. To define residual radiation effect on fluorodeoxyglucose (FDG) uptake, post-radiotherapy time (from radiotherapy to PET) of group I and II was compared with that of 24 surgically confirmed true-positive PET (group III) and 5 surgically confirmed true-negative PET (group IV).

Results: 80% of transformation (from negative to positive PET finding) in group I happened within 31 weeks. The smallest lesion had a maximal diameter of 1.5 cm on MR. Histological types were similar among groups. Post-radiotherapy times of groups I,II, III, IV were not significantly different ($P > 0.05$). Approximately the same number of patients in group I had steroid treatment close to the initial negative and the subsequent positive PET examination. 5 of 6 patients (group II) did not have steroid treatment before PET examination.

Conclusion: Tumour size, histology types, residual radiation effect or steroid medication was not the single, main cause of false-negative PET.

B-438 15:03

Whole body positron emission tomography (18FDG PET) in patients with brain metastases

M.B. Dolgushin, I.N. Pronin, T.P. Tissen, L.A. Radkevich, A.J. Zayceva, V.N. Kornienko; Moscow/RU

Purpose: Metastases account for a quarter (24%) of all brain tumors. CT and MR imaging are the main diagnostic methods used in the detection of brain lesions. However detecting the primary source of brain metastases with both these methods is difficult. The purpose of our study was to evaluate whole body 18FDG PET in the detection of the primary of brain metastases.

Materials and Methods: 42 patients with CT and MR imaging brains suspicious for metastases and treated surgically were assessed. The given diagnosis has been exposed for the first time at all patients. Diagnostic investigations include CT, CT+CE, MR imaging (T1, T2, T1+CE, FLAIR) and some patient underwent 1H MR spectroscopy and DWI. In all cases the tumor enhanced with contrast media, usually with a ring-like pattern of enhancement suggesting a necrotic component at the center of the lesion with peritumoral edema. Multifocal lesions were detected in 44% of all tumors, and in 22% three or less were detected.

Results: Whole body (PET 18FDG) detected the primary tumors in the following locations: lungs-26%, melanomas-21.5%, breast-10%, uterus-7%, intestinal tract and kidney-5% each, pancreas and stomach-2% each. In 21.5% cases there was no pathological accumulation of glucose in any organs. In these cases the disease was evaluated as a primary brain tumor. However histological examination has shown the metastatic nature in 7%. Such cases were evaluated as brain metastases from an undetected source.

Conclusions: Whole body 18FDG PET was efficient in the detection of primary tumors in 93%.

B-439 15:12

MR imaging guided feature evaluation of characteristic gene expression signatures in glioblastoma multiforme

M.D. Kuo¹, C. Nardini², D. Wang¹, S. Cha³, M. Diehn⁴; ¹San Diego, CA/US, ²Bologna/IT, ³San Francisco, CA/US, ⁴Stanford, CA/US

Purpose: Glioblastoma multiforme (GBM) is characterized by genetic instability and an extremely variable appearance on magnetic resonance imaging (MRI). We sought to determine whether characteristic imaging features of GBM seen on MRI could capture significant alterations in intrinsic gene expression signatures identified by gene expression microarrays.

Methods: 4 imaging parameters were defined *a priori* to reflect fundamental GBM-defining MRI characteristics (degree of contrast enhancement, necrosis, T2 signal, mass effect). MR images (T1, T2, contrast enhanced) of 20 GBMs in 20 patients

were evaluated and scored across these 4 parameters by 2 radiologists in consensus and without knowledge of the genomic information. Unsupervised and supervised analyses were performed for correlation of the imaging parameters against the corresponding matched GBM microarray data (each microarray containing 23,000 clones) to identify relationships between imaging traits and tumor gene expression.

Results: 4/4 imaging traits demonstrated statistically significant correlation with gene expression: degree of contrast enhancement ($P < .01$), necrosis ($P < .01$), T2 signal ($P < .01$) and mass effect ($P < .005$). Further, there was significant enrichment of genes identified by each of the imaging traits in several fundamental GBM gene expression signatures: degree of contrast enhancement was enriched for the hypoxia/angiogenesis ($P = 3.9 \times 10^{-43}$), extracellular matrix ($P = 1.6 \times 10^{-48}$), and immune infiltration ($p = 9.1 \times 10^{-56}$) signatures, and necrosis and mass effect were both enriched for the proliferation signature ($P = 1.6 \times 10^{-14}$ and $P = 3.2 \times 10^{-51}$ respectively).

Conclusion: Radiogenomic evaluation of GBM on MRI can potentially co-localize several characteristic imaging findings to fundamental GBM gene expression signatures and may provide plausible insights into GBM tumor biology based on imaging alone.

Low-dose cardiac imaging with volumetric CT

J. Hsieh, J. Londt, J. Li, B. Hoppel; Waukesha, WI/US

Purpose: Nearly all of the current cardiac CT imaging protocols utilize low-pitch helical scans in order to ensure a complete volume coverage over multiple cardiac cycles. Although this approach is effective, X-ray dose to patient is high. We present a step-and-shoot acquisition for VCT cardiac imaging.

Methods and Materials: On 16-slice scanners, the coverage of the detector is limited to 10 mm for sub-mm acquisition. Helical mode was selected to eliminate the inter-scan delays. For a heart size of 16 cm, the inter-scan delay could be as high as 21 s if a step-and-shoot acquisition is used. However, with 64-slice VCT coverage has been increased to 40 mm. For the same coverage, the inter-scan delay is reduced to 4.2 s. Because the table remains stationary within each data acquisition, the X-ray is turned on only during the desired phase of cardiac cycles. Unlike the low-pitch helical, overlapped regions of X-ray exposure is not present.

Results: The proposed acquisition allows a 67-83% dose reduction when compared to a helical acquisition at pitch 0.3:1 without tube current modulation (the percentage dose saving is higher for lower-helical pitches). Even with an optimal tube current modulation, the dose reduction enabled by the proposed technique is still well above 35%. When combined with advanced cone beam reconstruction techniques, superior image quality is obtained.

Conclusion: With VCT-64 scanners, step-and-shoot acquisition combined with the advanced EKG gating enables a significant dose reduction for cardiac imaging, as compared to the helical mode acquisition. Phantom and clinical studies have confirmed its superior image quality.

B-441 14:09

Clinical evaluation of an 'automatic exposure control' mechanism for dose optimization in multidetector computed tomography

T.H.E.J. Mulkens, P. Bellinck, M. Baeyaert, D. Ghysen, X. Van Dijck, E. Mussel, C. Venstermans, J.-L. Termote; Lier/BE

Purpose: Evaluate dose reduction and image quality of a new automatic exposure control system for multidetector CT (MDCT), based on both z-axis and angular (x-y axis) tube current modulation and compare it with an angular modulation system.

Methods and Materials: In 2 groups of 200 patients, 5 regions (thorax, abdomen-pelvis, abdomen-liver, lumbar spine and cervical spine) were scanned on a 6-MDCT (Somatom Emotion, Siemens, Erlangen, Germany) with this modulation system (CARE DOSE 4D) and compared with 200 patients scanned with an angular modulation system (CARE DOSE). Wilcoxon tests were used for statistical

Scientific Sessions

comparison of dose reduction (reduction of mean mAs level) in these 600 exams, noise level in 200 exams of each modulation system and subjective image quality scores in 100 exams of each modulation system.

Results: Mean dose reduction for the new and angular dose modulation system was respectively: Thorax 20% and 14%, liver 38% and 18%, pelvis 32% and 26%, lumbar spine 37% and 10%, and cervical spine 68% and 16%. These differences were statistical significant. There was no statistical difference in noise and image quality scores, except for cervical spine exams ($p = 0.0002$ and 0.0007), where the angular modulation system scored better. A good correlation between mean mAs level and the body-mass-index of patients was found with the new modulation system, not with the angular modulation system.

Conclusion: An automatic exposure control mechanism for CT, based on real time anatomy-dependent mAs modulation, delivers good diagnostic image quality at significantly reduced dose levels.

B-442 14:18

Organ dose reduction using CT automatic exposure control (AEC): TLD measurements in an anthropomorphic phantom

B.T. Schmidt¹, C.H. McCollough², R. Banckwitz³, M.R. Bruesewitz², C. Suess³, T. Flohr³; ¹Malvern, PA/US, ²Rochester, MN/US, ³Forchheim/DE

Purpose: To measure directly the dose reduction achieved in specific organs within an anthropomorphic phantom by using Automatic Exposure Control (AEC). **Methods and Materials:** An Alderson-phantom was scanned using a 16-slice CT system (Sensation-16, Siemens Medical Solutions). Fifty TLDs were placed in the phantom for each scan. Scans were acquired using our clinical chest (TX) and chest-abdomen-pelvis (CAP) scan parameters. For each protocol, scans were acquired without and with AEC (CareDose4D). After each of the scans, the TLDs were removed and organ doses determined. The dose-length-product (DLP) reported on the scanner console was also recorded.

Results: All dose reductions are reported relative to the dose for scans without tube current modulation. For TX scans, the DLP was reduced by 33% with AEC. The dose in the shoulder region (upper lung) was as much as 26% higher than with no modulation, but in the middle/lower chest region, it was as much as 45% lower. Dose reductions were 33%, 17% and 17% for the breast, thymus and liver, respectively. For CAP scans, AEC reduced the DLP by 38%. The average dose to the lungs, breast, liver, stomach and bladder was reduced by 47%, 63%, 45%, 43% and 14%, respectively. These measured dose reductions correlate well to the effective mAs reductions at the respective anatomic levels.

Conclusion: AEC provides a large dose reduction relative to no tube modulation. However, the dose reduction to specific organs depends strongly on the anatomic region, and may be estimated by the effective mAs value reported at that location.

B-443 14:27

Implementation of automated exposure control (AEC) in a large body CT

practice: Assessment of image quality and dose savings

C.H. McCollough, J.M. Kofler, M.R. Bruesewitz; Rochester, MN/US

Purpose: To compare the image quality and dose resulting from the use of patient-size technique charts and an automated exposure control (AEC) system.

Methods and Materials: Approximately 2200 patients were imaged using an AEC system to adjust the X-ray output according to patient size (CareDose 4D, Siemens Medical Solutions). The reference effective mAs used for thorax (TX) was 170 and for abdomen/pelvis (AP) was 240. Patients were imaged for body indications only. Technologists noted patient size, eff. mAs from our technique chart, average eff. mAs over the entire AEC scan and the eff. mAs for specific anatomic levels. Qualitative image quality (IQ) feedback was obtained from a large number of readers.

Results: Radiologist assessment of image quality of the AEC exams was overall positive. Increased image quality in large patients and streak-prone regions such as shoulders was noted. Concerns regarding an increased noise level at the top of the liver were resolved by a modification of the AEC algorithm by the manufacturer. Relative to our technique charts, average eff. mAs decreased globally by 21%, and 29.7%, 54.8%, 13.2% and 23.2% at the levels of the upper lung, breast, liver, and pelvis, respectively.

Conclusions: The AEC system delivered on average of 21% less dose relative to our technique chart. The AEC system relieved the technologist of the responsibility of measuring and adjusting for patient size. The image quality of the AEC images was judged to be unchanged or improved, relative to non-AEC exams.

B-444 14:36

Apparent discrepancy between image quality and dose (CTDI) in MSCT automatic modulation modality

D. Origgi, S. Vigorito, G. Villa, G. Tosi, M. Bellomi; Milan/IT

Purpose: In a GE Lightspeed 4.X multislice CT, used in the automatic z-modulation modality, we observed a great CTDI variability between similar configurations at fixed noise index (NI). We therefore investigated if a different image quality could justify these dose variations.

Methods and Materials: We acquired a RANDO phantom at fixed NI of 7 for the head protocol and of 11.57 for the thorax protocol at different detectors configurations (16x1.25, 8x2.5-20 mm; 16x0.625, 8x1.25-10 mm) and pitches. We chose the couples of similar configurations with the highest CTDI differences. For each image, tube current adjustments (mAs) were recorded and signal-to-noise ratio (S/R) was measured in a ROI of 841 mm² at the same position.

Results: Series performed at the same slice thickness, collimation and similar pitch, but different detector configurations, showed CTDI variations ranging from 8 to 38% for the thorax and from 9 to 44% for the head in agreement with mAs modulation. The Wilcoxon sign test, performed for each couple of series, has shown always statistically significant differences ($p < 0.005$) for mAs, but not for S/R.

Conclusion: Other studies have already shown dose reduction in the modulation mAs modality compared to the fixed mAs modality, but no investigation has yet been reported about CTDI in the automatic mode. Our results show that unexpected dose variations can be found. This is a very critical point in the choice of a clinical protocol, as a higher dose to the patient doesn't mean better image quality.

B-445 14:45

A tool for fast Monte Carlo-based patient and scanner-specific dose calculations for CT with arbitrary tube current modulation

C. Leidecker, P. Deak, M. Kachelriess, W.A. Kalender; Erlangen/DE

Purpose: To provide a tool for patient-specific estimates of organ dose and effective dose values for arbitrary scan parameters.

Methods and Materials: A Monte Carlo-based simulation tool which we developed in cooperation with VAMP (Moehrendorf, Germany) allows calculation of dose distributions for 3D voxel data sets, from either phantoms or acquired patient CT images. The user can fit the calculation to a specific scanner through specifying the prefiltration and scanner geometry. Additionally, scan-specific parameters can be read in, e.g., the actual tube current used in the scan as a function of projection angle and z-position for arbitrary tube current modulations. Tools for the user to derive dose values for selected volumes of interest are also provided. Thereby, organ doses and effective dose can be computed for arbitrary scan protocols. As an application example, we used ImpactMC to investigate the dose reduction of an automatic exposure control (AEC) in CT [European Radiology 14(2):247, 2004.]

Results: Patient-specific calculations of dose distributions can be performed for arbitrary scanners and scan protocols with ImpactMC. We investigated the effects of varying scan parameters and techniques on the patient dose. E.g., with AEC dose reductions of 10-50% (typically 10-20% higher than the mAs-reduction), depending on patient and scan region, are obtained when compared to a constant tube current.

Conclusion: Dosimetry is an essential element in the management of patient dose from CT in relation to optimization of patient protection. ImpactMC is a convenient tool for patient and scanner-specific calculations of dose distributions.

B-446 14:54

Estimating organ and effective dose from multidetector CT using Monte Carlo simulations: Initial results from voxelized patient models

J. DeMarco¹, C. Cagnon¹, D. Cody², J. O'Daniel², C. McCollough³, M. Zankl⁴, M.F. McNitt-Gray¹; ¹Los Angeles, CA/US, ²Houston, TX/US, ³Rochester, MN/US, ⁴Neuherberg/DE

Purpose: The overall goal of this work is to develop accurate estimates of patient radiation dose from multidetector CT (MDCT) scans using Monte Carlo based simulation methods. The purpose of this work was to use voxelized patient models to estimate organ and effective doses.

Methods and Materials: A detailed mathematical model was developed for an MDCT scanner. The model included a detailed description of the X-ray source (e.g. X-ray spectra and bowtie filter) and geometry factors (e.g. distance from focal spot to isocenter and source movement pattern in helical scans of any pitch). The patient model used was the voxelized adult female (Donna, GSF, Neuherberg, Germany). This model is based on an actual patient scan and has radiosensitive

Scientific Sessions

organs labeled on a voxel-by voxel basis. Simulations were performed using a method to tally dose deposited on an organ-by-organ basis. To obtain initial results, a scan of the thorax was simulated using different pitch values. For each condition, mean organ dose was tallied and used to estimate effective dose.

Results: For most large organs, the mean value varied as 1/pitch as expected. Effective doses were obtained that ranged from 5.23 mSv/100 mAs at pitch 1.0 to 3.48 mSv/100 mAs at pitch 1.5. Other results demonstrated that the effective dose also varied according to 1/pitch.

Conclusion: These initial results demonstrate the ability to perform Monte Carlo based simulations using detailed scanner models and established voxelized patient models to determine organ and effective doses. Future work will include other adult and pediatric models.

B-447 15:03

Extra tube rotations (Z-overscanning) in helical multislice computed tomography of the body: Relative effects on organ doses of the thyroid and testicles, and on effective dose

A.J. van der Molen, J. Geleijns; Leiden/NL

Purpose: To quantify Z-overscanning in multislice CT and to study the relative effects on organ doses and effective dose in dose-optimized protocols of the chest and abdomen.

Materials and Methods: Z-overscanning was quantified by dose measurements on four 16-slice scanners of different vendors. Overscan rotations were derived by varying the number of tube rotations for all collimations at clinically used pitch values. The effect of reconstructed slice width was analyzed at a constant number of tube rotations. Results were applied to dose-optimized volumetric imaging protocols of the chest and abdomen from clinical reference sites. As sensitive organs will lie in the primary radiation beam, relative contributions to organ doses of the thyroid and testes and to effective doses were assessed using the IMPACT dose calculator.

Results: The number of overscan rotations is highly dependent on the image reconstruction algorithm. They decreased with increasing pitch, ranging 2.18-4.37 at low pitch and 0.96-2.23 at high pitch. Collimation had little effect. To accommodate thin and thick slices from the raw data, overscans increase slightly with increasing slice width. In the analyzed protocols the average overscan length was 4.1 cm for chest CT and 4.4 cm for abdominal CT. Thyroid dose increased by $320 \pm 50\%$ while testes dose increased by $127 \pm 4\%$. Effective dose increased $16.5 \pm 0.03\%$ in chest CT and $15.3 \pm 0.04\%$ in abdominal CT.

Conclusion: Overscan number is highly vendor-specific but is lower at increased pitch. These overscans radiate radiosensitive organs and contribute significantly to organ and effective doses.

B-448 15:12

Dose in multislice computed tomography: A comparative study on five scanners and correlation to a recent field study

A.J. van der Molen, J. Geleijns; Leiden/NL

Purpose: Comparative dose measurements were employed to document changes in effective dose in multislice computed tomography (CT) with improvements in scanner technology.

Materials and Methods: Normalized CT dose indexes (CTDI) free-in-air and in 16- and 32 cm dose phantoms were measured on four 16-slice and one 4-slice CT scanners of all major vendors. All available collimation and kVp settings were analyzed. Automatic exposure control was not employed. Results were applied to dose-optimized volumetric imaging protocols from clinical reference sites. Protocols included brain, chest, pulmonary embolism (PE), abdomen and biphasic liver. Effective doses in miliSievert (mSv) were calculated using volumeCTDI, Dose-Length-Product and conversion factors. Results of the 16-slice scanners were correlated with the 2002 German field study on 4-slice scanners. In one hospital a direct comparison between a 16-slice scanner and a 4-slice scanner (Toshiba) could be made.

Results: Effective doses on the 16-slice scanners ranged: Brain sequential 0.8-1.7 mSv, brain helical 1.5-2.7 mSv, chest 3.3-4.5 mSv, PE 2.8-3.0 mSv, abdomen 4.7-6.4 mSv and biphasic liver 7.3-9.2 mSv. Average values were 25-45% lower than averages reported by the German study. In direct comparison with 4-slice CT, effective doses for 16-slice (4-slice) were: Brain sequential 1.6 (1.6) mSv, brain helical 2.0 (3.1) mSv, chest 3.5 (5.5) mSv, PE 3.0 (4.7) mSv, abdomen 5.7 (8.6) mSv and biphasic liver 8.0 (12.4) mSv. Here 16-slice showed a reduction in effective dose of 34-36%.

Conclusion: With improvements in scanner technology, there is a reduction of effective dose in routine CT examinations.

B-449 15:21

Radiation dose to the patient in MSCT: What is the impact in practice of moving to 16 slice scanners?

C. Alvey, S. Mutch, S.J. Golding; Oxford/UK

Purpose: CT is perceived to deliver an increasing collective radiation dose to patients. This has been claimed to be partly due to increasing flexibility of modern technology. Our longitudinal study was carried out to assess the effect of technological upgrade to different levels of MSCT in a typical hospital practice over five years.

Methods and Materials: A longitudinal study was conducted between 1999 and 2004 to assess average dose-length product for typical examinations carried out in a service which moved progressively from single slice systems through 4, 8 and 16 slices on one manufacturer's equipment. Examinations were grouped into categories dependent upon standard clinical applications and mean dose-length products calculated for each phase of technological upgrade.

Results: The study indicates that the improved image quality of MSCT is expressed in significant dose reduction in practice. Common examinations of the trunk show exposure reductions which range between 9 and 30%. Examination of the brain may achieve a dose reduction of 42%. However some examinations, notably CT pulmonary angiography, have shown rising mean exposure. Detailed information showing variability within common applications are presented. The study is ongoing.

Conclusion: Although concern has been expressed that the total collective dose due to CT is increasing significantly, our study indicates that the dose advantage of new technology is realised to a degree in practice. Variation between similar examinations remains a source of concern but some guidelines on further dose reduction may be drawn from our data.

Assessment of the prevalence and severity of carotid artery disease in patients with peripheral arterial disease

A. Drelich-Zbroja, M. Elfurah, T. Jargiello, M. Rzeszowska-Sieczka, M. Szczero-Brojanowska; Lublin/PL

Purpose: The aim of our study was to assess the correlation between severity of peripheral arterial disease and severity of the co-existent carotid artery disease.

Material and Method: 60 patients admitted with peripheral arterial disease (PAD) were included in the study. In every patient lower extremity angiography examination and carotid artery ultrasound examination were performed. Ultrasound examination was done using "ultrasound biopsy" classification to evaluate plaques and using Doppler measurements to assess blood flow hemodynamic changes.

Results: The prevalence of PAD according to TASC was: 15.0% patients had type A, 66.7% patients had type B, 11.7% patients had type C, 6.6% patients had type D. The prevalence of carotid artery disease was: 1.7% patients with 0% ICA stenosis, 68.3% with 1-39% ICA stenosis, 16.6% with 40-59% stenosis, 5% with 60-79% stenosis, 1.7% with 80-99% stenosis and 6.7% had unilateral ICA occlusion. Concerning hemodynamically significant ICA stenosis, that is $\geq 50\%$ or occlusion, the prevalence was 18.3% patients, of these 3 patients had 50-59% ICA stenosis, 3 had 60-79% stenosis, 1 had 80-99% stenosis and 4 had occlusion. The prevalence of carotid disease according to "ultrasound biopsy" classification was: 1.7% for class I, 1.7% II, 35% III, 31.6% IV, 18.3% V, 5% VI, 6.7% VII.

Conclusions: A high prevalence of carotid artery disease had been detected in patients with peripheral arterial disease. No correlation was confirmed between severity of peripheral arterial disease and severity of the co-existent carotid artery disease.

Scientific Sessions

B-451 14:09

Grading of carotid artery stenosis: Should we use estimation or measurement?

A. Waaijer, M.S. van Leeuwen, M. Olree, W. Niessen, M. Prokop; Utrecht/NL

Purpose: To compare accuracy and reproducibility of visual assessment and various objective measurement techniques for determining carotid artery stenosis on multislice CTA.

Materials and Methods: We performed 16-slice CTA in 23 patients with symptomatic carotid stenosis and used selective angiography of 32 carotids as the gold standard. We evaluated four methods for stenosis quantification on CTA: (1) stenosis estimation using 10% intervals; (2) measurement with calipers, using subjectively optimized window settings; (3) measurement with calipers using the Full Width at Half Maximum (FWHM) principle, (4) automatic measurement. Methods 1-3 were performed by two observers and repeated by one. Method 4 was performed twice by one observer. On DSA, carotid stenoses were measured twice by one observer using calipers on the projection showing the narrowest lumen. A Bland-Altman analysis was performed to determine mean intra- and inter-observer differences (bias) and standard deviation of differences (SDD). The same analysis was performed to compare CTA and DSA measurements by using the mean of two observers for CTA and the mean of two DSA readings.

Results: Intra-observer bias and SDD for stenosis grading were -1.7% ± 8.3% for DSA, and 0.9% ± 7.1%, 2.8% ± 8.9%, 1.3% ± 11.3%, and -0.2% ± 9.7% for methods 1-4, respectively. Inter-observer bias and SDD for methods 1-3 were 0% ± 9.7%, 8.0% ± 15.0%, and 8.2% ± 23.8%, respectively. Bias and SDD for comparison of methods 1-4 to DSA readings were 8.3% ± 10.6%, 3.2% ± 11.8%, -6.8% ± 16.6% and -15.4% ± 13.2%, respectively.

Conclusion: Stenosis grading on CTA based on estimation or subjectively using calipers outperformed stenosis grading based on FWHM or automated measurements.

B-452 14:18

Optimization of CT angiography of the carotid artery with a 16-multidetector-row CT scanner: Craniocaudal scan direction reduces contrast material-related perivenous streak artifacts

C. de Monyé, T.T. de Weert, W. Zaalberg, J. Roose, D. Siepman, A. van der Lugt; Rotterdam/NL

Purpose: To compare the effect of a caudocranial and a craniocaudal scan direction on arterial enhancement and perivenous artifacts in 16-multidetector-row CTA of the supra-aortic arteries.

Materials and Methods: Eighty consecutive patients (51 male; mean age = 62; range 28-89 yrs) were scanned in caudocranial (group 1; n = 40) or craniocaudal direction (group 2; n = 40). All patients received 80 mL contrast material followed by 40 mL saline i.v. at 4 mL/sec. Bolus tracking was applied. The attenuation inside the arterial lumen was measured at intervals of 1 second throughout the data set. The attenuation in the superior vena cava (SVC) was measured. Contrast material-related perivenous streak artifacts were graded on a scale of 0 to 3 (0=no; 1=minor; 2=moderate and 3=extensive).

Results: The attenuation in the ascending aorta, carotid bifurcation and intracranial arteries were slightly lower in group 2 versus 1 (231 ± 64 HU, 348 ± 52 HU and 258 ± 48 HU versus 282 ± 43 HU, 381 ± 73 HU and 291 ± 77 HU, respectively; p < 0.05). Also the maximum and mean arterial attenuation were slightly lower in group 2 versus 1 (369 ± 58 HU and 303 ± 48 HU versus 401 ± 71 HU and 334 ± 58 HU, respectively; p < 0.05). The attenuation in the SVC was much lower in group 2 versus 1 (169 ± 39 HU versus 783 ± 330 HU, respectively; p < 0.001). Mean streak-artifact-score was much lower in group 2 versus 1 (2.5 ± 0.6 versus 1.3 ± 0.9, respectively; p < 0.001).

Conclusion: A craniocaudal scan direction results in a slightly lower attenuation of the carotid artery, though still high enough for good evaluation, and a much lower attenuation of the SVC. Streak artifacts are significantly lower. This allows a better evaluation of the ascending aorta and supra-aortic side branches.

B-453 14:27

Optimization of stenosis quantification using 16-row MDCTA in a phantom model simulating soft and calcified plaque material

M. Fruth, M. Finke, K. Schliephake, F. Brassel, K. Papke; Duisburg/DE

Purpose: Quantification of vessel stenoses in CTA is hampered by window dependent blooming of either the plaque material in hyperdense plaques or the vessel lumen in hypodense plaques. It was the aim of our study to optimize stenosis measurements using a window independent method.

Materials and Methods: 110 stenoses from 0.5 to 2.5 mm were placed in tubes

with a diameter of 5 mm, simulating stenoses from 50 to 90% (NASCET method). 55 stenoses consisted of hyperdense material, the other 55 of hypodense material. Tubes were filled with diluted contrast and examined with 16-row MDCTA. Three methods were compared: 1. visual stenosis estimation, 2. diameter measurement with callipers at fixed window setting and 3. window independent quantification with a density profile across the stenosis; the full width at half maximum was taken as the stenosis diameter in soft stenoses, the full width at half the relative minimum between the peaks of the vessel walls was taken in calcified stenoses.

Results: Method 3 had the highest correlation between measurement result and gold standard ($r = 0.93$), as compared to $r = 0.83$ for method 2 and $r = 0.87$ for method 1. The difference between the methods was higher in stenoses with hyperdense plaque material.

Conclusion: Window independent stenosis quantification by using density profiles proved to be significantly more precise than the measurement methods used in clinical routine. We conclude that this method should be applied if a precise determination of the stenotic degree is crucial for clinical decisions, e.g., concerning treatment of carotid artery stenoses.

B-454 14:36

High resolution magnetic resonance angiography with iPAT compared to color Doppler and power Doppler in the assessment of carotid artery stenosis

D.-A. Clevert¹, S. Schoenberg¹, E. Jung², H. Michaely¹, M.F. Reiser¹;

¹Munich/DE, ²Passau/DE

Purpose: To compare the diagnostic accuracy of 3D contrast enhanced MR angiography (MRA) with parallel imaging techniques (iPAT) using a 32-channel MR-system with color Doppler (CD) and power Doppler (PD) in the grading of high grade stenosis of the internal carotid artery (ICA).

Material and Methods: 21 patients with known or suspected ICA-stenosis were examined with a 32-channel 1.5 T MR System with head, neck and spine array coils (Magnetom Avanto, Siemens, Germany) using iPAT sequences. MRA was acquired with a 512 matrix in a 20 second breath hold. Patients received a single i.v. dose of 20 ml gadobutrol (Gadovist®, Schering). MRA were analyzed for caliber irregularities and intravascular thrombi. In CD and PD sonography (Logiq 9, GE), the degree of stenosis (NASCET-criteria), the maximum peak systolic velocity at the stenotic site and the poststenotic flow parameters were evaluated. The degrees of stenosis were compared in MRA, CD and PD.

Results: Using the parallel acquisition technique, excellent visualization of vessels could be obtained in almost all cases. MRA revealed 10/21 stenosis between 70-80%, 7/21 stenosis between 80-90% 4/21 stenosis greater than 90%, which were correctly graded in MRA and CD/PD.

Conclusions: CE MRA with iPAT and PD/CD are highly accurate in the detection and grading of stenoses of the internal carotid artery. While duplex sonography is an excellent screening modality for the internal carotid artery, MRA is helpful for preoperative planning for the carotid internal artery.

B-455 14:45

Internal carotid artery (ICA) stenoses: Color Doppler ultrasound (CDUS), multidetector computed tomography (MDCT), and digital subtraction angiography (DSA) versus intraoperative plaque evaluation

R. Meroni, N. Flor, S. Soldi, L. Caverni, M. De Monti, F. Sardanelli, G.P. Cornalba; Milan/IT

Purpose: To compare CDUS, MDCT, and DSA with an intraoperative gold standard for evaluating ICA stenoses.

Materials and Methods: Twenty-seven ICA stenoses in 24 patients were prospectively studied with CDUS, contrast enhanced 4-row MDCT, and DSA. The stenosis rate was calculated using: CDUS with diameter (CDUS-d) or area method (CDUS-a); MDCT with area method on multiplanar reconstructions perpendicular to the vessel axis; DSA with NASCET diameter rate (DSA-NASCET-d), or NASCET diameter rate mathematically converted in area rate (DSA-NASCET-a), or common carotid diameter rate (DSA-CC-d) method, or common carotid diameter rate mathematically converted in area rate (DSA-CC-a). All patients underwent eversion endarterectomy (EEA) to obtain a precise stenosis measurement. A 4-point score was assigned to the plaque calcium and lipids content on MDCT and on gross specimens. Two-tail Sign test and Chi-square were used.

Results: The stenosis rate for the different measurement methods were as follows: 74.6 ± 10.8 (CDUS-d); 82.9 ± 7.0 (CDUS-a); 82.6 ± 8.1 (MDCT); 48.6 ± 22.7 (DSA-NASCET-d); 68.6 ± 26.2 (DSA-NASCET-a); 70.8 ± 13.6 (DSA-CC-d); 89.7 ± 8.5 (DSA-CC-a); 82.4 ± 9.9 (EEA). Significant differences with EEA ($p < 0.05$) were observed for DSA-NASCET-d, DSA-CC-a, and DSA-CC-d. Two

Scientific Sessions

plaques was not scored at MDCT (artifact from calcium at bifurcation); MDCT and EEA were in complete agreement for the calcium scoring in 17/25 and for the lipid scoring in 18/25 ($p < 0.001$).

Conclusions: Considering the high standard deviation of DSA-NASCET-a, MDCT and CDUS give better stenosis measurements than DSA. Moreover, MDCT enables prediction of the calcium and lipid content of the plaque. High calcium deposition at the bifurcation is a limitation for MDCT.

B-456 14:54

Changes of blood flow during carotid endarterectomy evaluated by transit-time flowmeter measurement

M. Alekšić, V. Matoussevitch, J. Heckenkamp, K. Krüger, M. Gawenda, J. Brunkwall; Cologne/DE

Purpose: Carotid endarterectomy (CEA) may be complicated by a cerebral hyperperfusion syndrome which clinically presents with various symptoms ranging from postoperative headache to convulsions. An association with the degree of the underlying stenosis of the internal carotid artery (ICA) is presumed. Such an association should be verified by evaluating intraoperative blood flow changes.

Methods and Materials: In 104 patients undergoing CEA for unilateral high-degree ICA stenosis, a preoperative intraarterial digital subtraction angiography of the supraaortic vessels was performed. The degree of the stenosis was digitally assessed by using graphical computer software (Adobe Photoshop®) according to the ECST-Index. Blood flow was measured before and after CEA with an ultrasound flowmeter which is based on the transit-time principle. These findings were correlated to the degree of stenosis.

Results: Preoperative median blood flow in the ICA was 180 ml/min (range 443 ml/min) with a significant ($p < 0.0001$) postoperative increase to 245 ml/min (range 96–345 ml/min). The relative increase in flow (post flow - pre flow / pre flow) was 85%. However, no direct correlation between the degree of stenosis and flow increase was found ($r = 0.18$, $p = 0.068$).

Conclusions: The increase of blood flow does not seem to be related to the degree of ICA stenosis. To describe the hemodynamic conditions and changes which takes place in CEA more precisely, further investigations using a perfusion model are required.

B-457 15:03

Intermediate follow-up of stented carotid arteries: Is it possible to define reliable ultrasound velocity criteria?

A. Vit, A. De Candia, G. Piccoli, S. Smania, A. Marzio, M. Bazzocchi, D. Gasparini; Udine/IT

Purpose: To develop blood flow velocity criteria reliable in Doppler follow-up of carotid artery stenting (CAS) and to compare Doppler velocity measurements and power Doppler (PD) geometric evaluation in identifying in-stent restenosis and in quantifying the degree of restenosis proven angiographically.

Methods and Materials: Intermediate 6-month follow-up US examinations were performed in 114 stented carotid arteries. Peak systolic velocity (PSV) inside the stent and internal carotid artery to common carotid artery ratio (ICA/CCA) were measured. PD evaluation was also performed to determine the geometrical degree of in-stent restenosis (significant if 50% or greater). The degree of restenosis based on PD evaluation and blow flow velocity measurements were compared with angiographic results. Receiver operator characteristic (ROC) curves were generated to develop appropriate US velocity measurements in the detection of restenosis.

Results: One US showed complete occlusion of the stent, which was confirmed by CT-angiography. Six significant in-stent restenoses on US were angiographically confirmed, with excellent correlation between geometric PD degree of stenosis and angiographic degree. Corresponding PSV was 213.8 ± 71.11 cm/s, with one case of 55% restenosis and PSV of 95 cm/s. The remaining 107 cases with no evidence of restenosis showed a PSV of 103.4 ± 28.5 cm/s, with 11 cases (10.3%) with PSV > 130 cm/s.

The area under the ROC curves for PSV (0.88) and ICA/CCA (0.80) demonstrated a moderate discriminant ability, but we could not identify reliable Doppler velocity criteria.

Conclusion: Doppler velocity evaluation after CAS is unreliable and leads to false positive and false negative results. PD geometric evaluation seems reliable in quantifying degree of restenosis.

Prospective evaluation of a comprehensive MR-protocol in patients with suspected cervical artery dissection (CAD)

R. Bachmann, I. Nassenstein, C. Stehling, T. Niederstadt, R. Dittrich, W. Heindel, S. Kraemer; Münster/DE

Purpose: To assess the diagnostic efficacy of a comprehensive MR-protocol for the diagnosis of CAD.

Methods and Materials: 36 consecutive patients (19m, 17f, mean 42 yrs.) with suspected CAD underwent cervical 1.5 T-MR (Gyroscan Intera, Philips). Imaging protocol consisted of axial T1w-TSE, T2w-TSE and contrast-enhanced T1w-TSE (MRI) and CE-MRA. Images were assessed for the presence of specific (mural hematoma, increased external diameter, pseudoaneurysmen, string sign) and unspecific (occlusion, stenosis, hyperintense lumen, perivascular enhancement) signs for MRI and MRA separately. CAD was judged definite, if any one specific sign was present in MRI or MRA, undetermined if an unspecific sign and normal if no pathologic signs were present. MR-diagnosis was verified by follow-up.

Results: 17 pts with no sign for CAD were rated normal. None had evidence of CAD in follow-up. In 19 pts pathologic findings occurred (12x ICA, 7x VA), which were judged specific in 7 pts by MRA and MRI, in 5 pts by MRA only and in 1 pt by MRI only. Diagnosis of CAD was confirmed in 13 pts with specific findings. In 6 pts vessel occlusion was diagnosed by MRI and MRA, but the etiology remained undetermined.

Conclusion: The presence of specific signs in MRA or MRI yields a high positive predictive value for the diagnosis of CAD. Furthermore, CAD can be excluded confidently in patients with normal findings. Thus, the presented comprehensive MR-protocol is well suited as first line study in pts with suspected CAD, assessing both luminal patency and vessel-wall pathology in a combined approach.

Detectability of specific radiological signs in cervical artery dissection: Comparative analysis of helical-CT, MR imaging, MRA and DSA

S.C. Krämer, G. Kuhlenbäumer, I. Nassenstein, L. Conrad, W. Heindel, R. Bachmann; Münster/DE

Purpose: Cervical artery dissection (CAD) is the main cause of stroke in young patients. Our purpose was to analyse the potential of different imaging modalities to detect specific radiological signs in CAD.

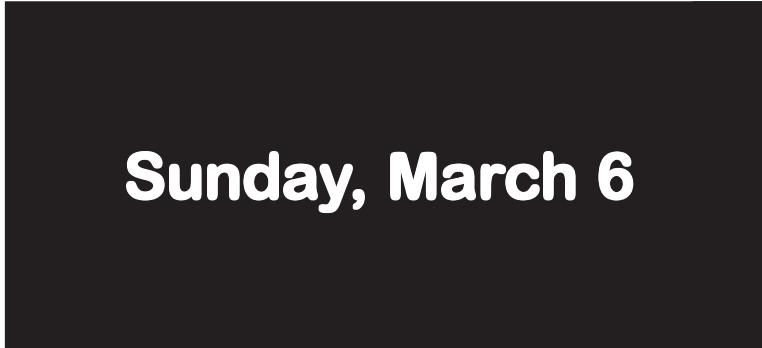

Methods and Materials: 46 clinically proven dissections of the carotid ($n = 29$) and vertebral ($n = 27$) arteries in 38 patients (female: 15, male: 23, mean age: 41 years) were retrospectively evaluated. Patients had at least one of the following imaging: Helical-CT, MR imaging (MRI), MR-angiography (MRA) or DSA. Specific signs such as mural hematoma, vessel diameter increase, string-sign or mural contrast deposit were defined for cross-sectional and angiographic imaging. Stenoses, occlusions and pseudoaneurysms were considered non-specific. Detection rates of specific and non-specific signs were compared by student's t-test.

Results: On cross-sectional imaging, specific signs could be detected in 11 of 19 cases (58%) with helical-CT and in 29 of 31 (95%) with MRI. Angiographic imaging was positive for specific signs in 7 of 29 cases (24%) with MRA and in 8 of 15 (53%) with DSA. Mural hematoma was seen in only 5 of 19 cases (26%) with CT whereas in 24 of 31 cases (77%) with MRI. Non-specific signs were present in 95% with helical-CT, 94% with MRI, 90% with MRA and 93% with DSA.

Conclusion: In cross-sectional imaging, MRI proved clearly superior to helical-CT in detecting specific signs of CAD. Although DSA is superior to MRA in angiographic imaging, the combined approach of MRI and MRA should be the modality of choice in patients with suspected CAD.

Osteoid osteoma: Role of dynamic MR imaging in detection of and definition of success after CT-guided radiofrequency ablation

V. Zampa¹, U. Albisinni², I. Bargellini¹, F. Odoguardi¹, R. Cioni¹, C. Bartolozzi¹; ¹Pisa/IT, ²Bologna/IT

Purpose: To evaluate the role of dynamic Gadolinium-enhanced MR imaging (D-MRI) in the nidus detection of osteoid osteoma (OO) and in the assessment of the results after radiofrequency (RF) thermal ablation.

Materials and Methods: Twenty-three patients with histologically proven OO underwent MRI before and 6 months after percutaneous CT-guided RF ablation. MRI protocol included a conventional study (C-MRI: SE-T1w, GRE-T2w and FSE-IR) and D-MRI (FastSPGR-T1w) after Gd injection. MRI images were evaluated by two blinded readers to assess bone edema and joint effusion on C-MRI, and degree of nidus contrast uptake on D-MRI.

Results: Pre-procedural C-MRI revealed specific abnormal findings in all cases, with clear nidus delineation only in 9; at D-MRI, early and high contrast uptake allowed accurate nidus identification in 20/23 cases. After treatment, 8 patients reported persistent pain. In these cases, where persistent edema and nidus contrast uptake was identified, patients underwent further treatment. In asymptomatic patients and in patients reporting residual discomfort not requiring medical therapy after treatment, D-MRI did not demonstrate residual nidus contrast uptake, and C-MRI showed reduction of bone edema and joint effusion, allowing definition of success. Moreover, in 6 cases of successful treatment, C-MRI showed an area of apparently normal bone marrow delineated by a rim (hypointense in T1-w and slightly hyperintense in T2-weighted images), recalling osteonecrosis in the site of previous RF ablation.

Conclusion: D-MRI allows nidus detection in OO. After RF ablation, MRI enables accurate assessment of results, and D-MRI is able to differentiate a persisting active nidus from bone edema.

B-462 10:39

Combined bipolar radiofrequency and cementoplasty in bone metastasis: Preliminary results in 8 patients

B.A.C. Kastler, H. Boulahdour, F.-G. Barral, P. Pereira, O. Saguet, P. Jacoulet, R. Lejoncour, R. Aubry, B. Fergane; Besancon/FR

Purpose: To evaluate the feasibility of combined bipolar radiofrequency and cementoplasty in the management of pain in bone metastasis. Cementoplasty is an already efficient and accepted method particularly when there is a risk of fracture. However the injection of acrylic glue has the potential drawback of spreading the disease as it may mechanically push out the malignant cells either in close proximity or at distance via the draining veins. Radiofrequency offers the possibility of a thermal ablation which can be optimized concerning the exact ablation size with a bipolar approach (Gelon generator). This is crucial when the lesion is close to major neural structures (motor nerves, spinal cord)

Method and Materials: 8 adult patients with bone metastasis in various locations (sternum, ribs, clavicle, vertebrae, iliac bone,) refractory to conventional pain treatment were included in the study. They first underwent RF ablation followed immediately by cementoplasty through the same Trocar, coaxially to optimize the intervention (namely reducing procedure time: range 30 to 90 min.). The trocar was placed under CT guidance.

Results: All patients had a significant pain relief persisting at 3 month.

Conclusions: This combined bipolar radiofrequency and cementoplasty approach appears to be an efficient alternative when other therapies provide no proper pain relief. Moreover it should reduce the risk of local recurrence and seeding at a distance, of the tumour. Thus it may have the potential of sterilizing lesions in unique locations. This novel combination deserves further investigation.

B-463 10:48

Benefit of peer-reviewed pathological examination of soft tissue tumors.

What is the role of radiology?

J.L.M.A. Gielen, A.M.A. De Schepper, E. Van Marck, P. Van Dyck, F. Vanhoenacker, P.M. Parizel; Edegem/BE

Purpose: The aim is to objectify the benefit of peer reviewed pathology of soft tissue tumors (STT) and to define the interaction between pathologist and radiologist.

Materials and Methods: Cases were selected from a multi-institutional prospective study on MR imaging of pathologically confirmed STT. Selected were all cases histologically diagnosed as malignant, cases with discrepancy between biopsy and resection histology and lesions with indefinite histology results, and cases with discrepancy between histology and MR imaging. 623 cases have a confirmed diagnosis. Of 173 cases, pathology slides are submitted to a peer review committee of 6 specialized pathologists.

Results: Initial histological diagnosis is confirmed in 124 cases, 41 malignant, 83 benign lesions. Diagnosis changed in 26 (39%) out of 67 malignant lesions and in 18 (17.5%) out of 103 benign lesions. Diagnostic accuracy of the referral pathologist concerning benign lesions (82.5%) is obviously better when compared with malignant lesions (61%). Histological phenotype changed in 11 (16.5%) out of 67 malignant cases and in 10 (9.5%) out of 103 benign lesions. Because of their therapeutic consequences cases with initially benign diagnoses, which became malignant diagnoses (8 out of 67) (false negatives) are of utmost importance, while the consequences of the vice versa situation (4 out of 103) (false positives) are not that significant.

Conclusion: The accuracy of the referring pathologist was calculated as follows, PPV 93.5%, NPV 92.5%, sensitivity 88%, specificity 96%. Discrepancy between MR imaging and pathology is an important selection criterion for pathological peer review optimizing the interaction between pathologist and radiologist.

B-464 10:57

MSCT versus MR imaging: Diagnostic sensitivity in the detection of spine metastases

A. Baur-Melnyk, S. Buhmann, A. Wieser, M.F. Reiser; Munich/DE

Purpose: The aim of the study was to evaluate the diagnostic sensitivity of Multi-Slice-computed tomography (MSCT) compared to the sensitivity of Magnetic Resonance imaging (MRI) concerning the detection of metastases in the spine.

Materials and Methods: In a retrospective clinical trial, 343 vertebral bodies of 27 patients with various primary malignancies, histologically attested, were analysed. The CT-images were acquired on a 16-row-MSCT (SIEMENS Sensation 16) with 120 kV, 100 mAs and 1 mm collimation. An image reconstruction in 3 mm axial slices and sagittal MPRs of the spine with an increment of 3 mm were performed. The MRI protocol consisted of STIR-sequences, T2-weighted SE-sequences and T1-weighted SE-sequences with and without application of contrast medium in all patients and was performed using a 1.5 Tesla-scanner (SIEMENS Symphony/Sonata). In a consensus reading the acquired CT and MRI images were evaluated by two experienced radiologists.

Results: 13% of the in MRI images detected metastases were not identified in MSCT-images. All osteoclastic metastases were detected in MSCT as well as in MRI due to the MSCT benefit of better evaluating bone structures. In our study, MRI reached a diagnostic accuracy of 100%. CT showed a sensitivity of 86% and a specificity of 100%.

Conclusion: 16-row-MSCT provides excellent image quality with high resolution but metastases at early stages of disease without bone destruction may only be visualized and detected with MRI.

B-465 11:06

Can 16-detector multislice CT rule out skeletal metastases whilst staging the soft tissues?

A.M. Groves, C.J. Beadsmoore, K.K. Balan, H.K. Cheow, H.M. Courtney, S. Kaptope, P.W.P. Bearcroft, A.K. Dixon; Cambridge/UK

Purpose: Presently in oncology, bone scintigraphy is used to stage the skeleton, whilst computed tomography (CT) stages the soft tissues. New CT technology has now, for the first-time, made it feasible to perform a whole-body bone CT and thus could save patients having to undergo duplication of investigations.

Methods and Materials: Over 6-months, 43 cancer patients presenting to the nuclear medicine department were recruited for additional whole body 16-detector multislice CT. Both studies were performed within six weeks of each other. CT was performed on a 16-detector multislice CT machine using 1.5 mm detectors and reconstructed in 2 mm slices from vertex to knee. Multiplanar reformatted

Scientific Sessions

images were then viewed interactively on a monitor. 4-hours after injection of 500 Mbq 99m Tc-MDP, whole-body planar images were taken using a dual-headed gamma camera. The findings were reported "blind" of each other. Discordant findings were reviewed at follow-up. The Newcombe-Wilson confidence interval method for testing equivalence of proportions was performed to determine if 16-detector multislice CT was statistically equivalent to skeletal scintigraphy in the detection of bone metastases.

Results: Skeletal scintigraphy detected bone metastases in 14/43 and CT in 13/43 patients. There were 7 discordances; 4 cases were positive on scintigraphy, but negative on CT. 3 cases were positive on CT and negative on scintigraphy. There was equivalence between scintigraphy and CT in detecting bone metastases within a $\pm 19\%$ equivalence limits.

Conclusions: Patients undergoing staging CT on a 16-detector multislice CT system may not always need additional skeletal scintigraphy to stage the bones.

B-466 11:15

Diagnostics of multiple myeloma using a 16-row-MSCT - low-dose whole body protocol

S. Buhmann, A. Baur-Melnyk, A. Wieser, M.F. Reiser; Munich/DE

Purpose: A comparison between a low-dose and a standard-dose protocol on a 16-row-multislice computed tomography scanner for the diagnosis of osteolytic bone lesions in patients suffering from multiple myeloma was the aim of our study.

Materials and Methods: In 30 patients with an attested diagnosis of multiple myeloma a whole-body MSCT (120 kV, 1.5 mm collimation, bone kernel) and consecutively a whole-body MR imaging (1.5 Tesla, Siemens Symphony, coronal/sagittal STIR and unenhanced T1-w SE sequences) serving as a gold standard was performed. The patients were divided into group A which was examined using 100 mAs compared to group B with 50 mAs. The images were reconstructed in 3 mm axial slices as well as the spine in 3 mm sagittal slices. The quality of MSCT images was evaluated by 2 experienced radiologists using a four-grade scaling reaching from 1=excellent to 4= not sufficient and the quantification was evaluated by ROI measurements (S/N+C/N ratio).

Results: The mean image noise value for groupA (12 HU) was significantly lower compared to groupB (24 HU) but the image quality for groupB was rated as excellent. The 100 mAs protocol resulted in an overall score of 1 while for the 50 mAs protocol a value of 1.3 was found. Mean radiation dose in groupA was 10 mSv, in groupB 5 mSv. All osteolytic lesions were identified using both modalities (MSCT, MRI).

Conclusion: Our low-dose whole-body MSCT reached similar dose values as X-rays of the skeleton and proved to be a valuable tool for the sensitive detection of osteolytic bone lesions in patients with multiple myeloma.

B-467 11:24

MR imaging of metastatic tumors in the spine: Are they different in signal intensity according to primary malignancy?

J. Koo, S. Hong, J.-Y. Choi, I. Lee, J. Lee, H. Kang, J.-A. Choi, Y. Koh; Seoul/KR

Purpose: The purpose of this study was to evaluate whether MR signal intensities of metastatic tumors are dependent on their primary malignancy.

Methods and Material: The T1-weighted images of 106 patients with spinal metastasis were reviewed retrospectively. Their primary lesions were hepatocellular carcinoma (HCC) ($n = 23$), lung cancer ($n = 31$), breast cancer ($n = 20$), GI malignancy ($n = 18$), and multiple myeloma ($n = 14$). The relative signal intensity of metastatic tumor was compared to adjacent intervertebral disc and spinal cord. We measured signal intensities of tumor, disc, and spinal cord and calculated signal ratios: tumor signal/disc signal (St/Sd) and tumor signal/cord signal (St/Sc).

Results: Both signal ratios St/Sd and St/Sc were significantly higher in HCC patients compared to patients with lung, breast, GI tract malignancies and multiple myeloma ($P = 0.00$, one-way ANOVA test). There was no signal difference amongst the other metastatic lesions. Six of 106 had hyperintense lesions compared with the spinal cord, all (100%) of which represented metastasis of HCC.

Conclusion: Metastatic tumors of HCC revealed significantly higher signal on T1-weighted MR images as compared to other metastatic tumors and multiple myeloma. Comparing with spinal cord signal, hyperintense lesions are highly suggestive of HCC metastasis.

B-468 11:33

Benign and malignant musculoskeletal masses: MR imaging differentiation with "maximum slope region"

K. Ishiyama, N. Tomura, R. Sashi, K. Okada, H. Nagasawa, K. Narita, J. Watarai; Akita/JP

Purpose: To evaluate the diagnostic potential of dynamic MR imaging in patients with musculoskeletal lesions.

Methods and Materials: Sixty-four patients with various musculoskeletal pathologies (37 benign lesions, 27 malignant lesions) were studied using dynamic MR imaging. Dynamic MR imaging was performed using a fast SPGR sequence (TR/TE = 90-200/4.2 ms). Dynamic images were transferred to an Advantage workstation 3.1 (GE) and analyzed using Functool. Functool can determine the location of strongest initial enhancement in the tumor (maximum slope region: MSR). MSR was categorized as peripheral, central, or absent. Progression of enhancement over time (time-signal intensity curve: TIC) was categorized as steep, steady or very low. Relationships between these parameters and histopathological findings were studied.

Results: For benign lesions, MSR was peripheral in 7 patients and central or absent in 30 patients. For malignant lesions, MSR was peripheral in 26 patients and central in 1 patient. For benign lesions, TIC was steep in 2 patients and steady or very low in 35 patients. For malignant lesions, TIC was steep in 19 patients and steady or very low in 8 patients. Differentiation between benign and malignant lesions was possible with 96.3% sensitivity, 83.8% specificity, 87.5% accuracy, 78.8% positive predictive value (PPV) and 96.8% negative predictive value (NPV) using MSR, and 70.3% sensitivity, 94.6% specificity, 84.4% accuracy, 90.4% PPV and 81.4% NPV using TIC.

Conclusion: Use of dynamic MR imaging to differentiate between benign and malignant lesions is feasible. MSR appears particularly useful as a new indicator of differential diagnoses.

Velocity-encoded MR imaging with sensitivity encoding (SENSE):

Reproducibility and measuring agreement for quantitative assessment of pulmonary and systemic blood flow

M. Nogami¹, Y. Ohno¹, T. Higashino¹, D. Takenaka², M. Fujii¹, K. Sugimura¹;

¹Kobe/JP, ²Kasai/JP

Purpose: The purpose of our study was to assess the reproducibility and measuring agreement of velocity-MR imaging with SENSE and to determine the optimal scan parameters for quantitative assessment of pulmonary and systemic blood flow.

Materials and Methods: 10 healthy volunteers underwent velocity-MR imaging with SENSE and Doppler echocardiography (cardiac US). Flow rate in the pulmonary artery (Qp) and aorta (Qs) and flow ratio Qp/Qs in each subject were assessed by both velocity-MR imaging and cardiac US on two occasions. All velocity-MR imagings were performed by 2D Fourier method with SENSE technique at 1.5 T scanner. SENSE reduction factor was changed from 0 to 4, and R-R interval was divided into 10 to 40 frames. The total number of velocity-MR imaging sequence was 16. Differences between first and second velocity-MR imaging examinations were statistically compared. Qp/Qs of velocity-MR imaging obtained by determined optimal scan parameters and that of cardiac US were statistically compared. For assessment of the limits of agreement and reproducibility, Bland-Altman's analyses were adapted.

Results: The best coefficient of reproducibility for Qp/Qs (± 0.21) between first and second velocity-MR imaging examinations was obtained by SENSE reduction factor 4 and R-R interval divided into 30 frames. Qp/Qs between velocity-MR imaging and cardiac US had good correlation ($r = 0.81$, $p < 0.05$). The limits of

Scientific Sessions

agreement of Qp/Qs between velocity-MR imaging and cardiac US was less than ± 0.57 .

Conclusion: Velocity-encoded MR imaging with SENSE is useful for quantitative assessment of pulmonary and systemic blood flow. High SENSE reduction factor and high frame number of R-R interval provide good reproducibility, measuring agreement, and short breath-holding time.

B-471 10:39

Primary pulmonary hypertension: Quantitative analysis of regional pulmonary perfusion using 3D dynamic MR imaging

Y. Ohno¹, M. Nogami¹, T. Higashino¹, D. Takenaka², K. Murase³, H. Hatabu⁴, K. Sugimura¹; ¹Kobe/JP, ²Kasai/JP, ³Osaka/JP, ⁴Boston, MA/US

Purpose: To determine the capability of quantitative pulmonary perfusion parameters evaluated from 3D dynamic contrast-enhanced MR perfusion data for assessment of disease severity as indicated by pulmonary vascular resistance (PVR) in PPH patients.

Materials and Methods: 3D dynamic contrast-enhanced MR perfusion imaging (TR 2.7 ms/ TE 0.6 ms/ Flip angle 40°, 100-240 mm slab thickness, 10-12 partitions) was performed in 14 normal volunteers and nine consecutive PPH patients. All PPH patients underwent catheterization of the right side of the heart. From the signal intensity-time course curves, pulmonary blood flow (PBF), pulmonary blood volume (PBV) and mean transit time (MTT) maps were generated using deconvolution analysis, indicator dilution theories and the central volume principle on a pixel-by-pixel basis. From all pulmonary perfusion parameter maps, regional PBF, PBV and MTT of each lung field were determined in 6 spatially defined regions of interest (ROIs) in both lungs. PBF, PBV and MTT were statistically compared between normal and PPH subjects by Student's t-test. Pulmonary perfusion parameters with significant difference between the two groups were correlated with PVR.

Results: Regional PBF, PBV and MTT showed significant differences between normal and PPH subjects ($p < 0.0001$). PBF had excellent negative correlation with PVR ($r = -0.89$, $p = 0.002$). MTT had good positive correlation with PVR ($r = 0.78$, $p = 0.014$).

Conclusion: 3D dynamic contrast-enhanced MR imaging has the potential for assessment of disease severity as indicated by PVR in primary pulmonary hypertension patients.

B-472 10:48

Value of high spatial and high temporal resolution MR angiography for differentiation between primary and secondary pulmonary arterial hypertension

S. Ley¹, C. Fink¹, M. Borst¹, J. Zaporozhan¹, M. Puderbach¹, J. Meyer¹, E. Gruenig¹, K.-F. Kreitner², H.-U. Kauczor¹; ¹Heidelberg/DE, ²Mainz/DE

Objective: Differentiation between different forms of pulmonary hypertension (PH) is essential for correct disease management. Goal of this study was to elucidate the clinical impact of high spatial resolution MR angiography (SR-MRA) and high temporal resolution MRA (TR-MRA) to differentiate between patients with chronic thromboembolic PH (CTEPH) and primary PH (PPH).

Materials and Methods: 10 patients with PH and 5 healthy volunteers (V) were examined (1.5 T-MRI). 20 TR-MRA datasets ($3.5 \times 1.9 \times 4$ mm³, each TA 1.5 s) and SR-MRA ($1.2 \times 1.0 \times 1.6$ mm³, TA 23 s) were acquired after automatic injection of 0.1 mmol/kg BW of Gd-DTPA using parallel imaging. TR-MRA datasets were subtracted as angiography and perfusion images. Image evaluation comprised analysis of vascular pathologies on a segmental basis and detection of perfusion defects by 2 readers in consensus.

Results: Visualization of the pulmonary arteries down to a subsegmental (SR-MRA) and to a segmental (TR-MRA) level was possible. SR-MRA outperformed TR-MRA in direct visualization of intravascular changes. Patients with PPH predominantly showed a tortuous course while in CTEPH wall irregularities and abnormal proximal to distal tapering of the pulmonary arteries was found. Perfusion images showed a diffuse pattern in PPH and focal defects in CTEPH. TR-MRA (angiography and perfusion) and SR-MRA resulted in the same final diagnosis which was confirmed by further clinical evaluation.

Conclusion: Both MRA techniques allowed for differentiation between PPH and CTEPH. Therefore, TR-MRA can be used for clinical purpose, especially in dyspneic patients.

Contrast-enhanced 3D-MR imaging of lung perfusion in children with cystic fibrosis

M. Eichinger, M. Puderbach, C. Fink, S. Ley, J. Gahr, M. Wiebel, S. Tuengerthal, F.-M. Müller, H.-U. Kauczor; Heidelberg/DE

Purpose: Feasibility study of lung perfusion imaging using contrast-enhanced 3D-MR imaging. To assess the correlation of lung perfusion changes with structural abnormalities of the lung in children with cystic fibrosis (CF).

Methods and Materials: 11 CF-patients (9 female, 2 male; 12-18 years) were examined at 1.5 T (Magneton, Symphony). **Morphology:** HASTE sequence in coronal and transversal orientation (TR/TE/α: 600 ms/28 ms/180°, slice thickness 6 mm), breathhold 18 s. **Perfusion:** Time-resolved 3D-GRE pulse sequence (FLASH, TE/TR/α: 0.8/1.9 msec/40°), each using parallel imaging (GRAPPA, PAT factor 2). A total of 25 data sets were acquired after intravenous injection of 0.1 mmol/kg body weight of Gadodiamide at a rate of 3-5 ml/s. 198 lung segments were analysed by two radiologists in consensus and scored for morphological changes (1=normal, 2=mild, 3=severe) and perfusion changes (0=normal, 1=defect). Statistical analysis was performed by Mantel-Haenszel Chi square test.

Results: Segmental perfusion defects were observed in all patients and present in 80% of the upper, and 39% of the lower lobes. Normal lung parenchyma showed a homogenous perfusion in 86% of analysed lung segments ($p < 0.0001$), while in 97% severe morphological changes led to perfusion defects ($p < 0.0001$). Segments with mild morphological changes showed normal (53%) or impaired perfusion (47%).

Conclusion: In CF-patients, impaired ventilation causes perfusion defects due to hypoxic vasoconstriction. While the function is easy to judge in segments with normal parenchyma or severe changes, this is not possible in mildly damaged segments. Here, MR-lung perfusion measurement may help to better assess actual functional impairment.

B-474 11:06

Diagnosis of pulmonary arterial hypertension in patients with idiopathic fibrosing alveolitis

V.I. Osipenko, S.K. Ternovoy, A.I. Schekhter, I.A. Sokolina, E.N. Popova; Moscow/RU

Background: Idiopathic fibrosing alveolitis (IFA) is the most frequent variant of interstitial lung disease. Pulmonary hypertension (PH) in IFA is a strong predictor of patient prognosis, therefore its detection is of great clinical importance.

Purpose: Aim of the study was to assess the role of CT and high-resolution CT in early diagnosis of PH in IFA patients.

Materials and Methods: We studied 81 patient with IFA with spiral CT, high-resolution CT and linear filtration. Studies of pulmonary respiratory function and echocardiographic determination of pulmonary artery pressure were performed.

Results: Severe PH was found in patients with usual interstitial pneumonia (mean PAP 39 ± 2 Hg, area of interstitial fibrosis (S), measured on high-resolution CT scans = $45.6 \pm 3.6\%$). Moderate PH was typical for non-specific interstitial pneumonia (mean PAP 23.8 ± 8 Hg, S = 25.4 ± 3). In patients with desquamative interstitial pneumonia, PAP was normal (mean PAP 19 ± 9 Hg, S = 5.2 ± 2). We have found that PH in IFA patients develops when S > 27.3 ± 3.5 . For quantification of PH we have suggested pulmonary-thoracic ratio (PTI): transverse diameter of the chest/diameter of pulmonary trunk. Normal value of PTI was 11.7 ± 1.7 , in moderate PH its mean value was 8.1 ± 1.3 and in severe PH - 5.7 ± 2.1 .

Conclusion: Development of PH in IFA depends on the area of interstitial fibrosis. PTI helps to quantify severity of PH.

Pulmonary arteriovenous malformations: Could multi-detector row helical CT and angiographic reconstructions replace diagnostic angiography?

M. Memeo, A.A. Stabile Ianora, C. De Leo, P. Pignataro, M.C. Resta, A. Scardapane, G. Angelelli; Bari/IT

Purpose: To evaluate the possibilities of multi-detector row helical CT (MDCT) and angiographic reconstructions for diagnosis and characterization of pulmonary arteriovenous malformations (PAVMs) in comparison with pulmonary digital subtraction angiography (DSA).

Methods and Materials: 30 consecutive HHT patients with positive chest MDCT for pulmonary involvement were studied with DSA. MDCT was performed after injection of contrast medium and angiographic reconstructions were then obtained. DSA was performed with selective catheterization of pulmonary arteries and unilateral anteroposterior and oblique views; when necessary further views were

Scientific Sessions

added. The following were considered: 1. presence of PAVMs (nodular or tubular "serpiginous" lesions; afferent/efferent vessels identification; early visualization of efferent vessels); 2. number (isolated, multiple if < 15 or diffuse if ≥ 15); 3. location (intraparenchymal, subpleural); 4. aneurysmal dimensions (> or < 1 cm); 5. type (simple, complex); 6. afferent vessels diameter (≥ 3 mm).

Results: MDCT found 115 PAVMs. In 24/30 patients these were multiple and in 6 cases diffuse and bilateral. 80/115 PAVMs were subpleural; 68/80 had aneurysm < 1 cm and 73/80 were simple. Of the intraparenchymal PAVMs, 21/35 had aneurysm > 1 cm and 7/35 were complex. The afferent and efferent vessels were identified in all cases: afferent artery diameter was ≥ 3 mm in 27/115 cases. DSA identified 76 PAVMs: 29 intraparenchymal and 47 subpleural. For better identification of the aneurysmal sac and of afferent and efferent vessels, additional projections were required in 22/30 patients.

Conclusion: MDCT with angiographic reconstructions seems to be highly accurate for diagnosis of PAVMs and could be considered a valid alternative to angiography for their characterization.

B-476 11:24

Diagnosis of pulmonary arteriovenous malformations in patients with hereditary hemorrhagic telangiectasia: Multi-detector row helical CT versus contrast echocardiography. Preliminary results

M. Memeo, A.A. Stabile Ianora, C. De Leo, C. Memmola, C. Sabbà, A. Scardapane, G. Angelelli; Bari/IT

Purpose: To evaluate the possibilities of a non-invasive approach based on the association of contrast echocardiography (CEUS) and multi-detector row helical CT (MDCT) for diagnosis of pulmonary arteriovenous malformations (PAVMs) in patients with Hereditary Hemorrhagic Telangiectasia (HHT).

Methods and Material: 71 consecutive patients diagnosed with HHT according to clinical criteria were evaluated with CEUS and MDCT. CEUS was performed twice, first using as contrast medium a bolus of agitated saline (5 cc), then a bolus of agitated polygelin (3 cc). Chest MDCT was performed before and after contrast medium injection; multiplanar and angiographic reconstructions were then obtained. CEUS was considered positive if: 1. air bubbles were visible in the left heart within 3-6 cardiac cycles from their visualization in the right heart; 2. pulmonary veins were evident during contrast injection; 3. there was concordance between the two different contrast mediums. Contrast enhanced MDCT was considered positive in presence of: 1. nodular or tubular "serpiginous" lesions; 2. lesions with afferent/efferent vessels; 3. lesions enhancement; 4. early visualization of efferent veins.

Results: 19/71 patients were considered positive at CEUS while 22/71 patients had MDCT positive for PAVMs, therefore concordance was present in 19 cases (86%). In the 3 patients with negative CEUS, MDCT found some small fistulas with a diameter of less than 10 millimetres and a subpleural localization.

Conclusion: CEUS and MDCT seem to have good accuracy for detection of hemodynamically consistent PAVMs. CEUS/MDCT combination could be considered in the future for the screening of pulmonary involvement in HHT patients.

B-477 11:33

Multidetector-row CT of right ventricular function: Can it be integrated into a standard multislice CT angiogram of the chest?

A. Teisseire, D. Delhaye, J. Bruzzi, V. Delannoy-Deken, A. Duhamel, J. Rémy, M. Rémy-Jardin; Lille/FR

Purpose: To evaluate the possibility of assessing right ventricular function during a multidetector row CT angiographic examination of the chest.

Material and Methods: 44 consecutive patients known to have or suspected of having right ventricular dysfunction secondary to chest disorders underwent a 16-channel multidetector row CT angiographic examination of the chest with standard technique, completed by an ECG-gated examination of the heart.

Results: At the time of data acquisition: (a) the mean (\pm SD) heart rate of the study group was 81 (\pm 16.7) beats per minute (bpm) (range: 40 - 120); (b) the ECG tracing showed sinus rhythm in 27 patients (61%) and frequent extrasystolic beats in 17 patients (38%). The mean (\pm SD) attenuation value within the RV was 209.3 (\pm 42.4) HU (range: 126-312). Manual tracing of endocardial borders was possible for all patients. Assessment of the RV valvular borders mainly relied on the identification of the transitional zones between the interatrial and interventricular septa (n = 41; 93%) and between the RV myocardium and pulmonary trunk (n = 35; 79.5%) with no statistically significant difference according to the presence (n = 17) or absence (n = 27) of extrasystolic beats (p = 0.27; p = 0.78, respectively). All CT scans were graded as suitable for calculation of the RVEF.

Conclusion: Assessment of RV function during a multidetector row CT angiogram of the chest is feasible for all patients, including those with high heart rates and arrhythmia.

B-478 11:42

Multidetector-row CT of right ventricular function: Impact of the methodological approach in the determination of the right ventricular ejection fraction

A. Teisseire, D. Delhaye, J. Bruzzi, V. Delannoy-Deken, A. Duhamel, J. Rémy, M. Rémy-Jardin; Lille/FR

Purpose: To evaluate the impact of the methodological approach in the multidetector row CT estimation of the right ventricular ejection fraction (RVEF).

Material and Methods: In 33 patients, 16-channel multidetector row CT of the heart was performed after standard CT angiographic examination of the chest with determination of the RVEF by two readers. The reconstruction windows were determined (a) with the ECG (reader 1) or (b) on transverse test images obtained in 5% steps through the entire RR interval (reader 2). After manual segmentation of the ventricular cavity on diastolic and systolic short-axis reformations by each reader, the end diastolic and systolic RV volumes were calculated with determination of the RVEF. CT results were compared to those of equilibrium radionuclide ventriculography.

Results: An agreement between the two methods for selecting the reconstruction windows was observed in 51% of cases (n = 17) for the systole and 45% of cases (n = 15) for the diastole (variations ranging between 5% and 15% for discordant selections). No statistically significant difference was found in the determination of mean (\pm SD) end diastolic (reader 1: 172.33 \pm 46.43 mL vs reader 2: 172.33 \pm 46.43 mL; p = 0.29) and end systolic (reader 1: 85.12 \pm 31.13 mL vs reader 2: 80.59 \pm 30.22 mL; p = 0.23) volumes, suggesting the lack of operator-dependence in the manual contour drawing process. Good correlation was found between RVEFs obtained with CT by each reader and scintigraphy (p < .0001).

Conclusion: RVEF can be routinely assessed with ECG-gated multidetector row CT using commercially available analysis software.

Right ventricular function measured during ECG-gated MSCT of the whole chest: Intra-and inter-observer variability

E.E.J.G. Coche¹, R. de Crombrugge¹, A. Vlassenbroek²; ¹Brussels/BE, ²Best/NL

Purpose: To test the reproducibility of measurements to assess right ventricular function during ECG-gated chest CT.

Methods and Materials: Eighteen patients with suspected acute pulmonary embolism were enrolled in this prospective study. Multislice CT was performed on 16-slice CT (MX IDT, Philips Medical Systems, Cleveland, OH) with retrospective ECG-gating. Acquisition was performed from the lung apices down to the diaphragm with the following parameters: 16 x 1.5 mm, 420-msec gantry rotation time, 120 kV, 150 mAs. 120 mL of contrast media were injected at a rate of 3 mL/sec. Contiguous thin slices (2 mm) were reconstructed every 12.5% of the R-R interval and reviewed on a dedicated cardiac workstation. Time of CT acquisition and CTDI were systematically recorded. End-diastolic, end-systolic volumes of RV were measured by two independent observers from a dedicated three-dimensional software. Ejection fractions of the RV was calculated by using the Simpson's rule. Measurements were repeated twice by one of the 2 observers. Intra and interobserver variability of measurements were estimated by using the intra-class correlation coefficients.

Results: Acquisition time to cover the entire chest with ECG-gating was 18.7 sec (13.2-25.3 sec). CTDI was 10.13 mGy. The intraclass correlation of measurements for the two observers for RV end-diastolic volumes, end-systolic volumes and ejection fraction was 0.97. The intraclass correlation for one observer was 0.98, 0.98 and 0.94 for the same parameters.

Conclusion: Measurements of RV volumes and ejection fraction obtained during ECG-gated CT are highly reproducible.

Correlation of secretin MRCP derived quantification of exocrine function with faecal elastase 1 and urinary pancreoelastase tests

A.R. Gillams, S. Pereira, W. Lees; London/UK

Purpose: Secretin MRCP (sMRCP) provides a non-invasive, direct technique for quantifying pancreatic exocrine function. Our aim was to correlate sMRCP derived pancreatico-duodenal flow rates with indirect non-invasive tests of pancreatic function i.e. faecal elastase 1 (FE1) and/or urinary pancreoelastase (PL), in a group of patients with suspected or known chronic pancreatitis.

Methods and Materials: Standard, multi-slice, single shot fast spin echo sequences were obtained before and at 2 minute intervals following 0.1 ml/kg IV Secretin (Sanochemia, Germany). Change in fluid volume = mean signal intensity/ voxel x volume of the region of interest: Signal intensity in a 100% water voxel. Volume was plotted against time and the flow rate derived from the gradient, with a rate of < 4.5 ml/min being defined as abnormal. FE1 ± PL tests were performed in all patients.

Results: There were 34 patients, 21 male, median age 52 years (34-79). In 27 patients there was complete concordance between MR flow rate and FE1/PL, with 16 patients having normal values (mean flow rate 7.7 ± 2.5) and 11 abnormal (3.5 ± 0.8 ; ($p = 0.001$ by Students t test). Two patients had normal FE1 and abnormal flow rates, 5 had abnormal FE1 but normal flow rates. The exact Fisher test was highly significant ($p = 0.001$).

Conclusion: There was very good correlation between sMRCP flow rates and standard, non-invasive, indirect pancreatic function tests. sMRCP provides ductal, parenchymal and functional information in a single test.

B-482 10:39

Evaluation of pancreatic duct abnormalities using secretin-stimulated MR pancreatography

F. Donati, P. Boraschi, R. Gigoni, A. Auci, M.C. Cossu, F. Falaschi; Pisa/IT

Purpose: To determine the usefulness of Secretin-stimulated MR Pancreatography (SSMRP) for evaluating pancreatic duct abnormalities.

Method and Materials: A series of fifty-six patients with suspected pancreatic duct abnormalities at US and/or CT underwent MR imaging at 1.5 T (Signa Infinity, GE Healthcare). In order to suppress the signal intensity of overlapping fluid-containing organs, a super-paramagnetic suspension (Lumirem®, Guerbet) was orally administered. After the acquisition of axial T1W and T2W sequences, MR pancreatography was performed using a coronal breath-hold, thick-slab (40-60 mm), single-shot T2W fast spin-echo sequence. After the intravenous administration of Secretin (Secretlux®, Sanochemia; 1 cU/kg body/weight), single-slice image acquisition was repeated every 30 seconds up to 15 minutes. The presence of pancreatic abnormalities, the changes of the pancreatic ductal system and the filling of duodenum after Secretin-stimulation were evaluated by two observers in conference. Imaging results were correlated with ERCP, surgery, and/or follow-up.

Results: In patients with pancreatic cystic lesions ($n = 23$), SSMRP allowed the correct diagnosis of 14 cases of intraductal papillary mucinous tumor showing the communication with the pancreatic duct. In all cases of chronic pancreatitis ($n = 11$), SSMRP improved the identification of ductal stenoses and demonstrated a reduced pancreatic exocrine reserve. Twelve of fourteen congenital abnormalities were identified as complete pancreas divisum on SSMRP. Furthermore, in two patients with post-traumatic pseudocyst, SSMRP revealed the direct continuity between the lesion and the main pancreatic duct. No abnormality was observed in six cases.

Conclusion: Improvement in image quality after Secretin-stimulation increases the diagnostic value of MR pancreatography for evaluating pancreatic duct abnormalities.

B-483 10:48

Exocrine function of pancreatic transplants: Evaluation with dynamic MR pancreatography after secretin administration

P. Boraschi, F. Donati, R. Gigoni, F. Odoguardi, E. Neri, U. Boggi, F. Falaschi, C. Bartolozzi; Pisa/IT

Purpose: To evaluate the exocrine function of pancreatic transplants using dynamic MR pancreatography after Secretin administration.

Materials and Methods: Thirteen asymptomatic patients previously submitted to isolated pancreas ($n = 6$) or combined kidney-pancreas ($n = 7$) transplantation with enteric-portal pancreatic drainage underwent MR imaging at 1.5 T (Signa Infinity; GE Healthcare) using a phased-array coil. After the acquisition of axial and coronal T1W and T2W sequences, dynamic MR pancreatography was performed using a coronal breath-hold, thick-slab (40-60 mm), single-shot T2W fast spin-echo sequence. After the intravenous administration of Secretin (Secretlux®, Sanochemia; 1 cU/kg body/weight), single-slice image acquisition was repeated every 30 seconds up to 15 minutes. Two observers in conference estimated the calibre changes of the pancreatic ductal system and the filling of the donor duodenum on the basis of pancreatic secretion after Secretin-stimulation, also evaluated by using a mean signal intensity/time histogram in a chosen region of interest (ROI) including the transplanted pancreas and the connected small bowel.

Results: All patients tolerated the examination well and no side effects were reported after Secretin administration. In 12 out of 13 cases a significant increase (more than 1 mm) of the mean pancreatic duct was observed after Secretin-stimulation; in all patients a noticeable filling of the duodenum was demonstrated during dynamic MR pancreatography both on qualitative and quantitative analysis.

Conclusions: Dynamic MR imaging after Secretin administration allows non-invasive evaluation of exocrine function of the pancreatic transplants and could be used to differentiate patients with graft rejection from those with normal graft function.

B-484 10:57

Evaluation of the natural history of pancreatic branch duct IPMTs by follow-up with cross-sectional imaging

A. Guarise¹, M. Ferrari¹, S. Turchetta¹, L. Romano¹, R. Salvia², ¹Negrar/IT, ²Verona/IT

Purpose: To clarify the natural history of branch duct type IPMT by evaluating serial changes in the MRCP and CT findings.

Methods and Materials: Fifty-two Patients with a diagnosis of branch duct IPMT obtained with ERCP and/or MRCP were followed-up over a period of more than 12 months (range 12-108, mean 30.6). All imaging data were retrospectively reviewed by two Radiologists in order to evaluate serial changes in size and structure. The maximum diameter of the cystic lesion, the presence of associated MPD dilatation and filling defects were evaluated in order to establish the correlation between these findings and changes in size. Statistical analysis was performed using the Fisher exact probability test.

Results: Growth in size on follow-up MRCP was observed only in 7 cases, the remainder demonstrated no changes or size reduction in two cases. There was a significant correlation between enlargement of the cystic lesion and the following features: size more than 3 cm and presence of mural nodules. Only 2/37 cystic lesions less than 3 cm in size, without papillary proliferations and MPD dilatation increased in size. No cystic lesion showed changes in morphology and structure.

Conclusion: Branch duct IPMTs smaller than 3 cm, without filling defects and MPD dilatation can be monitored with MRCP thus sparing operation.

B-485 11:06

The usefulness of MR pancreatography in the evaluation of cystic lesions and their relationship to the pancreatic ductal system

F. Donati, P. Boraschi, R. Gigoni, A. Auci, F. Falaschi; Pisa/IT

Purpose: To determine the usefulness of MR Pancreatography (MRP) in the evaluation of cystic pancreatic lesions and their relationship to the pancreatic ductal system.

Method and Materials: Eighty-two patients with radiological diagnosis of cystic pancreatic lesions underwent MR imaging at 1.5 T device (Signa Infinity, GE Healthcare). After acquisition of axial T1W and T2W sequences, MRP was obtained using coronal, thin and thick-slab, single-shot fast spin-echo (SSFSE) T2W sequence. Secretin-stimulated imaging was performed in 25/82 patients using coronal breath-hold, thick-slab, SSFSE T2W sequence, repeated every 30 seconds up to 15 minutes after intravenous administration of Secretin (Secretlux®, Sanochemia; 1 cU/kg body/weight). MR examinations were evaluated in

Scientific Sessions

conference by two observers to identify pancreatic abnormalities and their relationship to the ductal system.

Results: The cystic lesions were classified into two types: a) Lesions related to the pancreatic ductal system (42 patients). On the basis of presence of septa and filling defects in the lesion, a preliminary diagnosis of intraductal papillary mucinous tumor was made in 40/42 cases, in 15 of them histological confirmation was obtained. In two patients with post-traumatic pseudocyst MRP revealed the continuity between lesion and main pancreatic duct. b) Lesions not related to the pancreatic ductal system (40 patients); serous cystadenoma ($n = 6$), mucinous cystadenocarcinoma ($n = 2$), cystic neuroendocrine tumor ($n = 1$), all confirmed at surgery. The remaining indeterminate (< 2 cm) cystic lesions ($n = 28$) and pancreatic pseudocysts ($n = 3$) underwent imaging follow-up.

Conclusion: Our study highlights the usefulness of MRP particularly after Secretin-stimulation to detect cystic pancreatic lesions and establish their relationship to the ductal system.

B-486 11:15

Assessment with secretin-enhanced MR hydrometry of pancreatic exocrine function in patients with obstructive chronic pancreatitis before and after treatment

M.A. Bali, A. Sztantics, M. Delhaye, T. Metens, J. Deviere, C. Matos;
Brussels/BE

Purpose: To evaluate with secretin enhanced MR hydrometry (S-MRH) patients with obstructive chronic pancreatitis, the pancreatic exocrine function before and after main pancreatic duct (MPD) drainage procedures, by quantifying pancreatic exocrine flow output and total excreted volume.

Methods and Materials: Eighteen consecutive patients with obstructive chronic pancreatitis and no previous endoscopic or surgical treatment underwent S-MRH before and 24 hours after treatment. The treatment consisted of extracorporeal shock-wave lithotripsy followed by endoscopic decompression procedures. S-MRH consisted of a dynamic multislice TSE, heavily T2-weighted sequence acquired in the coronal plane (acquisition time 12 sec/dynamic). 30 dynamic acquisitions were performed after secretin administration followed by 6 dynamic acquisitions after ingestion of known volumes of water, realized for calibration purpose. To calculate pancreatic exocrine output and total excreted volume a linear regression was computed between MR calculated volumes and time. MPD diameter was measured before and after treatment. Two readers performed all of the evaluations independently.

Results: In all but two patients a statistically significant improvement of pancreatic flow output and of the total excreted volume was observed after treatment ($P < .05$). In the two patients who presented with post-procedural acute pancreatitis, this was responsible for the reduced exocrine function. In all patients the MPD diameter was reduced after treatment ($P < .05$) but the kinetics during secretin stimulation did not change ($P > .05$). The inter-observer variability was good ($R^2 = 0.9$).

Conclusion: Pancreatic exocrine function improved significantly after MPD drainage procedures. Secretin-enhanced MR hydrometry is a feasible, non invasive technique that allows monitoring of exocrine pancreatic reserve after endoscopic treatment in chronic pancreatitis.

B-487 11:24

MR imaging assisted visualisation of flow changes in the pancreatic duct

J.C. Hellund¹, T. Storås¹, K. Gjesdal¹, J. Geitung²; ¹Oslo/NO, ²Bergen/NO

Purpose: To see if an MR imaging sequence could be used to visualize flow changes in the pancreatic (PD) and common bile (CBD) duct. Increased flow should be seen as the loss of viewable ducts on the flow sensitized MRCP images.

Methods and Materials: An in-house developed, flow-sensitive, single-shot turbo spin-echo (SS-TSE) MR imaging sequence was used (Ref: Eur Radiol. 2004 Sep; 14(9):1692-7). Flow directions along the y and z-axis were evaluated. Nine healthy volunteers were examined on a 1.5 T scanner. Images were obtained before and after the administration of first Glucagon (to reduce artifacts from bowel movement) and secondly Secretin (to increase fluid flow in the ducts). B-factors (s/m^2) of 0, 6 and 12, were used. A total of 845 images were obtained and examined.

Results: All images showed both the PD and CBD on B-factor = 0. The CBD showed no significant differences in visualisation either in flow directions or drugs given on $B = 6$ or $B = 12$. The PD had, after administration of intravenous Secretin, a significantly lower rate of identification on both B-factors and flow directions (Y-axis and $b = 6$: 57% vs. 31%; $b = 12$: 46% vs. 23%. Z-axis and $b = 6$: 55% vs. 24%; $b = 12$: 52% vs. 17%).

Conclusion: The method made it possible to visualise flow changes in the PD before and after the administration of Secretin.

B-488 11:33

Macrocytic neoplasms of the pancreas: Differentiation of serous oligocystic adenoma from mucinous cystadenoma and intraductal papillary mucin-producing tumor with CT

S. Kim; Seoul/KR

Purpose: To describe typical CT findings of serous oligocystic adenoma (SOA) of the pancreas and to find out differential points from other macrocytic neoplasms such as mucinous cystadenoma and intraductal papillary mucin-producing tumor of branch type (IPMT).

Materials and Methods: A total of 41 patients with histologically confirmed macrocytic neoplasms of the pancreas were enrolled in this study (SOA:10; mucinous cystadenoma:13; branch type IPMT:18). Two experienced radiologists reviewed CT findings of those patients in consensus. The location, longest dimension, shape, presence of mural nodule, presence of wall calcification and extent and degree of main pancreatic duct (MPD) dilatation were analyzed. The shapes were categorized into 7 groups as below: multicystic; lobulated contour with/without internal septation; smooth contour with/without internal septation; pleomorphic cystic; clubbed finger-like cystic. Comparative studies of three types of lesions were performed using Fisher's exact test and Mann-Whitney U test.

Results: There was a significant difference in the shape of the lesion between SOA and the other macrocytic neoplasms such as mucinous cystadenoma ($P < 0.05$) IPMT ($P < 0.05$). SOA showed a shape of multicystic or lobulated contour while mucinous cystadenoma showed a shape of smooth contour and IPMT showed either pleomorphic cystic or clubbed finger-like cystic. Upstream MPD dilatation was predominantly observed in SOA compared to the other two diseases while diffuse MPD dilation was noted in IPMT ($p = 0.025$).

Conclusion: SOA of the pancreas has typical CT findings differing from other cystic tumors. It appears as a multicystic or lobulated cystic lesion with septation and with up-stream MPD dilatation from lesion.

B-489 11:42

CT criteria for predicting survival of patients with potentially resectable pancreatic carcinoma

S.S.K.S. Phoa, E. Tilleman, O. van Delden, P. Bossuyt, D.J. Gouma, J.S. Laméris; Amsterdam/NL

Purpose: To establish the prognostic value of CT data obtained from a pre-operative CT in patients with potentially resectable pancreatic carcinoma.

Material and Methods: In 71 consecutive patients with pancreatic head carcinoma prognostic CT criteria were scored (e.g. tumor size, peripancreatic infiltration, grade of vascular encasement) as well as criteria for irresectability (> 180 degrees vascular involvement, tumor concavity towards a vessel and presence of peripancreatic infiltration). All patients underwent surgical exploration. CT criteria were correlated with surgical and histopathological findings. Prognostic factors were analysed in single and multi-factor analysis, separately for resected and unresected tumors.

Results: A resection was performed in 41/71 patient (in 24 radical). The sensitivity, specificity and positive predictive value of CT with respect to surgical irresectability were 0.67, 0.63, and 0.57 respectively. With respect to a nonradical resection these were 0.62, 0.75 and 0.83 respectively. The median survival was 21 months for resected tumors and 9.7 months for unresected tumors. For resected tumors survival was poor if the tumor diameter was > 3 cm (relative hazard of 3.8) and if signs of local unresectability were seen at CT. Median survival of resected tumors < 2 cm was nearly 20 months. Encasement of the superior mesenteric artery had a poor prognostic value for all tumors.

Conclusion: CT signs of local unresectability and a tumor diameter > 3 cm predict a poor survival for resected tumors.

Staging and localizing prostate cancer using 3 T endorectal coil MR imaging

J.J. Fütterer, T.W.J. Scheenen, S.W.T.P. Heijmink,
C.A. Hulsbergen van der Kaa, F. Witjes, J.O. Barentsz; Nijmegen/NL

Purpose: To assess endorectal MR staging and localizing performance in prostate cancer at 3 T and to explore interobserver variability.

Methods and Materials: 3 T endorectal MR imaging was performed in 32 consecutive patients with biopsy proven prostate cancer, prior to radical prostatectomy. High resolution endorectal T2-weighted fast spin echo images (in plane resolution 0.18 x 0.18-mm) of the whole prostate in three planes were obtained. MR-images were prospectively evaluated by two experienced and one inexperienced radiologists with regard to local extent, prostate cancer localization and interobserver variability. Results were correlated with whole mount section histopathology.

Results: The local staging accuracy, sensitivity and specificity were respectively 94% (30/32), 88% (7/8) and 96% (23/24) for the experienced radiologists, and for the inexperienced radiologist 82% (26/32), 50% (4/8) and 92% (22/24). The localization accuracy was 79% for the experienced reader and for the inexperienced reader 64%, respectively. The interobserver variability between the readers showed substantial agreement ($\kappa = 0.68 - 0.79$) in staging and localizing prostate cancer. Two cases included minimal capsular invasion which were detected by both experienced radiologists.

Conclusion: Endorectal coil MR imaging at 3 T results in high staging and localization accuracies with substantial observer agreement ($\kappa = 0.68 - 0.79$). Minimal capsular invasion was detected. This may suggest a role in prostate staging at high fields.

B-491 10:39

MR imaging of prostate cancer: Comparison of imaging at 1.5 and 3 Tesla

D. Beyersdorff, C. Taymoorian, D. Schnorr, R. Felix, B. Hamm, H. Bruhn;
Berlin/DE

Purpose: To prospectively compare MR imaging of the prostate at 3 Tesla with MR imaging at 1.5 Tesla.

Materials and Methods: Twenty-four patients with histologically proven prostate cancer, PSA level of 2 to 14 ng/ml, underwent MR imaging comparing a phased-array body/endorectal coil at 1.5 Tesla with the body phased-array coil only at 3 Tesla. T2-weighted imaging was performed at both field strengths using axial and coronal TSE-sequences. Preoperative staging was done using all images acquired at 1.5-T and at 3-T. In a second, retrospective session, the images were evaluated separately for the two field strengths without knowledge of the histologic findings. The images were evaluated for image quality, delineation of zonal anatomy and prostate capsule, tumor detection, and presence of artifacts. MR imaging findings were compared with histologic results of prostatectomy specimens in 22 of the 24 patients. Wilcoxon test was applied.

Results: In the prospective analysis, the accuracy of staging was 73%. The retrospective analysis showed a better image quality ($p < 0.001$), a better delineation of zonal anatomy ($p = 0.003$), a better delineation of the prostate capsule ($p = 0.007$), and an improved tumor detection ($p = 0.012$) for endorectal MR imaging at 1.5-T. While there were no coil misplacements, also the incidence of artifacts was lower at 1.5-T ($p = 0.002$).

Conclusion: Endorectal coils will continue to be the gold standard of prostate MR imaging in future, most likely also at 3-T.

B-492 10:48

Comparison of 3 T body-coil MR imaging and endorectal-coil 1.5 MR imaging in evaluating prostate cancer

P. Torricelli, F. Cinquantini, G. Ligabue, F. Fiocchi, R. Romagnoli; Modena/IT

Purpose: To compare the results of body-coil 3 T MR imaging with endorectal-coil 1.5 T MR imaging in evaluating prostate cancer.

Methods and Materials: From November 2003 and August 2004, 30 consecutive patients, affected with pathological proven prostate cancer have been evaluated, in the same week, by both endorectal-coil 1.5 T MR imaging and cardiac-coil 3 T MR imaging. Two radiologists basing upon subjective criteria, independently scored the image quality focusing on the following items: cancer tissue conspicuity, capsule involvement, seminal vesicles involvement, neuro-vascular bundle involvement and apex involvement. The image-quality score ranged from 1 to 5 (1: invisible, 2: poorly visible, 3: fairly visible, 4: well visible with some artifacts, 5: well visible without artifacts). In 13/30 patients, who have undergone radical prostatectomy, the staging diagnostic accuracy was compared. Interobserver agreement (k value) and correlability in image quality (Spearman index) were calculated.

Results: The interobserver agreement was always good (k value higher than 0.7) and the image quality score was well correlateable for tumor conspicuity, capsule and apex involvement, (Spearman index higher than 0.3) while it was poorly correlateable for seminal vesicles and neuro-vascular bundle involvement (Spearman index lower than 0.3). The staging accuracy was 89% for endorectal-coil 1.5 T MR imaging and 87% for cardiac-coil 3 T MR imaging (the difference was not statistically significant).

Conclusions: The image quality of endorectal-coil 1.5 T MR imaging is fairly better than cardiac-coil 3 T MR imaging but in cancer staging cardiac-coil 3 T MR imaging can give almost the same diagnostic results of endorectal-coil 1.5 T MR imaging without any discomfort for the patients.

B-493 10:57

Differentiating prostate cancer from healthy prostatic tissue with dynamic contrast-enhanced MR imaging with an endorectal coil at 3 T

S.W.T.P. Heijmink, J.J. Fütterer, H.J. Huisman, T.W. Scheenen, C.A. Hulsbergen van der Kaa, J.A. Witjes, J.G. Blickman, J.O. Barentsz; Nijmegen/NL

Purpose: To evaluate prostate endorectal dynamic contrast enhanced MR imaging (DCE-MRI) at 3 Tesla (3 T) and determine characteristics that distinguish prostate cancer (PCA) from healthy prostatic tissue in PCA patients.

Materials and Methods: Ten patients with biopsy-proven PCA (mean age: 62 years, mean PSA level: 10.0 ng/ml) underwent 3 T endorectal DCE-MRI with subsequent radical prostatectomy. After administration of 15 ml of Gadolinium, T1-weighted 3D image volumes were acquired with a time resolution of 1 second (3D-turboflash, TR 34 ms, flip angle 10°, TE 1.6 ms) for two minutes. DCE-MRI analysis was performed with software developed at the institution. Whole-mount section pathology was used to determine the healthy and PCA regions of interest on MR images. The mean pharmacokinetic parameters of the regions were calculated. The parameters were: the start of enhancement, peak-enhancement, washout, vessel permeability and extracellular volume. PCA $< 0.5 \text{ cm}^3$ were considered beyond the limits of reliable correlation. For statistical analysis the paired Student t-test, ANOVA and ROC analysis were used.

Results: Twenty PCA foci (median Gleason score: 6) and 20 healthy segments were analyzed. The washout parameter (the disappearance of the contrast agent from PCA/healthy prostatic tissue at the end of the dynamic series) was a statistically significant predictor of PCA ($p < 0.05$) with a substantial area under the ROC curve (area under curve: 0.74). Other parameters were not statistically significant PCA predictors.

Conclusions: These preliminary results demonstrate that 3 T endorectal DCE-MRI shows promising results in distinguishing PCA from healthy prostatic tissue. The washout of contrast agent was a statistically significant predictor of PCA.

B-494 11:06

MR imaging and ^1H - MR spectroscopic imaging in the evaluation of prostate cancer

G. Manenti, E. Squillaci, M. Di Roma, S. Mancino, G. Simonetti; Rome/IT

Purpose: To determinate the accuracy of magnetic resonance (MR) imaging improved with proton magnetic resonance (MR) spectroscopic imaging in the detection and localization of human prostate cancer.

Materials and Methods: MR imaging and MR spectroscopic imaging examinations were performed in 38 patients with elevated prostate-specific antigen (PSA) levels or suspicious transrectal ultrasonography (TRUS). All patients underwent digital rectal examination (DRE) and the imaging results were proved with histopathologic examination findings. This population was examined with morphological sequences T2- weighted and T2 SPIR MR imaging at 1.5 T and PRESS spectroscopic sequence with C1-pelvic phased array. In the spectral data analysis, the ratios of choline (Cho) and creatine/phosphocreatine (Cr) to citrate (Cit) [Cho + Cr]/Cr, were compared in suspicious and control tissues, and the

Scientific Sessions

values obtained greater than 3 SDs were considered diagnostic for prostate cancer; conversely values at less than 2 SDs excluded the presence of cancer.

Results: At prospective analysis, MR imaging sensitivity and specificity, respectively, were 89% and 60%. The 3D MR spectroscopic imaging diagnosis of definite cancer had significantly higher sensitivity (97%) but lower specificity (83%).

Conclusion: The addition of proton magnetic resonance (MR) spectroscopic imaging to MR imaging provides better evaluation of prostatic pathologies and detection of prostate cancer than MR imaging alone.

B-495 11:15 ♂

Rapid therapeutic response from castration in prostate cancer demonstrated using ^1H -HRMAS NMR spectroscopy

J.R. Jones, K. Stenman, J. Hauksson, A. Bergh, A. Rydh; Umeå/SE

Purpose: To assess the value of high resolution magic angle spinning nuclear magnetic resonance spectroscopy (HRMAS NMR) in diagnosis of metabolic changes characteristic for prostate cancer.

Methods and Materials: Tumor specimens were achieved from highly differentiated Dunning R3327PAP experimental prostate tumors in rats. Samples were taken from four untreated tumors, and four tumors one, four and seven days each after castration. HRMAS NMR spectroscopy was performed on a NMR spectrometer operating at a ^1H NMR frequency of 500.13 MHz (11.7 T magnet). Regional integrals covering the chemical shift ranges corresponding to total choline, creatine and citrate were calculated.

Results: The characteristic high ratio of total choline to citrate in PCa was reduced already 1 day after castration. Total choline to citrate ratio for samples from castrated animals with induced PCa is highly variable, but tends overall to be significantly lower than for untreated animals, even as early as one day after castration.

Conclusion: HRMAS NMR spectroscopy can demonstrate early metabolic changes in PCa following endocrine therapy. These results could eventually be transferred to clinical practice using MR spectroscopy. Information about the effectiveness of castration treatment could thereby be achieved already within days from induction of endocrine therapy compared to serum prostate specific antigen testing, which demands up to three months waiting time.

B-496 11:24

Choline PET (-CT) and combined MR imaging+MR spectroscopy in the detection of intra-prostatic and pelvic lesions of prostate cancer

M.K. Scherr, B. Scher, M. Seitz, M.F. Reiser, U.G. Müller-Lisse; Munich/DE

Purpose: To determine if PET or PET-CT with C11-doted choline and combined MR imaging+MR spectroscopy (MRS) differ in the detection of intra-prostatic and pelvic lesions in patients with clinical suspicion of prostate cancer (PCA).

Material and Methods: Patients with clinical suspicion of PCA and previously negative biopsy ($n = 11$) or of recurrent PCA after radical prostatectomy/radiation therapy ($n = 4$), or biopsy-proven PCA ($n = 4$) underwent both PET ($n = 10$) or PET-CT ($n = 9$) with 800 MBq of C11-doted choline and combined MR imaging+MRS of the prostate within 1 week of each other. PET/PET-CT (skull base to proximal thigh) was analysed by two nuclear medicine physicians. MR imaging (T1ax, T2 ax, cor, sag) and 3D-SE-MRS of the prostate and pelvis was evaluated independently by two radiologists. Results were analysed as being positive or negative for PCA, PCA localization, and pelvic metastasis and validated by histopathology ($n = 15$) or follow-up imaging ($n = 4$).

Results: Sensitivity and specificity for PCA detection were 10/11 (91%) and 5/8 (63%) for PET/PET-CT, and 10/11 (91%) and 6/8 (67%) for MR imaging+MRS, respectively. MR imaging+MRS showed better per sextant localization of intra-prostatic PCA. All pelvic metastases (lymph nodes $n = 2$, osseous $n = 2$) were detected by both modalities, but PET/PET-CT provided additional metabolic information.

Conclusions: Results imply similarly high sensitivity for prostate cancer of PET/PET-CT with C11-doted choline and MR imaging+MRS. Both demonstrated pelvic metastasis. MR imaging+MRS was superior for intra-prostatic PCA localization, which may guide further biopsy in patients with previously negative biopsy.

B-497 11:33

Early detection of local prostate cancer recurrences after radiation therapy by means of endorectal dynamic contrast-enhanced MR imaging and 3D ^1H MR spectroscopy with biopsy confirmation

S.W.T.P. Heijmink, J.J. Fütterer, E. van Lin, T.W. Scheenen, C.A. Hulsbergen van der Kaa, J.A. Witjes, J.G. Blickman, J.O. Barentsz; Nijmegen/NL

Purpose: To determine the feasibility of early local prostate cancer (PCA) recurrence detection after radiation therapy using dynamic contrast-enhanced (DCE) endorectal MR imaging and ^1H MR spectroscopy followed by ultrasound-guided biopsy.

Methods and Materials: A cohort of 51 PCA patients that had undergone endorectal MR imaging prior to 3D conformal radiation therapy was followed up with half-yearly prostate-specific antigen (PSA) tests. Of this cohort, seven patients had three consecutive PSA rises (the ASTRO definition of biochemical recurrence). The mean PSA, PSA doubling time and PSA velocity were 3.4 ng/ml, 7.7 months and 3.1 ng/ml/year, respectively. Patients underwent MR imaging with an endorectal-phased array coil. T2-weighted FSE images in three directions, 3D ^1H MR spectroscopy (MRS) and T1-weighted postcontrast images were obtained. Three readers independently analyzed all MR images to determine recurrence localization and in consensus determined the spots for biopsy. Consequently, patients underwent ultrasound-guided biopsy. A sextant biopsy plus two transition zone cores were taken. Additionally, maximally four biopsies were taken based on MR/MRS findings.

Results: Two patients refused biopsy. A total of 40 sextant biopsy and 9 MR-guided biopsy cores were taken. On a core-by-core basis, the standard and MR/MRS-guided biopsies had positive biopsy rates of 23% (9/40) and 22% (2/9), respectively.

Conclusion: Using endorectal DCE MR and MRS imaging can importantly reduce the number of biopsy cores necessary with an equal detection rate for detecting early PCA local recurrence. MR-based biopsies needed only one-fifth (9/40) the number of cores that the standard biopsy used.

B-498 11:42

Retained seminal vesicles following prostatectomy: MR features

T. Sella¹, L.H. Schwartz², H. Hricak²; ¹Jerusalem/IL, ²New York, NY/US

Purpose: Seminal vesicle remnants following radical prostatectomy (RP) may present potential pitfalls in the interpretation of pelvic MR imaging. The purpose of this study is to define the frequency and the MR features of SV remnants, in patients following RP.

Materials and Methods: This retrospective review examined pelvic MR imagings of 126 consecutive post-RP patients between the years 1999–2003. The surgeon who performed RP, time interval between surgery and MR imaging, and presence of SV remnants on MR images were recorded. SV remnants were characterized for location, size, and signal intensity. Descriptive statistics were used for analysis.

Results: SV remnants were found in 72/126 patients (57%). These were bilateral in 57(79%) and unilateral in 15(21%). Complete SVs were seen in 6 patients (8%), partial SVs in 7(10%), and only tips of SVs in 59(82%). Overall, a total of 129 SV remnants were found in 72 patients. Fibrotic remnants were seen in 117/129(91%). 95/126 patients (75%) had surgery performed at a single institution, by 11 different surgeons. Average time from surgery to MR imaging was 39.5 months (range 2–156); 36.8 months (range 2–122; $n = 66$) for patients with fibrotic SV remnants, 41.8 months (range 6–84; $n = 8$) when SV remnants were intact.

Conclusion: Retained SV remnants are a common finding following RP. The majority are fibrosed distal tips. SV remnants must be recognized to avoid misinterpretation as local recurrences. We suggest reporting this finding as part of the standard report of a post-RP pelvic MR imaging, for the benefit of clinicians and radiologists involved in the patient's treatment.

MR-guided laser induced thermotherapy of liver metastases of gastric cancer

M.G. Mack, T. Lehnert, K. Eichler, R. Straub, J.O. Balzer, S. Zangos, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To analyze the potential of LITT for the treatment of liver metastases of gastric cancer.

Methods and Materials: 25 patients (average age of 61 years, range 36 to 86 years) were treated. The total number of metastases was n = 53, ablated in 43 session. The mean number of lesions per patient was 2.1 (range 1 - 4). Survival rates were calculated using the Kaplan-Meier method. 9.1% of patients had recurrent metastases after surgery, 48.0% metastases in both liver lobes, 28.0% refused surgical resection, 8.0% had contraindications for surgery, and 8.0% had metastases at difficult localization.

Results: All ablations could be done on an out patient basis using local anesthesia. The mean survival was 2.2 years (95% CI 1.5 - 2.9 years, median survival 1.3 years, one year survival rate 67%, two year survival rate 43%) after the first LITT treatment and 2.6 years after the diagnosis of the metastases, which was treated with LITT (95% confidence interval 1.9 - 3.3 years, median survival 1.6 years, one year survival rate 79%, two year survival rate 49%, three year survival rate 42%). The mean size of the lesion was 2.7 cm (range 0.8 cm to 7 cm, mean volume 14.7 ml), the mean size of necrosis was 4.7 cm (range 2.0 to 8.0 cm, mean volume 31.3 ml). The mean applied energy was 99.2 kJ (range 33.1 to 258.8 kJ)

Conclusion: Local ablation of liver metastases of gastric cancer using LITT is a safe minimal invasive treatment option in well selected cases.

B-501 10:39

Preoperative chemoembolization in patients eligible for liver transplantation affected by hepatocellular carcinoma: Evaluation of antitumoral response on explanted livers and tumor recurrence

D. Leni, R. Corso, C. Zavaglia, A. Rampoldi, M. Castoldi, A. Vanzulli; Milan/IT

Purpose: To assess the antitumoral efficacy and the incidence of tumor recurrence in a cohort of cirrhotic patients, with hepatocellular carcinoma (HCC), who were treated preoperatively by transarterial chemoembolization (TACE) followed by liver transplantation (OLT).

Materials and Methods: 79 patients in transplantation list affected by unresectable solitary HCC nodule ≤ 5 cm or no more than 3 HCC nodules with none > 3 cm, underwent selective TACE infusing a mixture of epirubicin, lipiodol and gelatin sponge powder. Treatment response was assessed by histology on explanted livers.

Results: The median follow-up was 47 months (range 0-165). The median time between inclusion onto the transplantation list and OLT was 6 months (range 0.2-52). There were 10 deaths within 3 months of OLT that were considered postoperative complications. Overall 1-, 3-, 5- and 10-year survival were 80%, 69%, 64% and 55%, respectively. At the end of follow-up, 8 patients (10%) experienced tumor recurrence: among these, 7 patients had no response to treatment. An objective response was achieved in 36.7% of the patients. Complete necrosis of the tumor was observed in 15 patients (18.9%), 9 of them with monofocal tumor ≤ 3 cm. None of the patients who experienced a complete antitumoral response to treatment had recurrence of HCC after transplantation. Partial antitumoral response was observed in 14 patients (17.7%) with 1 recurrence of HCC observed in the follow-up.

Conclusion: Preoperative TACE induces a low rate of histological antitumoral response in patients with HCC who undergo liver transplantation. However, tumor recurrence is rarely observed in responders to treatment.

B-502 10:48

Selective internal radiation therapy with Yttrium-90 resin microspheres (SIRT-Y) in extended metastatic disease of the liver: Initial experiences

T.F. Jakobs, R.-T. Hoffmann, K. Tatsch, M.F. Reiser, T.K. Helmberger; Munich/DE

Purpose: In patients with extensive malignant hepatic disease non-responding to classic chemotherapy no effective therapeutical options are existing. Selective internal radiation therapy with Yttrium-90 microspheres (SIRT-Y) represents a novel treatment concept. Initial results regarding feasibility and efficacy in advanced hepatic metastases will be presented.

Methods and Materials: 18 patients with advanced metastatic disease of the liver non-responding to polychemotherapy qualified for SIRT-Y. If maintainable neo-adjuvant chemotherapy was continued. During follow-up by contrast enhanced MSCT, MR imaging, and FDG-PET hepatic tumor load, tumor markers, survival, and time to progress were recorded.

Results: One major adverse event was caused by the SIRT-Y procedure (gastric ulcer due to extrahepatic embolization). All patients are still alive. Mean follow-up time is 20 weeks (6 - 56). One patient presented enlarged abdominal lymphnodes 6 months after therapy, one patient underwent RF-ablation of a residual metastasis, and 2 patients presented new moderate progress of the residual tumor 7 and 12 months after SIRT-Y. According to RECIST criteria, the hepatic tumor load decreased substantially paralleled by a significant drop of tumor markers.

Conclusion: SIRT-Y has the potential of a powerful palliative therapy concept in patients with non-resectable, otherwise non-treatable or to chemotherapy non-responding hepatic metastases. Further studies are imperatively necessary to prove if the efficacy of SIRT-Y can be increased even more in a multimodality therapy regimen, e.g. in early stages of metastatic disease.

B-503 10:57

Percutaneous injection therapy by Holmium-166-chitosan complex in small hepatocellular carcinoma: Initial experience as a primary treatment

H.-K. Ko, K. Kim, J.-T. Lee, D.-Y. Lee, J.-Y. Won, S. Kim, J.-Y. Choi; Seoul/KR

Purpose: To evaluate local therapeutic efficacy, side effects and complications of percutaneous injection therapy of Holmium-166-chitosan complex (o-Chi-Com) in the treatment of small Hepatocellular carcinoma (CC) lesions as a primary treatment.

Materials and Method: 56 patients (mean age, 58.4; male 47; female 9) with 63 HCC lesions measuring 1.1-3.0 cm in diameter (mean, 2.4 cm) underwent percutaneous injection therapy of Ho-Chi-Com as a primary treatment. By ultrasonography-guided puncture of Multi-side hole fine needle in the center of tumor, 20 mCi/cm³ in tumor diameter of Ho-Chi-Com was injected for complete tumor necrosis. A single lesion was treated in 49 patients, and double lesion were treated in 7 patients. Follow-up with serial CT scan ranged from 1 to 43 months (mean, 14.5 months).

Result: Complete necrosis was achieved in 54 (85.7%) of 63 lesions. Among the 54 lesions, complete necrosis required a single treatment session in 47 lesions (87%), and two treatment sessions in 6 lesion (9.5%), three treatment sessions in 1 lesion (3.5%). Three major complication (Bone marrow suppression) were observed and required transfusion. Six minor complication (3 hypersensitivity to chitosan, 3 mild fever) was completely recovered after conservative treatment. There is no mortality related to treatment.

Conclusion: Percutaneous injection therapy by Ho-Chi-Com is an effective method to treat small HCC as a primary treatment.

B-504 11:06

Transarterial chemoembolization (TACE) in comparison to transarterial chemoperfusion (TACP) in patients with inoperable intrahepatic cholangiocellular carcinomas (ICC)

M. Heller, S. Zangos, W. Schwarz, J.O. Balzer, M.G. Mack, T.J. Vogl; Frankfurt a. Main/DE

Background: The ICC is one of the most chemotherapy-resistant tumors and it is mostly diagnosed in an advanced inoperable stage. In this study we compared the tolerability and efficacy of an intraarterial chemotherapy via TACE and via TACP.

Material and Methods: 40 patients were randomized in TACE (group A = 20 patients) and TACP (group B = 20 patients) arms. Both groups were given 2000 mg/m² Gemcitabine with additionally application of spherex in group A. Tumor response rates were evaluated via MR imaging.

Results: All patients of both groups were successfully treated with a mean of 5 courses. Partial response was noted in 6 patients of group A (30%) and 4 patients

Scientific Sessions

of group B (32%). Stable disease was assessed in 11 patients of group A (55%) and 8 patients of group B (40%) for at least 3 months. Median time to progression was 7.9 months in group A and 5.9 months in group B.

Conclusion: Both used outpatient treatment protocols are minimal invasive and seem to be an effective palliative treatment option. However the usage of Gemcitabine in a TACE regimen in comparison to a TACP regimen shows significantly better response rates.

B-505 11:15

Polyvinyl alcohol embolization adjuvant to oily chemoembolization in hepatocellular carcinoma with arterioportal shunt

H.G. Lee, Y.J. Kim, Y.S. Lim, M.H. Chung, M.S. Sung, W.J. Yoo, H.W. Lim; Buchon/KR

Purpose: This study was performed to assess the feasibility and safety of polyvinyl alcohol embolization adjuvant to oily chemoembolization (P-TACE) in hepatocellular carcinoma (HCC) with arterioportal shunt (APS).

Materials and Methods: We retrospectively reviewed 20 HCC patients with APS. Polyvinyl alcohol embolization was performed to block APS before routine TACE. Ten patients underwent P-TACE one time due to progression of liver cirrhosis and/or HCC. The rest 10 patients underwent the first P-TACE and the repeated TACE 2-3 times with PVA ($n = 6$) and without PVA ($n = 12$). Hepatic function test before and after P-TACE, and post procedural complication were evaluated for safety. Grade of APS and portal flow direction were observed for feasibility.

Results: Of 26 P-TACE, 7 developed transient hepatic insufficiency and 2 showed progressive deterioration of hepatic function (survival: 28 and 114 days, respectively). No major complication was occurred. APS and portal hepatofugal flow were improved after P-TACE on 1-5 months follow-up angiogram ($P < 0.05$). Eight patients improved APS grade and 2 patients did not changed on follow-up angiogram. Six patients with hepatofugal flow showed hepatopetal flow immediately after P-TACE and hepatofugal flow recurred in 2 patients on follow-up. The mean survival day was 207 days.

Conclusion: P-TACE is feasible and safe in HCC patients with APS.

B-506 11:24

Percutaneous, transfemoral implantation of an IA port system for locoregional chemotherapy in liver metastasis: Long term outcome

J.O. Balzer¹, N. Fleiter¹, M.G. Mack¹, E. Böcher², T. Hamm², T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Soest/DE

Purpose: To evaluate the primary technical success rate and long term outcome after percutaneous port implantation for IA chemotherapy of liver metastasis.

Methods: Between September 2001 and September 2004 69 patients with liver metastasis presented for percutaneous IA port system implantation. The IA port system was implanted via a transfemoral approach and placement of the port chamber above the Trochanter minor. The chamber was connected to a 5F diagnostic catheter which was placed in the hepatic artery. The patency rate was determined using the Kaplan Meier analysis.

Results: In 63.3% a successful port implantation could be achieved. Not successful implantations were due to anatomical variation of the celiac trunk (44%), accessory liver arteries with anatomical variation of arterial liver supply (33%) or catheter displacement during intervention (23%). The mean duration of port utilization was 207 ± 71.4 days. The catheter tip was located in 22.6% patients within the A. hepatica propria, in 74.2% in the common hepatic artery and in 3.2% in gastroduodenal artery. The periinterventional complication rate was 9.7%, mainly due to local bleeding complications. Postinterventionally the complication rate was 22.6% with catheter displacement or kinking of the diagnostic catheter (19.3%) and catheter thrombosis (3.2%). All complications could be managed interventional. The primary patency rate was 80.6% and the secondary patency rate 87.1%.

Conclusion: Percutaneous placement of an i.a. port via a transfemoral approach is feasible. This technique represents an alternative to surgical implantation in the locoregional treatment of liver metastases and opens new therapeutic possibilities for the local prolonged treatment.

B-507 11:33

Hepatic intra-arterial chemotherapy with gemcitabine: An ongoing phase II study in patients with liver metastases of breast cancer

K. Eichler, M.G. Mack, J.O. Balzer, A. Thalhammer, W. Schwarz, M. Heller, S. Zangos, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To evaluate the efficacy and tolerability of hepatic intra-arterial chemoembolization with gemcitabine as a cytostatic agent in pts with inoperable liver metastases of breast cancer.

Material and Methods: Ongoing, open-label, single-center study design; pts had histologically confirmed breast cancer with inoperable liver metastases, adequate bone marrow reserve, sufficient liver/renal function, no active CNS metastases, KPS > 70%, and life expectancy > 12 weeks. A suspension of gemcitabine 1,200 mg/m², 10 ml/m² of iodised oil (Lipiodol), and 5 ml of a degradable starch microsphere (Spheraex) suspension, is administered intra-arterially up to 3 times every 4 wks. Dose-limiting toxicity (DLT) is defined as grade 4 thrombocytopenia, neutropenia, or nonhematologic toxicity > grade 3.

Results: 21 pts were enrolled (median 56 yrs, range 48-65). All pts tolerated the treatment well, with no DLTs. Tumor response was evaluated by magnetic resonance (MRT) and computed tomography (CT) imaging. Imaging revealed a decrease in the degree of vascularisation of the treated metastases, which was verified as a reduction in the Gd-DTPA enhanced T1-weighted transverse and sagittal MR imaging scans. Seven pts achieved a partial response, 10 stable disease, and 4 progressed. Progression was verified as an increase in size of the lesions or newly developing lesions.

Conclusion: Hepatic intra-arterial chemotherapy with gemcitabine is well tolerated and achieves encouraging response rates in pts with liver metastases of breast cancer.

B-508 11:42

PTFE-covered stent increases patency and clinical outcome in patients with TIPS for Budd-Chiari syndrome

R. Gandini, D. Konda, V. Pipitone, L. Maresca, A. Spinelli, E. Pampana, G. Simonetti; Rome/IT

Objective: to compare patency, re-intervention rate and clinical outcome of TIPS using uncovered and ePTFE-covered (VIATORR; W.L. Gore and Associates) stents in patients with Budd-Chiari Syndrome.

Materials and Methods: from January 1994 to November 2003 ten patients (mean age: 39 yrs, range: 17-65 yrs) affected by Budd-Chiari Syndrome underwent TIPS. In the first 5 patients TIPS was performed using uncovered Wallstents (group A). After April 2001, TIPS was carried out in 5 patients (group B) using an ePTFE-covered VIATORR stent-graft. Follow-up was performed with US at 7 and 30 days and subsequently every 3 months after the procedure. Liver function was evaluated every 3 months.

Results: All group A shunts underwent occlusion with a mean primary patency of 5.3 months (range: 7 days-10 months). During a 24.4-month mean follow-up (range: 7-37) an overall of 9 revisions with Wallstent and 20 balloon-angioplasty recanalizations were performed. The repeated re-occlusion of the Wallstents and worsening of liver function lead to one surgical mesocaval shunt, one orthotopic liver transplant and one death for liver insufficiency. One patient with re-occlusion of the shunt refused further treatment and was lost to follow-up. In one patient with re-occlusion, the shunt was revised with a VIATORR stent-graft and is still normally. In group B, a revision-free patency with persisting improvement of liver function was achieved in all patients with a mean follow-up of 22.0 months (range: 10-34).

Conclusion: ePTFE-covered VIATORR stent-graft significantly increases primary patency in TIPS for Budd-Chiari Syndrome with reduction of re-intervention rate and prolonged clinical improvement.

B-509 11:51

Porto-systemic shunt reduction for the treatment of hepatic encephalopathy after TIPS performed with E-PTFE covered stent-graft

G. Simonelli, F. Fanelli, F.M. Salvatori, M. Corona, D. Pepino, V. Dominelli, E. Boatta, P. Rossi, R. Passariello; Rome/IT

Purpose: To assess the rate of hepatic encephalopathy (HE) in patients who underwent a TIPS with PTFE covered stent-graft.

Materials and Methods: From January 2000, 98 TIPS were performed using an e- PTFE covered stent (Viatorr - WL Gore). In 10 cases the stent-grafts were 8 mm in diameter while in 88 patients a 10 mm diameter stent-graft was implanted. After a mean period of 1.2 months, 46 patients developed HE, not responding to medical care in 12 cases. In these cases a shunt reduction was performed with insertion inside the shunt of a balloon-expandable PTFE covered stent (Jostent-Jomed AG) with an hourglass shape.

Results: Technical success was achieved in all cases with immediate increase of the porto-systemic gradient and disappearance of symptoms. The mean pressure value increased from 7 to 14.8 mmHg. After a mean follow-up of 7.75 months 8 patients are alive without further episodes of HE or bleeding. In 1/12 pz (8%) a re-dilation of the shunt was necessary for reappearance of ascites. Three patients died after 6, 5 and 1 months for rebleeding ($n = 1$) and cardio-vascular failure ($n = 2$). No statistical correlations between shunt diameter and incidence of HE was observed.

Scientific Sessions

Conclusions: TIPS performed with the Viatorr stent-graft presented an increased rate of HE.

Mid-term experience with intracranial stenting

F. Brassel¹, R. Raabe¹, C. Haupt¹, K. Papke¹, H. Becker²; ¹Duisburg/DE,

²Hannover/DE

Purpose: The aim of this study was to demonstrate the outcome and identify potential problems with intracranial stenting for different indications.

Methods and Materials: Between 1998 and 2004, 40 patients were selected for treatment with intracranial stents. There were 19 male and 21 female patients with ages ranging from 4 to 80 years. The treatment included patients with aneurysms ($n = 25$), dissecting aneurysms ($n = 4$), stenoses ($n = 9$) and arteriovenous fistulas ($n = 2$). 22 lesions were located in the internal carotid artery, 9 in the basilar artery, 5 in the middle cerebral artery, 3 in the vertebral artery and 1 in the posterior cerebral artery. 11 different types of stents were used (3 self expandable and 8 balloon expandable). 15 patients underwent combined endovascular stent implantation and coil placement.

Results: In 7 cases, it was not possible to reach the lesion with the stent catheter. Four patients died within a week after treatment. Good mid-term clinical outcome was achieved in the remaining 29 patients (72.5%). All patients who died were high-risk patients with stent placement during the acute phase of e.g. subarachnoid haemorrhage or cerebral infarction.

Conclusions: Advances in stent technology allow the treatment of the cerebral vasculature. The technique of using a stent on intracranial lesions shows good results in patients without preinterventional cerebral bleeding or infarction. The higher flexibility of so called neurostents improves the access to intracranial vascular lesions even in distal vessels and tortuous anatomy.

B-511 10:39

Carotid artery stenting under cerebral protection: Experience in 96 patients

R. Gandini, D. Konda, A. Spinelli, S. Fabiano, C.A. Reale, E. Pampana,

G. Simonetti; Rome/IT

Purpose: To assess efficacy and safety of CAS performed under cerebral protection.

Materials/Methods: 96 patients with 104 internal carotid artery stenoses (72 primary and 32 post-CEA) underwent CAS under cerebral protection (97 carotid Wallstents + EPI-filter protection device, 5 Acculink carotid stents + Accunet device, 2 Conformex stents + EPI-filter). Postprocedural follow-up was performed by Doppler US at 7 days, 3 months, 6 months and, subsequently, every 6 months.

Results: Technical success was achieved in 100% of the cases. Pre-dilation of the stenosis was required in 8 cases. During the procedure, two patients developed a TIA due to temporary blood flow interruption within the treated artery which resolved immediately after removal of the filter. One minor stroke was observed. Three autolimiting vagal reflexes occurred during balloon inflation. The post-procedural revision of the filters revealed embolic debris in 6 cases with primary stenosis. In all cases, the post-procedural DSA confirmed the optimal caliber of the treated artery and a physiological intracranial blood flow. At follow-up, all stents were patent and a mild intimal hyperplasia was observed in two patients at 6 months, 1 patient at 12 months and 1 patient at 18 months after the procedure. No late neurological complications occurred.

Conclusion: CAS performed under cerebral protection is safe, effective and reduces the risk of intra-procedural embolism.

B-512 10:48

Stenting of the carotid arteries: 4 years of experience

F. Fanelli, F.M. Salvatori, S. Vagnarelli, M. Corona, A. Bruni, L. Di Rezze,

A. Pucci, P. Rossi, R. Passariello; Rome/IT

Purpose: To evaluate the safety and efficacy of carotid artery stenting (CAS) performed with cerebral protection devices.

Methods and Materials: From February 2000, CAS with cerebral protection was performed in 105 patients with extracranial carotid artery stenoses (> 70%). The plaque was ulcerated in 21 cases, soft in 44 cases and calcified in 46 cases. Seventy-nine stenoses were primary, while 32 were secondary to TEA. 113 stents were implanted: 102 carotid wallstent, 8 Acculink, 3 Precise, were implanted in 111 carotid arteries. All procedures were performed using a cerebral protection device: Parodi system (4), EPI filter wire (99), Angioguard (2), NeuroShield (3), Spider embolic protection (2), Accunet (1). All patients had independent neurologic examination before and after the procedure. A cerebral MR examination with diffusion and perfusion sequences was also performed before and after the procedure to evaluate neurologic complications occurred during CAS.

Results: Technical success (residual stenosis < 30%) was achieved in all cases. No death occurred during the whole follow-up ranging from 1 to 47 months. Six complications (5.4%) were observed: 1 major stroke (0.9%) and 5 minor stroke (4.5%). In 7 cases (6.5%) embolic material was found inside the cerebral protection. In two cases (1.8%) a moderate in-stent restenosis was detected and treated with angioplasty ($n = 1$) and angioplasty with restenting ($n = 1$).

Conclusions: CAS represent a feasible procedure that can be performed in high-risk patients and it is associated with a low restenosis rate.

B-513 10:57

Protected carotid artery angioplasty and stenting: Acute and long term outcomes in 225 interventions

G. Piccoli, A. Marzio, A. Vit, M. Sponza, B. Bais, G. Gigli, D. Gasparini; Udine/IT

Purpose: The aim of our investigation was to evaluate the benefit of carotid angioplasty and stenting for prevention of cerebrovascular disease.

Materials and Methods: We treated 225 lesions using always protection device; 51 patient have 30 day follow-up and 151 have 6 month or more. We used NASCET to select patients; every candidate was previously clinically evaluated by Neurologist and Hagiologists.

Results: 65% of patients had neurological symptoms before the treatment, 41.30% of them had a previous stroke, 34.8% a previous T.I.A. and 23.9% a specific events like dizziness. The outcome was evaluated on a mean follow-up of 10.2 months (range 1-32). 3 patients had a minor stroke and 1 had a major stroke. One of the asymptomatic group had a major stroke 39 days after treatment, but on the contralateral hemisphere. One patient died because of pulmonary emboli and one because of fatal stroke. 3 more patients died after several months because of unrelated reasons. The 6 month follow-up showed 4.7% restenosis rate and a secondary patency of 99%.

Conclusion: Our findings demonstrate that carotid angioplasty is a safe procedure and the results are the same as of surgical ones reported in the literature. Global complication rate was 6 cases (2.7%), of these the neurological ones were 5 (2.2%). The restenosis rate was 7 (4.7%) using a cut off of 50% of stenosis. Our results are in line with those of recent randomised studies.

B-514 11:06

Primary carotid stenting: 2 years follow-up of the first 100 cases

R. Rostagno¹, R. Llorens¹, T. Zander¹, I. Zerolo¹, E. Sanabria¹, F. Barajas¹,

Z. Qian², M. Maynar¹, W. Castañeda-Zúñiga²; ¹Santa Cruz de Tenerife/ES,

²New Orleans, LA/US

Purpose: A local inflammatory response to arterial wall injury after PTA has been blamed as the main cause of intimal hyperplasia and later instant restenosis. We report the incidence of instant restenosis after primary carotid stenting without pre- or post balloon dilatation in patients with carotid stenosis.

Materials and Methods: Between May 2002 and August 2004, 100 carotid arteries in 87 consecutive patients were treated with primary Stent placement (Acculink, Guidant), without pre or post balloon dilatation. Following the initial stent procedure neurological examination, doppler ultrasound and plain film were perform at 24 hours, 1 month, 3 month and every 6 months thereafter. If restenosis was suspected by the Doppler ultrasound, arteriography was performed and the patients were subjected to endovascular intervention if a restenosis over 70% was confirmed at arteriogram.

Results: All patients were included in the follow-up. Initial residual stenosis after stenting was: mean 21% (from 0% and 50%). Restenosis was detected in 6 cases (6%) at 7.5 months (from 3 to 12 month). These patients had residual stenosis after stenting of 29% (from 0% to 40%). Balloon dilatation was perform with a balloon (Maverick, Boston Scientific) using a protection device (Accunet, Guidant). Technical success was achieved in all patients, defined as stenotic lumen less than 20%. No patient experienced any major or minor neurological complications.

Conclusions: In this short pool of patients, primary carotid stenting without pre or post dilatation shows reduction of instant restenosis.

DW-MR imaging study after carotid stent placement with protection device (CASPD): Role of monitoring at 6 and 24 hours after procedure

I. Sansoni, A. Laghi, C. Miglio, M. Celestre, M. Rengo, M. Di Martino, L. Coletta, R. Passariello; *Rome/IT*

Purpose: To define the role of diffusion-weighted MR imaging performed within 6 hours from carotid angioplasty and stent placement with protection device (CASPD) in detecting new ischemic lesions.

Methods and Materials: We prospectively studied 34 consecutive patients (age range: 66-95 Ys, mean 75 ± 5.7) referred for CASPD procedure. Inclusion criteria were asymptomatic stenosis > 80% (30 pts) or symptomatic stenosis > 50% (4 pts). Patients underwent neurologic examination before, immediately after, and 1 day after CASPD. FLAIR and DW MR images were acquired immediately before (1-3 hours), within 6 and 24 hours after CASPD, in order to assess the number of symptomatic and silent new ischaemias. The pre- and post-intervention images obtained at b value of 1000 were examined by two independent blinded reviewers for new high-signal areas consistent with ischaemia. Total examination time was 5 minutes. We finally correlated positive results with risk factors, technical difficulties and plaque characteristics.

Results: Postprocedural (6 hours) DW-MR images showed one new symptomatic ischemic lesion (2.9%) on the opposite side of stent placement; the late (24 hour) DW-MR imaging detected recent ischaemic lesions on the side of stent placement in three more patients (8.82%), two symptomatic and one asymptomatic. All of them had at least two risk factors and fibrocalcified plaque.

Conclusion: CASPD may be associated with embolic events. The use of DW-MR imaging within 6 hours (early) confirm CASPD as a safe procedure, with few strictly procedure-related ischaemic complications. Twenty-four hour DW-MR imaging shows later embolization.

B-516 11:24

CT brain perfusion following carotid stenting

T. Jargiello, A. Trojanowska, J. Wojczal, A. Wolski, A. Drop, M. Szczero-Trojanowska; *Lublin/PL*

Purpose: The aim of our study was evaluation of brain CT-perfusion in patients undergoing CAS.

Material and Methods: CAS with filter neuroprotection was performed in 75 symptomatic patients (ICA stenosis > 70%). There were 59 patients with unilateral ICA stenosis and 16 with contralateral ICA occlusion or stenosis. CT examinations were performed using multidetector CT-scanner: non-contrast brain scans, dynamic perfusion imaging and CT-angiography. Maps showing absolute values of cerebral blood flow (CBF), cerebral blood volume (CBV) and mean transit time (MTT) were derived from brain tissue enhancement curves.

Results: CAS was successful in all patients. Among 59 patients with unilateral ICA stenosis, perfusion deficits were present in 54 (91%). MTT elongation was noted (average 6.6 s), together with decreased CBF (average 44 ml/100 g/min) and slightly increased CBV (average 3.4 ml/100 g). We observed perfusion improvement in all 54 patients after CAS. Normalization was found in 42 patients (77%) right after intervention, and after 6 months it was 49 (81%). In a group with contralateral ICA occlusion or stenosis, perfusion deficits were present in both hemispheres in all 16 patients (MTT average - 9.2 s; CBF average - 29 ml/100 g/min; CBV average - 3.7 ml/100 g). After CAS perfusion normalization was noticed in 9 patients (56%) and after 6 months in 4 more patients (13 - 81%).

Conclusion: CT-perfusion can assess brain perfusion before and after CAS. It helps to qualify patients for CAS and shows procedure's effectiveness.

B-517 11:33

Carotid stenting: Complications within 30 days using filter neuroprotection

T. Lupattelli, M.J. Fischer, S. Mosca, A. Maselli, P. Pozzilli, G. Scalera, L. Lupattelli; *Perugia/IT*

Purpose: To evaluate procedural complications using neuroprotection for carotid stenting.

Methods and Materials: 191 procedures for carotid stenting in patients with symptomatic or asymptomatic severe, and severe post-surgical restenosis were performed. For neuroprotection we used "TRAP" (Microvena, Italy) or "EPI-Filter" (Boston Scientific, USA) during primary stent with Carotid Wallstent (Boston scientific, USA).

Results: The TRAP and EPI-Filter device were used in 16% and 76% of the cases respectively. In the 8% of cases the filter device did not pass the stenosis. In 69 patients macroscopic debris in the filter device was revealed. Within 30 days neurological complications (n = 27), TIA (n = 11), and death due to ictus (n = 1) occurred.

Conclusion: Although filter neuroprotection reduces the risk of the intracerebral macroemboli due to carotid stenting, several peri- and postprocedural complications should be considered.

B-518 11:42

Occurrence of focal ischaemia after carotid artery stenting without using a neuroprotection device

A. Waaijer, T.H. Lo, T.H. Witkamp, M. Prokop; *Utrecht/NL*

Purpose: To identify the frequency of new focal ischaemic lesions after carotid artery stenting (CAS) without using neuroprotection.

Materials and Methods: Between October 2003 and June 2004, 24 patients with symptomatic stenosis of the internal carotid artery were consecutively treated with primary stent implantation. We did not use neuroprotection devices in any patient and focused on keeping the procedure time short and performing the intervention asatraumatic as possible. No additional procedures like rotational angiography or transcranial Doppler were performed during intervention. For the last 15 patients we performed DW-MR imaging before and within 24 hours after CAS. We obtained DW-MR imaging using a 1.5 Tesla system with a spin-echo sequence with b-values of 0-1000; the diffusion gradients were successively activated in the tree orthogonal space directions. Two neuroradiologists evaluated all MR images independently for the occurrence of new lesions by pair-wise comparison of pre- and post-images.

Results: All patients were treated successfully. Mean duration of the procedure was 54 minutes. Pre-dilatation was performed in most cases, post-dilatation only if necessary. Among the first nine patients one patient suffered from a TIA which lasted less than 2 minutes, and from which he recovered completely. In the next 15 patients no new lesions could be detected on DW-MR imaging.

Conclusion: Focal ischemia may be a rare event after carotid artery stenting without using a neuroprotection device if there is a focus on keeping the procedure as short and atraumatic as possible.

B-519 11:51

Use of covered stents in treatment of large neck internal carotid artery

R. Gandini, M. Chiocchi, M. Stefanini, V. Pipitone, G. Pendenza, G. Simonetti; *Rome/IT*

Purpose: To demonstrate efficacy and safety of the endovascular treatment of large neck internal carotid artery pseudoaneurysms, using covered stents.

Materials and Methods: Between 1999 and 2003 we treated 5 patients with large neck pseudoaneurysms. 4 pseudoaneurysms were post-traumatic and 1 was spontaneous. 4 patients were symptomatic, (headache, neck pain) while 1 was asymptomatic. The diameter of the pseudoaneurysms varied between 10 to 45 mm, with a wide neck between 8 and 25 mm. In all patients a 6Fr guiding catheter was positioned into the ICA. 3 Symbiot ePTFE covered stents, 1 JOSTENT, and 1 Advanta were deployed, using the monorail technique, over the neck of the pseudoaneurysms. During the procedure 1000 IU of Heparin were administered to all patients. Post procedurally all patients received an antiaggregant therapy (clopidogrel for six week and aspirin for six months).

Results: Post procedural DSA demonstrated, in all the patients, the complete exclusion of the aneurysms without complications. CT and ECD performed at 3, 9, 24 months confirmed the exclusion of the aneurysms and patency of ICA in 4 cases. In 1 case the controls revealed a rupture of the stent, in this patient a second stent graft was positioned.

Conclusion: Despite the limited experience with covered stents in the treatment of large neck internal carotid artery pseudoaneurysms, this technique seems very promising if combined with post-procedural anti-aggregant therapy.

B-520 10:30

16-detector row spiral CT versus MR imaging for the assessment of left ventricular function in acute myocardial infarction: An animal study

A.H. Mahnken, M. Katoh, P. Bruners, E. Spuentrup, J.E. Wildberger, R.W. Günther, A. Buecker; Aachen/DE

Purpose: To assess left ventricular (LV) function and regional wall motion using ECG-gated 16-slice computed tomography (MSCT) in comparison to magnetic resonance imaging (MRI).

Materials and Methods: In 15 pigs acute myocardial infarction was induced by occlusion of the left anterior descending coronary artery. Thereafter, MSCT and MRI were performed with standardized examination protocols. From manually drawn endo- and epicardial contours LV volumes (end-diastolic volume (EDV), end-systolic volume (ESV), stroke volume (SV)), ejection fraction (EF) peak filling rate (PFR), peak ejection rate (PER), time to PER (TPER), time from end-systole to PFR (TPFR) and myocardial mass were calculated. Regional wall motion was visually assessed from cine loops. LV function was analyzed using Bland-Altman method, Student's t-test and Pearson's correlation coefficient. Regional wall motion scores were compared with kappa-statistics.

Results: LV volumes as determined by MSCT correlated well with MRI with a mean ejection fraction (EF) of $46.1 \pm 6.5\%$ on MSCT and $46.8 \pm 5.9\%$ on MRI ($r = 0.97$). Bland-Altman plots revealed no systematic errors for EDV, ESV, SV and EF. PER, PFR, TPER and TPFR showed markedly worse results with a wide range of scattering and significant differences between MRI and MSCT for PER ($p = 0.04$) and TPFR ($p = 0.03$). Regional wall motion scores demonstrated a very high level of agreement between both modalities with $\kappa = 0.878$.

Conclusion: 16-slice CT allows for reliable assessment of LV volumes and regional wall motion at rest, but is not yet suited for the assessment of functional parameters, that directly depend on temporal resolution.

B-521 10:39

Evaluation of myocardial late enhancement using a low dose 40-slice CT protocol: A feasibility study

A. Rutten¹, S. de Vos¹, M.-J. Cramer¹, J. ten Berg², M. Prokop¹; ¹Utrecht/NL, ²Nieuwegein/NL

Purpose: To perform a feasibility study for the evaluation of late enhancement using a low dose protocol on a 40-slice CT scanner. The study group consisted of patients with hypertrophic obstructive cardiomyopathy (HOCM) who had undergone percutaneous transluminal septal myocardial ablation.

Methods: We included 10 patients with focal infarction of the interventricular septum induced by ethanol ablation (2-21 months post-ablation). We injected 100-120 ml contrast medium for cardiac CTA and performed an additional late scan 7-8 minutes after contrast injection. In order to keep dose to a minimum, we chose a non-gated protocol on a 40-slice scanner using 1.25 mm collimation, 1.25 pitch, 80 kVp and 120 mAs. Scan duration and dose were recorded. To assess late enhancement we used software to digitally subtract both image sets. Average CT numbers in non-enhanced and enhanced portions of the myocardium were determined on the late scan.

Results: The heart could be covered within an average of 0.84 s (0.78-0.96). Mean effective dose was 0.88 mSv (0.79-1.03). Digital subtraction appeared to be a useful aid for the assessment of late enhancement on low dose images. All regions of septal ablation showed higher CT numbers (average 132 HU (94-189)) than normal myocardium (average 82 HU (71-107)). In two patients we found patchy late enhancement in residual hypertrophic regions outside the infarcted area.

Conclusion: Even at a low effective dose of circa 0.9 mSv, evaluation of late enhancement with a 40-slice CT scanner appears feasible. This may be a useful tool in the non-invasive workup of patients with significant coronary artery disease.

B-522 10:48

Multislice spiral CT for assessment of myocardial viability: Comparison to contrast enhanced MR imaging

A.H. Mahnken, R. Koos, M. Katoh, J.E. Wildberger, E. Spuentrup, R.W. Günther, H.P. Kühl, A. Buecker; Aachen/DE

Purpose: To assess the value of arterial and late phase multislice spiral CT (MSCT) in the evaluation of acute myocardial infarction (MI) in comparison to magnetic resonance imaging (MRI).

Material and Methods: In 21 patients with reperfused MI contrast enhanced cardiac MSCT was performed. Images were acquired in the arterial phase and 15 minutes after administration of 120 ml contrast material. All patients underwent late enhancement MRI after administration of 0.2 mmol Gd-DTPA/kg/bodyweight. Area of MI was compared between the different imaging techniques using Bland-Altman method and multivariate analysis. Agreement of the contrast enhancement patterns was evaluated with a kappa test using a 16 segment model of the left ventricle.

Results: Mean infarct size on MRI was $36.8\% \pm 25.4\%$ of left ventricular area. Bland-Altman data showed a good agreement between MRI versus MSCT late enhancement (mean -2.3 ; lower and upper limits of agreement [LOA]: -12.4 ; 7.8). The corresponding values for MRI versus arterial phase MSCT were: 6.5 (-29.8 / 42.8). Comparing MSCT late enhancement with MSCT early perfusion deficit mean and LOA were: 8.8 (-28.7 / 46.3). Contrast enhancement patterns showed an excellent agreement between MRI and MSCT late enhancement ($\kappa=0.883$). The results were worse comparing MRI and early phase MSCT ($\kappa=0.613$) as well as early and late phase MSCT ($\kappa=0.592$). On early and on late phase CT density values of infarcted myocardium were significantly different from viable myocardium ($p < 0.0001$).

Conclusion: Contrast enhanced MSCT allows for the assessment of MI. MSCT late enhancement is as reliable as delayed contrast enhanced MRI in the assessment of infarct size.

B-523 10:57

Assessment of myocardial infarction with cardiac MSCT using model based heart segmentation and perfusion weighted color maps

A.H. Mahnken¹, E. Klotz², S. Lautenschläger², R. Koos¹, D. Fritz², M. Scheuerling², D. Rinck², R.W. Günther¹, J.E. Wildberger¹; ¹Aachen/DE, ²Forchheim/DE

Purpose: To optimize contrast-enhanced multislice spiral CT (MSCT) for detection of acute myocardial infarction (aMI) using perfusion weighted color maps and semi-automated assignment of infarcted areas to myocardial segments.

Material and Methods: First a model-based software tool for semi-automated detection of the long axis of the left ventricle and assignment of left-ventricular segments was developed using a region growing algorithm and a point distribution model. To visualize changes of the myocardial contrast enhancement pattern color coding was performed after low pass filtering and spreading of the attenuation values. 15 patients (12 men, mean age 57 ± 15 years) underwent cardiac MSCT (16x0.75 mm, 120 kV, 550 mAs_{eff}) after administration of 120 ml of contrast material. Contrast enhanced delayed enhanced magnetic resonance imaging (MRI) after administration of 0.2 mmol Gd-DTPA/kg/bodyweight was performed as reference standard. Areas of infarction were assessed from short axis reformats of routine MSCT images, post-processed MSCT images and MRI using a 17-segment model of the left ventricle.

Results: On MRI aMI was present in 78/255 myocardial segments. From routine MSCT images aMI was correctly detected in 58/255 segments (Sensitivity 74.4%; Specificity: 96.1%), while on post-processed images aMI was correctly diagnosed in 65/255 segments (Sensitivity 83.3%; Specificity: 96.0%). Agreement between MRI and routine MSCT images was $\kappa=0.76$. Using post-processed images agreement improved to $\kappa=0.81$.

Conclusion: Perfusion weighted color maps allow for an improved detection of aMI from cardiac MSCT data. On a segmental basis semi-automated assignment of infarcted areas to the left ventricular myocardium is feasible.

B-524 11:06

Determining treatment in patients with acute coronary syndrome using multidetector CT

J.B. Houwers, J. Dorgelo, T.P. Willems, C.H.C. Janssens, F. Zijlstra, M. Oudkerk; Groningen/NL

Purpose: Patients presenting with non-ST-elevation acute coronary syndrome (ACS) and evidence of myocardial ischemia are scheduled for diagnostic coronary angiography (CAG). In approximately 35% of patients no percutaneous coronary

Scientific Sessions

intervention (PCI) is performed. A study was designed to determine whether 16-slice multidetector CT (MDCT) in patients with ACS can predict the need for invasive therapy accurately and thus reduce the number of CAG's.

Material and Methods: Thirty patients with ACS (22 male, mean age 58.7 ± 11 years) were scanned prior to CAG. Data were observed in a blinded fashion. Scans were assigned a quality score, with segment, grade and composition of stenoses being recorded. Based on the MDCT data, a fictive treatment is proposed and compared to the real CAG based treatment.

Results: MDCT quality was good to excellent, with one exception, in the first 30 patients. Excellent accuracy was observed in the detection of significant stenoses using MDCT (sensitivity 91%, specificity 97%, PPV 78% and NPV 99%). In 48% of the cases, no PCI was performed during CAG, because of absence of or only slight coronary artery disease (27%) or severe coronary artery disease, demanding bypass graft operation (17%). MDCT predicted correct treatment in 79% of the cases. By using data obtained with MDCT, 27% of CAGs could have been avoided.

Conclusion: MDCT scanning prior to CAG in patients presenting with acute coronary syndrome can correctly determine the need for invasive treatment in a large majority of cases and leads to a reduction in diagnostic CAG's.

B-525 11:15

Assessment of myocardial bridging with 16-multidetector-row CT (16-MDCT)

P. Spagnolo¹, T. Khouri², M. Manfredi², M. Marks²; ¹Genoa/IT, ²Monza/IT

Purpose: To evaluate the ability of 16-MDCT coronary angiography to demonstrate myocardial bridging in the preoperative setting of patient candidates for coronary artery bypass.

Methods and Materials: 32 patients with coronary artery disease (CAD) and with a suspected diagnosis of tunneled course of the mid left anterior descending coronary artery (mid-LAD) on conventional coronary angiography (CA), underwent 16-MDCT coronary angiography. All examinations were performed with a 16-MDCT (Light Speed 16, GE Medical Systems) with retrospective ECG-triggering: 16x1.25 mm slice collimation, 0.5 s rotation time. Postprocessing methods included MPR, MIPs, and 3D volume rendering reconstructions. All patients underwent surgery bypass for CAD.

Results: In 12/32 patients 16-MDCT confirmed the diagnosis of myocardial bridging of the mid-LAD and allowed assessment of the location, length and thickness of the tunneled coronary segment. In 20/32 cases 16-MDCT correctly detected the epicardial course subsequently demonstrated by surgery.

Conclusion: Preoperative MDCT coronary angiography appears as a useful non-invasive method for identification and characterization of morphologic features of tunneled coronary artery, which may influence the choice of surgical modalities: myotomy versus CAGB.

B-526 11:24

Non-invasive assessment of drug-eluting coronary stents (DES) at 6-months follow-up: is there a role for multidetector-CT angiography (MDCTA)?

I. Carbone, M. Francone, M. Danti, K. Lanciotti, E. Doda, A. Granatelli, R. Passariello; Rome/IT

Purpose: DES are coated-stents capable of releasing bioactive agents into the bloodstream potentially reducing the incidence of restenosis. The aim of our study was to evaluate the feasibility of MDCTA in the evaluation of DES patency at 6-months follow-up.

Materials and Methods: Thirty-two patients who previously underwent coronary DES placement (27 Rapamycin-DES; 13 Paclitaxel-DES) were included in the study. After 6-9 months all patients were studied with MDCTA one week prior to SCA, in order to evaluate patency. ECG-gated MDCTA of the coronary arteries was performed with the following acquisition parameters: 4x1 mm collimation, 1.25 mm sl.thickness, 0.5 mm increment, 120 kV, 400 mAs. Images were analyzed by two radiologists on a dedicated workstation using a real-time interaction approach. Patency was evaluated qualitatively and quantitatively by measuring the attenuation values proximally, inside and distally to the stent. MDCT results were compared with SCA, considered the gold standard.

Results: In 6 cases stent patency was not assessable by MDCTA. Twenty-seven of 34 assessable DES were patent at SCA. MDCTA was able to detect in-stent re-stenosis in 6/7 cases by the first observer and in 5/7 cases by the second observer (overall Sensitivity 75%). One case of occlusion was detected by both observers. At MDCTA 25/27 stents were judged patent by the first observer and 24/27 by the second observer with an overall specificity of 88.6%. The interobserver agreement was substantial ($K = 0.72$).

Conclusions: MDCTA seems to be a reliable tool for assessment of DES patency. Faster CT scanners and "CT-dedicated" stents may improve detection of restenoses.

B-527 11:33

Multidetector-row spiral CT (MDSCT) angiography for the preoperative planning of minimally invasive coronary artery bypass (MICAB) grafting

M. Di Terlizzi, A. Puppi, R. Fossaceca, F. Caimmi, M. Sacco, A. Carrieri; Novara/IT

Purpose: To evaluate the capabilities of MDSCT in the assessment of vascular anatomy of the chest for patient selection and accurate planning of MICAB graft.

Materials and Methods: 20 consecutive patient candidates for MICAB for coronary artery disease underwent contrast-enhanced, ungated, MDSCT to obtain an accurate assessment of anatomy and to estimate availability of direct exposition of the structures involved in the surgical procedure. All the examinations were performed using a 4-row CT scanner (Lightspeed, GE, Milwaukee, USA) and the following protocol: collimation 4x1 mm, pitch 1.5, rotation time 500 msec, 120 kV and 300 mA. Images were analyzed both in the axial source view and after 3D reconstructions (MIP, VRT) using a dedicated workstation. Both internal mammary arteries (IMAs) were evaluated for the presence of anatomic variations, diameter, presence of wall calcifications and distance between IMAs and sternal margins.

Results: Both IMAs were clearly visualized in all 20 patients. 2/20 patients (10%) were excluded from the MICAB surgery due the presence of anatomical variations (anomalous origin and trifurcation). The remaining patients underwent successful, uneventful MICAB grafting.

Conclusion: Contrast-enhanced, ungated, MDSCT can be considered an optimal and minimally invasive tool for the preoperative planning in cardiac patients, (MDCT) giving robust and reliable information to surgeons in order to avoid complicated procedures.

B-528 11:42

MRA versus MSCT in the detection of coronary stenoses

M. Di Roma, A. Romagnoli, M. Sperandio, M. Tomassini, R. Cammarata, G. Simonetti; Rome/IT

Purpose: To assess the capability and clinical feasibility of the coronary MR angiography technique, comparing MR and MSCT results for detection of significant coronary artery stenoses.

Methods and Materials: MR and MSCT coronary angiographies were acquired from 26 patients. The MR protocol was performed using a 1.5 T whole-body unit (Philips Gyroscan; Best, The Netherlands) and included at least 2-3-dimensional navigator-echo-based respiratory-gated Balanced Turbo-Field-Echo sequences for the left and right coronary artery systems. MSCT coronary angiography was performed with a 16 slices scanner (Light Speed¹⁶, General Electric) with thin-slice collimation (0.625 mm). The MR and MSCT angiography results were compared with the DSA that was regarded as the standard of reference.

Results: Using an angiographic segmentation of coronary vessels, we analyzed 234 segments. 161 (69%) were judged evaluable by MRA and 213 (91%) by MSCT. In our series MSCT revealed significantly higher sensitivity (89%) and specificity (98%) than MR imaging (respectively 75% and 92% in the proximal branches).

Conclusion: The temporal and spatial resolution currently available with MRA cannot match MSCT results, still MRA does not expose the patients to radiation and potential nephrotoxic contrast. We believe MR will be the favourite non-invasive technique in patients with CAD, supplying morphological, kinetic and perfusional information about myocardial muscle and coronary anatomy.

B-529 11:51

MDCT coronary angiography in preoperative assessment of non-coronary cardiac surgery

V. Russo, L. Lovato, M. Renzulli, P. Bertaccini, G. Napoli, E. Pilato, G. Gavelli, R. Fattori; Bologna/IT

Purpose: To evaluate the clinical impact of MDCT coronary angiography as a preoperative screening test in patients candidate to major non-coronary cardiac surgery (heart valve replacement, aortic aneurysm, chronic aortic dissection), asymptomatic for ischemic heart disease.

Methods and Materials: 36 consecutive patients (29M-7F, years 43-74, mean 62.8) candidate to surgical treatment of non-coronary cardiovascular disease underwent MDCT coronary angiography (Somatom Sensation -16 Cardiac, Siemens, Forchheim, Germany; 0.75-mm collimation and 375-ms tube rotation), as preoperative assessment of the surgical risk. The left main (LM), left anterior descending (LAD), left circumflex (LCX), and right coronary artery (RCA), including

Scientific Sessions

2 mm side branches, were evaluated and screened for $\geq 50\%$ stenoses. All patients in whom MDCT detected a coronary lesion $\geq 50\%$ underwent catheter coronary angiography (CCA) while all patients without any coronary artery disease were submitted to surgery without any additional test.

Results: 12 patients presented coronary stenosis $\geq 50\%$ (RCA 5 pts, LCX 3 pts, LAD 1 pt, RCA+LCX 2 pts, LAD+LCX+RCA 1 pt), all confirmed by coronary angiography. Adjunctive by-pass surgery or PTCA were performed in 9/12 cases. 24 patients with no coronary artery disease at MDCT underwent surgery. None of the 36 patients presented any operative and/or post-operative cardiac complication, such as myocardial ischemia, myocardial infarction or cardiac failure.

Conclusions: MDCT coronary angiography is a reliable alternative to CCA in pre-operative assessment of non-coronary cardiac surgery avoiding the cost and the risk of an invasive procedure.

DTI-based assessment of corpus callosum infiltration by primary brain tumors: A marker for contralateral growth

B. Stieltjes¹, M. Schlüter², M.-A. Weber¹, H.K. Hahn², J. Rexilius², O. Konrad-Verse², M.R. Essig¹; ¹Heidelberg/DE, ²Bremen/DE

Purpose: Delineation of gliomas and assessment of contralateral involvement is challenging using conventional imaging but of great importance for therapy decisions. Here we present a method for visualization and automatic quantification of white matter integrity/infiltration of the Corpus Callosum (CC) using DTI.

Methods and Materials: Ten patients with gliomas (5 with and 5 without contralateral lesions) were included. Five healthy age-matched volunteers served as reference. Imaging: T1/T2 conventional imaging, diffusion sensitized SSEPI 1.5 T, 50 slices, 2.5 mm isotropic voxels, 6 non-collinear diffusion directions, b-values 0/1000, 10 averages. Main diffusion directions and complete diffusion tensors were visualized using color maps and ellipsoids. Infiltration was quantified measuring Fractional Anisotropy (FA) along CC cross sections for patients and volunteers using a robust, user-insensitive method for automatic classification into fiber, mixture tissue and background.

Results: CC infiltration could be detected on DTI data as demonstrated in the combined visualization of anatomical and DTI data. Profiles of FA of patients with suspect lesions contralaterally all had a significant, clearly delineated FA decrease whereas patients with no contralateral lesions showed similar profiles when compared to healthy volunteers. DTI yielded additional information concerning tumor extent and delineation when compared to conventional imaging.

Conclusion: The proposed DTI based visualization of fiber tissue permits the visualization of CC infiltration by gliomas. The presented method for FA quantification proved to be robust, allowed for detailed assessment of CC infiltration and provides detailed information of contralateral involvement in patients with gliomas. This can improve pre-therapeutic decision making and planning.

B-531 10:39

Diffusion weighted imaging and diffusion tensor imaging in the evaluation of intra-axial tumors

X. Hong¹, D. Wang¹, T. Shen², X. Chen²; ¹Nanjing/CN, ²Shanghai/CN

Purpose: DWI has mainly been used to study hyperacute ischemia; it is also useful in various other diseases. Our purpose was to evaluate the usefulness of ADC, Trace D, FA value in differentiating tumor, edema, and normal brain tissue, and in grading the malignancy of intra-axial tumors.

Methods and Materials: Using a GE 1.5 T super conducting MR unit, 30 grade 1-2 and 40 grade 3-4 intra-axial tumors underwent conventional MR imaging, DWI and DTI. The ADC values, Trace D values, and FA values of ROIs were measured. These ROIs were manually placed over the areas of tumor, edema, and normal brain tissue. Comparisons were made by analysis of variance.

Results: When ADC values and Trace D values were analyzed as a group, significant differences were found between tumor, edema, and normal brain

tissues, but not between tumor and adjacent edema. Significant differences were also found between low-grade tumors and high grade tumors in ADC and Trace D values. FA maps depicted white matter features not typically seen on conventional MR images. Fiber mapping images showed the ipsilateral white matter as either discontinuous due to impaired anisotropy or compressed due to mass effect.

Conclusion: ADC values and Trace D values helped to distinguish tumor from normal tissue but could not be used to separate tumor from adjacent edema. Individually, ADC values overlapped considerably. Combined with conventional MR imaging, the ADC values and Trace D values may predict the degree of malignancy of intra-axial tumors.

B-532 10:48

Differentiation of benign subtypes of meningiomas by diffusion tensor imaging-based calculation of tensor shape

A. Tropine, J. Gawehn, P.D. Dellani, M. Glaser, J. Bohl, P. Stoeter; Mainz/DE

Purpose: Preoperative knowledge of the elasticity of tumours facilitates neuro-surgical treatment planning. Fibroblastic meningiomas are usually considered to be of a harder consistency during operation than other non-calcified benign subtypes of meningiomas. The purpose of this study was to assess the potential of preoperative DTI in the prediction of histopathological subtype of meningioma.

Methods and Materials: In 17 patients with benign non-calcified meningiomas, diffusion tensor imaging ($b = 900$ or $b = 1000 \text{ s/mm}^2$) was performed. Diffusion tensors, mean diffusivity (MD) and fractional anisotropy (FA) values were calculated and the geometrical shape of the tensor computed. All examinations were performed on a 1.5 T scanner.

Results: Histological analysis revealed 8 meningotheelial, 3 mixed and 6 fibroblastic meningiomas. Whereas meningotheelial meningiomas were represented by spherical tensors corresponding to isotropic diffusion, all fibroblastic meningiomas predominantly showed disc-shaped tensors indicating in-plane diffusion. This may be caused by the fascicular arrangement of long, spindle-shaped tumor cells and the high content of intra- and interfascicular fibers as shown by histology. In addition, a capsule-like rim of in-plane diffusion surrounded most meningiomas irrespective of their histological type. The other DTI parameters did not show significant differences between the subtypes.

Conclusions: DTI-based analysis demonstrates a one to one correlation of the shape of the diffusion tensor and the histopathological type of benign meningiomas. It is a promising method to differentiate between fibroblastic and other subtypes of benign meningiomas in order to obtain information about their "hard" or "soft" consistency prior to removal.

Perfusion MR imaging in patients with non-enhancing brain gliomas:

A valuable tool to predict anaplasia and/or tumor progression?

M. Caudo¹, A. Tartaro¹, A. De Nicola¹, G. Maira², C. Colosimo¹; ¹Chieti/IT, ²Rome/IT

Purpose: To assess the relationship between MR perfusion patterns and tumor grading in non-enhancing gliomas.

Methods and Materials: 18 patients (mean age 50 years) with non-enhancing space occupying gliomas underwent perfusion MR imaging using a 1.5 T unit and EPI sequences (50 volumes, 10 preceding a single dose of contrast medium (1.0 mol/L Gadobutrol)). The standard outputs of the perfusion analysis included voxel-by-voxel maps of cerebral blood volume (CBV), cerebral blood flow (CBF) and mean transit time (MTT). Tissue segmentation was used in order to calculate the average CBV, CBF and MTT values in white (WM) and grey (GM) matter. The tumor was manually segmented and values of CBV, CBF and MTT were calculated from the tumor and the corresponding symmetrical contralateral volume (SCV) of normal brain from the hemisphere. Perfusion parameters of the tumors were compared with the segmented white and grey matter and with the SCV of brain tissue. 17 patients underwent surgery and 1 patient was inoperable.

Results: Pathology results revealed 6 high grade (Grade III WHO) and 11 low grade gliomas (Grade II). The inoperable patient did not have MR modifications at 30-month follow-up (non-anaplastic). All high grade gliomas had a higher CBV than segmented WM and SCV, but always lower than segmented GM.

Conclusion: Non-enhancing brain gliomas with a higher CBV than the segmented WM and the SCV are significantly correlated with anaplasia. Therefore, perfusion MR should be integrated in the diagnostic work-up of non-enhancing gliomas in order to predict grading and evolution.

B-535 11:06

Usefulness of diffusion/perfusion-weighted MR imaging in mouse gliomas: Correlation with histopathology

G. Fan, P. Zang, Q. Guo, Z. Wu; Shenyang/CN

Purpose: Diffusion/perfusion-weighted MR imaging (DWI/PWI) was performed to evaluate growth and vascularity of implanted C6 rat gliomas.

Methods and Materials: 36 Wistar rats were implanted with C6 glioma cells intracerebrally. Within 4 weeks, 8 to 10 rats were imaged with DWI/ PWI weekly. Apparent diffusion coefficient (ADC) values and maximal regional cerebral blood volume ($rCBV_{max}$) in both tumoral regions and peritumoral regions were calculated. After MR imaging, each rat brain was examined histologically using CD34 and assessment of tumor cellularity and microvascular density (MVD).

Results: Statistical differences of ADC values for both the solid tumor component and peritumoral region were present comparing 3-4 weeks with 1-2 weeks after implantation ($p < 0.01$). ADC value for the solid tumor was negatively correlated with tumor cellularity ($r = -0.682$, $p < 0.01$). Statistical difference of the $rCBV_{max}$ for the solid tumor components was present comparing 2-4 weeks with both 1 week after implantation and with contralateral white matter ($p < 0.01$). Native vessel dilatation in regions of normal brain at the periphery of the tumors at 1 week after implantation was observed, and $rCBV_{max}$ in these regions were elevated compared to the contralateral side ($p < 0.01$). Prominent positive correlation was present between $rCBV_{max}$ of the solid tumor component and MVD ($r = 0.716$, $p < 0.01$). **Conclusion:** Reduced ADC value for the solid tumor component is correlated with growth of C6 gliomas. $rCBV_{max}$ for the solid tumor component can evaluate tumoral microvessel in vivo, while those at the periphery may be useful for the differentiation between native vessel dilatation of normal brain and angiogenesis of the tumor.

B-536 11:15

Multiparametric MR assessment of cerebral gliomas at 3.0 Tesla:

Characterization of spatial heterogeneity and tumor malignancy

S. Pollici¹, T. Scarabino², A. Di Costanzo³, F. Troisi³, G. Giannatempo², F. Nemore³, U. Salvolini⁴, A. Carriero¹; ¹Novara/IT, ²San Giovanni Rotondo/IT, ³Naples/IT, ⁴Ancona/IT

Purpose: Characterize the spatial heterogeneity of metabolic, hemodynamic and diffusion features within gliomas and surrounding tissues.

Methods and Materials: Twenty-eight patients with different grade gliomas. Metabolic parameters were Cho, NAA, Cr and LL derived by 1H-MRSI; rCBV by PWI; ADC by DWI. ROI included tumor necrotic area, non-necrotic mass, margins, surrounding edematous areas and normal appearing tissue.

Results: In high-grade gliomas, necrotic ROIs of gliomas were divided in 2 groups: areas characterized by high ADC, no metabolites or high LL and no perfusion; areas characterized by low ADC, presence of Cho and LL, and low rCBV.

Apparently edematous ROI were divided in 3 groups: areas with very high Cho, abnormal Cho/NAA ratios, low ADC and high rCBV; areas with low metabolic signals, normal Cho/NAA ratios, high ADC and low rCBV; areas with Cho levels similar to normal, abnormal Cho/NAA ratios and intermediate ADC and rCBV values. In low-grade gliomas, cystic ROI presented low metabolite signals, high ADC, absent or low rCBV. In the differentiation of high-grade from low-grade gliomas, Cho was significantly higher in margins and NAA was significantly lower in mass and margins of high-grade gliomas. ADC was higher in masses of low-grade gliomas, although the difference was not significant. Mean rCBV of mass and margins were significantly higher in high-grade gliomas. LL peak were never detected in low-grade gliomas.

Conclusions: Multiparametric 3 T MR imaging discriminate high from low-grade gliomas; depict tissue heterogeneity within the tumor; provide useful information for stereotactic biopsies, surgical resection and radiotherapy.

B-537 11:24

Early postoperative diffusion-weighted MR imaging (DWI) of the brain parenchyma in the operative site following tumor resection

A. Ozturk, K. Karli Oguz, A. Cila, N. Akalan; Ankara/TR

Purpose: To evaluate diffusion changes in the brain parenchyma in the operative site of intracranial tumors in the first 24 hours following surgery.

Materials and Method: Seventeen patients (6 female, 11 male; 8-80 years) who underwent intracranial tumor surgery were included in the study. Postoperative MR imaging performed in the first 24 hours included DWI (TR/TE, 2800/78; b value of 0, 500, 1000; mtv:256x256) and routine cranial MR imaging including T2* imaging. Diffusion changes and any hemorrhage in the parenchyma that would interfere with diffusion abnormalities were noted. We also aimed to determine any effect of preoperative tumor size, tumor pathology and presence of residual tumor following surgery on these diffusion abnormalities.

Results: Pathological examination of the excised tissue revealed 2 oligodendrogiomas, 2 meningiomas, 1 medulloblastoma, 4 ependymomas, 2 hemangioblastomas, 1 pilocytic astrocytoma, 1 DNET, 2 PNET, 2 gangliogliomas. We found decreased diffusion in the parenchyma near the resection cavity of 11 patients. DWI showed increased ADC values in one patient and no diffusion abnormality in 3 patients. Among those 3 patients with no parenchymal diffusion change, 2 patients had signal abnormalities related to hemorrhage in the operation site. There was no relationship between diffusion abnormality and preoperative tumor size, pathology of the tumor or with the presence of residual tumor.

Conclusion: The most common abnormality in early postoperative DWI of the parenchyma in the operation site following surgery was restricted diffusion; suggesting cytotoxic edema probably resulting from ischemic damage to the tissue. Increased diffusion suggesting vasogenic edema and no diffusion abnormality may also be seen occasionally.

B-538 11:33

Diffusion changes in tumor and peritumoral brain regions following stereotactic irradiation for brain tumors

N. Tomura, J.-I. Izumi, T. Otani, I. Sakuma, S. Takahashi, J. Watarai; Akita/JP

Purpose: To evaluate the clinical role of diffusion-weighted MR imaging (DWI) in monitoring response of brain tumors to stereotactic irradiation (STI) by measuring changes in apparent diffusion coefficient (ADC) in tumor and peritumoral regions before and after STI.

Methods and Materials: MR studies including DWI were performed before and 2-4 weeks after STI in 19 patients with 20 brain tumors. The tumors comprised metastases ($n = 11$), glioblastomas ($n = 3$), meningiomas ($n = 2$), schwannoma ($n = 1$), chordoma ($n = 1$), malignant lymphoma ($n = 1$), and PNET ($n = 1$). Stereotactic radiosurgery was performed for 7 tumors, and fractionated stereotactic radiotherapy was performed for 13 tumors. Regions of interest (ROIs) were set on ADC maps in tumor and peritumoral regions. ADC values were normalized ($nADC$) by dividing ADC values for tumor by values for normal brain in the contralateral cerebral hemisphere. Follow-up MR imaging was performed 8-12 weeks following STI to evaluate the tumor response to STI.

Results: Mean $nADC$ values in tumor after STI was significantly higher after STI (1.91 ± 1.67) than before STI (1.40 ± 0.99) ($p < 0.05$). Mean $nADC$ values following STI were significantly higher in tumors with response to STI (2.5 ± 1.9) than in tumors without response to STI (1.0 ± 0.36) ($p < 0.05$). Increased $nADC$ levels of tumors suggested increased diffusivity due to tumor necrosis and interstitial edema.

Conclusion: Tumor ADC changes via STI-induced alterations in tumor diffusivity. Increased ADC at completion of STI can predict treatment effect. DWI is clinically valuable for evaluating treatment response to STI.

Pre- and postoperative DTI examination in patients with brainstem cavernoma

T.F. Beyer, J. Iwinska-Zelder, T. Dukatz, H. Bertalanffy, B. Tackenberg, U. Sure, S. Bien; Marburg/DE

Purpose: Diffusion-tensor imaging (DTI) has a broad range of applications by creating MR imaging-based quantitative maps of molecular water displacement in brain tissues. This imaging tool allows the direct examination of white matter fiber tracts *in vivo*. The aim of our study was to examine pre- and postoperatively patients with brain stem cavernomas in order to picture the eventual distortion or dislocation of the nervous tracts.

Methods and Materials: Forty three patients with brain stem cavernomas were prospectively evaluated by MR imaging (1.5 T Signa Tomograph; GE). In addition to the standard sequences we used DTI fractional anisotropy measurement presented by gray-scale and colored images. 9 patients were examined with Tensor-application preoperatively, 29 patients postoperatively and 5 patients pre- and postoperatively.

Results: MR imaging generated anisotropy maps correlated very well with clinical neurological symptoms. In the majority of postoperative cases we could recognize the elasticity of the nervous tracts, which were dislocated by huge cavernomas. In 16 cases of bleeding cavernomas, anisotropy maps showed the damage of white matter tracts, which corresponded very well with neurological impairment.

Conclusions: DTI proved to be very useful for clinicians to examine and visualize nervous tracts, which provides the possibility of observing the trajectories of fibers and the connectivity of the human brain *in vivo*. Clinical, neuroradiological and pathological aspects of brain stem cavernomas make this entity demanding. According to our experiences DTI has increased already the diagnostic possibilities of MR imaging.

Initial clinical evaluation of a monolithic passive-element direct digital (MOPEDD) radiography system for orthopedic imaging

G. Bartal¹, A. Breitgand¹, U. Soimu¹, R. Sebie¹, J.M. Gomori²; ¹Hadera/IL, ²Jerusalem/IL

Purpose: Orthopedic practices are reliant on use of screen/film radiography. Computed Radiography (CR) provides the orthopedic surgeon an intermediate solution. Digital Radiography (DR) has good workflow benefits but is currently very expensive with limited availability. Our aim was to compare diagnostic performance of a new flat panel technology, suitable for general radiography (retrofits and new systems) with that of a conventional screen-film in orthopedic patients.

Methods and Materials: Extremities and spine images produced by a retrofit MOPEDD Radiography system (Edge Medical Devices, Ltd., Raanana, Israel) were compared to reference conventional screen-film radiographs of the same patients taken consequently in the same room. The MOPEDD detector has an active imaging area of 17" x 17", pixel size 127μm and 200-speed sensitivity. Three certified radiologists and a certified orthopedic surgeon independently analyzed the digital and conventional images, and rated the diagnostic quality using a five-point scale. Digital images were rated twice: On a laser film and on a high-resolution grayscale monitor. The diagnostic quality of MOPEDD was assessed using Receiver Operating Characteristic (ROC) curves.

Results: The inter-observer reliability was 76% for the analog film rating, 77% for the laser-film rating and 81% for the grayscale monitor rating. MOPEDD ROC under-the-curve area was 0.594 for laser-film rating and 0.790 for grayscale monitor rating.

Conclusions: The diagnostic quality of MOPEDD technology printed on a laser imager provides orthopedic images slightly better than, or comparable to, conventional screen-film radiography. The digital display of MOPEDD images is significantly superior to films acquired using screen-film radiography.

B-541 10:39

Multiple photodiode sensor array digital receptor for radiographic and fluoroscopic applications

A.A. Nevhasymy, S.I. Miroshnichenko, A.A. Redchuk; Kiev/UA

Purpose: Digital X-ray receptor basic technical characteristics requirements for radiographic and fluoroscopic applications are contradictory. Fluoroscopic operating mode assumes image sequence acquisition at high frame rates; radiographic - separate frames acquisition at high resolution. Decreasing patient dose demands force the device to operate at quantum limited mode for both applications. The presented patented multiple photodiode sensors array (MPSA) technology allows developing single digital receptors implementing both operating modes.

Methods and Materials: MPSA receptor implements "virtual pixel" ideology. "Virtual pixel" is formed by the analog charge packets merging in the output matrix register. Until the total dark current noise exceeds read-out noise, the signal-to-noise ratio increases near proportionally to the merged cells number. "Virtual pixel" dimensions vary from 12.8x12.8 to 51.2x51.2 um² for each of 36 sensors at 8x11 inches field of view to fulfill the sensitivity and resolution requirements for operation modes.

Results: "Virtual pixel" mode along with real-time frames reconstruction ensures image acquisition at 12.5fps rate, 1.1 lp/mm resolution and 2% contrast sensitivity at 50uR/sec exposure dose while operating in fluoroscopic mode and 3 lp/mm image acquisition and below 1% contrast sensitivity at 1 mR exposure dose for radiographic mode. The fluoro-to-radiography mode switching time is below 0.3 sec. The acquired images spacial distortions are below 0.5% and essentially better comparing to Image Intensifiers.

Conclusion: Presented "virtual pixel" digital receptor technology provides high flexibility in constructing dual-mode receptors for real-time demanding X-ray applications.

B-542 10:48

Novel noise-reduction processing algorithm for digital radiography

K.N. Jabri, G.B. Avinash, N. Marinelli, T. Merisotis, G. Joglekar, C. Deodhar; Waukesha, WI/US

Purpose: To evaluate image quality improvement achievable by a novel noise-reduction algorithm for digital radiography. The algorithm is designed to reduce noise in highly attenuated (dense) regions of an image without affecting contrast and edge-sharpness in relatively low-attenuated regions.

Methods and Materials: The algorithm segments images into structures and non-structures; structures are anisotropically smoothed and sharpened, while non-structures are isotropically smoothed. A fraction of the original image is blended with the processed image to obtain an output image with improved noise characteristics. The blending fraction is spatially modulated by detector-signal level and image-structure content. Image quality was evaluated by reviewing adult chest radiographs without and with three different levels of noise-reduction filtering (none, *low*, *medium*, *high*) with 3 radiologists. Another radiologist rated (scale of 1 to 7) the noise level in 10 small (age 0-3) and 10 medium (age 3-8) pediatric chest radiographs, before and after *medium* noise reduction.

Results: For images that were originally low-noise, radiologists preferred, by consensus, the *low* or *medium* settings. For images that were relatively noisy to begin with, the *medium* setting was preferred. After noise reduction, ratings of pediatric radiographs improved by an average of 25% and 53% for small and medium pediatric patients, respectively.

Conclusion: We developed a novel noise-reduction algorithm that can improve image quality of low-dose digital radiographs. The algorithm can be used for image quality enhancement at nominal dose levels, or as a dose reduction technique by acquiring radiographs at lower doses and processing them to maintain image quality.

Image detail detectability in digital radiography: Comparison of new needle structured storage phosphor with a powder structured storage phosphor and a flat-panel detector

M. Körner, M. Treitl, C. Herrmann, S. Mair, M.F. Reiser; Munich/DE

Purpose: To compare image detail detectability of a needle structured image plate (NIP), a powder structured image plate (PIP) and a flat-panel detector (FPD).

Methods and Materials: 12 radiograms of 6 human foot specimens were obtained using a prototype NIP (AGFA, Belgium) and a FPD (Siemens, Germany). The reference image of each specimen (80 μGy entrance surface dose) was obtained using a PIP system. Entrance surface dose for all NIP and FPD images was

Scientific Sessions

63 µGy. NIP images were scanned with a newly developed ScanHead scanner (AGFA). Different post-processing software (NIP, PIP: AGFA, FPD: Siemens) was used. Hardcopies were evaluated on a standardized light box. Image evaluation was performed by 5 radiologists blinded to the imaging modality. Images were compared to the reference with respect to detail detectability of cortical bone, trabecular bone and soft tissue, and with respect to artefacts and noise, using a five-point scale (-2 clearly inferior, -1 inferior, 0 equivalent, +1 superior, +2 clearly superior to reference). Image quality was rated independently with marks 1-5.

Results: NIP images were rated superior to FPD and PIP concerning cortical bone (NIP: 1.267, FPD: 0.233), trabecular bone (NIP: 1.700, FPD 0.100), soft tissue (NIP: 0.867, FPD -0.233) and noise (NIP: 1.033, FPD: 0.767). Image quality of the was rated optimal (1.113) for NIP and good for FPD (1.900). Artefact rate of NIP images was slightly higher in the image background (-0.300).

Conclusion: Radiograms obtained with the new NIP were rated superior to both PIP and FPD for detail detection.

Radiation dose measurements and image quality evaluation in scoliosis radiography: Flat panel detector versus digital pulsed fluoroscopy

O. Heuga, O. Hauger, O. Bonnefoy, F. Diard, J.-F. Chateil; Bordeaux/FR

Purpose: To evaluate the radiation dose and the image quality of scoliosis radiography obtained with a flat panel detector versus digital pulsed fluoroscopy. **Methods and Materials:** Routine follow-up scoliosis evaluation was obtained from 120 consecutive patients using a digital pulsed fluoroscopy system (Siemens Iconos R 200, 60 patients) or a flat panel detector system (Siemens Aristos VX, 60 patients). Reconstructions were performed on a Leonardo Hardware System. Radiation dose was measured as kerma area-product and as entrance surface dose with three thermoluminescent dosimeters (TLD technology) placed on the thyroid, chest and gonads. Image quality was evaluated by two senior radiologists according to 19 specific items using a four point scale. An unpaired student t-test and a χ^2 test were respectively used for statistical comparison of entrance dose and qualitative assessment of both techniques.

Results: Dose measurements showed a statistically very significant ($p < .0001$) difference with the flat panel detector compared with the digital pulsed fluoroscopy with an estimated dose reduction of 72%. The image quality and visibility of anatomic structures obtained with the digital flat panel detector system were also rated significantly greater ($p < .01$) to those obtained with the digital pulsed fluoroscopy.

Conclusion: Compared to digital pulsed fluoroscopy, flat panel detector showed a major radiation dose reduction (72%) and a better image quality making it a very interesting technique in routine follow-up scoliosis.

B-545 11:15

A comparison of image quality and dose for digital flat panel detector and image intensifier fluoroscopy systems

C.P. Lawinski, H. Cole, A. Mackenzie; London/UK

Purpose: Many manufacturers now offer flat panel detectors for cardiac and other fluoroscopic applications in preference to image intensifiers. These offer certain advantages including compact design, improved geometric distortion and noise characteristics and the potential for improved image quality at lower dose levels. Comparative measurements of the imaging performance and dose characteristics were made on flat panel detector systems for cardiac applications from three major manufacturers. The results were also compared to those for cardiac image intensifier systems.

Methods and Materials: Image quality was assessed using typical threshold contrast detail detectability test objects under standard beam conditions at the recommended detector input exposure levels for each system. Detection index diagrams were plotted and, to aid comparison, the data was dose corrected to a mean exposure level. High contrast limiting spatial resolution was also measured.

Results: For fluoroscopy, the imaging performance of the flat panel systems was generally better than the equivalent image intensifier systems. In the digital acquisition mode the flat panel detectors again generally showed better performance. Unlike image intensifier systems, due to the pixelated nature of flat panel detectors, spatial resolution does not improve as the magnification is increased (field size reduced) but remains constant (depending on the pixel pitch). As expected, for all the flat panel systems geometric distortion and vignetting were insignificant. The detector input exposure levels were comparable for flat panel detectors and image intensifier systems.

Conclusions: In general, flat panel detector systems exhibit improved image quality over image intensifier systems at comparable exposure levels.

B-546 11:24

Scatter-to-primary evaluation in full field digital mammography

G. Gennaro¹, E. Bellan¹, M. Gambaccini², C. di Maggio¹; ¹Padua/IT, ²Ferrara/IT

Purpose: To quantify scatter radiation contribution in digital mammography and compare scatter-to-primary (SPR) ratios obtained by two different experimental methods.

Methods and Materials: SPR was evaluated as a function of both phantom thickness and beam energy, using the edge technique and the beam-stop method. Images were acquired without anti-scatter grid by a clinical digital mammography unit (GE Senograph 2000D). Both edge and beam-stops were obtained by a lead slab, 3 mm thick, absorbing the incident X-ray beam completely. The edge covered half of the field of view, whilst beam-stop diameters ranged between 4 and 40 mm. Grid absorption was also evaluated in terms of Bucky factor and contrast improvement factor.

Results: Images of phantoms with different thickness, acquired with and without grid, showed a Bucky factor greater than 2. SPR versus kV value, for phantoms 4 and 6 cm thick, revealed a weak dependence from beam energy; a quasi-linear trend of SPR versus phantom thickness was exhibited from 0.10 up to 0.75 for PMMA slabs between 1 and 8 cm. Scatter-to-primary ratios measured by edge and beam-stop techniques were comparable. Experimental results showed a good agreement with those published on literature.

Conclusions: Digital mammography permits proper quantification of the contribution of scatter radiation. The edge method appeared as reliable and preferable to the beam-stop method, but was more time consuming. There is a possibility of using the results to carry out a scatter correction algorithm; this could be applied to breast images acquired without grid, permitting a significant patient dose saving.

B-547 11:33

Physical characterization of the new FFDM system based on an a-Se detector

T. Mertelmeier, L. Bätz; Erlangen/DE

Purpose: To describe the physical performance of the new FFDM system Siemens Mammomat Novation^{DR} employing a large-area solid state detector based on direct conversion with amorphous selenium.

Methods and Materials: This detector is characterized by a usable area of 287 mm by 241 mm, and a pixel pitch of 0.07 mm corresponding to a Nyquist frequency of 7.1 lp/mm. For physical characterization we measured the gain factor, the linearity and the dynamic range. Spatial resolution is quantified by the modulation transfer function (MTF). The noise properties are described by the Noise Power Spectrum (NPS). From the X-ray spectrum and the measured quantities the Detective Quantum Efficiency (DQE) is determined as 2-D function of spatial frequency. The measurements are carried out according to the new IEC standard for DQE measurements.

Results: For example, the gain characteristic of the detector is strictly linear with entrance air kerma in a wide range of exposures. The MTF at Nyquist frequency turned out to be larger than 0.4. For a detector exposure of 60 microGy the DQE exceeds 0.6 at zero frequency and 0.15 at 7 lp/mm. The DQE is nearly independent of dose for exposure values larger than 30 microGy. Finally we present clinical images of early clinical installations.

Conclusion: The image quality of this detector can be considered as very satisfactory. Together with the unique features of the FFDM system, the selenium direct converting detection provides the potential to substantially reduce patient dose at superb image quality.

B-548 11:42

Characterization of CDMAM image observers

R. VanMeter¹, L. Fletcher-Heath²; ¹Washington, DC/US, ²Rochester, NY/US

Purpose: The "European Guidelines for Quality Assurance in Mammography Screening: Addendum on Digital Mammography" prescribes criteria for threshold contrast visibility based on images of the CDMAM phantom. The goals of this study were to: Quantify the performance of a group of CDMAM phantom observers; compare their performance with published scorings; compare visual scorings with software scorings generated by CDDCOM; analyze the performance of software scorings used as a prediction for visual observation; and understand the sources of variability associated with the prescribed protocols.

Methods and Materials: CDMAM phantom images downloaded from the EUREF website were compared using three scorings and two analysis methods. The scores included those of four expert readers from the EUREF website, 13 experienced observers from our laboratory, and those generated by the CDDCOM

Scientific Sessions

software. These were analyzed with the method described in the CDMAM-phantom 3.4 user manual and by a signal detection theory-based method.

Results: The average contrast sensitivity of our 13 observers and the published values were not significantly different. However, the 95% confidence limits for our observers averaged 38%, while those for the published data averaged 24.9% - with ANOVA showing significant interobserver variability. The software results were substantially different from both visual results, particularly for the small diameter targets. However, using the signal detection theory analysis significantly reduced these differences.

Conclusions: CDMAM scoring requires substantial time, and the results exhibit substantial variability. This suggests that further development of reliable software methods will be of considerable importance for practical implementation of threshold contrast visibility testing.

B-549 11:51

Dose reduction by technique optimization for FFDM based on an amorphous selenium detector

T. Mertelmeier¹, P. Bernhardt², M. Hoheisel², N. Palmberg¹; ¹Erlangen/DE, ²Forchheim/DE

Purpose: To optimize the radiographic technique for a new full-field digital mammography system based on an amorphous selenium detector by varying the anode/filter combinations.

Methods and Materials: The exposure parameters, i.e. anode material, tube voltage, filter material and thickness, are optimized by simulation and phantom experiments. Figure of merit (FOM) is the squared signal difference-to-noise ratio divided by the mean glandular dose. The simulations with both, monochromatic X-rays and real spectra, take into account the absorption properties of the new a-Se detector and scattered radiation, with and without grid, using Monte-Carlo methods. Breast equivalent phantoms (50% fat, 50% glandular; 30% fat, 70% glandular; 70% fat, 30% glandular) with breast thicknesses between 2 and 8 cm and additional lesion are used for simulations and measurements. The measurements are carried out with the FFDM system Siemens Mammomat Novation^{DR} employing a dual target (molybdenum (Mo) and tungsten (W)) anode with Mo and rhodium (Rh) filtration, respectively.

Results: We present results for constant image quality. The W/Rh combination gives a higher FOM than Mo/Mo or Mo/Rh for almost all cases investigated. With thick phantoms, up to 50% less dose is sufficient to maintain a constant image quality. The simulation results are confirmed by the phantom experiments.

Conclusion: For the specific a-Se-based system studied, a W anode with Rh filtration achieves higher image quality than Mo/Mo. Keeping the image quality constant, W/Rh allows to reduce dose by up to 50% compared to Mo/Mo.

Diagnostic accuracy of multidetector-row CT angiography (MDCTA) using 4, 8 and 16-row CT scanners in diseases of the abdominal aorta and aortic major branches: Results of a European multicenter prospective clinical trial

M. Nonent¹, F. Thouveny², P. Simons³, O. Cappeliez⁴, M.F. Reiser⁵, V. Duddalwar⁶, L. Bonomo⁷, G. Liessi⁸, ¹Brest/FR, ²Angers/FR, ³Aalst/BE, ⁴La Louvière/BE, ⁵Munich/DE, ⁶Aberdeen/UK, ⁷Chieti/IT, ⁸Castelfranco Veneto/IT

Purpose: To assess the accuracy and utility of MDCTA compared to surgery, vascular intervention or digital subtraction angiography (DSA) in the diagnosis of aortic disease.

Methods and Materials: 173 patients with known/suspected abdominal aortic or aortic major branches disease (stenosis or aneurysm) were prospectively enrolled in 7 European countries (14 centres). Iso-osmolar iodixanol (Visipaque™) 320 mg I/ml was injected at mean flow-rate of 3.8 ml/s (2.4-5.0 ml/s) and mean volume of 120.5 ml (80-150 ml). Saline chaser was injected in 55 (31.8%) patients. Scan delay was determined by bolus tracking (98.3%) or test bolus (1.7%). Images

were acquired on 4 (n = 63), 8 (n = 24) and 16 (n = 86) detector-row CT scanners using the routine acquisition and reconstruction parameters at each centre. MDCTA and reference diagnoses were assessed on-site and compared.

Results: 136 patients had a referral diagnosis of aneurysm (n = 75) or stenosis (n = 61), established either on surgical findings (22.1%), angiography during vascular intervention (17.6%) or DSA (60.3%). Image quality of MDCTA was excellent (85.0%) or good (13.3%), with a mean aortic attenuation of above 300 HU. MDCTA diagnosis matched the referral diagnosis in 132 out of 136 patients, yielding an agreement rate of 97.1% (95% CI [92.6, 99.2]). The four non-matches were in patients with a referral diagnosis based on DSA. One patient reported pain upon injection of iodixanol.

Conclusions: MDCTA using iodixanol 320 mg I/ml showed high diagnostic accuracy and utility in patients with aortic or aortic major branch disease. Tolerability was good. This study indicates that MDCTA can replace DSA for this indication.

B-551 10:39

Non-rigid registration for subtraction CT angiography of the abdomen and evaluation of various regularization models

S. Drisis, D. Seghers, S. Srivastava, E. D'Agostino, F. Maes, G. Marchal; Leuven/BE

Purpose: Subtraction CT Angiography of the abdomen is affected by artifacts related to misalignment of corresponding high-intensity structures in the pre- and post-contrast images due to motion and local deformation. The use of non-rigid image registration using different regularization models was investigated to optimally align both images prior to subtraction.

Materials and Methods: Pre- and post-contrast CT images of the abdomen of 5 patients with voxel size of $0.72 \times 0.72 \times [0.5-1] \text{ mm}^3$ were acquired using a 16-slice multi-detector CT scanner (Sensation16, Siemens, Erlangen). Each image pair was first globally aligned by Rigid Registration (RR) and subsequently the post-contrast image was locally deformed to the pre-contrast by Non-Rigid Registration (NRR) using maximization of mutual information. Various regularization schemes for NRR were evaluated, imposing elastic, viscous fluid or curvature-based constraints on the deformation. To evaluate registration quality achieved with each regularizer, objects of interest, bones and plaques, were manually delineated in each data set and the percentage of overlap of 223 object pairs after NRR was computed.

Results: Overall overlap values for bone varied between 88.88% for RR to 89.66% for curvature NRR, but differences between methods were not significant. Overall overlap values for plaques varied between 63.35% for RR to 69.82% for viscous fluid NRR. Viscous fluid NRR performed significantly better than RR ($p < 6 \times 10^{-7}$) and curvature-based NRR ($p < 0.006$) and marginally better than elastic NRR ($p = 0.063$).

Conclusion: Viscous fluid NRR significantly improves the alignment of structures in SCTA. However further development of more effective algorithms is essential for clinical use.

PET/CT in patients with acute aortic syndrome

H. Kuehl, H. Eggebrecht, P. Veit, G. Antoch, R. Erbel, J. Barkhausen; Essen/DE

Purpose: The acute aortic syndrome (AAS) is a potentially life-threatening disease. The aim of our study was to investigate whether PET-CT allows prediction of patients' outcome.

Methods and Materials: 20 patients with acute aortic syndrome (aneurysm TAA = 4, dissection TAD = 5, perforated aortic ulcer PAU = 6, intramural hematoma IMH = 5) were enrolled into this study. All exams were performed on a PET-CT scanner (Biograph, Siemens) 1 h after iv-administration of FDG and with iv-contrast. Follow-up CT exams were performed at 1, 3 and 6 months.

Results: 9 of 20 patients showed elevated tracer uptake in the aortic wall, whereas 11 patients were PET-negative. 7/9 PET-positive patients (78%) showed either progression from PAU or IMH to TAA or progression of the TAD. One of these patients with type-B dissection was treated by a stentgraft. 2/9 PET-positive patients showed a normalization of the glucose metabolism under anti-inflammatory therapy for inflammatory TAA. 6/11 PET-negative patients (55%) showed stable disease or regression of TAD-B or IMH during the follow-up period, whereas 5/11 (45%) patients showed progression of the AAS.

Scientific Sessions

Conclusions: In acute aortic syndrome PET-positive patients seem to be at higher risk for disease progression. The combination of morphologic and metabolic imaging might be able to predict patients' outcome. However, our results need to be confirmed in a larger patient cohort with acute aortic syndrome.

Demonstration of the sites of communication between true and false lumen in chronic aortic dissection with phase-contrast sequences

G.P. Spanos, I. Oikonomou, C. Kouskouras, A. Sarafopoulos, C. Giavroglou, I. Tsifountoudis, A.S. Dimitriadis; *Thessaloniki/GR*

Purpose: Our objective was to establish the sites of communication between true and false lumen, for assessment and planning of the intervention in patients with chronic aortic dissection.

Methods and Materials: During the last year, 9 patients with chronic aortic dissection (1 with dissection type A and 8 with type B according to the Stanford classification) were scanned at 1.5 T (Philips Intera and GE Infinity with EXCITE). Bright-blood sequences in three planes and contrast-enhanced 3D MR angiography were performed in all patients. A quick assessment of the angiography was followed by the use of multiplanar reformations in order to detect sites of communication. A localized phase-contrast sequence was used to confirm the site of the communication. An intraarterial DSA was performed in 7 patients after the MRA.

Results: Entry and re-entry tears were easily depicted with the 3D MR angiography. 15 sites of communication, apart from entry and re-entry sites, were found at 3D-MRA. 13 out of these 15 sites were demonstrated with phase-contrast sequence (sensitivity 100%- specificity 100% for phase-contrast technique, and sensitivity 100%- specificity 86% for 3D-MRA). All these sites were verified with DSA.

Conclusion: The use of focused phase-contrast sequences following 3D-MRA is an easily-applied, sensitive method for the evaluation of sites of communication in patients with chronic aortic dissection. Assessment of these sites is critical for planning intervention, especially those between the entry and re-entry tears, which are difficult to depict with intraarterial DSA.

B-555 11:06

Evaluation of aortic dissection: The role of ultra-fast three-dimensional dynamic contrast-enhanced magnetic resonance aortography

B. Jiang, Q. Meng, Y. Chen, B. Pan; *Guangzhou/CN*

Purpose: To assess the role of ultra-fast three-dimensional dynamic contrast-enhanced magnetic resonance aortography (UF 3D DCEMRA) in evaluating aortic dissection.

Methods and Materials: Twenty-four patients with aortic dissection underwent UF 3D DCEMRA in which the sequence of 3D Flash TurboMRA was used with the acquisition time at 8 sec and three consecutive phases of UF 3D DCEMRA images were obtained. The UF 3D DCEMRA were assessed for the detection of the intimal entrance tear and the origination of the celiac trunk (CT), superior mesenteric artery (SMA) and renal arteries (RA). The results were correlated with angiography.

Results: The tri-phasic display of the true lumen and false lumen of the aortic dissection were achieved in all 24 patients. 38 intimal entrance tears were detected on UF 3D DCEMRA in 24 patients, of which 21 were identified on the 1st phase, 13 on the 2nd phase and 4 on the 3rd phase. 41 intimal entrance tears were detected on angiography. The accuracy of intimal entrance tear-detection on UF 3D DCEMRA was 92.7%. 2 CT, 3 SMA and 5 RA were noted arising from the false lumen and the other 86 arteries from the true lumen on either UF 3D DCEMRA or angiography. The accuracy of the origination-detection by UF 3D DCEMRA of the 4 arteries was 100%.

Conclusion: UF 3D DCEMRA plays a vital role in the detection of the intimal entrance tear and the origination of aortic dissection.

B-556 11:15

MR evaluation of abdominal aorta: True-FISP versus Gd-enhanced MR angiography (Gd-MRA)

A. Iozzelli, G. D'Orta, T. Lupattelli, F. Sardanelli; *Milan/IT*

Purpose: To test true-FISP versus Gd-MRA for imaging abdominal aorta and major abdominal vessels.

Materials and Methods: Thirty-five consecutive patients (age 67 ± 11 years) with suspected abdominal and/or peripheral vascular disease underwent 2D true-FISP [TR/TE = 4.3/2.2 ms; FA 74°; NEX 2; thickness 3 mm (sagittal) or 5 mm (axial); 48 contiguous slices; pixel 1.4x1.4 mm; time 50 s (sagittal) or 73 s (axial) during

free breathing] and coronal 3D FLASH Gd-MRA (TR/TE = 3.3/1.2 ms; FA 25°; NEX 1; thickness 1.3 mm; pixel 1.4x0.8; breath-holding 24 s; 0.1 mmol/kg of Gd-DOTA at 2 ml/sec). We evaluated: suprarenal aorta, celiac trunk, superior mesenteric artery, right renal artery, left renal artery, infrarenal aorta, inferior mesenteric artery, aortic bifurcation/common iliac arteries, lumbar arteries, accessory renal arteries, collateral vasculature, aortic atheroma, and vascular prosthesis/stent. A quality score (0=non visible; 1=poor; 2=fair; 3=good) was assigned to each item on both sequences. Wilcoxon test.

Results: Main diagnosis: normal/atheromatous aorta (n = 26); aortic aneurysm (n = 4); patent vascular stent (n = 2); aneurysm of iliac arteries (n = 1); patent aortic prosthesis (n = 1); patent aorto-femoral bypass (n = 1). The score of true-FISP (25.9 ± 4.1 , median 27) was significantly greater than that of Gd-MRA (23.9 ± 3.6 , 24) ($p = 0.003$). True-FISP was better in visualizing inferior mesenteric artery (score 2.46 vs 1.00; $p < 0.001$) and detecting atherosomatic plaques (2.49 vs 1.23; $p < 0.001$). One collateral vasculature was demonstrated only with Gd-MRA.

Conclusions: True-FISP is a powerful and fast non-breath-hold sequence to be added to Gd-MRA, obtaining increased information. It can be used in non-cooperative patients and in cases of contraindication to contrast administration.

B-557 11:24

High-resolution (HR) renal magnetic resonance angiography (MRA): Prospective comparison of image quality and diagnostic value using integrated parallel acquisition techniques (iPAT) - factor 2 versus 3

H.J. Michaely, K.A. Herrmann, H. Kramer, M.F. Reiser, S.O. Schoenberg; *Munich/DE*

Purpose: To systematically compare the image quality and diagnostic value of renal HR-MRA using iPAT with acceleration factors of 2 and 3.

Material and Methods: 26 patients scheduled for renal MRA were included. All examinations were performed on a 32-channel whole body MR-scanner (Siemens Magnetom Avanto). For HR-MRA, a 3D GRE sequence with a spatial resolution of 0.9 mm x 0.9 mm x 1 mm and an iPAT factor of 2 (12 patients, acquisition time (TA) 28 sec) or an iPAT factor of 3 (14 patients, TA 19 sec) was applied. All other parameters were kept constant. Either 15 ml of gadobutrol or 25 ml of gadobenate dimeglumine were administered followed by a 30 ml saline flush, both at a flow rate of 2 ml/sec. Three independent radiologists analyzed the MRA images on 10 mm thin coronal MIPs regarding noise, artifacts and quality of depiction of the renal arteries (RA) using a three point rating scale. The RAs were assessed in four separate segments: ostium, proximal (until 1st division), segmental (until 2nd division) and sub-segmental portions.

Results: With iPAT factor 3, the noise increased significantly but the amount of motion artifacts was decreased significantly. Ostial and proximal portions of the RA were equally well delineated with both techniques. Segmental and subsegmental portions were significantly better depicted ($p < 0.001$) using an iPAT factor of 3.

Conclusion: The shorter scan time associated with iPAT factor 3 allows a better visualization of the peripheral segmental and subsegmental portions of the renal arteries. Increased noise seems not to be a diagnostic drawback.

B-558 11:33

Towards the identification of specific anatomic features of the renal artery influencing the results of renal artery percutaneous recanalization

I. Bargellini, M. Lazzereschi, C. Vignali, P. Petrucci, R. Cioni, V. Zampa, C. Bartolozzi; *Pisa/IT*

Purpose: To retrospectively identify the relationship between specific anatomic features of the renal artery and immediate and long-term results of renal artery percutaneous recanalization in patients with renovascular disease and atherosclerotic significant stenosis.

Materials and Methods: The study included 113 patients (134 lesions) with atherosclerotic significant (> 60%) renal artery stenosis and renovascular disease treated by PTCA (n = 44) or stenting (n = 90). Preprocedurally, MRA or CTA were performed in all patients. Images were retrospectively reviewed, to assess specific anatomical features of the stenosis such as site, grade, length, and presence of calcifications. Procedural data (balloon and stent length and diameters) were recorded, as well as immediate complications (residual stenosis, arterial dissection, distal embolization) and restenosis on follow-up.

Results: In the PTCA group, minor complications (not requiring further interventions) occurred in 7/43 (16.3%) patients and were significantly associated ($p < 0.05$) with higher stenosis grade, longer balloons, and smaller diameter balloons; restenosis on follow-up was observed in 7/43 patients (16.3%) and was more frequent when lower balloon oversizing was applied during the procedure.

Scientific Sessions

In the stent group, minor immediate complications were observed in 7/90 (7.8%) cases and in-stent restenosis on follow-up occurred in 14/90 (15.6%) cases. Immediate complications were significantly more frequent when longer stents were deployed ($P = .004$). No significant relationship was found between in-stent restenosis and morphological/procedural data.

Conclusion: The accurate assessment of lesion anatomy on MRA/CTA images could improve procedural planning, allowing selection of the proper devices to reduce the incidence of immediate complications.

B-559 11:42

Prevalence of renal artery stenosis in flash pulmonary oedema:

Determination using gadolinium-enhanced MRA

C.J. McMahon, M. Hennessy, G. Boyle, J. Feely, J.F.M. Meaney; Dublin/IE

Purpose: Flash pulmonary oedema, the association of recurrent acute onset pulmonary oedema in association with renal artery stenosis (RAS) is well known, as is the dramatic response to renal revascularization. However, the prevalence of RAS in patients with flash pulmonary oedema is unknown.

Materials and Methods: Contrast-enhanced MRA (CE-MRA) of the renal arteries was performed in patients with unexplained episodes of acute pulmonary oedema, to determine whether RAS could potentially be a contributory factor. Clinical parameters (blood pressure, serum creatinine, history of hypertension or hyperlipidaemia) were compared in patients with RAS and patients without RAS using an unpaired t-test. Results expressed; mean \pm SD.

Results: 20 eligible patients (4 male, 16 female, age 78.5 ± 11 years) underwent CE-MRA of renal arteries. 45% of patients had significant RAS ($> 50\%$ reduction of diameter). In two thirds of cases bilateral RAS was detected. Systolic BP was significantly higher in patients with RAS (191.9 ± 38.3 mmHg) than those without RAS (134.2 ± 29.6 mmHg) ($p < 0.005$). Diastolic BP was also significantly higher in patients with RAS (101.7 ± 22.8 mmHg) than those without RAS (76.1 ± 16.8 mmHg) ($p < 0.01$). All 11 patients with RAS and 5/9 patients (55%) without RAS had a history of hypertension. No significant differences in creatinine or hyperlipidaemia history were observed.

Conclusion: Renal artery stenosis causes flash pulmonary oedema and we recommend that renal artery stenosis should be actively excluded in all patients with unexplained recurrent pulmonary oedema. Contrast-enhanced MRA allows detection of renal artery stenosis without use of arterial catheterization, ionizing radiation or nephrotoxic iodinated contrast agents.

Heterotopic ossification in critically ill patients: Early diagnosis with MR imaging

E. Kostanti, A. Zikou, P. Kosta, D. Kastani, E. Galiatsou, A. Kitsakos, M.I. Argyropoulou, G. Nakos; Ioannina/GR

Purpose: Heterotopic ossification (HO) of the para-articular tissues is a potential complication in critically ill patients. We report a series of HO in the intensive care unit (ICU), which were diagnosed early with MR imaging.

Material and Methods: Thirty-one consecutive patients were included in the study. Sixteen had musculoskeletal or neurogenic trauma, while 15 had no recognized predisposing factor. Appropriate passive range-of-motion exercises were performed on a daily basis. Alkaline phosphate (ALP), Ca, P and CRP were measured on admission and every 4 days. Upon clinical suspicion of HO, conventional radiographs were performed in all patients and MR imaging in 8 of them. Three patients underwent a second MR imaging one month later.

Results: The most frequently involved joints were the knees (67.7%), the hips (64.5%) and the elbows (29%). ALP showed an acute elevation at 16.4 ± 7.7 days after admission, while the physical signs of HO became evident at 19.7 ± 7.2 days. MR imaging became positive for HO at 19.8 ± 7.3 days while conventional radiographs at 35 ± 7.7 days after admission. At early stage of HO, MR imaging of the knee joint depicted oedema of the subcutaneous fat and joint effusion associated with synovial enhancement. Moreover, the vastus medialis and lateral femoral muscles exhibited high signal on T2-weighted scans and intensive enhancement after intravenous contrast (Gadolinium-DTPA) injection. The follow-up MR imaging showed disappearance of the intra-articular fluid and synovial enhancement along with a decrease of muscular enhancement.

Conclusion: MR imaging is helpful in early detection of HO and may be included in the diagnostic work-up of these patients.

B-561 10:39

MR imaging involvement of the hands in early rheumatoid arthritis:

Comparison with systemic lupus erythematosus and primary Sjogren syndrome

N. Boutry, E. Hachulla, R.-M. Flipo, B. Cortet, A. Cotten; Lille/FR

Purpose: To compare magnetic resonance (MR) imaging involvement of the hands in patients with early rheumatoid arthritis (RA) with that of patients with lupus erythematosus (SLE) or primary Sjogren syndrome.

Method and Materials: Twenty-eight patients (16 women, 12 men; mean age, 42 years) with early RA and 19 patients (18 women, 1 men; mean age, 46 years) with SLE ($n = 14$) or primary Sjogren syndrome ($n = 5$) underwent MR imaging of both hands. They had presented with inflammatory polyarthralgia of the hands and no evidence of erosive changes on X-rays. Coronal STIR T2-weighted images, axial T1-weighted SE images, axial fat suppressed gadolinium-enhanced T1-weighted SE images, and axial gadolinium-enhanced 3D GE images were obtained. The following MR variables were assessed in the wrist and MCP joints: synovitis, bone lesions (erosion, defect, and edema) and tenosynovitis. Scoring of synovitis and bone lesions was done using the OMERACT RA-MR imaging score. Comparisons between patients with RA and those without RA were done using Mann-Whitney and Chi² tests.

Results: The only significant difference between the 2 groups was the presence of tenosynovitis of the right 4th extensor tendon in non-RA patients. There was no significant difference between RA and non-RA patients in terms of global scores for synovitis, bone lesions and tenosynovitis. However, in the MCP joints, bone marrow edema was seen most frequently in RA patients (71%), compared to non-RA patients (5%).

Conclusion: Distinction between early RA patients and non-RA patients using MR imaging may be impossible.

B-562 10:48

MR imaging of the phalangeal joints in cases of arthritis at 3 Tesla. Initial results

M.P. Lichy, C. Amberger, C. Müller-Horvat, I. Kötter, J. Schäfer, S. Lenk, C. Claussen, F. Schick, H.-P. Schlemmer; Tübingen/DE

Purpose: To evaluate the diagnostic potential of MR imaging at 3 Tesla for evaluation of arthritis.

Methods and Materials: High-resolution MR imaging was performed in 7 patients with arthritis with a 3 Tesla MR scanner (TRIO, Siemens), using a dedicated transmit-receive wrist-coil. The imaging protocol included: a) coronal TSE T2w (TR/TE = 4000/106 ms, 2 averages, 120 mm FOV, 384 matrix, fat suppressed) b) T1w MR imaging (TR/TE = 841/12 ms, 1 average, 120 mm FOV, 384 matrix, 1.5 mm slice thickness) c) multiphase angiography (T1w 3D FLASH; TR/TE = 4.3/1.29 ms, 20 mm FOV, flip angle = 20 degree, resulting voxel size = 1 mm³ [isotropic], time resolution = 12 s) d) coronal T1w MR imaging (fat suppressed). Signal-to-noise ratios (SNR) were calculated for volunteer examination at 1.5 and 3 Tesla MR imaging. Findings were compared with clinical, X-rays and ultrasound examinations. Evaluation of MR imaging was performed according to the OMERACT-criteria on high-resolution images. Image quality and diagnostic potential was also evaluated using recalculated images with lower resolutions (3 mm slice thickness, 256 matrix) by two radiologists.

Results: SNR and image quality of 3 Tesla MR imaging was significantly improved compared to 1.5 Tesla examinations. Synovial swelling and bone destruction were clearly visualized. Involved joints demonstrated intra-individual variations in degree and speed of contrast enhancement, indicating local variations in blood supply.

Conclusion: High-resolution MR-imaging of arthritic joints of the hand at 3 Tesla provides detailed information about bone destruction, synovial swelling and perfusion. This information can be used for early detection and therapy follow-up of arthritis.

B-563 10:57

Cervical spine involvement in rheumatoid arthritis: Correlation between neurologic manifestations and MR imaging findings

J.A. Narvaez, F.J. Narvaez, M. Serrallonga, J.M. Nolla, Y. Roca, J. Valverde; Barcelona/ES

Purpose: Our aim is to evaluate the correlation between neurological manifestations and MR findings in a series of patients with RA and involvement of the cervical spine.

Materials and Methods: Thirty-six RA patients were studied with MR imaging of the cervical spine from 1993 to 2002. All cases were symptomatic presenting neck pain not controlled with conservative management, symptoms or signs suggestive of cervical myopathy and/or atlanto-axial subluxation on radiographs. Clinical manifestations were categorized according to the Ranawat classification of rheumatoid myelopathy. MR imaging studies were interpreted in consensus by two radiologists. The spinal canal was graded as normal, stenosed without cord compression, and cord compression (with or without cord signal intensity changes), and evaluated at both atlanto-axial and sub-axial levels. At the atlanto-axial level, the presence of pannus, bone erosions, the cervico-medullary angle (normal > 135°), and anterior or vertical subluxation were evaluated. Multivariate Cox proportional hazards regression models were used to identify variables associated with the occurrence of neurological dysfunction (Ranawat class II or III).

Results: By Ranawat classification, 13 cases (36%) were in class I, 19 (53%) in class II, and 4 (11%) in class III. Only superior atlanto-axial subluxation, atlanto-axial stenosed spinal canal and cord compression at the atlanto-axial level showed a statistically significant risk of neurological dysfunction. The odds ratio were respectively 8.08 (95% IC: 1.23-53.25), 8.9 (95% IC: 1.48-54.78) and 21.25 (95% IC: 1.64-274.90).

Conclusion: In RA patients with symptomatic cervical spine involvement, neurological dysfunction correlates with MR identification of superior atlanto-axial subluxation, atlanto-axial spinal canal stenosis and atlanto-axial cord compression.

B-564 11:06

Longitudinal analysis of anti-citrulline (anti-CCP) antibodies during 5 years of follow-up in early rheumatoid arthritis: Anti-CCP status is a stable phenotype that predicts greater radiological progression and worse disease activity

M.C. Wick¹, J. Rönnelid², J. Lampa¹, S. Lindblad¹, B. Nordmark¹, L. Klareskog¹, R.F. van Vollenhoven¹; ¹Stockholm/SE, ²Uppsala/SE

Purpose: To study serum levels of anti-citrulline (anti-CCP) antibodies in patients with early rheumatoid arthritis (RA) during 5 years of follow-up, and relate this to

Scientific Sessions

radiological progression, disease course, and therapies in clinical practice.

Methods: 279 newly diagnosed early RA patients were prospectively followed with radiographs, clinical investigations, and measurements of anti-CCP antibodies up to 5 years. Radiographs were quantified using Larsen erosion score and the "X-ray RheumaCoach"-software. We utilized a novel method to estimate the expected radiological progression of untreated RA during the first years following diagnosis and to compare this rate to the observed progression under therapy.

Results: 57.3% (160/279) of patients were anti-CCP positive at baseline. The mean baseline Larsen score was 7.9 ± 9.1 , resulting in a mean pre-diagnosis progression rate of 15.5 ± 11.2 Larsen-units/year. All patients had similar disease activity at baseline, but during follow-up the anti-CCP-positive patients had worse clinical disease and greater radiological progression, despite equal anti-rheumatic therapies. Compared to the radiological progression predicted by the pre-diagnosis progression rates, in anti-CCP-negative patients the decrease in the rate of radiological progression was significantly greater compared to the reduction in progression-rates seen in anti-CCP-positive patients (-14.8 vs. -8.4 Larsen-units/year; $p < 0.01$).

Conclusion: Anti-CCP antibody status is a stable phenotype, suggesting that events before rather than after onset of disease determine this phenotype. The presence of anti-CCP antibodies at diagnosis predicts a greater radiological progression and less favorable disease-course despite anti-rheumatic therapy. These observations suggest that anti-CCP-positive RA is a distinct clinical and patho-physiological entity.

B-565 11:15

Relationship between bone marrow edema and cartilage degeneration assessed by high resolution MR imaging and clinical findings in patients with osteoarthritis

C.M. Phan, T.M. Link, G. Blumenkrantz, D.C. Newitt, S. Majumdar;
San Francisco, CA/US

Purpose: To assess the relationship between cartilage loss and bone marrow edema (BME) and to correlate these findings with the clinical Western Ontario and McMaster University Osteoarthritis (WOMAC) score in patients with advanced osteoarthritis over a 2-year period.

Methods: Seven females, seven males (44-76 years) with Kellgren-Lawrence scale ≥ 2 osteoarthritis were recruited. Baseline radiographs, 1.5 T MR imaging and WOMAC scores were obtained in all patients. MR imaging and WOMAC scores were repeated after one (FU1) ($n = 14$) and 2 years (FU2) ($n = 7$). Volume of femoral and tibial cartilage was calculated in fat suppressed spoiled gradient echo (SPGR) sagittal images. Nineteen BME volumes (BMEVo) were measured on T2-weighted images.

Results: At FU1, quantitative analysis showed an increase in BMEVo in 12/19 BME areas (mean increase: 199%) and a decrease in 7/19 areas (mean decrease: 66%). Patients showed a loss of cartilage volume of more than 60% at FU1 regardless of BMEVo variations. At FU2, an increase in BMEVo was found in 4/7 areas and a decrease in BMEVo in 3/7 areas. There was no significant correlation between WOMAC scores, cartilage loss and BME pattern ($p > 0.05$).

Conclusion: In this pilot study trends of decreasing cartilage volume in patients with osteoarthritis have been demonstrated regardless of changes in BME. Changes in BME patterns and size may be indicative of bone remodeling which may be linked to progression of osteoarthritis, but not necessarily to cartilage degeneration.

B-566 11:24

Importance of linear subchondral bone edema in MR imaging knee examination

B. Ciszewska-Lyson, Z. Czynny, R. Smigelski, A. Mioduszewski; Warsaw/PL

Purpose: To attempt to establish if the phenomenon of knee, subchondral linear bone edema of patellar, femoral and tibial surfaces is clinically important.

Materials and Methods: In the years 2003-2004 MR imaging of 759 knees were performed. Analysis was retrospective and included 25 MR imaging examinations in 24 (11-45 years old) patients with linear bone edema of patellar, femoral and tibial surfaces. Classic bone bruises were not a subject of this study. The examination was performed on 1.5 T unit with a dedicated extremity coil and included transverse and coronal STIR sequences. All patients from the group demonstrated linear subchondral edema of the patella or a combination: patella/femur/tibia. History, clinical examination, operational verification and control MR imaging were analyzed.

Results: Linear subchondral edema was found on patella in 25 knees, on femoral and tibial condyles in 11 knees. Prior to examination 23 patients encountered an injury (up to 90days) and/or 12 had knee operation. 18 patients presented with

knee pain (clinical symptoms of algodystrophy in 7). In arthroscopy: 7 patients revealed no macroscopic chondral lesions, 2 patients had osteochondritis dissecans of femoral condyles. In the control MR imaging study a total regression of changes was observed in three cases, transient osteoporosis in one case and transient osteoporosis followed with osteochondritis dissecans in one case. In 17 patients conservative treatment was sufficient.

Conclusion: Linear subchondral edema seems an important MR imaging examination feature, but the rarity of serious sequelae of this pathology indicates that aggressive treatment is not required based on this diagnosis.

B-567 11:33

Meniscal rim sign: Usefulness for evaluation of an extensive triangular or wedge-shaped signal in the meniscus on MR imaging of the knee

J.-Y. Choi, S. Hong, I. Lee, J. Lee, J. Koo, J.-A. Choi, Y. Koh, H. Kang;
Seoul/KR

Purpose: The purpose of our study is to define the meniscal rim sign on MR imaging and to assess the usefulness of this sign for evaluation of an extensive triangular or wedge-shaped signal in the meniscus on MR imaging of the knee.

Materials and Methods: Sagittal and coronal proton density MR images of 97 menisci showing triangular, wedge-shaped, extensive, or grade 2C signal in 74 patients who underwent arthroscopy were obtained, and were blindly reviewed by consensus of two musculoskeletal radiologists. Of 97 menisci, 46 meniscal tears were confirmed at arthroscopy. We grouped all 97 menisci as follows; type 1, intact meniscal rim (outline of the meniscus) with normal low signal intensity of the rim; type 2, intact meniscal rim, but with increased signal intensity of the rim; and type 3, loss of meniscal rim. Pearson χ^2 test was used to determine whether the types of meniscal rim on MR image and tears at arthroscopy were statistically significant.

Results: All menisci were grouped into type 1 in 38 (39.2%), type 2 in 27 (27.8%), and type 3 in 32 (33%). True meniscal tears were two (5.3%) in type 1, 16 (59.3%) in type 2, and 28 (87.5%) in type 3. Statistical analysis revealed significantly higher frequencies of meniscal tear in groups of type 2 and 3 than type 1 with linear by linear correlation ($P < 0.01$).

Conclusion: Meniscal rim sign was useful to evaluate an extensive triangular or wedge-shaped signal in the meniscus on MR imaging of the knee.

B-568 11:42

Calf muscle BOLD MR imaging: Comparison of healthy volunteers and grade II PAOD patients in a post-occlusive reactive hyperemia paradigm

H.P. Ledermann, A.C. Schulte, H.G. Heidecker, M. Aschwanden, K.A. Jäger, W. Steinbrich, D. Bilecen; Basle/CH

Purpose: To compare calf muscle BOLD measurements of healthy volunteers and patients with peripheral arterial occlusive disease (PAOD) grade II.

Patients and Methods: 17 healthy volunteers (mean age: 35 ± 9.2 years) and 17 patients (mean age: 63 ± 11.6 years) with PAOD grade IIA ($n = 8$) and grade IIB ($n = 9$) had BOLD MR imaging measurements of the calf muscles using an ischemia (6 min.) and reactive hyperemia (6 min.) paradigm with 50 mm Hg suprasystolic thigh compression. MR imaging was performed on a 1.5 T scanner (Sonata, Siemens) using a single-shot multi-echo GE-EPI sequence (TE ms: 16/38/61/83 TR: 1000 ms, flip angle: 90°, FOV: 380x238) with 1 measurement / sec in gastrocnemius muscle tissue. Comparison of both groups involved analysis of mean normalized and individual muscle BOLD curves, time to hyperemia-peak (TTP) after cuff deflation, hyperemia peak values (HPV) and slope of the initial 20 sec. of hyperemia (SL20) ($100 \times \Delta S_{20 \text{ sec.}} / 20 \text{ sec.}$).

Results: During ischemia progressive muscle BOLD signal decrease was similar for both groups with higher individual variation in the patient group. During reactive hyperemia the following mean values were calculated (volunteers / patients): TTP: 44.2 ± 8.2 sec / 103.1 ± 58.5 sec ($p < 0.001$), HPV: $19.7 \pm 5.5\%$ / $8.7 \pm 4.4\%$ ($p < 0.001$), SL 20: 41 ± 40 / 7 ± 18 ($p < 0.004$).

Conclusion: During reactive hyperemia PAOD patients have significantly slower BOLD signal ascents, decreased hyperemia peak values and a delayed time to peak compared to healthy volunteers. These BOLD signal alterations most probably reflect delayed reoxygenation of ischemic muscle tissue due to impaired calf perfusion.

B-569 11:51

High resolution imaging of the human wrist at 3.0 Tesla: A comparative study of carpal ligaments and TFCC in normal volunteers

V. Vieth¹, M. Langer¹, C. Stehling¹, S. Kraemer¹, H. Kooijmann², H. Kugel¹, W. Heindel¹, R. Bachmann¹; ¹Münster/DE, ²Hamburg/DE

Purpose: To assess the diagnostic capability of a new multi-contrast high

Scientific Sessions

resolution imaging protocol for the wrist at 3.0 T and to compare it to our standard 1.5 T protocol.

Methods and Materials: In 10 volunteers images were acquired at 1.5 T (standard surface coil) and 3.0 T (purpose build phased array coil) (Gyrosan Intera, Philips). Imaging protocols consisted of coronal T1-TSE, T2-TSE and PD-TSE-FS and sagittal T2-TSE and PD-TSE-FS sequences. Increased SNR at 3.0 T was used to reduce measured voxel size from 0.50 x 0.50 x 3.0 mm (1.5 T) to 0.20 x 0.20 x 1.5 mm (3.0 T). Total examination time was approximately 25 min. To compare the diagnostic capability of both protocols three observers assessed in consensus the visibility of 14 well-defined clinically important anatomical landmarks (origin and insertion of 5 intrinsic and extrinsic carpal ligaments, central portion of the TFCC and ulna, triquetral, and radial attachments). Image quality and artifacts were ranked qualitatively on a five-point scale.

Results: Out of a total of 140 detectable structures, 75 were detected at 1.5 T and 126 at 3.0. Overall image quality was significantly better at 3.0 T (3.8 vs. 4.9, $p = 0.002$), whereas artefact score did not differ significantly (4.3 vs. 4.5, $p = 0.317$).

Conclusion: Investing the higher SNR at 3.0 T into better spatial resolution, depiction of the normal anatomy of the wrist benefits significantly. We anticipate that increased spatial resolution at 3.0 T will also permit a more detailed analysis of pathologic findings.

Contrast enhanced dark lumen MR colonography in adenomatous versus hyperplastic colorectal polyps

B. Bassler, D. Hartmann, B. Pfeifer, D. Schilling, J.F. Riemann, G. Layer;
Ludwigshafen/DE

Purpose: To determine the influence of histology (adenomatous vs. hyperplastic intestinal mucosa) on the accuracy of contrast enhanced dark lumen MR colonography (MRC) for the detection of colonic polyps.

Materials and Methods: 100 consecutive patients with a clinical indication for colonic diagnostic workup were prospectively included in this study, undergoing MRC and subsequent conventional colonoscopy on the same day. All patients underwent standard preparation for colonoscopy. Two experienced readers interpreted each MRC, blinded to the results from CC, evaluating MPR's and virtual flight. In a second step, endoscopic and histologic results were compared to MRC.

Results: In 49 patients CC detected a total of 107 polyps: 82 adenomas, 25 hyperplastic polyps and 7 carcinomas. MRC could not detect any hyperplastic polyp which showed sizes ranging from 1 to 5 mm (22 polyps) and 6 to 9 mm (3 polyps). In adenoma the sensitivity was 18.2% in lesions up to 5 mm ($n = 22$), 84.2% from 6 to 9 mm ($n = 38$) and 100% larger than 9 mm ($n = 22$). Contrast uptake in adenomatous polyps was significantly higher than in normal mucous membrane.

Conclusion: Histology dependent mucous enhancement seems to be a size independent parameter for the detection of polyps by MRC. Contrast enhanced dark lumen MRC could not detect hyperplastic polyps, maybe because they don't develop a pathological wall enhancement due to their vascular architecture being similar to that of normal mucous membrane.

B-571 10:39

MR colonography without bowel purgation. Preliminary results of a new fecal tagging concept

C.A. Kuehle, W. Ajaj, S. Massing, J. Langhorst, M. Nuefer, S.C. Goehde,
J. Barkhausen, T.C. Lauenstein; Essen/DE

Purpose: For MR colonography (MRC) colonic cleansing has been unavoidable. However, the unpleasant bowel cleansing protocols reduce patient acceptance. This study was to evaluate the accuracy of a new MRC protocol without colonic cleansing.

Methods and Materials: 143 screening patients were included. In addition to their regular meals they ingested 2000 ml of a tagging solution starting 48 hours

prior to the MR examination. The solution contained 5% gastrografin, 1% barium and 0.2% locust bean gum. MRC was performed in conjunction with a rectal water enema on a 1.5 T MR System (Sonata, Siemens). A T1W 3D GRE sequence was acquired in a prone position pre- and 75 s after gadolinium administration. All patients underwent conventional colonoscopy within 3 weeks of the MR examination. MR data were analysed concerning image quality and the presence of colorectal masses. Additionally, patient acceptance was assessed for both methods.

Results: Image quality of fecal tagging based MRC was diagnostic in 87% of the examinations. Reasons for non-diagnostic examinations were related to motion artefacts and signal-intense stool in each of 8% of the procedures. Colorectal masses > 5 mm were detected with a sensitivity of 74% and a specificity of 97% compared to CC. Although MRC lacks therapeutic options 67% of the patients preferred MRC for future examinations.

Conclusions: Fecal tagging MRC is applicable for screening purposes. Major advantages are related to the high patient acceptance and the specific detection of colorectal masses. However, further investigations need to be performed to improve the detection rate for colorectal polyps.

B-572 10:48

Correlation of MR-hydrocolonography with endoscopic scores in inflammatory bowel disease

T. Robl, J. Raith, T. Hinterleitner, A. Ruppert-Kohlmayer, W. Petritsch, F. Ebner;
Graz/AT

Purpose: In a prospective series of patients with ulcerative colitis and Crohn's disease, MR-Colonography findings were correlated with endoscopic scores (0-3).

Method and Materials: MR-Hydrocolonography and Colonoscopy were performed in a series of 62 patients. MR examination took place after rectal filling of the large bowel with saline solution and including iv application of Gadolinium. MR findings were evaluated by 3 blinded radiologists and compared with the endoscopic scores (1-3).

Results: Series ($n = 56$, 32f/24m, mean 38 years): Crohn's disease ($n = 27$) colitis ($n = 29$), non-specific colitis ($n = 2$), colonoscopy incomplete ($n = 4$), MR not possible ($n = 1$). Global accuracy of MR imaging in the patient group with ulcerative colitis was 79% (rectum 69%, sigma 90%, descending colon 80%, transverse colon 83% and ascending colon 73%). The accuracy of MR imaging in the patient group with Crohn's disease was 69% (rectum 60%, sigma 70%, descending colon 63%, transverse colon 74% and ascending colon 78%). Endoscopic scores concerning the severity of disease (0-3) were established. In ulcerative colitis patients with score 0-1 ($n = 9$) MR imaging was positive in 72%; score 2 ($n = 7$) in 83% and score 3 ($n = 13$) in 82%. In Crohn's disease patients with scores of 0-1 ($n = 12$) MR imaging was positive in 62%, score 2 ($n = 7$) in 72% and score 3 ($n = 8$) in 78%.

Conclusion: MR was of higher diagnostic accuracy in patients with ulcerative colitis compared with Crohn's disease. The diagnostic accuracy of MR-Colonography increased with higher scores (2 and 3) and disease activity.

B-573 10:57

Blackberry and elderberry juice with high concentrations of manganese and iron ions as negative T2 and positive T1 contrast media: An in-vitro study

S. Puig, H. Redl; Vienna/AT

Purpose: To evaluate superparamagnetic and paramagnetic effects of blackberry (BB) and elderberry juice (EB) with high concentrations of manganese (Mn) and iron (Fe) ions as possible negative oral contrast agents.

Method and Materials: Two samples of unpreserved concentrates of BB and EB collected in Middle- and Eastern-European countries were analyzed for concentrations of Mn, Fe and other metallic ions (AAS, Phosyn Laboratories, Pocklington, York, GB). The juices were diluted with water 1:1, 1:2 and 1:4. Water served as control. Measurements were made with a 1.5 T scanner (Siemens, Symphony, Erlangen, Germany). Several T2 and T1 weighted sequences were used. We analyzed signal-to-noise ratio and relative contrast-to-noise ratio in relation to water and in relation to the background (BG).

Results: The undiluted BB and EB had Mn concentrations of 57 mg/l and 17.2 mg/l, and Fe concentrations of 13.3 mg/l and 52.8 mg/l, respectively. The lowest SNRs in T2W sequences were 2.68 and 28.2 for undiluted BB and EB, respectively. In T1W, juices showed a SNR of 44.72 and 60.71. The relative CNR of BB and EB in T2W sequences compared to BG was 3.60 (T2TSE) and 55.27 (T2TSE with fat saturation). The lowest CNR in T1W was -1.67 for BB (T1FLASH3D with fat saturation) and 382.15 for EB (T1FLASH2D with fat saturation).

Conclusions: BB has the potential to serve as a negative oral contrast agent in

Scientific Sessions

T2W and T1W sequences. EB can be used as a biphasic oral contrast agent, with negative signal effects in T2 and positive effects in T1W sequences.

B-574 11:06

Magnetic-resonance enteroclysis (MRE) in patients with Crohn's disease (CD): Complementary diagnostic value of additional retrograde large bowel filling

K.A. Herrmann, H.J.M. Michaely, C.J. Zech, J. Seiderer, T. Ochsenkuehn, S.O. Schoenberg, M.F. Reiser; *Munich/DE*

Purpose: To evaluate the complementary diagnostic impact of additional rectal water filling in MR-enteroclysis in patients with Crohn's disease (CD) and large bowel involvement.

Patients and Methods: From 12/2002 through 04/2004, 119 patients with proven CD underwent MRE with trans-jejunal intubation and instillation of iron-oxide containing contrast medium and additional retrograde rectal filling with water (extended(e) MRE). All examinations were performed on a 1.5 T MR-scanner (Magnetom Sonata, Siemens Medical Systems, Erlangen, Germany). eMRE images were reviewed by two board certified radiologists concerning large bowel involvement causing complications. Positive findings were correlated with colonoscopy and surgery.

Results: 15/119 (12.6%) patients were found to have significant involvement of the colon and the co-existing complication depicted with eMRE were; subtotal stenosis with sub-ileus (4), fistulae (3) and abscesses (7). One patient presented with adeno-carcinoma in a longstanding colonic stenosis. In 4/15 (26%) cases colonoscopy was refused by the patient (1) or incomplete (3) and MRE with rectal filling added conclusive information for appropriate therapy. 12/15 patients underwent surgery which confirmed eMRE diagnosis, one patient had percutaneous drainage of an abscess and 2 patients underwent conservative and medical treatment of stenosis due to its inflammatory character indicated by MRE. **Conclusion:** MRE combined with rectal filling is highly useful in the diagnosis of disease-related complications in CD with involvement of the large bowel.

B-575 11:15

Optimization of a new mixture of barium sulphate and sorbitol (Volumen) as oral contrast agent for MR of the small bowel in a pediatric population

P. Paolantonio, M. Rengo, A. Laghi, F. Lafrate, M. Di Martino, A. Guerrisi, R. Passariello; *Rome/IT*

Purpose: To evaluate the administration of barium sulphate and sorbitol mixture (Volumen; E-Z-EM, NY, USA) as an oral contrast agent for MR studies of the small bowel in a pediatric population.

Materials and Methods: We analyzed 20 paediatric subjects, ten with Crohn's disease and ten healthy subjects. Each patient underwent MR scan after oral administration of different amounts of Volumen (from 10 to 20 ml/kg/BW). MR protocol included HASTE T2W sequence, Tru-FISP sequence and FLASH T1W sequence acquired in coronal and axial planes every 5 minutes until the cecum was reached. Image analysis included a quantitative evaluation of small bowel distension by measuring small bowel caliber at 3 levels. A qualitative analysis of the signal properties of contrast media and of patients' compliance was also performed.

Results: Volumen has signal properties similar to water. An adequate small bowel distension after administration of 15 ml/kg/BW was observed. Optimal distension was observed for the proximal ileum in all subjects after 10 minutes from contrast agent administration. We observed some inter-individual differences in transit time of Volumen with an adequate distension of the terminal ileum after a mean time of 25 min. We did not observe any significant side effects except for mild diarrhoea for a dose of 20 ml/kg/BW.

Conclusions: Volumen is a safe and useful oral contrast agent for MR studies of the small bowel with biphasic properties in terms of signal intensity. Patient compliance during oral administration is high. The adequate dose in a pediatric population is of 15 ml/kg/BW.

B-576 11:24

MR-colonography in incomplete endoscopy of the colon: A prospective study

B. Bassler, D. Hartmann, B. Pfeifer, D. Schilling, J.F. Riemann, G. Layer; *Ludwigshafen/DE*

Purpose: The purpose of this study was the prospective segmental assessment of the colon using MR-colonography (MRC) in a dark lumen technique in incomplete endoscopy.

Material and Methods: 31 patients (21 female and 10 male, mean age 60.2 a

± 13.2 a) with an incomplete colonoscopy have been included in the study. All patients underwent standard preparation for colonoscopy. MRC protocol (1.5 T Magnetom Sonata, Siemens) included T1W 3D VIBE sequences before and 70 seconds after 0.2 mmol/kg bw Gd-BOPTA (Multihance™, Altana) in a prone position (rectal enema tube, approximately 3000 ml of water, 40 mg butylscopolamine i.v.). Evaluation for colonic distension, demonstration of morphologic stenoses, elongation /curvature was done by two experienced readers (one radiologist, one gastroenterologist) in consensus for six segments of the colon each.

Results: MRC demonstrated in 4 cases, that the inability of complete endoscopy was due to anatomical problems like elongation or curvature of colonic segments. Inflammatory stenoses were seen in 17 patients, stenotic tumors in 6 and postoperative adhesions in 1. MRC was diagnostically sufficient in 128 of 134 proximal prestenotic segments. Suboptimal distension was found in 5/134, stool artifacts in 6.5% and movement artifacts in 16.1%. Altogether 23 pathological findings could be detected in the endoscopically not evaluated 134 segments of the colon (8 polyps, 3 stenoses 4 inflammatory, 7 webs and 1 fistula).

Conclusion: MRC is a new diagnostic tool with excellent diagnostic performance to complete evaluation of the colon after incomplete colonoscopy. Compared with CT it has the advantage of no exposure to ionising radiation.

B-577 11:33

Crohn's disease: Comparison of MR enteroclysis with MR imaging using polyethylene glycol (PEG) solution as oral contrast medium

G. Masselli, L. Menchini, L. Minordi, A. Vecchioli, L. Bonomo; *Rome/IT*

Purpose: To compare the diagnostic value of MR enteroclysis (MRE) with MR imaging using Polyethylene Glycol (PEG) Solution as an oral contrast medium (MR imaging per OS).

Method and Materials: We undertook a prospective randomized trial of forty patients with known Crohn's disease who were examined with MRE ($n = 22$) or with MR imaging per OS ($n = 18$) on 1.5 T magnet. MRE was performed by injection of 1.5-2 l of PEG solution via a nasojejunal catheter, whereas MR imaging per OS was performed with orally administration of 700-1100 ml of PEG solution. Two radiologists reached a consensus about the following imaging findings: Small bowel filling and distension of the small bowel, bowel wall conspicuity and depiction of ulcer wall, bowel wall thickness and fistulas. Conventional enteroclysis was employed as a standard of reference. The imaging findings of the two procedures were compared using Mann-Whitney test, with $p < 0.05$ considered statistically significant.

Results: Good or excellent small bowel filling and distension was obtained in 21/22 patients (95%) examined with MRE and in 12/18 (66%) with MR imaging per OS ($p = 0.0001$) and bowel wall conspicuity was graded good or excellent in 21/22 (95%) and in 13/18 (72%) ($p = 0.02$) respectively. Ulcers of the bowel wall were statistically better delineated with MRE than MR imaging per OS ($p = 0.02$) whereas the specificity and sensitivity of detection of stenosis segments and fistulas although higher with MRE didn't reach statistical significance ($p > 0.05$).

Conclusions: Both MRE and MR imaging using per os PEG offer reliable information on superficial, mural and extramural abnormalities, however depiction of mural ulcers was statistically better with MRE.

B-578 11:42

Comparison of true-FISP MR imaging with and without i.v.-contrast-enhancement in patients with inflammatory bowel disease (IBD)

C. Hohl, G.A. Krombach, T. Schmidt, G. Staatz, R.W. Günther, P. Haage; *Aachen/DE*

Purpose: To evaluate the necessity of i.v.-contrast administration in the diagnosis of IBD with MR imaging using standard- and true-FISP sequences.

Materials and Methods: 40 patients aged 7-62 years with suspected or known IBD underwent MR imaging of the small bowel on a 1.5 T-scanner. 1 hour after 1 l mannitol-solution was given orally, MR imaging was performed using coronal HASTE-M2D, coronal fat-suppressed T2-TSE, axial dynamic T1-weighted GE-sequences before and after i.v.-contrast (Gd-DTPA) and true-FISP sequences before and after i.v.-contrast in coronal and axial planes. MR-images were correlated with endoscopy and clinical findings. The MR imaging sequences were evaluated for sensitivity and specificity regarding the detection of inflammatory bowel-wall changes by three experienced radiologists. Particularly the true-FISP sequences pre- and post-contrast were compared with one another using the Pearson-correlation.

Results: True-FISP MR imaging enabled an excellent assessment of inflammatory activity in IBD. With sensitivities of 95% (axial pre-contrast, coronal post-contrast) and 97.5% (axial post-contrast, coronal pre-contrast) the true-FISP sequences

Scientific Sessions

were superior to the other sequences (T1 = 85%, HASTE = 17.5% and T2-TSE = 55%). The comparison between true-FISP and contrast enhanced T1 showed no significant difference ($p = 0.21$). Pre- and post-contrast true-FISP sequences showed a good concordance of sensitivity values (correlation coefficient = 0.92). In one patient an ambiguous finding in the true-FISP could be confirmed as IBD by increased Gd-DTPA uptake in the T1-weighted dynamic.

Conclusion: I.V. contrast administration has no benefit for true-FISP sequences in bowel MR imaging. In most cases unenhanced true-FISP sequences in different planes are sufficient for diagnosis of IBD. In questionable cases Gd-enhanced T1-images can help to validate the true-FISP findings.

B-579 11:51

Outcome of patients with choledocholithiasis at MR cholangio-pancreatography

L.H. Bushby, A. Gimson, D.J. Lomas; Cambridge/UK

Purpose: To evaluate patient management following a positive diagnosis of choledocholithiasis at MRCP, associated presenting features and false positive rate.

Methods and Materials: Reports of 906 patients who underwent MRCP from 1996 to 2002 were reviewed retrospectively for positive diagnoses of choledocholithiasis. Imaging features were recorded by review of the examinations on a workstation. Presenting clinical features and subsequent therapeutic procedures were established by review of patient records.

Results: 100 MRCP examinations in 906 patients were reported positive for choledocholithiasis. 99 had medical records available for review, in whom 87 subsequent procedures were performed to confirm or refute the presence of choledocholithiasis. In 6 cases a procedure was attempted, but failed and in 12 cases no therapeutic procedure was attempted. Choledocholithiasis was confirmed in 65 of the 81 cases that underwent a successful procedure, giving a false positive rate of 19.8%. The likelihood of a false positive examination was not significantly associated with the presence of abdominal pain at presentation or the presence of multiple calculi at MRCP but was significantly inversely related to maximum stone diameter ($p = 0.002$). Whether or not a therapeutic procedure was performed was not significantly associated with patient age or the presence of comorbid disease or maximum stone diameter.

Conclusion: In the majority of patients with choledocholithiasis at MRCP a therapeutic procedure will be attempted. In our practice this is likely to confirm the diagnosis in at least 80% of cases. False positive diagnoses were significantly associated with small diameter calculi.

Results of the radiology monitoring of breast in women with gynecological malignant tumors

V.B. Myakinkov; Kherson/UA

Purpose: There is contradictory data of breast cancer (BC) appearance frequency in women with gynecological malignant tumors (GMT). The purpose of this research is evaluation of BC appearance frequency in women with GMT depending on time passed after GMT detection, age when GMT were diagnosed, GMT types; definition of examination tactic.

Methods and Materials: Breast examination results of 2412 women with GMT were analysed (ovarian cancer - 442 patients; cervical carcinoma - 998; endometrial carcinoma - 972). During 5 years following the operation 868 women were being observed (36%); 6-10=699 (29%); 11-15=531 (22%); over 15=314 (13%). Mammography, ductography, pneumocystography and sonography were used.

Results: Breast cancer was revealed in 27 (1.1%) women; with ovarian cancer - 10 cases (2.2%); cervical carcinoma - 7 (0.7%); endometrial carcinoma - 10 (1.0%). During 5 years following the operation 7 cases (0.8%); 6-10=7 (1.0%); 11-15=7 (1.3%); over 15=6 (1.9%). The frequency of disease for BC at the moment of revealing the GMT before the age of 34=0.7%; 35-44=1.3%; 45-54=0.8%; 55-64=1.6%; 65 and older = 0.8%.

Conclusion: Frequency of BC appearance in women with GMT prevails morbidity in female population of region by 19 times and has 2 peaks. For breast monitoring the following tactic of using radiation methods of diagnosis was recommended: If GMT is detected under the age of 34 - mammography and sonography; 35-64 - annual mammography; over 65 - mammography every 2 years.

B-581 10:39

Benign breast diseases associated with cyclosporine A therapy in renal transplant recipients

Y. Seo, C. Choi, D. Yoon, E. Yun, S.-H. Lee, S. Park, J. Moon; Seoul/KR

Purpose: To determine radiologic characteristics of cyclosporine A induced benign breast diseases and to report clinical and pathologic findings.

Methods and Materials: The clinical, mammographic and ultrasonographic records of 33 female renal transplant recipients who received cyclosporine A were retrospectively reviewed. Eleven patients had 46 breast masses on ultrasonography. We performed core needle biopsies on 20 masses and reviewed pathologic findings.

Results: Among 33 female renal transplant recipients, 11 patients (33%) had 46 breast lesions on ultrasonography, which showed benign characteristics. We performed core needle biopsies on 20 out of 46 masses. On pathologic examinations, 12 were fibroadenomas, 6 were fibrocystic changes and 2 were dense fibrosis. Regardless of the final pathologic diagnosis, more than half of the lesions revealed severe lymphatic and venular swellings. Among 11 patients with breast lesions on ultrasonography, 10(91%) showed multiplicity, and 7(64%) showed bilaterality. Mammographically, patients with breast lesions revealed heterogeneously or extremely dense breast patterns and 8 of 11 patients showed positive findings, which were circumscribed masses. 22 patients without breast lesions showed scattered fibroglandular densities ($n = 7$), heterogeneously dense ($n = 11$) and extremely dense ($n = 4$) breast pattern, and 3 of 22 patients showed vague or asymmetric densities that needed further evaluation.

Conclusion: With the development of new breast lesions in patients after renal transplantation, the diagnosis of cyclosporine A induced benign breast diseases which are fibroadenoma, fibrocystic changes and dense fibrosis, should be considered. Also, understanding these entities will relieve the fear for the unexpected lumps in those who received transplantation.

B-582 10:48

Breast sonography in asymptomatic women with mammographically dense breasts

A. Memis Oktay, O. Oktay; Izmir/TR

Purpose: The sensitivity of mammography decreases in women with dense breast parenchyma. The objective of this study was to evaluate the efficacy of breast sonography (US) as an adjunct to mammography in screening asymptomatic women with dense breasts.

Methods and Materials: Between October 2000 - June 2004, 2821 asymptomatic women with dense breasts and negative mammograms were examined with breast sonography. In 59 women US showed solid lesions, and biopsy was performed with US guidance. The lesions were in BIRADS 3 category in 43 patients, and in BIRADS 4 category in 16. Within this group, histopathologic results were correlated with US findings.

Results: Histopathologic examination revealed 10 breast cancers in 59 patients who underwent biopsy. Cancer detection rate in 2821 women was 0.35%. All 43 BIRADS category-3 lesions were benign in histology (fibroadenoma, fibrocystic disease, etc.) and no cancer was detected in this group. Of 16 BIRADS category 4 lesions, 10 were diagnosed as malignant. All cancers were in stage T1.

Conclusion: Dense glandular tissue is the most important limitation of screening mammography. Breast sonography can detect small breast cancers in screening population that are not detected on mammography due to dense breast parenchyma. After a proper categorization of lesions by US, follow-up of the BIRADS category-3 lesions can reduce unnecessary biopsies and false positive results.

B-583 10:57

The value of normal mammographic and sonographic findings in evaluating palpable breast abnormalities

M.G. Skilakaki, I.V. Kalogeropoulos, B. Galina, E. Antipa, E.E. Maragaki, P.N. Piperopoulos; Athens/GR

Purpose: To retrospectively determine frequency of cancer in women with breast lumps and negative mammographic and sonographic findings.

Methods and Materials: 110 patients with a palpable abnormality at presentation

Scientific Sessions

and no corresponding mammographic or sonographic lesion were retrospectively identified from our mammography database. The study group consisted of 95 women who had a minimum mammographic and clinical follow-up of 3 years and 15 patients who underwent surgical biopsy. Evaluated parameters included the level of suspicion on physical examination, breast parenchymal density, mammographic and sonographic characteristics in the area of concern, whether there was any change in imaging and/or clinical findings at follow-up and biopsy results.

Results: Of the 110 women, 102 had radiographically dense breast tissue (Breast Imaging Reporting and Data System - BI-RADS - category 3 or 4) and only 8 had predominantly fatty breasts. All patients with histologically sampled lesions had a BI-RADS tissue pattern 3 or 4. No patient in the non-biopsy group developed carcinoma at the initial site of concern during a follow-up period of 3 years. Only one of the 15 women who underwent biopsy received a diagnosis of breast cancer in the area of palpable abnormality.

Conclusion: Results of this retrospective study suggest that if the mammogram and ultrasound depict normal breast tissue, the likelihood of a palpable abnormality being malignant is extremely low even in radiographically dense breasts.

B-584 11:06

Gray-scale and power Doppler US in the preoperative evaluation of axillary metastases in breast cancer patients with no palpable lymph nodes

G. Esen, B. Gurses, M.H. Yilmaz, S. Ilvan, S. Ulus, V. Celik; *Istanbul/TR*

Purpose: The purpose of this study is to evaluate prospectively the predictive value of gray scale and Doppler US findings for the preoperative detection of axillary metastases in breast cancer patients with no clinical evidence of axillary involvement.

Methods and Materials: 198 axillary lymph nodes detected in 83 women with breast cancer were evaluated. Each node was localized with peroperative US before full axillary dissection. Abscence of echogenic hilum, asymmetrical cortical thickening, and presence of peripheral flow on power Doppler US were considered signs of malignancy. The longest diameters and longitudinal/transverse axis ratios were also documented.

Results: Histopathologically 93 nodes were malignant, and 105 were benign. All three prospective criteria as well as a low longitudinal/transverse axis ratio were statistically significant for malignancy. Size was not a significant criterion. In lymph nodes smaller than 1 cm, only asymmetric cortical thickening ($p < 0.001$) and presence of peripheral flow ($p = 0.012$) were significant. The sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 86.49%, 93.62%, 91.43%, 89.8%, 90.48% respectively. On patient basis, the positive and negative predictive values for the presence of axillary metastasis were 93.33%, and 88.57%.

Conclusion: US is successful and reliable in the preoperative determination of nonpalpable axillary metastatic lymph nodes. Sentinel node biopsy is the standard procedure for determining lymph node status in these patients. Inclusion of axillary US in the preoperative diagnostic evaluation, would be complimentary to and would also eliminate the need for sentinel node biopsy in those patients with positive US results.

B-585 11:15

Breast masses characterization: Use of ACR BI-RADS US lexicon in our experience

P. Belli, A. Magistrelli, R. Lombardi, G. Franceschini, M. Costantini; *Rome/IT*

Purpose: Ultrasound characterization of breast lesions improves the specificity of mammography in evaluating masses. Ultrasound is often the only diagnostic examination in detecting non palpable breast masses and is most often the imaging guide for percutaneous procedures. Our aim was to determine positive and negative predictive value (PPV and PNV) of each ultrasound descriptor and category of ACR BI-RADS US lexicon.

Methods and Materials: 178 breast masses were studied with a multifrequency 10-13 MHz linear-array probe. All lesions were classified by two breast imaging experienced radiologists using ACR BI-RADS US lexicon. Age, site, size, shape, orientation, margins, lesion boundary, echo pattern, posterior acoustic features, surrounding tissue and final assessment category were considered. All lesions underwent cytological/histological examination and results were compared to ultrasound features. PPV and PNV for descriptors and categories were calculated.

Results: Lesions were classified as: 2 class II, 24 class III, 73 class IV and 79 class V. PNV for class II and III was 100% and 83.3%. PPV for class IV and V was 46.6% and 84.8%. Irregular shape, spiculated and angular margins, non-parallel orientation, hypoechoic echopattern, echogenic halo and posterior shadowing were associated with the highest PPV. Mean horizontal diameter was 14.82 mm

(26.50 class II, 15.63 class III, 15.60 class IV, 13.57 class V). Mean vertical diameter was 11.14 mm (13 class II, 8.76 class III, 11.23 class IV, 11.73 class V).

Conclusion: ACR BI-RADS US lexicon is an important system to describe and to classify breast lesions and to determine the management of patients.

B-586 11:24

Comparison of BI-RADS categories and final diagnosis in case of second opinion assessment

J.H. Lorenzen, A.K. Wedel, B.W. Lisboa, G. Adam; *Hamburg/DE*

Purpose: To evaluate the value of second opinion assessment by using the BI-RADS system.

Methods and Materials: We analysed 374 diagnostic mammography and sonography examinations. All patients received mammography and sonography examinations at different outside facilities and all patients received an additional sonography examination at the university radiology department and if necessary supplemental mammographic views. Final diagnosis (Histology: 316; follow-up: 58) was ascertained and correlation of BI-RADS-assessment for mammography and sonography at both sides and final diagnosis was analysed.

Results: Final diagnosis yielded 146 benign lesions and 228 cancers (61%). Concordance of BI-RADS assessment was achieved in 62.8% of category 4 and 5 and only 10.7% of category 1,2 and 3. Overall agreement was documented in 73.5% of the cases. Correlation between the BI-RADS assessment and final diagnosis showed only a kappa value of 0.266 for the outside facilities, but a significant higher correlation of 0.753 ($p = 0.000$) for the second opinion rating at the university. Combination of mammography and sonography BI-RADS assessment reached the highest correlation of 0.838 for the radiology department and only 0.389 for the outside facilities, followed by mammography (0.727 versus 0.298) and sonography (0.683/0.358).

Conclusion: Second opinion leads to a significant improvement in the correlation of BI-RADS assessment and final diagnosis in case of diagnostic mammography and sonography.

B-587 11:33

The microcalcification matrix-system: A novel method to classify clusters of microcalcifications according to BI-RADS

A. Fischmann¹, R. Läufle¹, K. Siegmann¹, A. Wersebe¹, T. Xydeas¹, S. Miller¹, C.D. Claussen¹, M. Müller-Schimpffle²; ¹Tübingen/DE, ²Frankfurt a. Main/DE

Purpose: To evaluate a novel method to standardize the classification of breast microcalcifications according to the assessment categories of BI-RADS™.

Methods and Materials: A matrix system was developed to classify clusters of microcalcifications into the BI-RADS categories according to shape and distribution. In 75 clusters of microcalcifications with biopsy proven histology, the calcifications were classified according to the novel matrix system and with subjective malignancy estimation. Reading was done by 4 blinded readers with different experience in mammography (1 to 5 years), leading to a total of 300 readings. The negative and positive predictive values were calculated for each BI-RADS™ category. The relationship between BI-RADS™ assessment categories 2, 3, 4, and 5 with histological results was statistically evaluated with the χ^2 test.

Results: Using the microcalcification matrix, the prospectively classified BI-RADS™ 2/3/4/5 findings revealed a malignant histological diagnosis in 0%/38%/50%/78%, respectively. Conventional reading yielded malignant diagnosis in 27%/36%/53%/79% respectively. The relationship between BI-RADS™ categories 2 to 5 and histology was statistically significant ($p < 0.001$). No influence of the experience of the readers on the results with the matrix system could be found. Inter-reader variability was high with both methods, ranging from 0 to 0.78, as was intra-reader variability, ranging from -0.02 to 0.28.

Conclusion: The microcalcification matrix system allows for a standardized classification of microcalcifications, to enable especially less experienced readers to reliably classify microcalcifications according to BI-RADS™. High malignancy rates in BI-RADS™ category 3 could mainly be explained by a sampling bias, as only biopsy proven cases were evaluated.

B-588 11:42

Assessment of the image quality in a new mammography film-screen combination compared to a standard state of the art film-screen system

V.C. Romano, F. Diekmann, R. Juran, B. Hamm, U. Bick; *Berlin/DE*

Purpose: To compare image quality in a new film-screen combination and in a standard state of the art mammography film-screen system.

Methods and Materials: Investigations were performed with a new combination (KODAK Min-R EV 190 screen/Min-R EV Film= System-A) in comparison to a

Scientific Sessions

well known system (KODAK Min-R 2190 screen/MinR 2000 film= System-B) on a clinical setup and a mammography contrast-detail phantom (CDMAM 3.2, Med.Dept. Nijmegen, Netherlands). In 19 patients one of the views (CC/MLO) was randomly performed with system-A, the other with B. Three readers (I,II,III) compared the two in terms of sharpness, contrast and overall impression using a scale from -2 to +2. In addition, all readers evaluated five phantom studies performed with each system at following settings: 27 kVp with respectively 56, 80, 110, 160 and 280 mAs. The number of detected phantom fields was recorded.

Results: Subjective sharpness, contrast and overall impression of system-A was superior than in system-B (average score for contrast:0.91, sharpness:0.72, overall impression:0.51). The average number of detected fields for each reader was higher in the phantom studies performed with system-A than with B (System-A, I/II/III: 89.8/94.2/98.4; System-B: 89.6/89.2/95.8). The average amount of detected fields pooled for all readers was 94.13 with system-A and 91.5 with B. The difference was not statistically significant (Chi2-Test, p = 0.8939).

Conclusion: The results suggest that image quality obtained with system-A is equal or slightly better than with system-B, higher optical density and contrast at equal exposure was seen as the main advantage of the new combination.

B-589 11:51

Mammographic technique: Frontal oblique approach versus traditional lateral approach

M. Calabrese, C. Faedda, D. Brizzi, G. Baio, E. Bertoli, L. Bacigalupo;
Genoa/IT

Purpose: We try to demonstrate that a frontal oblique approach (FOA) permits visualization of more breast in comparison to the lateral approach (LA).

Methods and Materials: A mammographic system that permits the 2 different approaches (Giotto Image, IMS, Bologna, Italy) has been used. Each patient has undergone mammography (Mx) with FOA on the right side and LA on the left side or the opposite in a randomized mode, but in order to have equal number of left and right mammographies with the 2 approaches. One radiologist, after assessing that the examinations were qualitatively adequate and having excluded the presence of pathology (only Bi-Rads 1 patients were included in the study), has evaluated (blinded to the approach used) the presence of the pectoral muscle in the CC Mx, the presence of the whole pectoral muscle in the MLO Mx and in both projections the distance in mm between nipple and pectoral muscle or mammography image end in the absence of the pectoral muscle. 50 consecutive patients have been studied.

Results: The FOA showed better for the visualization of the pectoral muscle in the CC Mx (Mc Nemar test: p < 0.0001) and in the MLO Mx (Mc Nemar test: p = 0.0002); furthermore it improves (One sample t-test) the nipple-pectoral muscle distance in the CC Mx ($|Pr > |t| = 0.0020$) and in the MLO Mx ($|Pr > |t| < 0.0001$).

Conclusion: From the analysis of these data it seems that the FOA allows more breast to be examined with respect to the LA.

Optimization of enhancement in pulmonary CT-angiography using a 16 slice CT scanner: Influence of a scanning delay

J.C. Petersen¹, M.C. Freund¹, H. Jamnig², W.R. Jaschke¹; ¹Innsbruck/AT,
²Natters/AT

Purpose: To evaluate the physiological pressure-vacuum-pump-effect of inspiration resulting from mixing of unopacified blood from the inferior vena cava with well-opacified blood from the superior vena cava and right atrium, and subsequent insufficient enhancement of the pulmonary arteries.

Methods and Materials: 2 different groups of patients underwent CT-angiography of the pulmonary arteries utilizing a 16 slice CT (2.5 mm slice thickness, 13.75 table feed/rotation, 0.5 sec rotation period) with baso-apical scan direction during intravenous injection of 100-130 mL of non-ionic iodinated contrast media followed by 30 mL of sterile isotonic 0.9% saline using a power injector. The start of the CT

exam was automatically triggered by a smart-prep® function after sufficient enhancement of the right ventricle with a breathing command for deep inspiration. Scan delay was 0 sec. in group 1 (Dt1, 96 patients) and 10 sec. in group 2 (Dt1+10 sec, 29 patients) after deep inspiration and sufficient enhancement of the right ventricle.

Results: The enhancement of group 2 resulted in a significant higher density within the pulmonary artery system (e.g. segmental artery Dt1280 HU, SD ± 85 HU, Dt1+10 sec 342 HU, SD ± 87 HU; Mann Whitney, p below 0.002); additionally this resulted in a reduced influence of admixture of unopacified blood from the inferior vena cava within the pulmonary artery system (Fisher's exact test, p below 0.001).

Conclusion: Utilizing a 16 slice CT scanner for CT-angiography of the pulmonary arteries, a scan delay of 10 sec. after inspiration reduces the physiological pressure-vacuum-pump-effect and results in a higher enhancement within the pulmonary artery system.

B-591 10:39

16-slice multidetector CT angiography of the pulmonary circulation using gadolinium-based contrast agents: Prospective evaluation in 60 patients

M. Rémy-Jardin, J. Bahépar, J.-J. Lafitte, P. Dequiedt, O. Ertzbischoff,

J. Bruzzi, A. Duhamel, J. Rémy; Lille/FR

Purpose: To evaluate the safety and diagnostic value of gadolinium-enhanced 16-slice multidetector CT angiograms of the pulmonary circulation according to the dose administered.

Material and Methods: 60 patients with contraindications to the administration of iodinated contrast agents underwent a multislice spiral CT examination of the pulmonary circulation with a 0.5 mmol/L gadolinium contrast agent administered at 0.3 mmol/kg (n = 29; Group A) or 0.4 mmol/kg (n = 31; Group B) with a systematic evaluation of the clinical and biological tolerance of gadolinium.

Results: The mean (± SD) volume of gadolinium administered was 50.09 ± 8.45 mL, enabling one to obtain diagnostic CT angiograms in 55 (92%) patients with confident analysis of pulmonary arteries down to the subsegmental level in 26 patients (44%); and the segmental level in 21 patients (35%). In Group B: (a) the mean attenuation value within central and segmental pulmonary arteries was significantly higher compared with Group A patients; (b) the number of diagnostic CT angiograms was significantly higher than in Group A (n = 31; 100% vs n = 24; 83%; p = 0.02). Transient worsening of renal function was observed in one Group A patient with pre-existing marked chronic renal failure. A second Group A patient showed acute worsening of renal function in a context of multi-organ failure due to fulminant hepatic tumor.

Conclusion: (1) Diagnostic image quality was obtained in 92% of gadolinium-enhanced CT angiograms; (2) the doses administered did not alter renal function except in two cases.

B-592 10:48

80-kVp multislice CT of pulmonary arteries (msCTPA) to minimize contrast medium (CM) doses to diagnose pulmonary embolism (PE) in patients with decreased renal function

F. Holmquist, U. Nyman; Trelleborg/SE

Purpose: To report that 80 kVp msCTPA (increased iodine X-ray attenuation, reduced scanning time and bolus tracking) significantly reduces CM doses to diagnose PE in comparison with conventional 120 kVp single-slice CT often utilizing the 30-45 grams of iodine.

Methods and Materials: Eighteen patients (73-93 years; 38-79 kg) with an estimated GFR of 12-49 mL/min underwent msCTPA [80 kVp, 162-350 effective mAs (related to patient circumference), pitch 0.5-0.75, 16-detector row CT] for suspected PE using 40-80 mL 160-200 mg I/mL (6.4-14.7 g I), 4-5 mL/s, with an ROI in the PA for bolus tracking (100 HU threshold, 5 second delay). Contrast-to-noise ratio (CNR) in a central PA assuming a 70 HU-value for a fresh thrombus, subjective quality rating, follow-up of renal function and outcome of negative examinations were retrospectively analyzed.

Results: Mean CM dose per kg was 180 mg I/kg (12 mg I/kg/s). Mean PA density was 333 (range 250-694) HU, mean PA CNR 25 (range 19-40). Examination quality was judged as adequate or excellent in sixteen patients and suboptimal in two, but not related to CM enhancement (patient related artefacts). A transient 28 and 33% sCr increase was noted in two patients, respectively. Three patients were diagnosed with PE. Three months follow-up revealed a diagnosed DVT in one patient, one of whom had a suboptimal CTPA.

Conclusion: High quality 80 kVp msCTPA may be performed with significantly reduced CM doses in elderly patients with a reduced renal function, implying a lower risk for CM nephropathy.

Evaluation of pulmonary artery flow with MR imaging in acute massive pulmonary thromboembolism

Y. Li; Beijing/CN

Objective: To investigate the value of MR imaging in evaluating pulmonary artery hemodynamics and pulmonary artery pressure in acute massive pulmonary embolism.

Methods: MR studies were performed in 21 patients with acute massive pulmonary embolism (diagnosed by contrast enhanced MR pulmonary angiography) and 20 healthy volunteers, to measure pulmonary artery hemodynamic parameters including the diameters of main and right pulmonary artery, peak velocity, average velocity, flow volume, flow patterns and ejection acceleration time in main pulmonary artery. The hemodynamic parameters in the patient group were correlated with mean pulmonary artery pressure acquired with right heart catheterization.

Results: The diameters of the main pulmonary artery (2.93 vs 2.52 cm) and right pulmonary artery (2.49 vs 1.92 cm) in patients and volunteers showed significant differences ($P < 0.01$, respectively); peak velocity (85.29 vs 100.63 cm/s), average velocity (11.00 vs 17.12 cm/s), flow volume (89.15 vs 98.96 ml/s) and ejection acceleration time (105.09 vs 163.85 ms) in the main pulmonary artery were significantly different between patients and volunteers (P values were 0.01, < 0.01 , 0.03 and < 0.01 , respectively). The peak velocity-time curve of the main pulmonary artery acquired with velocity encoded cine-MR demonstrated earlier and lower peak velocity in the patient group, as well as abnormal retrograde flow. In addition, linear correlations were seen between the mean pulmonary pressure and the diameter of main pulmonary artery ($r = 0.62$, $P = 0.01$), diameter of right pulmonary artery ($r = 0.63$, $P = 0.01$), and ejection acceleration time ($r = -0.55$, $P = 0.005$).

Conclusion: MR imaging is a promising technique not only for the detection of pulmonary thromboemboli but also for the evaluation of hemodynamic parameters in pulmonary hypertension.

B-594 11:06

Subsegmental pulmonary embolism: Comparison of 16row-CT and MR imaging

A. Kluge, G. Bachmann; Bad Nauheim/DE

Purpose: To assess the individual and combined value of three MR imaging techniques for the diagnosis of acute pulmonary embolism (PE) and to compare them to 16row-CT with an emphasis on subsegmental embolism.

Materials and Methods: Fifty-nine patients with symptoms indicating acute PE underwent both 16row-CT angiography with 0.75 mm collimation and a combined, step by step protocol progressing from Real-time MR imaging (RT-MRI) to MR perfusion and MR angiography (MRA)

Results: With CT, PE was diagnosed in 18 patients in 88 lobar, 240 segmental and 427 subsegmental arteries. CT imaged 97% of all subsegmental pulmonary arteries.

Sensitivity for acute PE for RT-MRI, MRA and MR perfusion was 85%, 76%, and 100%, respectively. Sensitivity for lobar PE was 78%, 62%, and 100%, while segmental PE was diagnosed with 87%, 83%, and 97% respectively. Subsegmental PE was diagnosed by MR perfusion with 93% sensitivity. Kappa values compared to CT were 0.85, 0.84, and 0.85 for RT-MRI, MRA and MR perfusion respectively.

Conclusion: The combined MRI protocol was both reliable in emergency diagnosis and as sensitive as the latest generation 16row-CT for diagnosing subsegmental pulmonary embolism. These results may contribute to a less reluctant use of MRI in suspected cases of PE.

B-595 11:15

Complete chest CTA versus a limited range CTA for the diagnosis of PE: What do we miss?

C. Schaefer-Prokop¹, A.A. Bankier¹, K. Janata¹, N. Riechling¹, M. Prokop²; ¹Vienna/AT, ²Utrecht/NL

Purpose: To examine how a reduction in scan range affects the detection of acute pulmonary emboli and other pulmonary findings relative to the radiation dose saved.

Methods: We retrospectively evaluated MD-CTAs of 58 outpatients suspected of having acute PE with positive D-dimer. We recorded the presence of PE and other chest abnormalities with respect to their location along the z-axis. We determined which findings would have been missed if the scan range was reduced to (a) between aortic arch and 2 cm below the lower pulmonary veins, and (b) between 2 cm above aortic arch and the lower hemidiaphragm.

Results: We found signs of acute PE on full chest CTA in 20/58 patients. With range (a), one patient would have been falsely classified as negative due to a subsegmental embolus. None of the patients would have been classified incorrectly with range (b). We found 67 additional chest abnormalities in 32 patients. 24 of these findings affected the clinical management in 18 patients. With range (a), 26/67 findings would have been missed and the management would have been different in 4 patients. With range (b), 11 findings would have been missed but none would have affected the patient's treatment. Relative to a full chest scan, scan dose would have been $45 \pm 8\%$ less with range (a) and $22 \pm 11\%$ less with range (b).

Conclusion: Preliminary results in this relatively small patient group suggest that for the majority of outpatients the scan range and thus the patient dose can be reduced by approximately 20% without affecting relevant diagnoses.

B-596 11:24

Acute pulmonary embolism: Predictive value of degree of arterial obstruction quantified with the CT obstruction index

G. Etechami, F. Doenz, A. Denys, J. Cornuz, P. Schnyder, S.-D. Qanadli; Lausanne/CH

Purpose: To evaluate the prognostic value of arterial obstruction quantification using a dedicated CT obstruction index (Io) in acute pulmonary embolism (PE).

Methods and Materials: The Io is defined as $\text{Io} = (n.d)/40 \times 100$, where n is the value of the proximal thrombus in the pulmonary arterial tree and d is the degree of obstruction. The study was derived from 1054 consecutive patients with clinical suspicion of PE. In 254 patients, PE was confirmed with CT angiography. Io index was calculated for each patient and correlated to one and 6 months follow-up, considering mortality and recurrence of thrombo-embolism (RTE). 40% was considered as the threshold value for group differentiation: group A with $\text{Io} < 40\%$ and group B with $\text{Io} > 40\%$. Predictive values of Io were calculated.

Results: The mean Io was $26 \pm 17\%$. Mortality rates at 1 and 6 months follow-up were 5.9% and 8.6%. At 1 month follow-up, 14 of 15 deaths were considered directly related to PE. Among these patients, 8 patients had pre-existing cardiopulmonary disease (CPD) with 7 in group A. Among 6 patients without CPD 4 were in group B. Regarding mortality in patients without CPD the negative predictive value of the Io was 98% and a significant difference was seen between groups A and B. No significant difference was observed regarding RTE.

Conclusion: The degree of arterial obstruction in PE may be quantified by this CT index. This index seems to provide a stratification of patient prognosis and to be predictive of mortality in patients without pre-existing CPD.

B-597 11:33

Acute pulmonary embolism: Correlation of computed tomography arterial obstruction index with blood gas values

Z.M. Metafratz, G. Maglaras, M. Vassiliou, S. Constantopoulos, S. Efremidis; Ioannina/GR

Objective: To investigate the relationship between the pulmonary arterial obstruction index assessed with Computed Tomography (CT) and the blood gases abnormalities in patients with acute pulmonary embolism.

Materials and Methods: Spiral CT pulmonary angiography was performed in 68 patients without prior cardiopulmonary disease suspected of having pulmonary embolism. Findings consistent with acute pulmonary embolism were observed in 32 patients. The severity was assessed by the pulmonary arterial obstruction index, defined as $\Sigma (n \times d)$ (n: number of segmental arteries occluded, d: degree of obstruction). The correlation of this index with PaO_2 , PaCO_2 and SaO_2 values was investigated by linear regression. Blood gases were comparatively evaluated below and above different index values (from 40% to 70%). PaCO_2 values of 25, 30 and 35 mm Hg were examined as possible indices of severity.

Results: Significant correlation was observed between obstruction index and PaCO_2 ($r = 0.46$, $p = 0.017$) and a marginally non-significant correlation between index and PaO_2 and SaO_2 ($r = 0.34$, $p = 0.057$). PaCO_2 differed significantly at above and below 40% ($p = 0.02$), 50% ($p = 0.02$) and 60% ($p < 0.001$) of obstruction. PaO_2 differed significantly at obstruction $> 60\%$ ($p = 0.001$). SaO_2 differed significantly at 60% ($p = 0.04$) and 70% ($p = 0.02$). A PaCO_2 value of 30 mmHg indicates an obstruction index higher than 50% with a sensitivity and specificity of 78% and 82% respectively.

Conclusion: PaCO_2 is a clinically useful predictor of pulmonary embolism severity, evaluated by obstruction index in patients with acute pulmonary embolism and without prior cardiopulmonary disease. An obstruction index, $> 50\%$ may be expected for $\text{PaCO}_2 \leq 30$ mmHg.

B-598 11:42

Severity assessment and quantification of pulmonary embolism with CT pulmonary angiography as a predictor of patient outcome

S.K. Venkatesh, S. Wang; Singapore/SG

Purpose: To evaluate (a) whether quantification of pulmonary embolus (PE) with CT pulmonary angiography (CTPA) by using a standardized index is a predictor of clinical outcome; and (b) CT features which indicate severe pulmonary embolism (PE).

Materials and Methods: Multi-detector row CT was performed in 100 patients (mean age; 59.43 years, range; 27-94 years). The presence of PE was documented per vessel till the sub-segmental level. A pulmonary arterial obstruction index (PAOI) was derived for each patient based on embolus size and location using a standardized obstruction index. We also evaluated ventricular chamber sizes, chamber ratio and pulmonary artery diameter on CTPA for assessment of severity of PE. Patients were followed up for a minimum of 6 months and clinical outcome was compared. Ten patients died of pulmonary embolism, 13 patients due to other causes and 77 were alive at the time of data collection.

Results: Patients who died of PE had significantly higher PAOI (65.10 vs. 37.83, p = 0.03) and are likely to have significantly more central emboli (5.8 vs. 3.07, p = 0.047) as compared to those who die of other causes following PE. Patients who survive PE are likely to have lower PAOI (50.59, p = 0.09). The mean right ventricle chamber diameter is significantly higher in patients who die of pulmonary embolism as compared to others (58.80 vs. 52.98 and 41.12, p = 0.016).

Conclusion: High PAOI (> 65) is an important predictor of adverse outcome in cases of pulmonary embolism. Acute right ventricular dilatation and presence of more central emboli indicates severe pulmonary embolism.

B-599 11:51

Central pulmonary embolism in oncology patients: An underestimated phenomenon

A.J. Sebastian, A.J. Paddon; Hull/UK

Purpose: Incidental pulmonary embolism (PE) is often observed at staging or follow-up chest computerised tomography (CT) in oncology patients. A prospective study to determine the rate of such findings was undertaken.

Methods and Materials: 368 consecutive chest CTs were prospectively assessed during a 7 month period between October 2003 and April 2004. These were spiral acquisitions between 6 and 8 mm collimation acquired 25 seconds after intravenous contrast administration. PE was diagnosed if a filling defect was seen in the central pulmonary arteries on two or more consecutive slices.

Results: 2.5% (9/368) of patients had incidentally detected PE. 4% of patients with haematological malignancy had PE. This was not attributable to any specific chemotherapeutic regimen. These emboli were all central, between the main pulmonary artery and the lobar level. Though the significance of these findings in patients not suspected of having PE could be contentious, certainly these are not physiological. All our patients admitted to clinical features compatible with PE on direct questioning, though this information was not forthcoming during the routine oncological review. As a result all the patients received therapeutic anticoagulation.

Conclusion: One in forty oncology patients and up to one in twenty five patients with haematological malignancy have incidental central PE visible on the CT scans performed to assess their malignancy. This is a significant finding in this high-risk population. A more aggressive approach to diagnosing PE is required, the precise practice change should be debated, but screening CT pulmonary angiography is an option.

Abnormal hepatic vein Doppler waveform in patients without liver disease

J.F. Pedersen, A.Z. Dakhil, D.B. Jensen, B. Soendergaard, P. Bytzer; Glostrup/DK

Purpose: In patients with liver cirrhosis Doppler ultrasound often detects absence of the retrograde (hepatopetal) flow phase in the hepatic vein, suggestive of an

increased stiffness of the liver parenchyma around the vein. This is rarely or never reported in healthy control persons. Our study examines the frequency of absent retrograde flow in unselected patients referred to abdominal sonography.

Methods and Materials: We studied a consecutive series of 139 patients referred for abdominal sonography. We used state-of-the-art ultrasound scanners, and placed the Doppler gate so that in non-forced end-expiration it would sample the right hepatic vein 4-6 cm from the vena cava.

Results: There was no association between the hepatic vein flow pattern and age, sex or body mass index. Forty-three of 139 studied patients showed absent retrograde flow. Review of the case records revealed liver disease in 26 patients: cirrhosis, 3; alcohol related liver disease, 14; non-alcoholic steatohepatitis 3, hepatitis 1, metastases, 4; hemangioma, 1. No liver disease could be suggested in 17 patients.

Conclusion: Absent retrograde flow in the hepatic veins may be seen not only in patients with overt liver disease but also in apparently liver-healthy patients.

B-601 10:39

Contrast-enhanced US imaging of splenic lymphomas

O. Catalano¹, F. Sandomenico¹, A. Nunziata¹, R. Lobianco², A. Siani¹;

¹Naples/IT, ²Pozzuoli/IT

Purpose: To illustrate our experience in the evaluation of splenic haematological malignancies with CE-US.

Methods and Materials: January to December 2003 we studied 45 patients (20 with Hodgkin disease and 25 with non-Hodgkin lymphoma): 24 M and 21 F aged 27-79 years. After a baseline exam, we injected 2.4-4.8 mL of contrast agent SonoVue (Bracco, Italy). Contrast-enhanced studies were carried out with a contrast-specific software (CnTi, Esaote, Italy) using continuous-mode, harmonic acquisition and low acoustic pressure. US studies outcome was correlated with standard tools, including CT (23 cases), MR imaging (3), US follow-up (16), FNAB (4) and splenectomy (1).

Results: Among 26 cases with focal involvement CE-US detected 67/72 lesions demonstrated altogether by reference tools. Conventional US recognised 55/72 lesions. Lesion extent defined by CE-US correlated with standard tools, being similar (80% of cases), underestimated (12%) and overestimated (6%). Baseline US defined lesion size correctly in 56% of cases, underestimating in 30% and overestimating in 14%. Lesion-to-parenchyma contrast of CE-US resulted low (12% of cases), intermediate (62%), and high (26%). Conspicuity at conventional US imaging was low (52% of cases), intermediate (35%), and high (13%). Lesions appeared as constantly hypoechoic (hypovascular) defects, better definable during intermediate-delayed phase of enhancement than on early phase. Arteries were visible around the lesion and perpendicularly entering along intralesional septa. Intralesional microcirculation was visible. Loss of microcirculation and marked hypoechogenicity were visible in case of response to chemotherapy.

Conclusion: CE-US is a simple and poorly invasive tool in morphological and functional imaging of lymphomatous splenic disease.

B-602 10:48

Contrast enhancement patterns and diagnostic confidence in splenic tumor characterization after microbubble-based contrast agent injection

E. Quaia, F. Degobbi, S. Rossi, M. Cova, R. Pozzi Mucelli; Trieste/IT

Purpose: To describe the different contrast enhancement patterns in focal lesions of the spleen after microbubble-based contrast agent injection and to evaluate whether diagnostic confidence in benign or malignant nature characterization is improved at contrast-enhanced US.

Methods and Materials: A series of 25 solid (10 splenic hemangiomas, 10 splenic metastases and 5 splenic nodular lymphomas) ≤ 4 cm from 25 consecutive patients (15 male and 10 female, age 65 ± 15) were assessed as indeterminate at baseline US by 2 on-site sonologists. Lesions were scanned by high (mechanical index: 0.9-1.1) or low (mechanical index: 0.08 - 0.12) transmit power after air-filled or sulphur hexafluoride-filled microbubble injection, during arterial (15-40 secs) and late (100-300 secs from injection) phase. Contrast enhancement patterns were assessed by 2 on-site sonologists in consensus. Off-site review of baseline and contrast-enhanced US scans was performed by 2 independent blinded readers who expressed a benign or malignant diagnosis according to reference criteria. The appearance at cross-sectional imaging (n = 20 tumours) or histologic findings (n = 5 tumours) were considered as the reference standards.

Results: Splenic hemangiomas revealed persistent rim-like peripheral contrast enhancement without (n = 8) or with (n = 2) progressive complete fill-in. Splenic metastases and nodular lymphomas revealed persistent hypovascular appearance. Diagnostic confidence in malignancy diagnosis improved after microbubble injection (area under ROC curve for observer 1/observer 2: 0.688/0.506 for baseline, 0.890/0.877 for contrast-enhanced scan; P < 0.05).

Scientific Sessions

Conclusion: Microbubble injection allows identification of different contrast enhancement patterns in focal lesions of the spleen and thus improves diagnostic confidence in the diagnosis of malignancy.

B-603 10:57

Vascularization of liver tumors: First results with coded harmonic angio (CHA), phase inversion imaging, 3-D power Doppler and contrast medium-enhanced B-flow with Optison®

E.M. Jung¹, D.-A. Clevert², R. Kubale³, K.-P. Jungius⁴, J. Tacke¹; ¹Passau/DE, ²Munich/DE, ³Pirmasens/DE, ⁴Brig/CH

Aim: To evaluate the possibility of successful evaluation of vascularization of liver tumors using harmonic imaging, 3-D power Doppler and B-flow after a bolus injection of Optison.

Materials and Methods: This prospective study was performed on 60 patients with 93 liver tumor foci. Comparative investigations were performed with multislice-CT and contrast medium-enhanced ultrasound. B-scan was performed with power Doppler followed by a bolus injection of Optison®. Arterial and capillary vascularization was then evaluated with coded harmonic angio (CHA). Portal venous vascularization was assessed with pulse inversion imaging with power Doppler, 3-D power Doppler and, in the late phase, (> 5 min.) with B-flow.

Results: In comparison to spiral-CT/MRT, only 72/93 (77%) of the lesions could be demarcated in the B-scan, 75/93 (81%) with CHA and 93/93 (100%) in the pulse inversion mode. Tumor vascularization was detectable in 43/93 (46%) of lesions with native power Doppler, in 75/93 (81%) of lesions after CM administration in the CHA mode, in 81/93 (87%) of lesions in the pulse inversion mode with power Doppler and in 77/93 (83%) of lesions with contrast-enhanced B-flow. Early arterial and capillary perfusion was best detected with CHA, particularly in 20/20 (100%) of the HCC lesions. Up to 20 min after CM injection, B-flow was capable of detecting increased metastatic tumor vascularization in 42/54 (78%) of cases and intratumoral perfusion in 17/20 (85%) of HCC cases.

Conclusion: Contrast medium-enhanced ultrasound investigation of liver tumors with Optison® allowed reliable detection of tumor foci and, in most cases, tumor vascularization.

B-604 11:06

Characterisation of focal liver lesions with SonoVue: Update with blinded off-site reading

T. Albrecht, J. Skrok, R. Basilico, M. Jenett, A. Oldenburg, J. Hohmann, K.-J. Wolf; Berlin/DE

Purpose: To investigate the ability of low MI real time phase inversion imaging with SonoVue® (Bracco) to characterize focal liver lesions in comparison to unenhanced B-mode and power Doppler sonography.

Methods: 99 patients with 53 malignant and 46 benign liver lesions were studied with unenhanced ultrasound (US) including B-mode and power Doppler, followed by SonoVue (2.4 - 4.8 ml) enhanced low MI real time US (phase inversion, contrast pulse sequencing) during arterial, portal-venous and delayed phases. Representative digital movie clips of each phase were reviewed off-site by a blinded reader with minimal clinical information available (age, sex, pre-existing diffuse liver disease). Findings obtained before and after contrast agent were compared with each other and with reference examinations (histology, imaging with follow-up).

Results: The number of correctly diagnosed lesions increased from 57 (58%) pre to 75 (76%) post contrast ($p < 0.05$). Correct differentiation of malignant from benign lesions improved from 69 (70%) to 88 (89%, $p < 0.05$). Most lesions were judged to have typical features as described previously. Common sources of error were incompletely filling haemangiomas misinterpreted as metastases (4 of 18) and FNH without a spoke wheel pattern or central scar misinterpreted as adenoma (3 of 16). Also 2 of 2 inflammatory lesions were interpreted as metastases.

Conclusion: Low MI real time US with SonoVue improves the characterization of focal hepatic lesions in comparison with unenhanced sonography. These results of blinded, off-site reading are less favourable than our own previous results with on-site reading of the same study population.

B-605 11:15

Blinded readers study of contrast-enhanced US in the characterisation of focal liver lesions (FLL): Impact on decision making

E. Leen, P. Ceccotti, C. Kalogeropoulou, W. Angerson, P. Horgan; Glasgow/UK

Purpose: The aim of the study was to assess the clinical value and potential impact of real time SonoVue-enhanced ultrasonography (CE-US) in the characterization of focal liver lesions (FLL).

Methods: 127 patients with 82 malignant and 52 benign lesions were studied
