using unenhanced ultrasound (US) and CE-US. CE-US was performed using non-linear imaging modes at low mechanical index (0.1-0.3) to enable real-time visualization of arterial, portal and late phase contrast enhancement. Digital video recordings of the US and CEUS acquired were reviewed by two off-site blinded readers. Using histology and/or combined CT/MR as the standard of reference, the diagnostic accuracy of CEUS in identifying the lesion (a) as benign or malignant or indeterminate (b) as its actual tumour type, were compared with baseline US. The impact upon subsequent alteration in decision making was also documented.

Results: CE-US reduced the number of indeterminate diagnosis by 51-56% ($p < 0.001$); sensitivity and specificity significantly improved to 90.8-95.4% and 83.7-89.8% respectively ($p < 0.001$). CE-US eliminated observers' variability (kappa coefficient: 0.66-0.77) and there was no significant difference in all comparisons in the analysis of lesions measuring < 1.5 cm, 1.5-2.5 cm & all sizes combined. Diagnosis of metastases, HCCs, haemangiomas and FNHs were significantly improved on CE-US ($p < 0.0001$) with close correlation between the observers ($r = 0.87$). CE-US did not rely on availability of clinical history to enable diagnoses. There was a 23.7% to 90.4% reduction in the need for further imaging investigations following CE-US.

Conclusions: CE-US improves the characterization of focal liver lesions and may limit the need for further investigations.

B-606 11:24

Detection and characterization of focal liver lesions with the new RES penetrating US contrast agent BR14: First results of a phase II research

J. Hohmann, T. Albrecht, J. Skrok, C.W. Hoffmann, K.-J. Wolf; Berlin/DE

Purpose: BR14 (Bracco, Milano, Italy) is a new US contrast agent (CA) which is incorporated into the Kupffer cells a few minutes after injection. The microbubbles are composed of a gas phase of perfluorbutane (C_4F_{10}) encased by a phospholipid-stabilized membrane. We investigated focal liver lesions (metastases and HCC) during vascular and liver specific late phases to determine the detection and characterization of the lesions using phase inversion US (PIUS).

Methods: In all 12 patients we first conducted a baseline scan of the liver (grayscale and power Doppler). After three CA applications (0.25, 1.0, 4.0 ml, dosed 5 mg/ml) we scanned with PIUS (Accuson Sequoia, CCI) using low Mechanical Index (MI=0.2-0.4) in vascular (arterial and portalvenous) as well as in late phase (5-10 min p.i.). For each patient we conducted an MR imaging as a reference (in 9 patients with liver specific CA).

Results: In nine patients we found a total of 31 focal liver lesions (Baseline: 19; 0.25 ml: 11; 1.0 ml: 20; 4.0 ml: 26), and in three patients a disseminated disease of the liver. The MR imaging confirmed 20 of these focal lesions as well as the disseminated ones. In MR imaging, two additional lesions could be detected which had not been seen in PIUS. The lesions additionally found in PIUS were either < 11 mm ($n = 6$) or classified as benign ($n = 5$).

Conclusion: Detection and characterization of focal liver lesions with BR14 apparently provides results comparable to MR imaging. Additionally lesions detected in PIUS even seem to imply higher sensitivity and specificity.

B-607 11:33

Focal liver lesions: Malignant vs benign - the value of the sinusoidal phase of contrast-enhanced ultrasonography

M. D'Onofrio, B. Masinielli, S. Caffarri, R. Malago', G. Zamboni, R. Pozzi Mucelli; Verona/IT

Purpose: To evaluate the sinusoidal phase of contrast-enhanced ultrasonography (CEUS) in the study of solid focal liver lesions to distinguish malignancy from benignity.

Methods: 200 focal liver lesions, suspected for malignancy being hypoechoic and/or in high risk patients (cirrhotic or oncologic) were studied with contrast-enhanced ultrasonography (CEUS). The final diagnosis was obtained with spiral CT, MR, angiography, biopsy.

Results: 73/200 lesions were benign: 38 angiomas, 3 capillary angiomas, 19 FNHs, 7 areas spared by steatosis, 4 adenomas, and 2 necrotic nodules. All the benign lesions were followed-up. 127/200 lesions were malignant: 87 HCCs, 26 metastases, 10 endocrine metastases, 2 cholangiocarcinomas and 2 lymphomas. 108/127 (85%) malignant lesions resulted hypoechoic at CEUS in the sinusoidal phase. 68/87 (78%) HCCs resulted hypoechoic in the sinusoidal phase. 64/73 (88%) benign lesions resulted hyperechoic or isoechoic at CEUS in the sinusoidal phase. Hypoechoic aspect of the studied lesion in the sinusoidal phase of CEUS allowed diagnosis of malignancy with an accuracy of 86%, increasing the diagnostic confidence compared to basal US (receiver operating characteristic curve area increased from 0.536 for basal US to 0.902 for CEUS). Excluding HCCs, hypoechoic lesion aspect in the sinusoidal phase of CEUS allowed diagnosis of malignancy with an accuracy of 92%.

Scientific Sessions

Conclusions: Sinusoidal phase of CEUS can distinguish malignancy from benignancy during hepatic staging with an accuracy of about 90%.

Comparison of B-mode and contrast enhanced ultrasound of the liver in patients undergoing chemotherapy for known primary malignancy

S.D. Yarmenitis, A. Bakantaki, Y. Papantoniou, N. Gourtsoyiannis; Iraklion/GR

Purpose: To define the benefit of routine contrast enhanced ultrasound (CEUS) in the follow-up investigation of the liver in patients treated with chemotherapy for known primary malignant neoplasia.

Methods and Materials: Between January 2004 and July 2004, 283 patients were examined consecutively in our ultrasound unit during their routine follow-up to rule-out liver metastases. One hundred and eighty-six of them (breast:122, colorectal:32, endometrial:8, ovarian:5, gastric:5, prostatic:4, bladder:3, lung:2, renal:2, melanoma:2, thyroid:1) had a combined B-mode ultrasound (BMUS) and CEUS. Tissue Harmonic and Spatial Compounding techniques were used for the BMUS session. A second-generation ultrasound contrast agent was administered for the CEUS. Two independent radiologists examined, blindly, digital video-clips from each session. The presence and the characteristics of any focal lesions were recorded. MDCT, MR imaging and/or biopsy were used as reference. A correlation was not performed with these modalities in this study.

Results: Hepatic metastases were detected in 28/186 (15%) patients. BMUS missed 15/28 (54%) metastases which were successfully diagnosed by CEUS. Among them, 12 (43%) were solitary lesions. In 3 of the rest of the 13 cases that both techniques have diagnosed, CEUS depicted a more extensive spread of the disease. In 13/186 (7%) cases of atypical hemangiomas on BMUS, CEUS was diagnostic with certainty. Forty-three livers had heavy fatty infiltration and CEUS did not improve image quality.

Conclusion: CEUS may detect 50% more cases of hepatic metastases than BMUS in patients under chemotherapy for known primary malignant neoplasia. It is a promising routine technique in the follow-up investigation of the liver of these individuals.

B-609 11:51

Liver metastases treated with chemotherapy: Assessment of tumor vitality during arterial phase with contrast enhanced harmonic sonography (CEUS).

Work in progress

P. Cabassa, L. Romanini, L. Grazioli, V. Portugalli, M. Cristinelli, C. Avigo; Brescia/IT

Purpose: To evaluate the capability of Sonovue enhancement in the assessment of tumor response to chemotherapy.

Materials and Methods: To date, 17 liver metastases in 12 cancer patients (10 male, age range 42-74) were studied with CEUS before and after chemotherapy. CEUS was performed with second generation contrast media (Sonovue, Bracco) at the standard dose of 2.4 ml with continuous real time scanning at low mechanical index. The inclusion criteria are: At least one focal liver lesion visible at B-mode ultrasonography; biopsy proven pathologic specimen before treatment; at least one cross sectional examination (CT/MR) before treatment. The origins of disease were: Gastro-intestinal (n = 7), breast (n = 2), pancreas, lung and eye (n = 1 each). Pretreatment, the lesions mean maximum diameter was 25.1 mm (range 8-60 mm). Pre and post treatment maximum tumor diameter and pattern of enhancement were assessed lesion by lesion. We considered the arterial phase the most important phase to assess tumor necrosis.

Results: Before treatment 5/17 lesions in 5/12 patients enhanced homogeneously during the arterial phase. After therapy a reduction of intraleisonal enhancement was observed in all lesions. In 5/17 nodules the enhancement was totally absent and these lesions were considered completely treated. 4/5 of these decreased in size more than 30%. In the remaining 12/17 lesions the enhancement was persistent at the periphery (8/12 lesions) or inhomogeneous (4/12 lesions). 5/12 lesions decreased in size more than 30%.

Conclusions: CEUS during the arterial phase could be a valid and unique method to assess vitality (vascularization) of liver metastases. Further experience is mandatory to confirm these preliminary results.

R. Garcia Figueiras; Santiago de Compostela/ES

B-610 10:30

Delineation of upper urinary tract segments at multidetector CT urography:

Retrospective comparison of routine and low-dose protocols

U.G. Mueller-Lisse, T. Meindl, E.M. Coppenrath, U.L. Mueller-Lisse, C. Degenhardt, K. Rami, M.F. Reiser; Munich/DE

Purpose: CT urography (CTU), as an add-on to contrast-enhanced CT of the abdomen and pelvis, may replace excretory urography in patients with pelvic tumors. However, radiation exposure is a concern. We retrospectively compared upper urinary tract (UUT) delineation in low-dose and routine CTU.

Materials and Methods: CTU (1-2 phases) was obtained with 120 kV, 4x2.5 mm collimation, and pitch 0.875 after i.v. injection of 120 ml of non-ionic contrast media with 300 mg of iodine/ml with routine (14 patients, n = 116 UUT segments, average 175.6 mAs/slice, average delay 16.8 minutes) or low-dose (26 patients, n = 344 UUT segments, 29 mAs/slice, average delay 19.6 minutes) protocols. UUT segments included intrarenal collecting system (IRCS), upper, middle, and lower ureter (UU,MU,LU). Two independent readers (R1,R2) graded UUT segment delineation as 1-absent, 2-partial, 3-complete (noisy margins), 4-complete and clear. Chi square statistics were calculated for grades 1-2 vs. 3-4 (delineates course of UUT, may locate obstruction/dilation) and 1-3 vs. 4 (may locate intraluminal lesions).

Results: Delineation of UUT was equally good for all segments in routine and low-dose CTU (R1, chi²=0.0036-1.74, p > 0.15; R2, chi²=0.074-1.308, p > 0.2). IRCS, UU, and MU were as often clearly delineated in routine as in low-dose CTU (R1, chi²=0.074-1.013, p > 0.25; R2, chi²=0.919-2.159, p > 0.1). However, LU was more often clearly delineated in routine CTU (R1, 18/24 routine, 38/69 low-dose, chi²=2.178, p > 0.1; R2 18/24 routine, 21/69 low-dose, chi²=12.75, p < 0.05).

Conclusions: Low-dose CTU was sufficient to determine the course of UUT and perhaps locate obstruction/dilation, but would have been unlikely to locate intraluminal LU lesions.

B-611 10:39

CT-urography: Dose reduction in multidetector technique

E.M. Coppenrath, U.G. Mueller-Lisse, T. Meindl, P. Herzog, U. Mueller-Lisse, R. Khalil, M.F. Reiser; Munich/DE

Purpose: CT urography depicts ureter and bladder with distinct contrast to adjacent tissues. This allows for substantial dose reduction compared with standard dose abdomen CT. CT density values of ureter in clinical studies were compared with systematic dose variation in ureter phantom in order to find threshold of dose reduction.

Material and Methods: A novel contrast phantom consists of parallel plastic tubes (diameter 2.7 mm) filled with different dilutions of contrast media (1:10, 1:20, 1:40, 1:80, 1:160) embedded in a water-filled box (14 x 32 cm). Four row and sixteen row multidetector scanners were used with variation of tube current (15-100 mAs/slice), voltage (90, 100, 120 kV), pitch (0.875, 1.0, 1.25, 1.5, 1.75), slice thickness (1 mm, 2 mm, 3.2 mm). CT-density and signal-to-noise ratio of contrast-filled tubes were compared with patient studies in low and standard dose protocol.

Results: CT-density was dose-independent for different dilutions of contrast media in the phantom study, and could be matched with CT density values of patients' ureters. Signal-to-noise ratio as a parameter of image quality proved to be better with 90 kV than with 100 kV or 120 kV in the low dose range, whereas pitch and slice thickness did not show significant change.

Conclusions: The new contrast phantom seems to be suitable for further studies in CT urography. Initial results demonstrate favourable effects of low tube voltage (90 kV versus 100 and 120 kV) on signal-noise ratio in the low dose range. This may lead to substantial dose reduction in CT urography.

Does ultralow-dose CT suffice for detecting urolithiasis?

E. Hein, C. Klüner, P. Hein, T. Elgeti, P. Rogalla, B. Hamm; Berlin/DE

Purpose: To evaluate the diagnostic yield of unenhanced multislice-CT with radically reduced radiation dose equivalent to that of a conventional radiograph (KUB) in assessing patients with renal colic.

Methods: 50 patients presenting with renal colic were prospectively examined with a CT scan (parameters: tube voltage 120 kV, 4.4 effective mAs, rotation time 0.5 s, pitch 23, collimation 16*1) and ultrasound. Radiation exposure was calculated using CT-EXPO V.1.3. The CT scans were randomly and independently evaluated by two radiologists blinded to the patients' data. Site, size, and number of calculi, and urinary-tract dilatation (UTD) were recorded. In addition, the readers rated their subjective diagnostic confidence on a 10-point scale. CT and ultrasound findings were compared statistically using the χ^2 -test.

Results: The mean effective whole body dose of the CT scan was 0.5 mSv in men and 0.7 mSv in women. These values are fairly equivalent to the dose of KUB (0.5-0.9 mSv). The incidence of renal calculi detected by CT was 69% in all cases, 78% in the presence of hematuria, and 54% without hematuria. All renal calculi identified by ultrasound were detected on CT. Significantly more ureteral calculi were identified on CT than on ultrasound ($p = 0.001$), whereas there was no significant difference in the diagnosis of renal calculi or UTD ($p > 0.05$). The readers' subjective diagnostic confidence in interpreting the ultralow-dose CT scans was 80% (range: 60-100%) for detection of calculi and 91% (range: 70-100%) for the diagnosis of UTD.

Conclusion: The ultralow-dose CT protocol presented here has a radiation dose comparable to one conventional radiograph and is reliable in detecting urolithiasis.

B-613 10:57

URO-CT vs IVU: Optimisation of URO-CT protocol with multislice CT (MSCT), comparing doses with conventional intravenous urography

M. Vergendo¹, F. Toso², C. Del Frate², C. Zuiani², R. Padovani², M. Bazzocchi²; ¹Spilimbergo/IT, ²Udine/IT

Purpose: Compare the dose of MSCT-URO-CT and IVU, and optimise URO-CT protocol in order to maintain high diagnostic power reducing as-much-as-possible the dose to the patient.

Materials and Methods: 30 patients underwent conventional-IVU; DAP, fluoroscopy-time and number-of-images acquired were recorded. Effective dose for average-procedure was estimated using MonteCarlo-conversion. Image quality and dose for CT were evaluated with a body phantom with high and low contrast-details, using 4 slices-MSCT with 2 uro-CT-protocols: 3 mm raw-thickness, pitch 0.75(Prot1) and pitch 1.4(Prot2) using decreasing values of mAs. Noise and image quality was estimated by two radiologists who compared standard-deviations of a constant ROI and degradation of high-contrast images at different milliAmperage. Effective dose to the patient for the different protocols were calculated using CTDIvol and DLP values and a selected conversion factors for abdomen and pelvic regions.

Results: Noise properties of images show significant increase under 150 mAs for both protocols. In particular image noise of Prot1 at 125 mAs was comparable to that of Prot2 at 200 mAs. Comparative study of high contrast-inserts in the test phantom shows a significant reduction of image quality under 150 mAs for both protocols and better spatial resolution of Prot1 at 100 mAs than Prot2 at 200 mAs. **Conclusions:** Image quality evaluation on test phantom would recommend a pitch 0.75 with 125 mAs for the basal phase (where there is mandatory high contrast resolution for stones) and a pitch of 1.4 with 150 mAs for the urographic-phase and the eventual nephrographic-phase. This three-phase protocol has total effective dose of 22 mSv that is 5 time greater than IVU.

B-614 11:06

Multislice-CT-urography (MSCTU): Experimental evaluation of low-dose protocols

J. Kemper, P.G.C. Begemann, M. Regier, A. Stork, G. Adam, C. Nolte-Ernsting; Hamburg/DE

Purpose: Experimental optimisation of MSCTU protocols for dose reduction with regard to image quality.

Material and Methods: MSCTU was performed in 8 healthy pigs under general anesthesia (weight \pm 70 kg). Examinations were performed with a gradual reduction of the tube current time product at 120 kV (100, 80, 70, 60, 50, 40, 30, 20 eff.mAs) and 80 kV (80, 50 eff.mAs). MIPs were postprocessed. Subjective image quality was rated for transverse images and MIPs using a five-point scale by two experienced radiologists. In addition, objective image noise was determined.

Image quality was correlated to radiation dose. Statistics included comparison of mean scores and calculation of multi-rater-kappa-coefficient.

Results: Adequate image quality for a detailed visibility of the upper urinary tract was obtained using a tube current time product of 70 eff.mAs and a voltage of 120 kV. Image noise did not impair image quality to a relevant degree using these parameters. There was a good agreement between the 2 observers ($\kappa > 0.75$).

Conclusion: In the experimental setting, image quality of low-dose MSCT-urography proved to be adequate at 70 eff.mAs and 120 kV offering advantageous reduction of radiation exposure. Systematic clinical studies are now required for the evaluation of the diagnostic potential and reliability of low dose MSCTU.

B-615 11:15

Systematic evaluation of optimal delay time for CT urography

T. Meindl, E. Coppenrath, R. Khalil, U. Mueller-Lisse, M.F. Reiser, U. Mueller-Lisse; Munich/DE

Purpose: To evaluate the optimal time delay between i.v. contrast-media application and CT urography (CTU).

Material and Methods: 31 patients underwent MDCT, including 1-2 CTU phases. After portovenous-phase CT and i.v. infusion of 250 mL of normal saline, CTU started at least 5 minutes after contrast-media administration. Individual upper urinary tracts (UUT) were divided into 4 segments: intrarenal collecting system (IRCS), proximal, middle and distal ureter. Two independent readers scored segmental opacification from none (1 point) to complete (5 points). Delay time between i.v. contrast and CTU was divided into 4 groups: 1=5-10 min, 2=11-20 min, 3 = 21-30 min, and 4 > 31 min.

Results: In all, 86 UUTs/344 segments were analysed (group 1, n = 15, 2, n = 43, 3, n = 14, 4, n = 14 UUTs). IRCS, proximal and middle ureter showed median opacification values > 4 in all groups. The distal ureter showed values of 4 and 3 in group 1, 3 in group 2, 1.5 in group 3, and 2 in group 4. In the IRCS and proximal ureter, > 90% of segments were completely opacified in each group. In the middle ureter, > 80% of segments were completely filled in groups 2 and 3. The distal ureter showed complete filling in 60% in group 1, 40% in group 2, and 36% and 11% in groups 3 and 4, respectively.

Conclusion: With respect to the distal ureter, CTU should be performed within 10 minutes after contrast-media injection. Delay times exceeding 30 minutes should be avoided.

B-616 11:24

Demonstration of ureteral calculus by thick planar reformation of multislice CT

M. Wehrscheutz¹, G. Fritz¹, G. Gallé¹, M. Tillich¹, A. Ruppert-Kohlmayr²; ¹Graz/AT, ²Leoben/AT

Purpose: This study evaluated optimal thickness of CPR of urinary tract to demonstrate it quickly and in an optimal quality.

Materials and Methods: In a prospective study MS-CT (coll. 3.75 mm, pitch 6, RI 3 mm, 120 kV, 100 mA) reconstructions of ureters of 75 patients with acute flank pain and suspected ureteral calculi were made. Curved planar reformation was performed with different slice thicknesses from 3 mm to 20 mm. Three radiologists evaluated quality of reformatted images using optimal visibility of all parts of ureter and correlated quality with slice thickness of CPR. Clinical impact was evaluated by urologists grading usefulness of CPR-images for therapeutic approach with a 10-point scale.

Results: Fifty-two patients of our cohort had urolithiasis. CPR could be made in all patients. We found reconstruction more difficult in thin patients and easier in obstructed ureter. Evaluation showed as optimal slice thickness 8 mm (7 mm was best in 5%, 8 mm in 65%, 9 mm in 15% and 10 mm in 15%). Acceptance of CPR-images was graded by urologists as very helpful for decision of therapeutic approach in 90% of patients.

Conclusion: Coronal reconstructed imaging is a feasible and quick useful tool with a good clinical impact. We recommend a 8-10 mm slice thickness for the optimal visualization of the whole ureter with or without calculi.

B-617 11:33

Multi-detector row CT urography in the evaluation of painless hematuria

A.C. Tsili, C. Tsampoulas, F. Katzioti, D. Giannakis, A. Silakos, N. Sofikitis, S.C. Efremidis; Ioannina/GR

Purpose: To assess multi-detector row CT urography in the evaluation of the urinary tract in patients with painless hematuria.

Methods and Materials: Forty-seven patients referred for painless hematuria underwent CT urography. Our CT protocol included unenhanced images obtained

Scientific Sessions

with a detector configuration of 16x1.5 mm and pitch 1.2. After intravenous administration of iodinated contrast material and 250 ml of saline solution nephrographic-phase and excretory-phase images were obtained, with collimation thickness 16x0.75 mm and pitch 1.2. Axial and coronal images were evaluated. Three-dimensional reformation of the excretory-phase images was performed using volume-rendering technique. The standard of reference included clinical and imaging follow-up, cystoscopic, surgical and histologic findings.

Results: In 16 of 47 patients (34%), no cause of hematuria was identified. In 31 of 47 patients (66%), the causes of hematuria were the following: urinary tract stones ($n = 14$), carcinoma of the urinary bladder ($n = 10$), carcinoma of the renal pelvis ($n = 4$), benign ureteral tumor ($n = 1$), acute pyelonephritis ($n = 1$), hyperdense renal cyst ($n = 1$).

Conclusion: Multi-detector CT urography is a highly accurate technique in the assessment of patients with painless hematuria. It can demonstrate a wide spectrum of diseases in these patients with a single study.

B-618 11:42 ♂

Multidetector CT of kidneys: Vascular collateral findings in pre-surgical management of renal masses

F. Toso¹, G. Ciccarese¹, M. Vergendo², R. Girometti¹, C. Del Frate¹, C. Zuiani¹, M. Bazzocchi¹; ¹Udine/IT, ²Spilimbergo/IT

Purpose: To evaluate the role of three-dimensional reconstruction MDCT in pre-surgical examination of renal masses, particularly in the precise definition of the vascular anatomy, due to the high percentage of anatomical variants, which may lead to a change in surgical approach.

Material and Methods: 48 patients with renal mass detected by US or CT, underwent MDCT (Aquilion, TOSHIBA) with multiphase protocol (pre-contrast, arterial, nephrographic and urographic phases). Iodine-contrast media (400 g/ml/ml) has been injected at flow-rate of 4 ml/s using an automated injection system and a Sure Start® software for bolus-tracking.

The acquired data after contrast media injection were processed to obtain coronal MPR and three-dimensional MIP and VR for angiographic, nephrographic and urographic assessment. Vascular collateral findings were classified as significant when they added information for surgical planning (laparoscopy or laparotomy).

Results: Anatomic variants of renal vascularization were found in 20/48 patients (40%): 16 arterial and 4 venous. Surgeon used these adjunctive information to pre-plan the surgery in 16/20 cases (75%) (polar arteries, proximal bifurcation of renal artery, renal artery calcification at the origin of the vessel), while he changed completely the surgical approach in 4/20 (25%) cases.

Conclusions: In our experience the multiphasic protocol used for pre-surgical evaluation of renal masses, permits the detection of vascular collateral findings which are relevant for the surgical planning.

B-619 11:51

Patients with acute flank pain: A stone and/or something else?

R. Studer, A. Spreng, A. Christe, G. Thalmann, P. Vock, H.C. Thoeny; Berne/CH

Purpose: To know whether CT performed for suspected renal colic provides additional information which may be relevant for the patient, either immediately or at a later stage.

Methods and Materials: Between July 1997 and July 2004 a consecutive series of 1100 patients with a median age of 50 years (range: 13-80) underwent spiral CT due to acute flank pain. The patients were examined on a single- or a multidetector spiral CT with continuous 5 mm slices from the upper pole of the kidneys to the symphysis without oral or i.v. contrast medium administration.

Results: Seventy-three patients had normal CT scans, 755 pts revealed urolithiasis (282 ureterolithiasis, 195 nephrolithiasis, 278 nephro-and ureterolithiasis), 272 pts had minor or major pathological findings, but no urolithiasis (22 acute pathologies, 31 findings with high importance, 82 with moderate and 137 with low importance were found). Of the pts with urolithiasis 535/755 had additional pathologies: 26 acute pathologies, 33 findings with high importance, 118 with moderate and 358 with low importance.

Conclusion: CT-scan in patients with acute flank pain is not only an excellent tool for the diagnosis of calcified and non calcified urolithiasis, but reveals additional pathologies which influences not only the management of the emergency situation but may also provide important diagnoses with therapeutic consequences.

Sedation and analgesia in patients undergoing percutaneous liver radiofrequency ablation. Comparison of two protocols

S. Mylona¹, A.A. Hatzidakis², L. Thanos¹, E. Charonitakis², K.N. Chamalakis², N. Mpatakis¹; ¹Athens/GR, ²Iraklion/GR

Purpose: To compare two different protocols of intravenous sedoanalgesia for percutaneous radiofrequency ablation of metastatic liver nodules.

Methods and Materials: The study comprised 40 patients in two equal groups. Group A patients received initial dose of 0.02 mg fentanyl and 2 mg midazolam. If needed, maintenance dose of 0.01 mg fentanyl and 1 mg midazolam was administered. Forty-five minutes before the procedure, Group B patients received 3 mg bromazepam per os and 50 mg pethidine intramuscularly. During ablation, 2% lidocaine was injected through the side infusion-port. All patients were continuously monitored. In all cases RITA model 1500 was used. Following procedure, patient's pain score was recorded based on a 0 to 10 scale.

Results: All procedures were completed except one in group A, because of excessive pain. Average doses were 0.047 mg (0.03-0.09 mg) for fentanyl and 6.25 mg (3-8 mg) for midazolam. The pain-scale score points recorded were 1-7 (mean 4.5) in group A and 1-5 (mean 1.4) in group B. Three group A patients recorded pain score > 5 points, compared to one patient of group B with pain score 5. In group A, pain score was higher when lesion was close to the liver capsule, while in group B no such relation was found. No serious complications were noted.

Conclusions: Both protocols were safe under patient monitoring. Group B sedoanalgesia protocol seems to be more effective in controlling pain during liver ablation independent of the lesion localization.

B-621 10:39

MR-guided radiofrequency ablation of liver tumors using internally cooled electrodes: Clinical results in 28 patients

S. Clasen, A. Boss, D. Schmidt, J. Fritz, H. Graf, F. Schick, C. Claussen, P. Pereira; Tübingen/DE

Purpose: To evaluate effectiveness of MR-guided radiofrequency (RF) ablation of primary and secondary liver malignancies.

Methods and Materials: In 28 patients 38 primary ($n = 4$) or metastatic ($n = 34$) liver tumors (10-65 mm; mean: 26.7 mm) were treated with 41 sessions of RF ablation under guidance at an open 0.2 Tesla MR-Imager (Concerto, Siemens, Germany). MR-compatible internally cooled single or cluster electrodes (Cool-tip®, Valleylab, Boulder, CO) were used. Preinterventional MR-imaging was performed using non-enhanced T1w (TR:300 ms/TE:20 ms) and T2w (4400 ms/154 ms) sequences. Placement of the RF electrodes was performed under MR-fluoroscopy (45 ms/13 ms; acquisition-time: 2.3 sec.). T2w sequences were used to monitor therapy effects during a procedure. Follow-up (mean:12.9 months) was performed at a high-field MR-Imager (Magnetom, Sonata, Siemens).

Results: MR-guided RF ablations were technical successful in 82.9%. assessed at the end of each session. Clinical effectiveness, defined as complete ablation evidenced at MR-imaging within four months after RF ablation, was achieved in 32 of 38 liver tumors (84.2%). Intraoperative T2w sequences were accurate to near-online monitor the extend of induced coagulation and were helpful to guide the exact repositioning of the RF-electrode if overlapping coagulations were necessary. In seven of 32 tumours (21.9%), initially defined as effective RF ablation, a local relapse was detected more than four months after RF ablation. In 14 of 28 patients (50%) heterotopic liver tumors were detected at MR imaging follow-up.

Conclusion: MR-guided percutaneous RF ablation is a safe and effective therapy in the local treatment of primary and secondary liver tumors. Intraoperative T2w sequences are accurate to monitor acute effects of induced coagulation.

Usefulness of SonoVue-enhanced ultrasound in the assessment of the efficacy of percutaneous ablation of hepatocellular carcinomas

C. Nicolau, R. Vilana, L. Bianchi, M. Varela, M. Garcia, M. Sanchez, C. Ayuso, J. Bruix, C. Bru; Barcelona/ES

Purpose: Spiral computed tomography (CT) is considered the gold standard imaging technique to assess the efficacy of percutaneous ablation of Hepatocellular Carcinoma (HCC). SonoVue®(Bracco, Italy) is a new microbubble contrast agent. The aim of this study was to assess the accuracy of Contrast-Enhanced Ultrasound (CEUS) using SonoVue in the evaluation of the response to percutaneous treatment of HCC, one month after treatment, compared with CT.

Methods: Forty-one early-stage untreated HCC (40 of them < 3 cm, mean diameter 22.5 mm) of 41 cirrhotic patients were treated with ethanol injection (36) or radiofrequency ablation (5). CT and CEUS were performed 1 month after treatment. CEUS was performed with Contrast Coherent Imaging software (ACUSON Sequoia™, Siemens Ultrasound), at a low mechanical index (< 0.2), after a bolus injection of 2.4 ml of SonoVue. The results of CEUS examination were compared with CT, which is considered the gold standard technique.

Results: The complete response at 1 month was achieved in 30/41 (73%) HCCs. CEUS was able to detect residual tumor in 10 out of 11 cases not completely treated (sensitivity of 91%), and correctly suggested the absence of residual tumor in 29 out of 30 tumors with complete response (specificity of 97%), with a 95% accuracy compared with CT.

Conclusion: CEUS using SonoVue has a very high accuracy at 1 month after treatment, and can be used as an alternative of CT in the assessment of treatment response.

B-623 10:57

Breast cancer hepatic metastases: Survival analysis by the tumor radiofrequency ablation Italian network (TRAIN)

R. Lencioni; Pisa/IT

Purpose: To determine the long-term results of percutaneous radiofrequency ablation (RFA) in the treatment of hepatic metastases from breast cancer.

Methods and Materials: One hundred and two breast cancer patients (mean age 53.8 years ± 12.1) with 153 hepatic metastases ranging 0.8-5 cm in diameter (mean, 2.4 cm ± 0.8) were treated with RFA at 12 centers that were part of the tumor radiofrequency ablation Italian network (TRAIN). Surgical option had been excluded or refused by the patient. RFA was performed percutaneously by using 50- or 150-W generators and 14-G expandable multitined electrodes with 4-9 prongs (RITA Medical Systems, Mountain View, CA). The follow-up period ranged 1-64 months (mean, 18.7 months ± 15.5).

Results: Complete tumor ablation was achieved in 93 (91.2%) of 102 patients after 121 treatment sessions. The primary effectiveness rate on a lesion-by-lesion basis was 86.9%. The 1-, 2-, 3-, 4- and 5-year overall survival rates by the Kaplan-Meier method were 95.2%, 77.3%, 49.6%, 39.7%, and 29.8% respectively. Median survival was 36 months. Analysis of proportional hazards showed that survival was significantly dependent on lesion size ($p = 0.0062$) and lesion multiplicity ($p = 0.039$). The 1-, 3-, and 5-year local tumor progression rates in a patient-by-patient analysis were 19.7%, 32.3%, and 32.3%, respectively. The 1-, 3-, and 5-year recurrence rates were 35.2%, 71.0%, and 85.0% for new hepatic lesions; and 24.8%, 44.0%, and 65.0% for extrahepatic disease.

Conclusion: RFA may be a viable complementary treatment method for selected patients with isolated breast cancer hepatic metastases.

B-624 11:06

Tumor radiofrequency ablation Italian network (TRAIN): Long-term survival outcomes in patients with stage 0 hepatocellular carcinoma

R. Lencioni; Pisa/IT

Purpose: Stage 0 hepatocellular carcinoma (HCC) defines a solitary tumor smaller than 2 cm in patients with well-compensated cirrhosis (Child-Pugh class A) and performance status of 0. Purpose of this study is to investigate the long-term results of radiofrequency ablation (RFA) in the treatment of stage 0 HCC.

Materials and Methods: We retrospectively analyzed a series of 96 consecutive patients (mean age, 63 years ± 12) with stage 0 HCC who received percutaneous RFA at 12 centers that were part of the tumor radiofrequency ablation Italian network (TRAIN). RFA was performed under US guidance by using 50- or 150-W generators and 14-G expandable multitined electrodes with 4-9 prongs (RITA Medical Systems, Mountain View, CA). The follow-up period ranged 8-84 months (mean, 33 months ± 23).

Results: Complete tumor ablation was achieved in 93/96 patients after 100

treatment sessions (primary effectiveness rate, 96.9%). The overall survival rates were 98.7% at 1 year, 95.7% at 2 years, 87.5% at 3 years, 78.1% at 4 years, 64.5% at 5 years, 57.3% at 6 years, and 45.9% at 7 years. The 1-, 2-, and 3-year local tumor progression rates were 1.1%, 5.0%, and 7.4% respectively. No later local tumor progressions were observed. The 1-, 3-, 5-, and 7-year recurrence rates with development of new HCC lesions were 3.5%, 37.6%, 70.2%, and 76.9% respectively.

Conclusion: RF ablation is an effective treatment for cirrhotic patients with stage 0 HCC. Long-term survival rates of RFA-treated patients are equivalent to those reported in Western patients who underwent resection.

B-625 11:15

Tumor radiofrequency ablation Italian network (TRAIN): Long-term results in hepatic colorectal cancer metastases

R. Lencioni; Pisa/IT

Purpose: To determine the long-term survival of patients with hepatic metastases from colorectal cancer who received percutaneous image-guided radiofrequency ablation (RFA).

Methods and Materials: From June 1996 to January 2004, 423 patients (mean age, 66 years ± 10) with 615 hepatic colorectal metastases (1-4 per patient) ranging 0.5-5 cm in diameter (mean, 2.7 cm ± 0.9) received RFA at 12 centers which were part of the tumor radiofrequency ablation Italian network (TRAIN). Surgical option had been excluded or refused by the patient. RFA was performed by using 50- or 150-W generators and 14-G expandable multitined electrodes with 4-9 prongs (RITA Medical Systems, Mountain View, CA). The follow-up period ranged 1-78 months (mean, 19 months ± 15).

Results: Complete tumor ablation was achieved in 373 (88.2%) of 423 patients after 503 treatment sessions. The primary effectiveness rate on a lesion-by-lesion basis was 85.4%. The 1-, 2-, 3-, 4-, and 5-year overall survival were 85.6%, 62.6%, 46.8%, 29.1%, and 24.1% respectively. Median survival was 33 months. Survival was significantly longer in patients with single lesion ≤ 2.5 cm (55.7% at 5 years) than in patients with single lesion > 2.5 cm (13.1% at 5 years) or multiple lesions (11.3% at 5 years) ($p = 0.0002$). The 1-, 3-, and 5-year local tumor progression rates in the patient-by-patient analysis were 21.5%, 32.0%, and 34.1% respectively.

Conclusion: Long-term follow-up data show that RFA is an effective treatment for hepatic colorectal cancer metastases. Results in patients with small solitary lesions are equivalent to those reported for resection.

B-626 11:24

Complications after radiofrequency thermal ablation (RFA) of abdominal tumors: A retrospective review

F.M. Danza, A. Crucitti, G. Pirulli, M. Cirillo, P. Magistrelli, E. Bock, L. Bonomo; Rome/IT

Purpose: We retrospectively reviewed a series of Patients with primitive and secondary abdominal neoplasms treated with RFA, in order to analyze complications related to this procedure.

Methods and Materials: From June 1998 to June 2004, 116 controlled Patients with hepatocellular carcinoma (HCC) or liver metastasis (LM) underwent to RFA; few cases concerned renal (11), adrenal (2) and bone (3) lesions. We performed percutaneously 130 US/CT-guided RFA procedures, using a cool-tip needle, single or cluster; 37 were performed during laparotomy, with US/direct control. Clinical records, symptoms, imaging and therapeutics data were reviewed.

Results: In our series a relatively low rate of complications was observed. We noted 15 complications out of 167 RFA procedures: 3 liver abscess in LM; 1 perihepatic abscess in HCC; 2 biliary duct stenosis, treated with biliary stenting, in LM; 2 acute colecystitis in HCC; 1 biliary-bronchial fistula in LM; 1 partial thrombosis of the left portal branch, spontaneously recovered; 1 duodenal perforation in LM.; 1 intrahepatic-FAV (without progression in 12 months) in LM; 1 liver fracture (7th p.o. day) in LM; 1 myocardial infarction in 3rd p.o. day (dead); 1 parietal seeding in LM, after laparotomic approach.

Conclusion: The biliary tree has an high sensibility to the thermal damage, due to its extremely slow flow. The heat diffusion into surrounding structures (gut, gallbladder) can lead to mild/severe complications. To avoiding them, an accurate treatment planning is mandatory (number and timing of applications, volume of necrosis), in one with a careful selection between percutaneous and open approach.

B-627 11:33

Radiofrequency ablation of pulmonary tumors response evaluation (RAPTURE) trial

R. Lencioni¹, L. Crocetti¹, D. Glenn², D. Morris², R. Suh³, D. Regge⁴, T. Helmberger⁵, W. Lees⁶, C. Bartolozzi¹; ¹Pisa/IT, ²Sydney/AU, ³Los Angeles, CA/US, ⁴Candiolo/IT, ⁵Munich/DE, ⁶London/UK

Purpose: To determine the feasibility, safety, and effectiveness of percutaneous CT-guided radiofrequency ablation (RFA) of pulmonary malignancies.

Methods and Materials: One-hundred patients (35 females and 65 males; mean age, 64 years \pm 11) with 169 malignant lung tumors \leq 3.5 cm in diameter (mean, 1.6 cm \pm 0.8) were enrolled in a prospective, multicenter, single-arm clinical trial. Diagnoses included non-small cell lung cancer (NSCLC) in 33 patients, metastasis from colorectal adenocarcinoma in 52, and metastasis from other primary malignancy in 15. All patients were considered unfit for surgery. CT-guided RFA was performed by using a 150-200-W generator and expandable multi-tined needles (RITA Medical Systems, Mountain View, CA). Follow-up period ranged 1-18 months (mean, 6 months \pm 5).

Results: RFA was technically feasible in 99 (99%) of 100 patients. Overall, 168 lesions were treated in 124 treatment sessions. Major complications consisted of pneumothorax ($n = 18$) and pleural effusion ($n = 4$) requiring treatment, atelectasis ($n = 1$), and pneumonia ($n = 1$). Eighty-one (89%) of 91 lesions in 68 patients who were followed up for 6 months or more after RFA showed no tumor progression on CT. Complete ablation of treated lesions was confirmed by the absence of tumor re-growth over a follow-up period of 1 year or more in 48 (91%) of 53 lesions in 44 patients.

Conclusion: CT-guided RFA yields high local tumor control rates in patients with pulmonary malignancies, and is associated with acceptable morbidity. RFA may prove a viable alternate or complementary treatment for patients with NSCLC or metastases who are not candidates for surgery.

B-628 11:42

CT-guided percutaneous RF ablation of pulmonary neoplastic lesions

E. Mazza, L. Sali, C. Vannini, L. Bonasera, F. Toccafondi, E. Fabbri, M. Zini; Florence/IT

Purpose: To evaluate the effectiveness of percutaneous radiofrequency thermo-ablation (PRFTA) of inoperable primary and secondary pulmonary tumors.

Methods and Materials: From July 2002 to February 2004, 48 patients (age range, 42-82; mean age, 62) underwent PRFTA of malignant pulmonary lesions. Eleven patients were affected by primitive tumours and thirty-seven suffered from metastatic lesions. All nodules were equal to or smaller than 3 cm and were treated by means of Radionics Cool-tip Ablation System probes applied for 12 minutes in the centre of the lesions under CT guidance.

Results: Patients were hospitalized for 1 to 8 days. PRFTA resulted in complete necrosis in all cases as evaluated on CT and PET images. On follow-up at 3 and 6 months a reduction in diameter of pulmonary nodules was verified on CT images. In smaller lesions restitutio ad integrum of pulmonary parenchyma was observed. In 9 cases pneumothorax developed during the procedure. In 8 patients it was treated by positioning a pleural drainage under CT guidance at the end of thermoablation. In 1 case a hypertensive pneumothorax became clinically evident after 6 hours and was subsequently and equally dealt with percutaneous drainage.

Conclusion: PRFTA of primary and secondary pulmonary lesions demonstrated to be a straightforward, practically uncomplicated, low-cost procedure that allows the eradication of inoperable malignant nodules. Adequate follow-up studies are nevertheless necessary to determine the actual survival rate of these patients.

B-629 11:51

CT-guided radiofrequency ablation (RF) for lung metastases

T.J. Vogl, J. Li, T. Lehnert, Y. Wang, M. Mack; Frankfurt a. Main/DE

Objective: The purpose of this study is to evaluate experience and technical feasibility of percutaneous radiofrequency ablation (RF) for treatment of lung metastases.

Materials and Methods: Fifty-nine lung metastases (0.62-3.3 cm in largest diameter; mean, 2.64 cm) in 46 patients were treated with CT-guided percutaneous RF ablation. There were 29 men and 17 women (average age, 62.8 years). After the RF electrode was placed in tumor with computed tomography (CT) fluoroscopic guidance, RF ablation was performed by using a single internally cooled electrode. Follow-up was performed with CT and MR images; enhancement of the treated region on images were considered to indicate complete tumor necrosis.

Results: Average follow-up was 12.8 months (range, 1-28 months). The mean RF power was 22 W (range, 20-25 W), and the mean treatment time was 10.6 minutes

(range, 9.5-12.8 minutes). In follow-up, 52 (88.1% of 59) tumors were achieved total destruction with RF ablation. 2 (3.4% of 59) tumors were uncompleted ablation which enhancement of residual tissue was observed after treatment; 5 (8.5% of 59) tumors were difficult to definite ablation effect because of consolidation, no tumor regrowth at the treated site. Death occurred in 3 patients (6.5%, 3/46) during follow-up. Complications included pneumothorax 41 (69%, 41/59) during and after procedure (5 cases, 12% of 41 requiring pleural drainage), Pleural effusion 18 (30.5%, 18/59), subcutaneous emphysema 22 (37%, 22/59), intraparenchymal hemorrhage 28 (47.5% of 59), moderate pain 11 (18.6%, 11/59).

Conclusion: This study illustrates that CT-guided RF ablation is a promising minimally invasive, effective technique of treatment of small peripheral lung metastases.

Impact of intravascular ultrasound (IVUS) on balloon sizing for interventional treatment of atherosclerotic superficial femoral artery (SFA) lesions

M. Treitl, J. Rieger, C. Weber, S. Wirth, K.-J. Pfeifer, M.F. Reiser; Munich/DE

Purpose: Intravascular Ultrasound (IVUS) represents the gold standard for balloon/stent sizing in coronary interventions. To reveal its impact on balloon sizing during peripheral percutaneous transluminal angioplasty (PTA) of the superficial femoral artery (SFA) we compared digital subtraction angiography (DSA) to IVUS to assess possible intermodality differences regarding selection of the balloon/stent size.

Methods and Materials: DSA and IVUS were carried out during interventional treatment of 32 patients with untreated short SFA lesions. Both modalities (32 examinations each) were randomly presented to 3 blinded readers, comprising of one interventional cardiologist (IC), radiologist (IR) and angiologist (IA) with > 10 years interventional experience. IC and IR were experienced IVUS users, IA was not. The collected data were analysed statistically.

Results: Mean balloon diameter was 4.73 mm ($SD \pm 0.67$ mm, 4-7 mm) for DSA and 5.77 mm ($SD \pm 0.75$ mm, 4-8 mm) for IVUS ($p < 0.0001$). Intramodality difference was significant for DSA and between IR (4.88 ± 0.55 mm, $p < 0.0001$) and IA (4.34 ± 0.48 mm) and IC (4.97 ± 0.78 mm) and IA ($p < 0.0001$), but not between IR and IC. There was no significant intramodality difference for IVUS (5.69 ± 0.84 mm, 5.88 ± 0.71 mm and 5.69 ± 0.72 mm). Intrareader intermodality difference was significant for all readers ($p < 0.0001$).

Conclusion: IVUS analysis is associated with a significant increase of the selected balloon diameter and improves interobserver agreement. Our study raises the question whether DSA may be misleading for correct balloon sizing in SFA stenosis.

B-631 10:39

Angio-seal vascular closure device for brachial artery access punctures

D. Bilecen¹, W. Ostheim-Dzerowycz²; ¹Basle/CH, ²Bad Saeckingen/DE

Introduction and aim: The feasibility of Angio-Seal vascular closure device in the brachial artery was investigated after transbrachial percutaneous transluminal angioplasty (PTA). The technique was modified to encompass the different anatomical skin condition of the cubital fossa.

Materials and Methods: After Transbrachial PTA, Angio-Seal vascular closure device (St. Jude Medical, Minnetonka, MN, USA) was applied in 36 patients (mean age 63.5 years). The procedure of arterial closure is demonstrated in the following in detail:

- Local anesthesia (2% procaine). Hump formation to increase the space.
- After arterial puncture subcutaneous pouch is created by a blade.
- Angio-Seal device is introduced via guide wire. The collagen stripe is pushed towards the artery and remains visible. The preformed pouch is used to cover the collagen stripe.
- Skin is taped by Leukostrip (Smith and Nephew, Largo, Florida, USA).

The patients were monitored clinically for pain, local bleeding and pulse status of the radial artery on day 1, 3, day of discharge and one year later.

Scientific Sessions

Results: In 65% of the patients the device deployed successfully without bleeding, pain or other complications, 19% of the patients experienced mild local bleeding within the cubital fossa, 9% of the patients reported mild transient pain during deployment of the device and 3% of the patient were diagnosed with mild phlebitis. **Conclusion:** Angio-Seal Vascular Closure Device is effective in sealing brachial artery access punctures. A dedicated protocol for closure is demonstrated.

B-632 10:48

Percutaneous treatment in iliac artery occlusion: Long-term results

R. Gandini, M. Chiocchi, S. Fabiano, E. Pampana, A. Spinelli, G. Simonetti; Rome/IT

Purpose: To evaluate long-term outcomes after recanalization of chronic iliac artery occlusion with primary stenting and to underline predictive factors of clinical success.

Materials and Methods: From January 1995 to August 2001, 128 consecutive patients (104 men, mean age 68.2 yrs), with occlusive iliac artery disease (12 bilateral occlusions), underwent recanalization with primary stenting. Pre-procedure evaluation was made according to Fontaine classification, ecocolor-Doppler, digital subtraction angiography (DSA) findings and ankle-brachial pressure index (ABI). The mean ABI at hospitalization was 0.52 (range: 0.23-0.72). Follow-ups included ABI measurements, vascular clinical control, ecocolor-Doppler, and, from September 2000, CT-multislice angiography at one, three, six months and every year thereafter. In case of significant ABI reduction (> 0.15) or worsening of clinical conditions, a DSA was performed. Length of occluded vessels ranged from 2 to 15 cm (mean, 10.5).

Results: Technical success was 98.5%. A clinical improvement was present in all patients in whom a technical success was achieved. Primary patencies were 91.2, 85, 80, 73.7 and 68% at one, two, three, four and five years; secondary patencies were 97, 94, 90.7, 85.9 and 80.4%, respectively.

Conclusion: Primary stenting is safe and effective in case of chronic occlusion, with long-term results of primary and secondary patencies similar to traditional surgery.

B-633 10:57

Cutting balloon angioplasty for the treatment of the stenosis of fistula due to haemodialysis, peripheral bypass, and stent

T. Lupattelli, G. Scalera, M.J. Fischer, F. Crusco, L. Lupattelli; Perugia/IT

Purpose: To present our experience in treating stenosis of arterial anastomosis of peripheral bypass, stent, native artery, and dialysis fistula by cutting balloon angioplasty (CBPTA).

Methods and Materials: From January 2003 to November 2003 we performed in 19 patients 24 CBPTA (4 prosthesis graft stenosis, 3 vein graft stenosis, 2 post PTA native arteries, 1 post-radiotherapy stenosis, 2 stent restenosis, and 12 haemodialysis fistulae. A cutting balloon of 4 mm/20 mm, 6 mm/20 mm, 8 mm/20 mm were used in 2, 12, and 10 lesions respectively. For each procedure we used before and post CBPTA a conventional PTA. The technical success was a residual stenosis less than 30% revealed by angiography or absence of pressure gradient. The follow-up of 15 patients (1-9 months) was performed by Doppler US.

Results: The procedure was technically successful in 84% of cases. The follow-up revealed: 2 restenosis, and 1 bypass occlusion. In the immediate post CBPTA, 2 patients had thrombosis of haemodialysis fistula. 4 restenosis (3 fistulae, and 1 bypass) were retreated with cutting balloon at 4 weeks and 12 months after primary procedure. The primary patency was 54% after 12 months, and 80% after 15 months in haemodialysis fistulae and peripheral bypass respectively.

Conclusion: CBPTA is a feasible and easy alternative treatment to conventional PTA.

B-634 11:06

The use of carbon coated stents (Carbostent) in aortoiliac stenosis. Our experience

M. Pomoni, K. Papadopoulos, A. Tsanis, S. Tanteles, D. Tzavoulis, A. Pagonas, N. Batakis; Athens/GR

Purpose: To present our preliminary results in the use of carbon coated stents (Carbostent) for the treatment of patients with aortoiliac stenosis.

Material and Method: During the last two years we treated 51 patients (46 men 5 women) with severe iliac stenoses. The majority of the patients were heavy smokers (60%), diabetics (30%), with high blood pressure (43%), hypercholesterolemia (22%) and presented with intermittent claudication or severe leg ischemia. Inclusion criteria were symptomatic ischemia, unilateral or bilateral

common or external iliac critical stenosis or occlusion, a limit of two stents to correct the lesion, and satisfactory outflow. 79 stents were placed. In 17 cases we used kissing stents because stenoses involved the aortoiliac bifurcation in 6 patients stenoses involved common and external iliac artery. In 5 patients we used the stent to stent technique in order to deal with long stenosis. Follow-up of the patient involves interview by phone on the first month and color Doppler ultrasound on the 3, 6, 9 and 12 month as well as every 6 months after the first year.

Results: In all cases the stent placement was successful and the patients reported improvement of the claudication. There were no immediate complications. Restenosis occurred in one patient 12 months after the stent placement and was treated with a new stent placement.

Conclusion: Carbon coated stents are easy and safe to use. Our results indicate that they are very promising for low restenosis and low intimal hyperplasia rate.

B-635 11:15

Subintimal angioplasty: Experience in 58 patients

R. Gandini, L. Maresca, V. Pipitone, E. Pampana, D. Konda, C. Reale, G. Simonetti; Rome/IT

Purpose: To evaluate indications, feasibility and results of subintimal angioplasty of long femoral-popliteal occlusions in patients with severe claudication and/or critical limbs ischaemia.

Materials and Methods: Fifty-eight patients (46 males and 12 females; mean age: 71 yrs) with long femoral-popliteal occlusion (> 15 cm) were included in our study. Thirty-four patients were symptomatic for claudication, 3 patients had rest pain and 21 patients presented with gangrene. All patients were studied with Angio-MR and Doppler-US. Recanalization of the superficial femoral artery was performed in all patients. A contemporary recanalization of limb arteries was carried out in 11 patients. In 54 cases recanalization was obtained by antegrade femoral approach, in 1 case by retrograde trans-popliteal approach and in 3 cases by combined femoral-popliteal approach. Follow-up was performed by physical examination and Doppler US 1, 3 and 6 months after the procedure and subsequently after every 6 months.

Results: Technical success was 96.5% with resolution of rest pain or claudication in 30/35 patients and complete resolution of gangrene in 19/21 patients. Two patients had a partial resolution of gangrene underwent only a minor amputation. A mean follow-up of 10.3 months (range: 3-18) demonstrated the patency of the treated vessels in 49/56 patients.

Conclusions: Subintimal angioplasty of long femoral-popliteal occlusions is a safe and effective technique that may be considered as a valid alternative to surgery.

B-636 11:24

Subintimal angioplasty of infrapopliteal vessel occlusions in the treatment of critical limb ischaemia

S. Tartari, L. Zattoni, A. Sacco; Rovigo/IT

Purpose: To evaluate the feasibility and results of subintimal angioplasty (SIA) of tibial occlusions in critical limb ischaemia (CLI).

Methods and Materials: From 2002 through June 2004 42 patients with tibial occlusions and rest pain or tissue loss underwent SIA: we treated 71 tibial vessel occlusions and 23 associated superficial femoral artery occlusions. Patients were followed for 6-21 months (mean 9 months); in all cases clinical and duplex examination was performed at 6 months.

Results: Technical success was obtained in 35 of 42 patients (83%); in this group 2 patient had below-the-knee amputation and 2 underwent surgical revascularization. Of the patients in whom complete recanalization of occluded vessel with SIA failed, 2 required major amputation. The 9-months limb salvage rate was 90% and the survival rate was 90%. Clinical recurrence occurred in 2 patients, who underwent a second successful treatment with SIA. There were 1 major and 5 minor complications; all of them were treated by endovascular procedures.

Conclusion: SIA is feasible and is effective for foot revascularization in patients with CLI. It offers a high rate of success and low complications rate. Clinical recurrence is infrequent. These results, plus SIA's many advantages, support an increasing role for SIA in the treatment of CLI.

Scientific Sessions

Giant cell arteritis of the upper extremities: Follow-up after treatment with percutaneous transluminal angioplasty

M. Both¹, P.M. Aries², S. Müller-Hülsbeck¹, T. Jahnke¹, H. Bolte¹, J. Biederer¹, W.L. Gross², M. Heller¹, M. Reuter¹; ¹Kiel/DE, ²Bad Bramstedt/DE

Purpose: To evaluate the feasibility and long-term outcome of upper extremity balloon angioplasty in stenotic and occlusive lesions due to giant cell arteritis.

Methods and Materials: 10 patients (10 female, mean age 66 years) with the diagnosis of extracranial giant cell arteritis underwent balloon angioplasty in 30 vascular territories (subclavian artery: n = 4, axillary artery: n = 11, brachial artery: n = 15) for treatment of symptomatic upper limb artery stenoses (n = 23) and occlusions (n = 1). Interventional therapy was accompanied with immunosuppressive therapy. In all patients, follow-up included imaging methods (Duplex ultrasound (n = 10), magnetic resonance angiography (n = 9)) and clinical examination.

Results: Initial technical success was achieved in all vascular lesions. During follow-up (mean 25 months), severe restenoses (vascular territories: n = 12) occurred in 4/10 patients (primary patency rate: 60%). Repeated PTA (lesions: n = 4, patients: n = 2) provided a secondary patency rate of 73% (22/30 lesions) and a clinical success rate of 80% (8/10 patients).

Conclusions: Despite a tendency to re-stenoses, upper extremity artery balloon angioplasty represents an efficient method for treatment of extracranial giant cell arteritis.

B-638 11:42

A prospective controlled trial on endovascular vs surgical treatment of stenosis in forearm arterious fistulae (AVF)

G. Mansueto, N. Tessitore, D. Cenzi, V. Bedogna, E. Baggio, A. Lupo, R. Pozzi Mucelli; Verona/IT

Purpose: to compare PTA versus surgery in the treatment of venous perianastomotic stenoses in forearm AVF.

Materials and Methods: A prospective controlled trial was performed in 62 forearm AVF. 40 AVF were treated by PTA and 22 by surgery. The two groups were comparable for subject and AVF age and for pre- and post-treatment QoL. Primary and assisted primary patency were reviewed at 6, 12, 24, 36 and 48 months. Endpoints for primary patency and assisted primary patency were restenosis and technique failure (reintervention by another technique or access loss). In surgery the two patencies corresponded, since restenosis was treated by PTA.

Results: Success rate at 6 months was 100% for surgery and $98 \pm 2\%$ for PTA assisted primary patency, while at 48 months success rate was $50 \pm 14\%$ for surgery and $64 \pm 12\%$ for PTA. The primary patency was lower in PTA than in surgery ($p = 0.02$) while assisted primary patencies were similar ($p = 0.22$) at Kaplan Meyer analysis. At multivariate Cox analysis PTA ad surgery have a similar risk of technique failure (HR 0.5; 95% CI 0.2-1.5; $p = 0.23$).

Conclusion: In our experience in forearm AVF the technique survival was similar for PTA and surgery. Even if restenosis rate after pre-emptive correction of perianastomotic stenosis is higher with PTA than surgery, PTA allows repeat intervention and primary assisted patency is better for PTA.

Percutaneous arm port device placement: Feasibility, efficacy and impact on quality of life in 1000 cancer patients using arm venography exclusively

P.-Y. Marcy¹, A. Chaturvedi¹, P. Brunner², P.-Y. Bondiau¹, O. Hericord¹, J.-C. Gallard³; ¹Nice/FR, ²Monaco/MC, ³Caen/FR

Purpose: To determine the feasibility and outcome of radiologically implanted arm port devices, the impact on quality of life in cancer patients and to select the specific indications for.

Methods and Materials: Arm port implantation was attempted in 1000 cancer patients. Ports were placed via the basilic vein under fluoroscopy guidance exclusively. Indications for port placement included chemotherapy (n = 861), blood transfusion (n = 78), other (n = 61). Feasibility and outcome were recorded. Quality of life was scored using a visual analogic score of 0 (worst imaginable pain) to 100/100 (no pain or discomfort) to evaluate interference with daily life (VAS1) and the practical aspects of chemotherapy (VAS2).

Results: Initial technical failures (6.3%) included inability to perform the venogram (1.9%), occurrence of a contrast medium hematoma (0.2%), inability to puncture/catheterize the veins (4.2%). Accidental puncture of the humeral artery occurred in four cases. Mean implantation duration was 255.9 days, the overall complications rate was 9.5%. 5.3% of the devices had to be removed prematurely. Complications included device related sepsis (n = 33), febrile neutropenia (n = 15), septicemia

(n = 7), port sepsis (n = 9), skin dehiscence (n = 11), deep venous thrombosis (n = 12), catheter occlusion (n = 7), drug extravasation (n = 2), embolization (n = 4), mechanical stimulation of the median nerve (n = 1), twist of the port (n = 2). VAS (1.2) mean scores were 0.87 and 0.92 respectively.

Conclusion: Specific indications for arm port implantation include young women (cosmetic aspect), patients who underwent previous radiation therapy of the chest or neck, patients who had previous upper extremity venous thrombosis, respiratory insufficiency, pacemaker, severe kyphosis.

Evaluation of lenticulostriate artery haemodynamics with color Doppler sonography (CDS) in infancy

S.P. Deftereos, I. Manavis, J. Sigalas, T. Giannoudi, P. Prassopoulos; Alexandroupolis/GR

Purpose: To measure lenticulostriate artery (LSA) haemodynamic parameters with CDS in neonatal brains and to establish normal data for LSA blood flow velocity (BFV), resistive index (RI) and pulsatility index (PI) to be used as reference in clinical practice.

Methods and Materials: The study comprised 132 consecutive neonates (47 preterm 85 term; 1 d to 8 m old) without any evidence of neurological abnormality or respiratory distress. Measurements of BFV, RI and PI were performed through the anterior fontanelle on the middle cerebral artery (MCA), its LSAs and the internal carotid artery (ICA), used as reference.

Results: The ICA, MCA and LSAs were invariably seen in all cases. Normal values of BFV, RI and PI were calculated for all measured arteries and corresponding tables were formulated for 9 age groups: 1 preterm and 8 month-groups for full-terms. BFV measurements showed progressive decrease with advancing age ($p < 0.01$) for LSAs, MCA and ICA. RI was also decreased with age for MCA and ICA ($p < 0.05$), but did not show age-related variations among the fullterm groups ($p > 0.10$) for LSAs. However, RI values of LSAs are significantly lower in preterm than in full-term neonates ($p < 0.05$). PI did not exhibit age-related differences for all arteries measured. BFV measurements for LSAs differ significantly ($p < 0.01$) from MCA with LSAs mean values being about half of the corresponding MCA values.

Conclusion: BFV, RI and PI measurements can be obtained from lenticulostriate arteries and narmal data established here may be useful in evaluating cerebral and basal ganglia abnormalities in neonates.

B-641 10:39

Hypertensive encephalopathy: Clinical and MR imaging findings

Y.-W. Kim¹, I.-O. Kim², W. Kim², K. Yeon²; ¹Busan/KR, ²Seoul/KR

Purpose: To investigate the MR imaging findings and associated clinical findings of hypertensive encephalopathy in children.

Methods and Materials: A retrospective study of 24 MR examinations was performed in 16 patients (M:F=9:6, age range: 2-17 yrs.) with clinically diagnosed hypertensive encephalopathy. Initial imaging was performed within 1 day of the attack and follow-up imaging was performed in 5 patients. The presence of underlying disease, BP, and neurological abnormalities at the time of imaging were recorded. We assessed the MR imaging findings and correlated with the clinical findings.

Results: 14 patients had abnormal MR imaging findings and two patients had negative MR imaging findings. MR images showed bilateral, nearly symmetrical areas of high signal intensity in the subcortical white matter of the occipital lobes. In five cases in which follow-up MR imaging was performed after the hypertension was corrected, there was either complete resolution or marked improvement of signal abnormalities on T2WI with contrast enhancement. Nine patients had suffered from renal disease; most frequently FSGS. The BP at the time was recorded as ranging from 103/50 to 170/120 in these patients. The clinical symptoms were headache in 10, seizure in 8, visual symptoms in 8, and focal neurological abnormalities in 8. Neurological symptoms and signs were correlated with the location of MR abnormalities.

Scientific Sessions

Conclusion: Characteristic MR imaging findings may be useful in establishing early diagnosis in the appropriate clinical setting, which allows timely initiation of appropriate therapy in hypertensive children.

B-642 10:48

Hypoxic-ischemic (HI) brain injury in neonatal rats: The relationship between early post HI apparent diffusion coefficient (ADC) and irreversible infarction

Y. Wang, P.-T. Cheung, G.X. Shen, E.X. Wu, G. Cao, P.-L. Khong; Hong Kong/CN

Purpose: Animal models are increasingly studied for the evaluation of neuro-protective interventions in perinatal HI brain injury. The significance of MR imaging findings at early time-points post HI is of interest because of the potential therapeutic window. We aim to study the relationship between early post-HI ADC, T2-weighted signal change and irreversible infarction.

Methods and Materials: Twenty-three 7-day-old rats underwent right common carotid artery ligation followed by hypoxia. MR imaging (MRI) was performed 1-2 hours post HI using diffusion-weighted imaging (DWI) and T2-weighted imaging (T2WI) (early MRI), and at day 4 post-HI using T2WI (late MRI). Lesion volumes relative to whole brain (LV) were measured on ADC maps at different relative ADC thresholds from 50%-80% of mean contralateral ADC, on T2WI and histopathology at day10 post-HI. Spearman's correlation was used to study the relationship between LV at various ADC thresholds, T2WI and histopathology.

Results: LV (mean \pm sd) at 50%, 60%, 70% and 80% ADC thresholds were $1.9\% \pm 4.9\%$, $7.4\% \pm 11.7\%$, $13.2\% \pm 14.0\%$ and $20.9\% \pm 14.5\%$ respectively. T2WI LV at early and late MRI were $2.8\% \pm 3.5\%$ and $23.3\% \pm 8.6\%$ respectively. Histopathology LV was $28.6\% \pm 7.8\%$. Significant correlation was found between LV at histopathology and 80% ADC threshold ($r = 0.466$, $p = 0.025$), but not with lower ADC thresholds or early T2WI. Significant correlation was also found between LV at histopathology and late T2WI ($r = 0.531$ and $p = 0.009$).

Conclusion: There is a weak correlation between LV at 80% ADC threshold early post HI and irreversible infarction. Reduced ADC thresholds do not strengthen this correlation.

B-643 10:57

Prediction of outcome of hypoxic-ischemic encephalopathy in term neonates with proton MR spectroscopy and diffusion weighted imaging

G. Fan, Z. Wu, Q. Guo; Shenyang/CN

Purpose: To evaluate Proton MR Spectroscopy (1HMRS) and diffusion weighted imaging (DWI) for outcome prediction of hypoxic-ischemic encephalopathy (HIE) in term neonates.

Methods: 42 HIE newborns were evaluated using DWI and 1HMRS. Follow-up MR examinations were performed after 6 months. Apparent diffusion coefficients (ADCs) were measured in the basal ganglia, subcortical white matter, and the cortex respectively. 1HMRS placed in the basal ganglia and thalamic areas. Long-term clinical outcome was classified as normal, abnormal and sequelae according to follow-up MR imaging findings. Logistic regression was performed to examine the predictive value of each ADC value and metabolite ratio relative to creatine (CR) for predicting clinical outcome.

Results: DWI showed a diffuse or symmetrical pattern of injury involving both the basal ganglia and the cortex or subcortical white matter in 12 cases (group 1); multifocal injury which was confined to single arterial territory in 17 (group 2); single lesion within periventricular white matter or basal ganglia was present in 13 (group 3). MR reexamination results showed that 57.14% of sequela were present in group2 (4/7) and 61.11% of abnormal present in group3 (11/18), while 58.82% of normal was present in group1 (10/17). Logistic regression confirmed that ADCs in basal ganglia could be used to differentiate normal from abnormal or sequela ($p < 0.01$), while lactate (LAC)/CR ratio could be used to differentiate normal from abnormal or sequela ($p < 0.001$). The probability of sequelae exceeded 97% for glutamate and glutamine (Glu-n)/CR ratio of 1.5.

Conclusion: Both DWI and 1HMRS play important roles in the quantitative prediction of worse clinical outcomes for HIE.

B-644 11:06

Contrast-enhanced MR imaging of pediatric CNS: Comparison of gadobenate dimeglumine and gadopentetate dimeglumine for lesion enhancement

C. Colosimo¹, G. Pirovano², M.A. Kirchin³, B. Hogstrom², A. Spinazzi²; ¹Chieti/IT, ²Princeton, NJ/US, ³Milan/IT

Purpose: To compare gadobenate dimeglumine (Gd-BOPTA), a contrast agent

with high T1-relaxivity ($9.7 \text{ mmol}^{-1}\text{s}^{-1}$) with gadopentetate dimeglumine (Gd-DTPA) for enhancement and visualization of central nervous system (CNS) lesions in pediatric patients.

Methods and Materials: 63 pediatric patients with CNS (brain and spine) lesions received 0.1 mmol/kg BW doses of Gd-BOPTA ($n = 29$; mean age 7.5 ± 4.8 years) or Gd-DTPA ($n = 34$; mean age 7.9 ± 4.7 years). Images were acquired before (T1-T2wSE) and within 10 minutes (T1wSE) of contrast agent injection. Blinded unpaired and paired qualitative assessment in 26 (Gd-BOPTA) and 32 (Gd-DTPA) patients compared pre- to post-dose changes in quality of lesion visualization (5-point scales for border delineation, visualization of internal morphology, contrast enhancement). Quantitative evaluation in 19 (Gd-BOPTA) and 23 (Gd-DTPA) patients compared changes in lesion-to-background ratio (L/B), contrast-to-noise ratio (CNR) and% enhancement (%En).

Results: Unpaired post-dose scores for lesion border delineation, visualization of internal morphology and contrast enhancement were 3.3 ± 0.6 , 3.4 ± 0.6 and 3.4 ± 0.6 for Gd-BOPTA and 3.1 ± 0.7 , 3.4 ± 0.6 and 3.1 ± 0.7 for Gd-DTPA. The pre- to post-dose changes were significantly superior for Gd-BOPTA for border delineation ($p = 0.018$) and contrast enhancement ($p = 0.006$) and equivalent for visualization of internal morphology ($p = 0.126$). Paired assessments revealed non-significant superiority for Gd-BOPTA for border delineation and visualization of internal morphology and significant superiority for contrast enhancement ($p = 0.04$). Mean post-dose values for L/B, CNR and%En were all superior for Gd-BOPTA (0.5 ± 0.4 vs. 0.3 ± 0.4 ; 9.1 ± 15.4 vs. 2.2 ± 9.9 ; 66.6 ± 47.4 vs. 42.8 ± 39.0 , respectively).

Conclusion: Gd-BOPTA demonstrates qualitative and quantitative superiority over Gd-DTPA for contrast enhancement of CNS lesions in pediatric patients.

B-645 11:15

Value of gadolinium administration in brain MR imaging examinations for developmental delay in children less than two years of age

B. Foerster, J. Ksar, M. Petrou, P. Eldevik, P. Maly, P.C. Sundgren; Ann Arbor, MI/US

Purpose: To review the radiological findings and associated clinical symptoms in the MR imaging work-up of developmental delay in children less than two years of age and evaluate the added utility of gadolinium administration.

Methods and Materials: During a 7.5 year period (1995-2002), 192 gadolinium enhanced brain MR imaging examinations were performed on children under two years of age at our institution for the evaluation of clinical developmental delay. We retrospectively reviewed the medical records, stated indications and MR imaging findings in all of these patients.

Results: Developmental delay was the primary clinical concern that prompted MR imaging examination in 117 studies (Group A). 75 patients (Group B) had other more significant clinical symptoms with developmental delay as a secondary concern. Out of the total 192 examinations, abnormal contrast enhancement was present in 16 cases (8%). In Group A, there were 4 cases (3%) with abnormal contrast enhancement, all of which represented incidental findings not related to the primary clinical question. In Group B, there were 12 cases (16%) with abnormal contrast enhancement. Gadolinium increased the confidence and/or clarified the diagnosis in 8 cases (4 neoplasms, 3 tuberous sclerosis, and 1 neurofibromatosis) with incidental findings in the remaining 4.

Conclusion: Administration of gadolinium in the MR imaging work-up of children under the age of 2 with developmental delay and no other symptoms does not help in the diagnosis of an underlying cause. Based on the results of this study, gadolinium is no longer administered in this population at our institution.

B-646 11:24

Magnetization transfer ratio in the brain of preterm subjects: Age related changes during the first 2 years of life

V.G. Xydis, A.G. Zikou, L. Astrakas, K. Pantou, S. Andronikou, M.I. Argyropoulou; Ioannina/GR

Purpose: Magnetization transfer (MT) imaging is a magnetic resonance imaging technique that has the potential for monitoring cerebral myelination in vivo. Our purpose was to study the progress of myelination in preterm born subjects by measuring the MT Ratio (MTR) from birth, up to 24 months of corrected age.

Methods and Materials: 125 preterm subjects (64 males, 61 females, of gestational age 33 ± 2.4 weeks, chronological and corrected age 9.3 ± 5.1 , 7.7 ± 5.1 months respectively) with normal brain MR using classic sequences, were further evaluated for MTR by using a three-dimensional gradient-echo sequence (TR = 32/TE = 8/ flip angle = 6° 4 mm/2 mm overlapping sections) without and with magnetization transfer prepulse. The magnetization transfer ratio was calculated as: $\text{MTR} = (\text{SI}_{\text{0}} - \text{SI}_{\text{m}}) / \text{SI}_{\text{0}} \times 100\%$, where SI_m refers to the signal

Scientific Sessions

intensity from an image acquired with a magnetization transfer prepulse and Slo the signal intensity from the image acquired without a magnetization transfer prepulse.

Results: MTR increased asymptotically in the white matter of frontal lobe ($R^2 = 0.91$), occipital lobe ($R^2 = 0.82$), genu ($R^2 = 0.85$), splenium of the corpus callosum ($R^2 = 0.85$), thalamus ($R^2 = 0.86$), putamen ($R^2 = 0.71$) and caudate nucleus ($R^2 = 0.67$), reaching a plateau at corrected age 1.3, 12.9, 18.7, 17.7, 10.4, 6.4, 9.2 months respectively.

Conclusion: This study in preterm subjects shows age related changes of the brain MTR and provides normal data that may be useful to assess disturbances in the progress of myelination.

B-647 11:33

Magnetization transfer imaging of the pituitary gland in patients with Prop1 gene mutations discloses a well-defined "mass" with normal secretory activity within the pituitary

A. Voutetakis¹, A. Sertedaki², M. Maniatzi-Christidi², D. Kiortsis³, I. Bossis¹, C. Dacou-Voutetakis², M.I. Argyropoulou³; ¹Bethesda, MD/US, ²Athens/GR, ³Ioannina/GR

Purpose: To apply Magnetization Transfer (MT) imaging in the evaluation of the pituitary enlargement observed in Prop1 deficient patients.

Methods and Materials: In 3 Prop1 deficient patients dynamic hormonal testing and genomic analysis of the Prop1 gene were performed using established methods. Classic MR and MT sequences were carried out. The MT phenomenon was quantified by the magnetization transfer ratio (MTR).

Results: All patients had low values of GH, TSH and Prl, whereas cortisol values were normal. The initial MR imaging of all three patients revealed an enlarged pituitary gland. The enlargement consisted of a "mass" interposed between the anterior and posterior lobes. MTR of the adenohypophysis was subnormal [patient A (male, 9 yrs): 37% vs 55.3% \pm 2.6 normal values, patient B (female, 3 yrs): 47.3% vs 57.6% \pm 2.68 normal values, patient C (male, 2.5 yrs): 48% vs 55.3% \pm 2.6 normal values], whereas the MTR of the "mass" was normal: patient B: 55.4%, patient C 58.5%.

Conclusion: MT indirectly reflects the secretory status of the tissue. The low MTR of the adenohypophysis reflects the low synthetic-secretory activity of the gland which is in agreement with the hormonal data. Conversely, the normal MTR of the well-defined "mass" causing the pituitary enlargement suggests the presence of tissue with normal synthetic-secretory activity. Cells normally residing in the intermediate lobe are Prop1 independent and could therefore expand, cause the enlargement and account for the normal MTR observed within the "mass". Our findings could help the differential diagnosis between enlargement from other causes and those associated with Prop1 mutations.

B-648 11:42

Diffusion tensor imaging of healthy neonates and children up to adolescence

U. Löbel, D. Güllmar, H.-J. Mentzel, J. Sedlacik, J.R. Reichenbach, W.A. Kaiser; Jena/DE

Purpose: Diffusion tensor imaging (DTI) provides a new diagnostic method for estimating myelination *in vivo*. We studied the development of the human brain using apparent diffusion coefficient (ADC) and fractional anisotropy (FA) in children and adolescents.

Methods and Materials: 133 subjects (68 females, 65 males; age-range 20 days to 25 years) without neuroradiological pathological findings were examined. MR imaging was performed on a 1.5 T MR scanner using a TRSE-epi-dti-sequence (6 directions; b=0/1000 sec/mm²; FOV=240; Matrix=128; in-plane resolution 1.8x1.8 mm²; 19 slices, 5 mm thick). ADC and FA were calculated and 20 bilateral ROIs were manually drawn into each brain.

Results: There was a significant decrease of ADC with age in 32 of 40 regions, most prominent in the frontal regions. FA increased with age significantly in 35 of 40 regions. A logarithmic function best fit the data. Spearman correlation coefficients (r) ranged from 0.188 to 0.688 for FA and from -0.182 to -0.817 for ADC. In the left frontal white matter ADC of all measured patients ranged from 139.8×10^{-5} mm²/sec to 51.0×10^{-5} mm²/sec with r = -0.785 (p < 0.01). Its FA ranged between 0.3077 and 0.8186 with r = 0.44 (p < 0.01). For the left caudate nucleus, ADC was highest with 112.8×10^{-5} mm²/sec, lowest with 56.4×10^{-5} mm²/sec, r = -0.72 (p < 0.01). FA ranged from 0.203 to 0.597, r = 0.195 (p < 0.05).

Conclusion: ADC and FA are able to describe the development of the human brain in most regions with ADC being more steady than FA. Our results suggest that water diffusion is dependent on subject age and brain region. The dimension of change in ADC and FA gives information about the stage of myelination.

B-649 11:51

Appropriate use and benefits of eye-lens bismuth shielding in pediatric head CT examinations

M. Raissaki, K. Perisinakis, A. Tzedakis, M. Daskalogiannaki, I. Damilakis, N. Gourtsoyiannis; Iraklion/GR

Purpose: To evaluate the optimal use of commercially available bismuth garments for eye-lens shielding in children undergoing head CT and to assess the resulting eye-lens dose reduction.

Methods and Material: We prospectively placed a bismuth shield over the eyelids of 27 consecutive children, aged 3 months-16 years (mean:7), referred for a CT scan that might involve lens exposure. Four thermoluminescent crystals were placed, two below and two above each shield, for the calculation of the shielded and unshielded eye-lens dose, respectively. The first 5 children were scanned with a distal shield, 3 cm over the eyes, to eliminate potential artifacts. Depending on the indication, 9 children were scanned with a total eye-sparing technique (Group A). In 11 children the eyes were partly exposed (Group B) and in 6 the eyes were entirely exposed (group C). Two independent readers assessed the scans for artifacts and their effect on the diagnosis.

Results: All but 1 child accepted the shield. Median dose reduction was 34% for group C, 20% for group B and < 2% for Group A.

Dose reduction was 5-30% less for children with distant shielding, compared to the reduction achieved for children in respective groups with direct shielding. Artifacts were noted in 1 scan, not considered to affect the diagnosis.

Conclusion: Direct eye-lens shielding should be applied in all children undergoing brain, sinuses, mastoid CT when the eyes are included entirely or partly in the scan. Resulting dose reduction is at least 20% reaching 43%. Shields are not of value when total eye-sparing technique is performed.

L. Natale; Rome/IT
E. Spüntrup; Aachen/DE

B-650 10:30

MR flow measurements in the coronary arteries before and after aortic valve surgery: Initial results

N.D. Abolmaali¹, M. Schiemann¹, V. Hietschold², A. Koch¹, P. Kleine¹, T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Dresden/DE

Purpose: To evaluate the velocity profiles in the coronary arteries before and after aortic valve surgery (AVS) in patients without coronary artery disease (CAD).

Material and Methods: 29 patients (median: 68 y) with angiographically excluded relevant CAD received MR-based coronary flow examinations of the LCA and the RCA (58 vessels) before and after AVS. Prospectively ECG-triggered breath hold phase-contrast flash sequences with high temporal resolution were used (1.5 T, Sonata). Noise reduction was done with the second order Savitzky-Golay equalization. Forward velocities and the foot of the curve related to the individual cardiac cycle time were analyzed.

Results: Before AVS, physiological velocity profiles were found in 38 CA (66%). Mean systolic/diastolic velocities were $14.8 \text{ cm/s} \pm 5.4$ / 23.5 ± 10.6 in the LCA and $12.1 \text{ cm/s} \pm 5.3$ / 13.9 ± 5.2 in the RCA. 20 CA showed non-physiological flow pattern pre-AVS, in part reverse flow was detectable. After AVS, 53 CA (91%) revealed physiological velocity profiles. Mean systolic/diastolic velocities increased significantly and were $20.8 \text{ cm/s} \pm 5.8$ / 27.4 ± 6.9 in the LCA and $15.5 \text{ cm/s} \pm 4.7$ / 17.6 ± 6.5 in the RCA. The foot of the heart cycle time of the velocity curves did not show significant differences before (LCA:34.0%; RCA:41.1%) and after (LCA:36.0%; RCA:42.9%) AVS. The velocity profiles of the remaining 5 CA showed steady forward velocities.

Conclusion: MR-based coronary flow measurements are capable of performing follow-up of aortic valve surgery. The increase in flow velocity after surgery, as well as the normalization of the velocity profiles can be quantified non-invasively. The MR-based detection of distorted flow patterns in the CA might add helpful information to the indication before aortic valve surgery.

Accuracy of whole heart coronary magnetic resonance angiography for the detection of significant coronary stenoses in 92 patients with suspected coronary artery disease

H. Sakuma¹, Y. Ichikawa², K. Makino², S. Chino², T. Hirano², K. Takeda¹, M. VanCauteren³; ¹Tsu, Mie/JP, ²Matsusaka, Mie/JP, ³Tokyo/JP

Purpose: The purpose of this study was to evaluate the diagnostic accuracy of whole heart coronary MRA for the detection of significant stenoses in the coronary arteries in patients with suspected coronary artery disease.

Methods and Materials: Ninety-two patients with suspected coronary artery disease were evaluated. Three dimensional coronary MR images covering the entire heart were obtained with a navigator-gated, steady state free precession sequence with radial k-space sampling (TR/TE = 4.6/2.3 ms, SENSE factor = 2, FOV = 280x280x120 mm, acquisition matrices = 256x256x80, reconstruction matrices of 512x512x160). All subjects underwent coronary angiography within two weeks of MRA. All coronary arteries and side branches with a diameter of 1.5 mm or more on coronary angiography were evaluated by two blinded observers, and luminal diameter reduction of 50% or more on quantitative coronary angiography was considered to be significant.

Results: The averaged acquisition time of whole heart coronary MRA was 13.3 ± 4.4 minutes. High quality images (score 3 or 4 on 4-point scale) were observed in all segments of the coronary arteries in 75 (82.0%) of the 92 patients. The sensitivity, specificity, positive and negative predictive values, and accuracy of the whole heart coronary MRA for detecting patients having at least one coronary arterial stenosis was 85.3%, 90.2%, 87.9%, 88.1% and 88.0%, respectively. The sensitivity and specificity were 93.3% and 95.0% for RCA, 82.4% and 94.8% for LAD, and 84.6% and 93.1% for LCX, respectively.

Conclusion: Whole heart coronary MRA with a navigator-gated steady state sequence can provide noninvasive detection of coronary artery disease with high diagnostic accuracy.

B-652 10:48

Feasibility of balanced steady-state free precession and conventional gradient echo for coronary magnetic resonance angiography at 3 Tesla

M.G. Kaul, A. Stork, P.M. Bansmann, C. Nolte-Ernsting, G.K. Lund, C. Weber, G. Adam; Hamburg/DE

Purpose: To investigate the feasibility of coronary magnetic resonance angiography with balanced steady-state-free-precession (b-TFE, TrueFISP) and gradient-echo (TFE, turboFLASH) sequences at 3 Tesla.

Material and Methods: 15 volunteers were investigated with a 3 T MR-scanner. TFE and b-TFE were fat-suppressed, T2-prepared and respiratory-motion-compensated. First RCA was imaged with both sequences. Additionally, LM/LAD was examined in 10 volunteers with TFE. The images were analysed by two investigators. RCA was subdivided into three segments, LM/LAD into four. Visibility was graded on a five point scale (0=not visualized, 4=excellent). Contrast-to-noise-ratio (CNR), length, diameter in the first 4 cm and sharpness of the vessels were analysed.

Results: All 15 main and proximal segments of RCA were visualized with TFE and b-TFE. 14 distal segments were seen with TFE and 9 with b-TFE. The graded visibility for the three segments was higher for TFE (2.6/2.6/1.4) than for b-TFE (1.8/1.6/0.9). Kappa-interobserver variability was 0.75 for TFE and 0.8 for b-TFE. CNR was higher for TFE (10.1 ± 3.4) than for b-TFE (6.6 ± 2.2 , $p < 0.02$). Length, diameter and sharpness of RCA were for TFE (95 ± 22 mm, 2.4 ± 0.3 mm, $62\% \pm 6$) and b-TFE (80 ± 40 mm, 2.4 ± 0.3 mm, $60\% \pm 5$). All ten main and proximal segments of LM/LAD were visible with grade 2.5 and 2.1. Middle segments were visible in 7 cases with grade 1.3. In 3 cases distal segments were visible with grade 0.5. Length, diameter and sharpness were (78 ± 27 mm, 2.5 ± 0.3 mm, $64\% \pm 7$) and CNR 11.9 ± 2.4 .

Conclusion: The TFE sequence proved to be superior to the balanced-TFE at 3 T. It seems that the balanced-TFE suffers from offresonance effects.

B-653 10:57

Navigator-gated cardiac-triggered 3D SSFP coronary MRA: Improved image quality using a short RF-pulse

K.M. Ruhl¹, M. Katoh¹, R.M. Botnar², R.W. Günther¹, E. Spüntrup¹; ¹Aachen/DE, ²Boston, MA/US

Purpose: The investigation of the impact of a short RF-pulse on image quality in free-breathing navigator-gated and cardiac-triggered 3D steady-state-free-precession (SSFP) coronary MR angiography (cMRA).

Methods and Materials: cMRA was performed in six healthy volunteers on a

1.5 Tesla MR system (Gyroscan Intera, Philips Medical Systems, Best, The Netherlands) using four navigator-gated and cardiac-triggered SSFP sequences: standard SSFP (sSSFP), SSFP applying the short RF-pulse resulting in a shorter TR/TE and a decreased acquisition window (spSSFPshort), SSFP with the short RF-pulse maintaining the TR/TE of the standard SSFP sequence (spSSFPlongT) and SSFP with the short RF-pulse increasing the acquisition window by adapting the profiles/cardiac cycle (spSSFPlongAQ). Vessel border was analyzed using an edge detection tool. In addition, signal-to-noise-ratio (SNR) and contrast-to-noise-ratio (CNR) of the coronary vessel were assessed.

Results: Mean vessel sharpness was 41.0 ± 2.3 for the sSSFP, 44.6 ± 5.3 for the spSSFPshort, 43.1 ± 6.3 for the spSSFPlongT and 42.8 ± 8.3 for the spSSFPlongAQ. Mean SNR was 30.1 ± 5.8 (sSSFP), 31.8 ± 6.3 (spSSFPshort), 31.7 ± 12.1 (spSSFPlongT) and 31.6 ± 7.5 (spSSFPlongAQ). Mean CNR was 21.8 ± 5.1 (sSSFP), 24.6 ± 5.1 (spSSFPshort), 25.4 ± 9.2 (spSSFPlongT) and 22.2 ± 4.2 (spSSFPlongAQ).

Conclusion: Increased vessel sharpness can be obtained in free-breathing 3D SSFP cMRA by using a short RF-pulse. Consequently shorter TR/TE results also in a more brief acquisition window.

Coronary magnetic resonance angiography using parallel acquisition techniques and intravascular contrast media

K.-U. Waltering, K. Nassenstein, S. Massing, T. Schlosser, P. Hunold, J. Barkhausen; Essen/DE

Purpose: To investigate the use of a parallel acquisition technique (PAT) for breath-hold MRCA in increasing the overall coverage.

Methods and Materials: 12 healthy volunteers (6 male, 6 female, mean age 30 ± 5 years, range 22 - 40) were included in this study. All examinations were performed on a 1.5 T MR scanner (Magnetom Sonata, Siemens). MRCA was performed using an inversion recovery prepared fast low angle shot (IR-FLASH) sequence (TR/TE 3.8/1.6 ms, bandwidth 490 Hz/pixel, matrix 320) after i.v. administration of a Gadolinium-based intravascular contrast media (SH L 643A, Schering). Scans were performed without and with PAT in a single breath-hold. The use of GRAPPA with a PAT-factor of 2 and 37 reference lines allowed increasing spatial coverage. Signal-to-noise-ratio (SNR) and contrast-to-noise-ratio (CNR) values were calculated. Image quality was assessed based on a 5-point Likert scale ranging from 1=excellent to 5=non-diagnostic.

Results: The mean image quality score was higher for FLASH imaging without PAT (2.9 ± 0.8) compared to MRCA with parallel imaging (3.5 ± 0.9). Signal intensity measurements showed higher SNR for FLASH imaging without PAT (blood pool: 15.7 ± 2.8 versus 13.0 ± 3.6), whereas the CNR measurements showed no significant differences (12.2 ± 2.6 versus 10.4 ± 3.3).

Conclusion: Our results show that GRAPPA with a PAT-factor of 2 allows increasing spatial coverage without increasing the acquisition time. Although, overall image quality and SNR values were slightly reduced, delineation of the proximal and middle coronary segments was possible.

B-655 11:15

MR flow measurements in the coronary arteries: First results in patients without coronary artery disease

N.D. Abolmaali¹, M. Schiemann¹, V. Hietschold², A. Koch¹, P. Kleine¹, T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Dresden/DE

Purpose: To evaluate the feasibility of MR-based coronary flow measurements in patients without coronary artery disease (CAD) after aortic valve surgery.

Material and Methods: 70 patients (median: 67 y) with angiographically excluded relevant CAD received MR-based coronary flow measurements of the proximal segments of the LCA and the RCA (140 vessels). Using a prospectively ECG-triggered breath hold phase-contrast flash sequence (1.5 T, Sonata) with high temporal resolution, flow data were technically acquirable in 115 (82%) of the coronary arteries (CA). To reduce noise in the velocity quantification, the flow curves were filtered using the second order Savitzky-Golay equalization. Early and late forward velocities and the foot of the curve related to the individual cardiac cycle time were analyzed.

Results: Physiological velocity profiles were only found in 55 CA (48%). Mean systolic and diastolic velocities in these CA were significantly higher in the LCA ($21 \text{ cm/s} \pm 5.8$; $25 \text{ cm/s} \pm 8.0$) than in the RCA ($14.4 \text{ cm/s} \pm 5.4$; $16.1 \text{ cm/s} \pm 6.5$). The time of the foot of the heart cycle time of the velocity curves did not show significant differences (LCA: 37.5%; RCA: 40.9%). The velocity profiles of the remaining CA revealed severe alterations of the physiologic velocity profile with reduced flow undulations and steady velocities but forward flow was measurable in all CA.

Scientific Sessions

Conclusion: MR based coronary flow measurements were possible in most patients. Physiological velocity profiles were derivable from the acquired data sets. In the LCA, blood velocity is higher than in the RCA. Optimized MR flow measurements are feasible to evaluate the CA non-invasively in patients without CAD.

B-656 11:24

Comparison of conventional free-breathing coronary magnetic resonance angiography with affine motion compensated whole-heart MRA at 3 Tesla
M.G. Kaul, P.M. Bansmann, A. Stork, C. Nolte-Ernsting, K. Nehrke, G. Adam; *Hamburg/DE*

Purpose: To compare conventional free-breathing coronary magnetic resonance angiography (cMRA) with affine motion compensated whole-heart MRA (whMRA) at 3 Tesla.

Materials and Methods: Five volunteers were examined with a whole-body 3 T scanner (Philips Medical System, Netherlands) in combination with a vector-ECG and a six-element phased-array cardiac coil. Navigator driven prospective respiratory motion compensation for the segmented gradient-echo sequences was used. Double oblique scans of the RCA were performed with a gating window (GW) of 5 mm and a correlation of 0.6. The whMRA scan was performed with a 20 mm GW and a patient-specific affine motion compensation. CNR, visualized vessel length, diameter and vessel sharpness of the visualized coronaries were statistically analyzed.

Results: The mean scantime for whMRA was 12 min with a scan efficiency of 98% and 7 min for cMRA with a scan efficiency of 61%. In all volunteers, all major segments of the RCA were visualized. A significant increase in CNR with whMRA in comparison with cMRA was observed ($7.0 \pm 1.5 / 10.1 \pm 1.9 / p < 0.023$). The vessel length was measured longer for whMRA than for cMRA ($10.0 \pm 2.4 \text{ mm} / 11.6 \pm 1.8 \text{ cm} / p < 0.25$), while the vessel diameter was measured smaller for cMRA ($2.46 \pm 0.21 / 2.76 \pm 0.27 / p < 0.66$). A similar vessel sharpness ($0.59 \pm 0.6 / 0.60 \pm 0.02 / p < 0.76$) was estimated for cMRA and whMRA. For the whMRA also the left coronary arteries were visualized.

Conclusion: Comparable results for the affine motion compensated whMRA and the cMRA have been demonstrated. The whMRA shows up to be a time saving procedure because in a single scan information of all coronary arteries can be found.

B-657 11:33

Slice-selective inversion prepared steady-state free-precession (SSFP) MR angiography: Visualization of inflowing coronary blood

M. Katoh¹, E. Spüntrup¹, M. Stüber², A. Buecker¹, W.J. Manning³, R.W. Günther¹, R.M. Botnar³; ¹Aachen/DE, ²Baltimore, MD/US, ³Boston, MA/US

Purpose: Visualization of inflowing coronary blood by means of an inversion prepared bright-blood coronary MRA approach.

Materials and Methods: The right coronary artery (RCA) of seven volunteers (6 men, 1 woman, 39 years) was imaged on a 1.5 Tesla MR system (Gyroscan ACS-NT, Philips Medical Systems, Best, NL) using a navigator-gated cardiac-triggered 3D SSFP sequence with radial k-space sampling (TR/TE 6.3/3.2 ms, FA 120, FOV 360 mm², matrix 384 radial trajectories, spatial resolution 0.9x0.9x3 mm³). Imaging was performed a) with and b) without a slice-selective inversion prepulse, which was positioned along the main axis of the RCA. Hence, RCA and adjacent tissue included in the inversion volume are signal suppressed while unsaturated blood from the ascending aorta that subsequently enters into the coronary artery during an inversion delay appears with a bright signal. SNR, CNR, maximal visible vessel length, and vessel border definition were analyzed.

Results: The use of a selective inversion pre-pulse allowed for direct visualization of inflowing coronary blood. In addition, CNR between the RCA and right ventricular blood was increased (13 vs. 1; $p < 0.01$) and a tendency towards better vessel sharpness was found (68 vs. 60; n.s.). Blood SNR and CNR between RCA blood and epicardial fat were comparable in both sequences.

Conclusion: The combination of a free-breathing navigator-gated and cardiac-triggered 3D SSFP sequence with a slice-selective inversion pre-pulse allows for direct and directional visualization of inflowing coronary blood with the additional benefit of improved contrast between the RCA and right ventricular blood.

B-658 11:42

MR coronary vessel wall imaging: Comparison of radial and spiral k-space sampling

M. Katoh¹, E. Spüntrup¹, A. Buecker¹, W.J. Manning², R.W. Günther¹, R.M. Botnar²; ¹Aachen/DE, ²Boston, MA/US

Purpose: The aim of this study was to compare navigator-gated and cardiac-triggered 3D gradient-echo MR coronary vessel wall imaging using radial and spiral k-space sampling.

Materials and Methods: Right coronary artery vessel walls of eight healthy volunteers (6 men, 2 women; mean age: 37 years) were imaged on a 1.5 Tesla MR system (Gyroscan ACS-NT, Philips Medical Systems, Best, NL) using two double-inversion prepared black-blood gradient-echo sequences (radial: TR/TE 8.0/2.0 ms, FA 30, excitation/cardiac cycle 13; spiral: TR/TE 30.0/2.0 ms, FA 45/90, spiral interleaves 42, excitation/cardiac cycle 2) with identical spatial resolution (0.6 x 0.6 x 2.0 mm³). For data analysis, SNR, CNR and vessel wall definition were objectively analyzed. Furthermore, two investigators blinded to sequence parameters subjectively assessed image quality in terms of artifacts and vessel wall visualization.

Results: Radial k-space sampling demonstrated fewer artifacts and led to improved visualization of the coronary vessel wall compared to spiral imaging. In addition, significantly better vessel wall definition was found in radial imaging ($62 \text{ vs. } 56, p < 0.05$). However, a tendency towards increased SNR and CNR were found using spiral k-space sampling (n.s.).

Conclusion: Radial k-space sampling in free-breathing navigator-gated and cardiac-triggered MR imaging of the coronary vessel wall resulted in fewer motion artifacts and improved vessel wall definition compared to spiral k-space sampling.

B-659 11:51

Role of magnetic resonance angiography in coronary artery ectasia and Kawasaki disease

S.I. Mavrogeni, D.D. Cokkinos, A. Manginas, G. Papadopoulos, M. Douskou, S. Kaklis, S. Foussas, J. Seimenis, D.V. Cokkinos; *Athens/GR*

Purpose: Coronary artery ectasia (CAE) is defined as dilatation to a diameter at least 1.5 times of the normal. Differential diagnosis includes aneurysm due to Kawasaki Disease (KD). We compared each vessel's most ectatic/aneurysmatic diameter using quantitative coronary angiography (QCA) and MRA.

Methods and Materials: Twenty patients with isolated CAE 45-65 years old, 10 patients with KD 1-12 years y.o. and 5 controls with normal coronaries 45-55 y.o. were studied. Coronary MRA was performed using a 1.5 T Philips Intera CV MR scanner with two ECG-triggered pulse sequences, a 3-D segmented k-space GRE sequence (TE = 2.1 ms, TR = 7.5 ms, flip angle = 30°, eff. slice thickness = 1.5 mm) employing a T2W preparation prepulse and a frequency selective fat-sat prepulse to enhance "bright blood" coronaries' contrast. Data acquisition was performed in mid-diastole. We used a 2D real time navigator beam placed on the right hemidiaphragm. All patients underwent QCA. The diameter of the proximal/ middle most ectatic/ aneurysmatic part of each vessel was measured and compared to MRA.

Results: In CAE there was close correlation between MRA and QCA in the diameter ($r = 0.87, p < 0.001$) and length ($r = 0.82, p < 0.001$) of the most ectatic vessel part. In 7 patients with KD, aneurysms were identified. CAE alone was present in the remaining 3 patients. MRA-QCA differentiation of discrete aneurysms vs. ectasia showed complete agreement. In controls, no abnormalities were seen.

Conclusion: MRA is equivalent to QCA for coronary artery anatomy in patients with CEA and KD. It may prove of great value for serial noninvasive evaluation.

Comparison of angular and combined automatic tube current modulation techniques with constant tube current CT scanning of the abdomen and pelvis

S.M.R. Rizzo¹, M.K. Kalra¹, M.A. Blake¹, T. Dalal¹, M.M. Maher¹, B. Schmidt², C. Suess², T. Flohr², S. Saini³; ¹Boston, MA/US, ²Forchheim/DE, ³Atlanta, GA/US

Purpose: To compare image quality and radiation dose associated with abdominal-pelvic CT using combined modulation, angular modulation and constant tube current.

Methods and Materials: Study cohort included 152 patients (mean age = 60 years, range = 25-101 years; M:F = 78:74) undergoing abdominal-pelvic CT with a 16-slice MDCT (Sensation 16, Siemens Medical Solutions) using either angular modulation ($n = 42$), combined modulation (weak decrease-strong increase type, $n = 42$, or average decrease-average increase type, $n = 37$; image quality reference mAs 160) or constant tube current ($n = 31$; effective mAs = 160-200). Remaining scanning parameters (held constant) included 140 kVp, 0.5 s rotation time, 16x1.5 mm detector configuration, 24 mm table feed per gantry rotation and 5 mm reconstructed slice thickness. Two radiologists assessed image noise, diagnostic acceptability, presence of streak artifacts and visibility of small structures at three levels (confluence of the hepatic veins, porta hepatis, and acetabulum). Quantitative image noise at the porta hepatis level, patients' weight, CTDIvol and DLP were recorded.

Results: Subjective noise and diagnostic acceptability in studies performed with angular modulation, combined modulation or constant tube current were acceptable. Compared to constant tube current, combined modulation resulted in 42% (weak decrease-strong increase type) to 44% (average decrease-average increase type) reduction in radiation dose ($p < 0.0001$), whereas angular modulation resulted in a 19% reduction ($p < 0.0001$). Significant correlation was found between patients' weight, CTDI-vol and DLP for combined modulation ($r = 0.6-0.8$, $p < 0.0001$) but not with constant tube current or angular modulation ($r = 0.01-0.19$, $p > 0.2$).

Conclusion: Compared to constant tube current scanning of abdominal-pelvic CT, combined modulation results in substantial reduction (42-44%) in radiation dose with acceptable image noise and diagnostic acceptability.

B-661 10:39

Impact of the z-flying focal spot (zFFS) on resolution and artifact behaviour for a 64-slice spiral-CT scanner

Y. Kyriakou, M. Kachelriess, M. Knaup, J.U. Krause, W.A. Kalender; Erlangen/DE

Purpose: To verify the effect of the zFFS by measurement with respect to resolution and artifact behaviour for a 64-slice spiral CT.

Methods and Materials: The Sensation 64 CT scanner (Siemens Medical Solutions, Forchheim, Germany) allows measuring of 64 overlapping slices of 0.6 mm thickness. The zFFS switches between two z-positions acquiring two slices per detector row which results in oversampling in the z-direction. We implemented a modified ASSR reconstruction (syngoeplorer, VAMP, Möhrendorf, Germany) that is able to obtain images as they would be without zFFS. A delta phantom equipped with a tiny gold disc was used to measure the slice sensitivity profiles (SSP). We evaluated the SSPs for standard spiral scan modes for various pitch values with and without the zFFS. A high-contrast bar phantom was used to quantify the resolution in the x/z-plane for both cases. Further, we performed cadaver and phantom measurements to determine the effect of the zFFS on spiral windmill artifacts.

Results: Applying the zFFS decreased the FWHM of the SSPs by a factor of about 1.4. The z-oversampling allowed the separation of 0.4 mm bars in the z-direction compared to 0.6 mm in the case of no zFFS. The zFFS reduced windmill artifacts in the reconstructed images while maintaining the transverse resolution even at the largest pitch value of 1.5.

Conclusions: Oversampling in the z-direction by means of the zFFS achieves a high spatial resolution in the z-direction of 0.4 mm, whilst diminishing the effect of spiral windmill artifacts.

B-662 10:48

Validating measures for temporal resolution on multi-slice CT scanners (MSCT)

K. Shanneik, M. Kachelrieß, S. Achenbach, W.A. Kalender; Erlangen/DE

Purpose: To evaluate the temporal resolution of modern MSCT scanners by introducing and validating numerical indicators for temporal resolution.

Methods and Materials: Computer simulations and a dynamic phantom assembly yielding a realistic 3D motion of the human heart were used to move a 100 μm tungsten bead. Heart rates were varied from 40-120 min⁻¹. Data were acquired from standard cardiac scans (pitch = 0.23, rotation time = 0.37 s) on a Sensation 64 CT scanner (Siemens Medical Solutions, Forchheim, Germany) and reconstructed with the ASSR algorithm at cardiac phases ranging from 0-90% R-R interval in 10% steps. We considered the full 3D properties of the point spread function to define the full volume at half maximum (FVHM). Correlation of the FVHM with visually assessed image quality, rated by 6 specialists, and also to the expected theoretical temporal resolution given by the phase contribution profile (PCP) were investigated.

Results: Simulations show that increasing the rotation speed from 0.5 s to 0.33 s improves FVHM results for heart rates between 105-120 min⁻¹ indicating better temporal resolution. Measurements for different reconstruction phases and gantry rotation times showed a good correlation of the FVHM with the PCP of the algorithm (Spearman's rank correlation $r = 0.85$). E.g. at an exemplary cardiac phase of 50% R-R, the FVHM ranged from 2.9 mm³ (no motion) to 9.8 mm³ over the range of heart rates.

Conclusion: The FVHM is an objective and reproducible measure of the temporal resolution, and correlates well with visual impression of image quality.

B-663 10:57

Large field-of-view ultrahigh-resolution flat-panel CT imaging system

J. Eberhard, W.R. Ross, S.K. Basu, P. Fitzgerald, M.A. Rumsey, A.M. Schmitz, B.D. Yanoff, C.J. Ritchie; Niskayuna, NY/US

Purpose: To develop an ultrahigh-resolution experimental clinical CT system, and evaluate the impact of ultrahigh-resolution CT on clinical applications.

Methods and Materials: Three 20 cm square (1024x1024, 200 μm pixels) flat panel detectors were integrated side by side in a clinical CT gantry, incorporating a vascular X-ray source (all components from GE Healthcare) to provide a 50 cm field-of-view (FOV). The detectors were modified to reduce gaps between them to 3.4 cm. Operating modes acquire 500-1000 projections of 180-360 detector rows, at 8 seconds per rotation. System magnification is 1.5; z-coverage per rotation ranges from 17-34 mm. A Beowulf cluster provides short reconstruction times.

Results: A cone-beam reconstruction algorithm that corrects for the gaps between detectors provides uniform image quality over the FOV. Spatial resolution of < 200 microns (MTF > 25 lp/cm, 10% modulation) is uniform over the central 35 cm of the FOV, in both the radial and azimuthal directions. Reconstruction times are 3 minutes for 512x512x180 voxels.

Conclusions: The first ultrahigh-resolution CT system capable of clinical imaging has been developed. Uniform image quality and ultrahigh isotropic spatial resolution have been achieved over a FOV covering the human thorax. The volumetric resolution, > 10X higher than current multi-slice CT systems, provides the ability to precisely quantify volumes on the order of a few mm³. This improved resolution may enable sufficiently precise lung tumor sizing to determine doubling times more quickly, potentially leading to earlier and more accurate diagnosis. In addition, this exceptional performance may enable new clinical CT applications, especially in the area of lung cancer detection.

Cone beam filtered back projection algorithms for image reconstruction in volumetric CT

X. Tang¹, J. Hsieh¹, A. Hagiwara², R.A. Nilsen¹, C. Shaughnessy¹, E.C. Williams¹, E. Drapkin¹; ¹Waukesha, WI/US, ²Hino/JP

Purpose: With increased cone angle, maintaining reconstruction accuracy in volumetric CT becomes more challenging. To obtain well-balanced image qualities,

Scientific Sessions

we propose a novel CB-FBP reconstruction algorithm using 3D view weighting (3D-VW) for both helical and axial scanning geometries, along with a comprehensive experimental evaluation.

Methods and Materials: Through a row-wise fan-to-parallel rebinning, the filtering in the proposed algorithm is naturally carried out along the tangential direction of source trajectory. The 3D-VW is utilized to: (a) suppress artifacts at both axial and helical scanning geometries; (b) improve noise characteristics by allowing redundant projection data in reconstruction; (c) extend FOV at high helical pitches by maintaining data redundancy. Both simulated and scanned projection data (detector dimension: 64x0.625 mm) are used for algorithm evaluation.

Results: At helical mode, the 3D-VW enables the proposed algorithm to reach the reconstruction accuracy possessed by the exact CB-FBP algorithms while providing significantly improved noise characteristics, spatial resolution and temporal resolution. At axial mode, the 3D-VW is dependent on individual reconstruction plane and suppresses CB artifact substantially in comparison to the original FDK algorithm. Moreover, a comparison study shows that, the proposed algorithm outperforms other reconstruction algorithms, such as the titled-plane-based algorithms, in term of artifacts suppression even with large FOV at very high helical pitches.

Conclusions: It is the 3D-VW that assures the proposed algorithm to obtain optimal image qualities and the freedom in image quality controllability. It is believed that the proposed algorithm is applicable in and robust over diagnostic and functional CT imaging applications.

B-666 11:15

Conjugate cone beam back projection scheme for VCT thin slice imaging

J. Hsieh, X. Tang, J.-B. Thibault, C. Shaughnessy, E. Williams, D. Samsonov; Waukesha, WI/US

Purpose: One of the important CT performance parameters is the z-resolution. This parameter is impacted not only by the spot size, detector aperture, and geometry, but also by the reconstruction algorithm. We present a conjugate cone beam back projection approach that allows the reconstructed slice thickness comparable to the detector aperture.

Methods and Materials: One key step in the filtered back projection reconstruction algorithms is the three-dimensional back projection. The most widely used method is the row-to-row interpolation (interpolation takes place between two rows of the same view). The drawback of this approach is a degraded z-resolution. In this paper, we present a conjugate interpolation (CI) in which interpolation takes place between dynamically selected conjugate projection samples that are 180° apart. When appropriate helical pitch is selected, the conjugate rays form interlaced samples along z. For computation simplicity, a row-wise fan-parallel rebinning is first applied.

Results: Theoretical analysis has shown that CI enables a 30% improvement in SSP, as compared to the conventional back projection. This result is confirmed with a thin foil phantom. For a 64x0.625 mm acquisition, FWHM was measured at 0.6 mm, as compared to 0.84 mm for conventional back projection. The 0.4 mm air bars in the AAPM phantom insert can be clearly visualized with the proposed reconstruction.

Conclusion: Theoretical and phantom experiments have shown that CI algorithm enables a 30% improvement in SSP, as compared to the conventional method. It allows a simpler and more robust VCT system design.

B-667 11:24

Influence of increasing convolution kernels filtering on plaque imaging with multislice CT using an ex-vivo model of coronary angiography

G. Runza¹, F. Cademartiri², N.R. Mollet², M. Belgrano³, F. Barbiera⁴, M. Midiri¹, R. Hamers², N. Bruining²; ¹Palermo/IT, ²Rotterdam/NL, ³Trieste/IT, ⁴Sciaccia/IT

Purpose: To assess the variability in attenuation of coronary plaques with multislice CT-angiography (MSCT-CA) in an ex-vivo model with varying convolution kernels.

Methods and Materials: MSCT-CA (Sensation 16, Siemens) was performed in three ex-vivo left coronary arteries after instillation of contrast material solution (Iomeprol 400 mg/ml, dilution: 1/80). The specimens were put into oil to simulate the epicardial fat. Scan parameters: slices 16/0.75 mm, rotation time 375 ms, feed/rotation 3.0 mm, mAs 500, slice thickness 1 mm and FOV 50 mm. Datasets were reconstructed using 4 different kernels (B30f-smooth, B36f-medium smooth, B46f-medium and B60f-sharp). Each scan was scored for the presence of plaques. Once a plaque was detected, the operator performed attenuation measurements (HU) in coronary lumen, oil, calcified and soft plaque tissue using the same settings in all datasets. The results were compared with T-test and correlated with Pearson's test.

Results: Significant differences ($p < 0.05$) were found for the mean attenuation of lumen (B30f/B36f, B30f/B60f, B36f/B46f, B36f/B60f, and B46f/B60f), oil (B30f/B36f, B30f/B60f, B36f/B46f, and B46f/B60f), calcium (all kernels) and plaque (B30f/B36f, B30f/B46f, B30f/B60f, and B46f/B60f) using 4 different kernels. The attenuation values (mean \pm SD) within the lumen (246 \pm 6, 215 \pm 13, 248 \pm 5, and 270 \pm 7), oil (-123 \pm 3, -127 \pm 1, -121 \pm 6, and -127 \pm 4), calcified plaque tissue (703 \pm 334, 739 \pm 364, 817 \pm 381, and 1181 \pm 503) and soft plaque tissue (134 \pm 56, 111 \pm 49, 120 \pm 56, and 102 \pm 41) showed high correlation ($p < 0.01$). When attenuation of all structures were compared in different kernels.

Conclusion: Use of sharper convolution kernels significantly increases the attenuation of the calcium within coronary plaques and reduces the attenuation of soft plaque tissue.

B-668 11:33

Real-time prediction of the heart phase for tube current modulation (TCM) by kymogram detection from spiral CT scans of the heart

D. Ertel, M. Kachelriess, D.-A. Sennst, W.A. Kalender; Erlangen/DE

Purpose: To provide a rawdata-based synchronization signal alternative to the commonly used ECG as a basis for online heart-phase dependent TCM.

Method and Materials: The synchronization signal -the kymogram function- is generated by three different methods: A derivation of the projected mass with respect to the view angle, the difference of the projected mass after half a rotation and the published method [Med. Phys., 29 (7):1489-1503, 2002] based on a center-of-mass tracking of the scanned object. The technique to compute a kymogram is enhanced to be performed in real time. We used data of 12 patients scanned with a collimation of 12°*0.75 mm, a table increment of 2.8 mm/rotation, a rotation time of 0.42 s and a concurrent ECG recording (Sensation 16, Siemens, Forchheim, Germany). The signal extrapolation is performed on basis of the normalized least-mean-square algorithm by predicting the heart rate according to the prior values. The real-time capability of the kymogram calculation was verified by observing the time needed for signal processing with a standard PC.

Results: In 9 of 12 patient data-sets our method achieved a high correlation with the ECG. The derivation of the projected mass with respect to the view angle showed the least reliable results. All three methods satisfied the prerequisite of being able to perform in real time.

Conclusion: Sync peaks predicted on the basis of a kymogram correlated well with the ECG in most cases. We conclude that a kymogram-based tube current modulation for dose reduction in cardiac CT is feasible.

B-669 11:42

Assessment of automatic exposure control systems on CT scanners using a custom made phantom

N. Keat, M. Aplin, S. Edyvean, D.J. Platten, M.A. Lewis; London/UK

Purpose: Automatic exposure control (AEC) systems are now available on CT scanners from the four major manufacturers. These systems compensate for changes in attenuation of the X-ray beam by adjusting the tube current (mA). A phantom has been developed and used to test the capabilities of these systems to control image quality and radiation dose.

Method and Materials: A 300 mm long, cone shaped PMMA (Perspex) phantom with an elliptical cross section (major and minor diameters increasing from 61.2x40.8 to 428.7x285.8 mm) was constructed. The phantom was tested on four sixteen-slice CT scanners. The mA used by the scanner gave information on relative radiation dose with AEC on and off, and image quality was characterised using the standard deviation of the CT number values.

Results: Each AEC system used different methods for scan setup and implementation of exposure control. Selected results will be presented. For example, the GE scanner allows the user to set a required image noise level, which the AEC aims to achieve by setting the mA for each rotation. A helical scan (pitch 0.938, length 150 mm) with the noise index set to 8 gave measured noise values between 7.1 and 9.5 (mean of 7.9).

Conclusions: The elliptical cone phantom was capable of assessing the performance of AEC systems. All were largely successful in achieving their aims. Introduction of AEC systems into clinical use requires understanding of their operation so that the aims of consistent image quality and optimised patient radiation dose are achieved.

Flare-up arthritis imaging with native Cy5.5 versus albumin bound Cy5.5

A. Hansch, I. Hilger, O. Frey, D. Sauner, A. Malich, J. Boettcher, R. Brauer, W.A. Kaiser; Jena/DE

Purpose: The aim of our study was to visualize arthritis with near-infrared fluorescence imaging (NIRF) in a murine arthritis model. The flare-up arthritis is an established arthritis model for human rheumatoid arthritis. NIRF was done for two preparations of the fluorochrome Cy5.5, one native, the other albumin conjugated. Albumin uptake is increased in arthritic joints.

Methods and Materials: Flare-up arthritis was induced in 8 mice. On day 7 after induction of flare-up arthritis, 4 mice received 50 nmol/kg Cy5.5 and 4 mice equimolar concentrations of the dye as albumin-dye conjugate intravenously. NIRF imaging was performed immediately before injection (baseline) and until 72 hours thereafter.

Results: NIRF imaging revealed higher fluorochrome uptake in all inflamed knees compared to contralateral ones. Cy5.5 labeled albumin uptake in arthritic joints was lower than native Cy5.5 uptake (e.g. mean signal intensity in arthritic knee joints 2 hours after application of Cy5.5 labeled albumin: 864a.u. \pm 89 and after application of Cy5.5: 1235a.u. \pm 102).

Conclusion: Imaging of flare-up arthritis with NIRF is feasible. Albumin conjugation prior injection does not improve the uptake of dye in arthritic joints. Therefore native dye seems to be favorable for arthritis imaging with NIRF.

B-671 10:39

Synthesis of a combined optical/MR imaging contrast agent for imaging endothelial E-selectin expression

M.A. Funovics¹, R. Weissleder², F. Reynolds², L. Josephson²; ¹Vienna/AT,

²Boston, MA/US

Purpose: Receptor-specific molecular imaging is limited by compartmental delivery barriers, lack of high affinity in monovalent receptor-probe interactions, and lack of efficient coupling chemistries to generate suitable multivalent systems. We attempted to overcome these problems by synthesizing a multivalent conjugate specifically targeting E-Selectin, which is upregulated on vascular endothelium in inflammation.

Methods and Materials: Two linear peptides containing DITWDQLWDLMK (sequence_1) and IELLQAR (sequence_2), which have been reported to bind to human E-selectin were synthesised and coupled to a nanoparticle consisting of an iron oxide core coated with cross-linked FITC-labelled aminodextran. Peptides were coupled C- and N-terminally using neutral or negatively charged spacer amino-acids by reacting the particle with N-hydroxysuccinimide esters to yield thioether- and disulfide-linkages, respectively, to the terminal cysteine of the peptide (@6-27_peptides/nanoparticle). The conjugates were incubated on stimulated and receptor negative unstimulated human umbilical vein endothelial cells. Amounts of bound conjugate were compared using a competitive anti-FITC immunoassay, FACS, and confocal microscopy.

Results: Particles containing sequence_1 showed no selective binding, the peptide containing sequence_2 with N-terminal attachment and negatively charged linker arm (S4) showed the specific affinity to e-selectin. During 4 h-incubations with 80-320fM conjugate, S4-binding was 80-1200x higher compared to neutral linker arm peptide, and 200-10000x higher compared to C-terminally attached peptide. Maximal uptake of S4-conjugate was 0.1 fmol/cell. Unstimulated cells showed at least 80x less uptake. Stimulated cells after incubation were brightly fluorescent due to receptor-mediated endocytosis of the conjugate.

Conclusion: A nanoparticle for receptor imaging of E-Selectin has been developed using a multivalent peptide-nanoparticle conjugate and has been used for imaging in vivo and in vitro.

B-672 10:48

MR imaging of Her-2/neu protein using high-affinity magnetic nanoparticles

C. Fritzsche, I. Hilger, R. Trost, J.R. Reichenbach, W.A. Kaiser; Jena/DE

Purpose: To detect Her-2/neu overexpressing tumor cells in vitro and in animal tumor models by MR imaging using high affinity magnetic nanoparticles.

Methods and Materials: High affinity magnetic nanoparticles (probes) were designed by coupling anti-Her-2/neu antibodies or gamma globulin (4 micrograms protein per milligram Fe). Her-2/neu overexpressing cells (SK-BR-3) were incubated with anti Her-2/neu (high affinity) and gamma globulin (non-affinity) labelled magnetic nanoparticles. Cell labelling was investigated MR imaging (1.5 T, Magnetom Vision, Siemens) using an inversion recovery sequence and verified by electron microscopy. Moreover, probes (high affinity or non-affinity, approximately 2 mg Fe) were injected into the tail vein from Her-2/neu over-expressing (SK-BR-3) and normal expressing tumor (MX-1) bearing mice (n = 8). Images were recorded before and 20 min, 6 and 24 hours after probe application using T1, T2 and PD spin echo sequences in coronal orientation. Signal intensity at the tumor region was analyzed in relation to normal tissue.

Results: In vitro, Her-2/neu overexpressing cells incubated with high affinity magnetic nanoparticles showed distinctly lower T1 relaxation times as compared to the treatment with non-affinity probes. Electron microscopic examinations were in agreement with MR imaging findings. In vivo whole body MR imaging showed a distinct relative decrease (-20%) in signal intensity in Her-2/neu overexpressing tumors after application of the high affinity probe as compared to controls (e.g. normal expressing tumors with high or non-affinity probes).

Conclusion: The whole body molecular detection of Her-2/neu overexpressing tumors using clinical MR imaging with high affinity magnetic nanoparticles is feasible.

B-673 10:57

The study of Gd-labelled liposomes with long circulation time

D. Zhang; Shanghai/CN

Purpose: To study Gd-labelled liposomes with long circulation time.

Methods and Materials: A 3/2/0.15(mole ratio) blend of HSPC (hydrogenated soy phosphatidyl choline), Chol (cholesterol) and mPEG-HSPE (methoxy poly ethylene glycol hydrogenated soy phosphatidyl ethanolamine) was employed for long circulating liposome preparation by the thin film hydration method. The blend was dissolved in chloroform. Then the solvent was rotary evaporated to dryness and the resulting film was further dried under vacuum over night. The lipids were hydrated with 0.5 mol/L Gd-DTPA. The lipid dispersion was allowed to swell for two hours and was then subjected to five freeze-thaw cycles in liquid nitrogen and warm water respectively. The liposomes was then passed through 0.08-0.1um polycarbonate membranes using a Lipex extruder, to give primarily vesicles of approx. 100 nm in diameter. Untrapped Gd-DTPA was removed by dialysis against isosmotic glucose solution. The effective Gd concentration within the liposome was determined by inductively coupled plasma atomic emission spectrophotometry. MR imaging scan was performed after the liposome was injected intravenously into rat with glioma.

Results: The mean intensity-weighted diameter of the liposome preparation ranged from 71 to 376 nm. The polydispersity index, a numerical expression of the breadth of the size distribution, varied from 0.13 to 0.22. MR imaging scan showed that the tumor had obviously contrast, but liver and spleen had no obviously contrast.

Conclusion: The Gd-labelled long circulating liposome can not be phagocytized by the cells of the reticuloendothelial system. It is possible to make targeted enhancement MR imaging by binding antibody or peptide to the surface of the liposome.

B-674 11:06

MR imaging of the Her2/neu and 9.2.27 tumor antigens using immunospecific contrast agents

M.A. Funovics, B. Kapeller, K. Macfelda; Vienna/AT

Purpose: Molecular imaging of tumor antigens using immunospecific MR contrast agents is a rapidly evolving field, which can potentially aid in early disease detection, monitoring of treatment efficacy, and drug development. In this study, we designed, synthesized, and tested in vitro, two novel monocrystalline iron oxide nanoparticles (MION) conjugated to antibodies against the her2/neu tyrosine kinase receptor and the 9.2.27 proteoglycane sulfate.

Methods and Materials: MION was synthesized by coprecipitation of iron(II) and iron(III) salts in 12 kD-dextran solution, antibody coupling was performed by reductive amination. The relaxivity of the conjugates was 24.1-29.1 mM-1sec-1,

Scientific Sessions

with 1.8-2.1 antibody molecules per nanoparticle. A panel of cultured melanoma and mammary cell lines was used for testing. The cells were incubated with the particles at 16-32 µg Fe/ml in culture medium for 3 h at 37 °C, and investigated with immune fluorescence, transmission electron microscopy (TEM), MR imaging of cell suspensions in gelatine, and spectrophotometric iron determination.

Results: All receptor-positive cell lines, but not the controls, showed receptor-specific immune fluorescence, and strong changes in T2 signal intensity at 1.5 T. The changes in 1/T2 were between 1.5-4.6 sec-1 and correlated with the amount of cell-bound iron ($R = 0.92$). The relaxivity of cell-bound MION increased to 55.9 ± 10.4 mM⁻¹sec⁻¹. TEM showed anti-9.2.27 conjugates binding to the plasma membrane, while the anti-her2/neu conjugates underwent receptor-mediated endocytosis.

Conclusion: We obtained receptor-specific T2 MR contrast with novel covalently bound, multivalent MION conjugates with anti-9.2.27 and anti-her2/neu to image tumor surface antigens. This concept can potentially be expanded to a large number of targets and to in vivo applications.

B-675 11:15

Whole-body MR imaging in staging cancer patients: A comparison with conventional CT and MR imaging

N.A. Ghanem, P. Franke, G. Pache, T. Bley, J. Winterer, M. Langer; *Freiburg/DE*

Purpose: Comparison of whole-body MR imaging and conventional CT and MR imaging in tumor detection and staging in cancer patients.

Methods and Materials: 103 patients were studied prospectively by whole-body MR imaging (WBM). The WBM examinations were performed using the rolling table platform "angiosurf" for unlimited field of view with a 1.5 Tesla system (Magnetom Sonata, Siemens, Erlangen, Germany). A coronal STIR-sequence was used for imaging of the different body regions. The findings of conventional CT and MR imaging and WBM were compared using region by region analysis evaluating the primary tumor, lymph nodes, bone and visceral metastases.

Results: In respect of tumor detection ($n = 64$), WBM and conventional CT and MR imaging concordantly revealed a tumor in 42 patients and in 15 patients both imaging techniques excluded a tumor. In 5 patients CT and MR imaging was positive, whereas WBM was false negative. In 2 patients WBM was superior to CT and MR imaging by detecting the primary tumor. In comparison to conventional CT and MR imaging, WBM detected only 39/50 lymph node metastases, 14/22 visceral metastases, 5/28 pulmonary metastases and 70/76 bone metastases. However, WBM revealed 163 new pathologies due to its band-width which were missed by conventional investigations.

Conclusion: WBM is an effective and fast method for examining cancer patients by the use of a rolling table platform. The wide range of WBM eases detection of new pathologies, but cannot reach accuracy of conventional CT and MR imaging.

B-676 11:24

Positron emission tomography can predict tumor response in prostate cancer gene therapy by oncolytic herpes simplex virus

C.C. Riedl, M. Mullerad, D.P. Eisenberg, T.J. Akhurst, P.S. Adusumilli, A. Bhargava, H. Hricak, P.T. Scardino, Y. Fong; *New York, NY/US*

Purpose: To assess if an enhanced response to oncolytic viral therapy in prostate cancer due to an androgen-induced increase in cellular metabolism can be predicted by Positron Emission Tomography (PET) scan.

Methods and Materials: Bilateral CWR22 flank tumors were implanted in seven athymic rats. Baseline ¹⁸FDG-PET scanning was performed after two weeks with an average tumor volume of 596 mm³. Subsequently, animals were randomized to undergo either orchietomy or sham-operation. ¹⁸FDG-PET imaging was then repeated at 108 hours. In a separate cohort, bilateral flank tumors were implanted in 14 rats. Seven days after tumor implantation, animals were again randomized to orchietomy or sham-operation. After two weeks, tumors were treated with a single intratumoral injection of NV1066 (1×10^7 plaque forming units). Viral replication was quantified 72 hours following infection by real-time quantitative PCR for the viral gene ICPO ($n = 14$).

Results: Decreased tumor metabolism induced by androgen withdrawal resulted in a significant decrease in FDG accumulation in the orchietomy group (32% decrease of maximum standardized uptake value, SUV_{max}) compared to hormonally intact animals (12% SUV_{max} increase) ($p = 0.002$). The presence of androgens in hormonally intact animals enhanced viral titer by a factor of 2.4 compared to orchietomized animals.

Conclusion: PET measured SUV_{max} predicted the enhanced efficacy of oncolytic herpes viruses in the treatment of androgen-sensitive prostate cancer cells. This proof-of-concept study provides the mechanistic basis for the selection of a subgroup of patients for oncolytic viral therapy by means of a non-invasive molecular imaging method.

B-677 11:33

Accuracy of whole-body FDG-PET/CT for tumor staging in oncology

P. Veit, N. Saoudi, L.S. Freudenberg, H. Kuehl, T. Beyer, A. Bockisch, G. Antoch; *Essen/DE*

Purpose: To assess the accuracy of PET/CT in staging different malignant diseases and to determine a potential benefit of PET/CT concerning the patients' management.

Methods and Materials: 260 consecutive patients with different oncological diseases underwent [¹⁸F]-2-Fluoro-2-deoxy-D-glucose (FDG) PET/CT for tumor staging. Image evaluation was performed for CT alone, PET alone, PET + CT viewed side by side, and fused PET/CT data. Histopathology and a clinical follow-up of 311 (± 125) days served as standards of reference.

Results: Fused PET/CT proved significantly more accurate in assessing the overall TNM stage compared to CT alone ($p < 0.05$), PET alone ($p < 0.05$), and side-by-side CT + PET ($p < 0.05$). Of all 260 patients 218 (84%) were correctly staged with PET/CT, 197 (76%) with side-by-side CT + PET, 166 (64%) with PET alone, and 163 (63%) with CT alone. No statistically significant difference could be detected between PET/CT and CT + PET when separately assessing M-staging. Combined PET/CT had an impact on the treatment plan in 6% of patients compared to side-by-side CT + PET, in 15% of patients compared to CT alone, and in 17% of patients compared to PET alone.

Conclusion: Dual-modality FDG-PET/CT is significantly more accurate than CT alone, PET alone, and side-by-side CT + PET when staging different malignant diseases. This diagnostic advantage translates into treatment plan changes in a substantial number of patients.

B-678 11:42

IV-contrast enhanced protocols for high-resolution whole-body PET/CT imaging: Optimization of CT-imaging

K. Brechtel¹, T. Beyer², S.M. Eschmann¹, M.S. Horger¹, M. Vogel¹, R. Bares¹, C.A. Pfannenberg¹, C.D. Claussen¹; ¹Tübingen/DE, ²Essen/DE

Purpose: PET/CT imaging requires the adoption of standard imaging protocols of standalone CT and PET examinations. We present strategies to optimize contrast enhanced CT protocols in high-resolution PET-CT imaging with a 16-row MD-CT scanner.

Methods and Materials: 45 patients were referred for 3 whole-body PET/CT scanning protocols, 1 h pi of 400 MBq FDG. IV contrast was administered as a single bolus of 100 ml followed by a 40 ml saline flush. Protocol A ($n = 15$) included a single-spiral CT scan during pv-enhancement in shallow breathing. In Protocol B ($n = 15$) the CT was divided into a multi-phasic study involving a pre-contrast liver, an arterial phase liver/thorax, and a pv-abdomen scan during breath hold in NormExp. Protocol C ($n = 15$) was similar to B with the patients being allowed to breathe shallowly.

Results: Protocols A and C resulted in the best alignment of CT and PET data. Overall misalignment of CT and PET was less than 10 mm in reference areas of maximum mobility (eg diaphragm) in all protocols. While B provided almost standard state-of-the-art diagnostic quality for multi-phase contrast enhancement, it was limited by the reproducibility of the NormExp state. A and C, however, resulted in a somewhat reduced diagnostic quality due to blurring effects caused by shallow breathing.

Conclusion: High resolution, whole body PET-CT imaging is feasible in clinical routine with optimized IV-contrast enhancement for nearly state-of-the-art multi-phase MD-CT examinations and without contrast induced artefacts on the corrected PET. However, an additional low-dose CT of the thorax may be required in full inspiration for the detection of small lesions.

In-vivo ¹H MRS study of the vertebral body

V.A. Rogozhyn, Z.Z. Rozhkova, E.G. Pedachenko, A.R. Garmish; Kiev/UA

Purpose: Our goal is to describe the vertebral body state on the basis of ¹H MRS data of the vertebra.

Materials and Methods: Three groups of subjects are examined by ¹H MRS using 1.5 T MagnetomVision (Siemens). The 1st group (G1) includes 30 healthy volunteers (23-64 y). The 2nd group (G2) includes 30 patients (42-73 y) with vertebral osteoporosis. The 3rd group (G3) includes 45 patients (36-67 y) with vertebral hemangioma. The spectra are recorded with 2DCSI:TR/TE = 3000/20 ms.

Results: We consider the signals from water (4.7 ppm) and lipids: CH₃ (1.0 - 1.1 ppm), (CH₂)_n (1.5, 2.3 - 2.5, 5.4 ppm). We define the content A^M as peak amplitude (PA) and the concentration C^M=A^M/S, S = A^{Lip}+A^{Wat}. We describe the state of vertebra in each VOI by the pair T* = { A^{Wat}, A^{Lip} }, where A^{Lip} and A^{Wat} are the PA of the signals from water and lipids. The configuration 1* = { A^{Wat}> A^{Lip} } is observed in the spectra of young volunteers, in the spectra of G3 patients and in the spectra, overlying the intact tissue of vertebrae of those patients. The configuration 2* = { A^{Wat}< A^{Lip} } is observed in the spectra of elderly volunteers and in the spectra of G2 patients. In G1 and G2 the average values of A^{Lip} are equal to 0.793 and 0.639, in G3 in the tumor and in intact tissue these values are 0.131 and 0.178, respectively.

Conclusion: Quantitative classification of the state of vertebra according to the dyad spectral configurations allows us to differentiate vertebral pathologies.

B-681 14:09

Clinical application study of ¹H MRS on bone and soft tissue diseases in the lower limbs

C. Zhou, Q. Meng, M. Fan, B. Luo; Guangzhou/CN

Purpose: To investigate and analyze spectroscopic characteristics of ¹H MRS in benign and malignant bone diseases and in soft tissue tumors of the limbs.

Methods and Materials: 38 cases of bone diseases and 20 soft tissue tumors which were pathologically proven, and 24 normal bone marrows of the lower limbs were studied by a 1.5-T system and a ¹H MRS software package supplied by Siemens Company in Germany. Each had a routine MR imaging scan before ¹H MRS examination. SVS-STEAM was used. Parameters for ¹H MRS were TE 270 ms, TR 1500 ms, no. of acquisitions 256, and volumes of interests 2x2x2 cm³.

Results: 1. ¹H MRS of the normal bone marrow presented with a single wave peak. The single wave peak near 1.6 ppm was called lip1; the single wave peak near 0.9 ppm called lip2 in our study. 2. Increased Choline and Lactate signal, and decreased Lip1 signal in malignant bone and soft tissue tumors of the limbs, representing two higher peaks and one lower peak in wave shape, whereas, in benign lesions of the limbs, increased Lip1, decreased Choline and Lactate, presenting with two lower peaks and one higher peak in wave shape.

Conclusion: With ¹H MRS combining with routine MR imaging, the differentiation diagnostic accuracy between the benign and malignant bone lesions, as well as soft tissue tumors of the limbs should be elevated.

B-682 14:18

Validation of tMIX estimated T1-T2 values in correlation with relaxometry determined values in a phantom

I. Van Breuseghem¹, I.M. Van Mieghem¹, L. Vanderelst², H.T.C. Bosmans¹, S. Pans¹; ¹Leuven/BE, ²Mons/BE

Purpose: The turbo mixed T1 and T2 quantification sequence (tMIX) is used for cartilage mapping on a clinical 1.5 T system. In this study, we evaluated the correlation of T1 and T2 values determined with this tMIX sequence and with an accepted spectroscopic method in a phantom.

Materials and Methods: A phantom comprising 7 tubes with different gadolinium-DTPA/water solutions was made. T1 and T2 relaxation time of these solutions

were determined with relaxometry measurements on a Bruker minispec Mq 60. The tMIX sequence was run on a 1.5 T MR imaging system to determine the T1 and T2 relaxation times of the same solutions. The correlation between spectroscopy determined and tMIX estimated T1 and T2 values was calculated with Pearson correlation coefficient. Relative differences between both values were calculated.

Results: A high correlation between spectroscopy and tMIX obtained values is shown for T1 ($r = .99$) as well as for T2 ($r = .99$), but a broad range of relative differences exist (from 0.3 to 190.2%). The differences in the expected cartilage relaxation ranges however are low: for T1 in the interval 150 ms to 400 ms, relative differences vary between 15 and 20% (and can be linearly corrected), for T2 in the interval 20 ms to 100 ms, relative differences vary between 0.3 and 11.5%.

Conclusion: Obtained tMIX relaxation values correspond well in the expected cartilage relaxation times. However, errors need to be considered, but they can be corrected for.

B-683 14:27

Reduction of T2 relaxation times in articular cartilage after enzymatic proteoglycan depletion

C. Glaser, T. Mendlik, E. Rauch, S. Milz, S. Schulz, R. Putz, M.F. Reiser; Munich/DE

Purpose: To analyze changes of T2 relaxation times in human articular cartilage following enzymatic depletion of proteoglycans.

Material and Methods: Seven macroscopically intact human patellae were imaged within 48 hours of death in a clinical 1.5 T scanner before and after 6 hours of exposition of the medial patellar facets to 330 u/ml hyaluronidase. 20 transverse partitions/ sections (resolution: 0.6 x 0.6 x 3.0 mm³) were acquired with a 3D FLASH WE sequence (17.6/8.8 ms; 25°) and a multi echo sequence (TR/Temin = 3000/13.2 ms; 8 echoes). After segmentation of the cartilage (WE sequence) and superposition of the segmentation on the multi echo images, T2 values were calculated (pixel-by-pixel, monoexponential fit). Average T2 values were extracted for the medial and lateral patellar facets in both, the superficial and lower layers of the cartilage. Safranin O staining and Scanning Electron Microscopy (SEM) were performed on excised cartilage-on-bone samples from both facets.

Results: T2 values varied between 29 and 48 ms. Average T2 was decreased by 13% in the lower and by 23% in the superficial layer after hyaluronidase. NaCl controls showed but a small decrease of T2 in the superficial and no changes in the deep layers. There was good correlation between changes in staining intensity and T2 distribution after hyaluronidase. SEM showed an intact collagenous fibre architecture in all excised samples.

Conclusion: T2 relaxation times of articular cartilage are reduced after treatment by hyaluronidase. A possible explanation may be a reduced water content of cartilage consecutive to depletion of proteoglycans.

B-684 14:36

The value of three dimensional dual echo in steady state MR imaging (3D-DESS) as a standard technique in the evaluation of knee internal derangement

I.M. Van Mieghem, F. Frans, I. Van Breuseghem, S. Pans; Leuven/BE

Purpose: To correlate the diagnostic accuracy for evaluation of knee internal derangement using an optimised 3D-DESS MR imaging sequence with arthroscopy findings.

Methods and Materials: We retrospectively reviewed the MR examinations, MR reports and arthroscopy reports of 199 patients who were referred for assessment of internal derangement of the knee. All MR imaging was done with a 1.0 T MR imaging system where a 3D-DESS sequence was performed. The MR imaging interpretations were compared with the arthroscopy reports, being considered as the gold standard. Images were scored for the presence or absence of meniscal tear (medial/lateral), cruciate ligament tear (anterior/posterior) and morphological cartilage lesions. Per group sensitivity, specificity and diagnostic accuracy were calculated; the diagnostic value of the sequence was determined.

Results: At surgery, 41 lateral meniscus tears, 106 medial meniscus tears, 59 anterior cruciate ligament tears, 3 posterior cruciate ligaments tears and 96 cartilage lesions were observed. The sensitivity, specificity and accuracy was 93%, 96% and 95% for lateral meniscus tears; 99%, 92% and 96% for medial meniscus tears; 95%, 91% and 92% for anterior cruciate ligament tears; 100%, 100% and 100% for posterior cruciate ligament tears; and 89%, 79% and 85% for cartilage lesions, respectively. The overall sensitivity was 86%. For all sub-groups the technique is considered as highly diagnostic accurate ($p < .001$).

Conclusion: MR imaging with an optimised 3D-DESS technique is a highly accurate method in the evaluation of knee internal derangement.

B-685 14:45

Fast magnetic resonance imaging of the knee using a parallel acquisition technique (mSENSE): A prospective performance study

K.-F. Kreitner, B. Romaneehsen, K. Oberholzer, F. Krummenauer, M. Thelen; Mainz/DE

Purpose: To evaluate overall image quality and performance of a magnetic resonance (MR) imaging strategy that uses multiple receiver coil elements for application of time saving integrated parallel imaging techniques (iPAT) in traumatic disorders of the knee.

Material and Methods: 90 patients with suspected traumatic derangements of the knee joint underwent MR imaging at 1.5 T. For signal detection we used a 6-channel body array coil that was wrapped around the knee joint. All patients were examined using a standard imaging protocol, which consisted of different turbo spin-echo sequences (PD-, T₂-weighted TSE with and without fat suppression). All sequences were repeated with an integrated parallel acquisition technique (iPAT) using modified sensitivity encoding (mSENSE) with an acceleration factor of 2. Overall image quality, artifacts as well as pathologic findings were evaluated by two radiologists using a four-point scale.

Results: There were no significant differences between standard imaging and imaging using mSENSE with inter- and intra-observer agreements ranging between 0.78 and 1.0 using Cohens' kappa test. All pathologic findings (occult fractures, meniscal and ligament tears, torn and interpositioned Hoffa's cleft, cartilage damages) were detected by both techniques. iPAT lead to a 48% reduction of acquisition time compared with standard technique. Additionally, time savings with iPAT can lead to a decrease of pain induced motion artifacts in selected cases.

Conclusion: The application of parallel imaging techniques proved to be an efficient and economic tool for fast musculoskeletal MR imaging of the knee joint as it revealed a comparable diagnostic performance to conventional techniques.

B-686 14:54

Computer-assisted quantitative analysis of bone marrow edema of the knee: STIR versus T1-weighted fat-suppressed contrast-enhanced MR imaging at 1.0 and 1.5 Tesla

M.E. Mayerhofer¹, M.J. Breitenseher², N. Aigner¹, S. Hofmann³, J. Kramer⁴; ¹Vienna/AT, ²Vienna / Horn/AT, ³Stolzalpe/AT, ⁴Linz/AT

Purpose: To compare STIR and T1-weighted contrast-enhanced fat-suppressed MR imaging of bone marrow edema of the knee (BME) using a new computer-assisted method of quantification.

Methods and Materials: For 59 patients with BME of the knee, STIR and T1-weighted Gadolinium-enhanced fat-suppressed MR images were obtained. 32 patients (group 1) were examined at 1.0 Tesla, with a contrast-media volume adapted to their body mass. The remaining 27 patients (group 2) were examined at 1.5 Tesla, with a fixed contrast-media volume regardless of their body mass. BME volume and signal contrast were assessed by computer-assisted quantification, based on calculation of a gray-scale threshold value between healthy and edematous bone marrow. MR sequences were compared through arithmetic means of BME volume and signal contrast and their correlation coefficients (r^2).

Results: In both patient groups, correlation was high between STIR and Gadolinium-enhanced images for both BME volume (r^2 : 0.96 to 0.99) and BME signal contrast (r^2 : 0.84 to 0.94). Whilst in group 1, mean BME volume was slightly larger on Gadolinium-enhanced images, the opposite was true for group 2. Gadolinium-enhanced images demonstrated higher BME signal intensity than STIR images in both groups.

Conclusion: STIR and Gadolinium-enhanced MR images depict almost identical BME volume. BME signal contrast, on the other hand, is significantly higher on Gadolinium-enhanced images. Factors like contrast-media volume, magnetic field strength and MR acquisition parameters also seem to affect apparent BME image pattern.

B-687 15:03

Evaluation of trabecular bone structure with high resolution MR imaging at 1.5 T. A comparison of spin echo and gradient echo sequences

J.S. Bauer¹, C.J. Roß², M. Settles², D. Mueller², F. Eckstein³, E.-M. Lochmueller², T.M. Link¹; ¹San Francisco, CA/US, ²Munich/DE, ³Salzburg/AT

Purpose: To compare spin echo and gradient echo sequences concerning trabecular bone structure analysis in the assessment of osteoporosis. Specific aims were to compare structure measurements derived from both MR sequences

with the corresponding true structure parameters obtained with Micro-CT (μ CT) in an in vitro study and to compare the ability of the individual structure measures to differentiate between donors with and without osteoporotic spine fractures.

Material and Methods: Fifty-six post-mortem distal forearm specimens were scanned with a 1.5 T MR scanner using a dedicated wrist-coil and optimized spin echo and gradient echo sequences. The contralateral radius specimens were scanned with μ CT. Structure parameters were calculated from μ CT and MR images analogous to standard bone histo-morphometry. Fracture status of the spine was classified on conventional radiographs. Diagnostic performance in differentiation of donors with and without vertebral fractures was assessed using receiver-operator-characteristics (ROC) analysis.

Results: All parameters obtained in the MR images correlated significantly with the corresponding μ CT-parameters. Highest correlation coefficients were found for apparent trabecular separation (Tr.Sp) with the spin echo sequence (up to $r^2=0.76$). For the spin echo sequence slightly higher ROC-values were also found compared to the gradient echo sequence (up to $Az = 0.75$ vs. $Az = 0.73$). These were lower than those for the μ CT (up to $Az = 0.81$), but the differences were not significant.

Conclusion: Spin echo sequences performed slightly better than gradient echo sequences in predicting true trabecular bone structure and in differentiating donors with and without osteoporotic fractures, but differences were not significant.

Imaging of advanced articular cartilage disease using 3D SPGR, 3D CISS and proton FSE imaging and arthroscopic correlation

R. Arunk, S. Gur, S. Aydogdu, M. Argin; Izmir/TR

Purpose: To determine the accuracy of 3D SPGR, 3D CISS and proton density FSE articular cartilage imaging in the identification of grades 3 and 4 chondromalacia of the knee.

Materials and Method: A prospective evaluation of 27 patients who underwent MR imaging and following 1-3 days arthroscopic evaluation was performed. The images were interpreted by an observer without knowledge of the surgical results. The medial and lateral femoral condyles, the medial and lateral tibial plateau, the patellar cartilage and trochlear groove were evaluated. Greater than 50% loss of cartilage thickness showed grade 3, and complete loss of cartilage thickness showed grade 4 chondromalacia. Comparison of the MR results with the arthroscopic findings was performed.

Results: 27 patients, 162 articular cartilage sites were evaluated with MR imaging and arthroscopy. Results of MR identification of grade 3 and 4 chondromalacia, all sites combined were: for 3D SPGR; sensitivity 85.3%, specificity 90.8%, positive predictive value 76%, negative predictive value 94.7% and overall accuracy 89.4%; for 3D CISS: sensitivity 65%, specificity 90.9%, positive predictive value 76.4%, negative predictive value 89% and overall accuracy 86.4%; for proton FSE; sensitivity 78.9%, specificity 91.9%, positive predictive value 75%, negative predictive value 93.4% and overall accuracy: 88.8%.

Conclusion: The results demonstrate that 3D SPGR, 3D CISS and proton FSE MR imaging can identify advanced chondromalacia. However, 3D CISS sequence is a new parameter for using in cartilage imaging and seems to be another useful sequence to image and evaluate articular cartilage.

B-689 15:21

Prospective analysis of the value of different MR imaging sequences for the detection of early stages of arthropathy in patients with hemophilia

M.G. Mack, K. Hochmuth, J.K.E. Müller, A. Thalhammer, M. Krause, A. Kurth, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To analyse the value of different MR imaging sequences for diagnosis of early stages of arthropathy in patients with hemophilia.

Material and Methods: We evaluated 31 joints of 17 patients with hemophilia A (median age 42 years) with at least one intra-articular bleeding or a Pettersson Score of 8 or less. The sequence protocol included TIRM, Flash2D, Medic2D, PDw sequence, DESS, FLASH3D, T1SE and Vibe without contrast. Post-contrast fat saturated T1 SE sequence was repeated immediately and 1.5 hours later. We evaluated erosions, subchondral cysts, hyperplasia of the synovia, synovitis, hemosiderin depositions, joint effusion, focal cartilage defects, thickness of cartilage.

Results: The FLASH2D sequence was superior to regarding detection of hemosiderin depositions. For diagnosis of cartilage defects the best sequence was the DESS sequence with water excitation. The diagnosis of synovitis was best on enhanced T1SE FATSAT sequence. The diagnosis of bone marrow edema and joint effusion was best on the TIRM sequence. The PD sequence and T1SE sequence were optimal for the detection of ligaments and bony structures.

Scientific Sessions

FLASH3D, Medic2D, and Vibe sequence resulted not in additional information. Based on this evaluation we are recommending the following imaging protocol: TIRM, PD, DESS WE, standard and contrast enhanced T1 SE.

Conclusions: The optimised imaging protocol is suited for the diagnosis of early pathologies of the knee and ankle joint in patients with hemophilia. The early detection of synovial hyperplasia, synovitis and hemosiderin depositions may result in improved and prompt therapy in order to avoid further destruction of cartilage and joint.

Time efficiency of CT colonography: 2D vs 3D visualization

E. Neri, F. Vannozzi, S. Picchietti, P. Vagli, A. Bardine, C. Bartolozzi; Pisa/IT

Purpose: To compare the time efficiency of 2D and 3D analysis in CT colonography.

Materials and Methods: Three visualization methods of CT colonography datasets were prospectively compared for time efficiency in a routine clinical work: Primary 2D image analysis with the use of 3D as problem solving tool, primary 3D viewing with manual navigation and primary 3D viewing with automated navigation (with the use of 2D as problem solving tool). Three radiologists were involved in the analysis, each performing separately the CTC evaluation of the same 20 cases consecutively.

Results: Time for 2D analysis ranged between 6 and 18 minutes (mean 12) for evaluation of both supine and prone decubitus with a synchronization method. In 3 cases a 3D integration was used, increasing time analysis from 6, 8 and 12, to 18 minutes, respectively. Time for manual navigation in supine + prone ranged between 9 and 24 minutes (mean 14) No time increase was caused by the 2D integration. Time for automated navigation ranged between 6 and 20 minutes (mean 12) for evaluation of both supine and prone decubitus. No time increase was caused by the 2D integration.

Conclusions: 2D and automated 3D navigation analysis have comparable time efficiency in a routine clinical setting. Manual navigation reduces the time efficiency.

B-691 14:09

Dose reduction and image quality assessment in multi-detector row CT virtual colonography by online z-axis tube current modulation

A. Graser¹, C.R. Becker¹, C. Suess², M.F. Reiser¹; ¹Munich/DE, ²Forchheim/DE

Purpose: To evaluate the effect of online attenuation-based X-ray tube current modulation (TCM) in virtual CT colonography of a screening population.

Materials and Methods: Eighty asymptomatic patients underwent virtual CT colonography for colon polyp screening. All patients were scanned using 16-detector row helical CT scanners (Sensation 16, Siemens Medical Systems, Forchheim, Germany). 40 pts were examined with a standard protocol with 120 kV tube current at 120 mAs in the supine and 40 mAs in the prone position. Another 40 pts were scanned using an on-line attenuation-based X-ray TCM that adjusts the tube current over the patient's z-axis (CareDose4D, Siemens Medical Systems, Forchheim, Germany). Individual patient radiation exposure was determined using the dose length product (DLP). To assess image quality, image noise was determined by Hounsfield unit measurements in the colonic lumen at four anatomic levels. The two-tailed Student's T-Test was used to test for statistically significant differences between these values.

Results: Radiation dose was significantly lower in the patient group scanned with TCM (supine position: 4.24 vs 6.55 mSv, p < 0.0001; prone position: 1.61 vs 2.38 mSv, p < 0.0001). Overall, radiation dose was reduced by 35% in the supine and 32% in the prone position. There was no statistically significant difference in image noise.

Conclusion: Attenuation-based on-line z-axis TCM leads to a significant reduction of radiation exposure in CT-based virtual colonography without loss of image quality. This is important in particular for patients examined for screening purposes.

B-692 14:18

Detection of colorectal polyps: Low-dose multi-detector CT (MDCT) colonography evaluated by back-to-back colonoscopies

R. Iannaccone, A. Laghi, C. Catalano, F. Mangiapane, D. Marin, R. Passariello; Rome/IT

Purpose: To prospectively evaluate the performance of low-dose MDCT colonography for the detection of colorectal polyps using back-to-back colonoscopies.

Methods and Materials: 88 patients underwent same-day MDCT colonography and an initial conventional colonoscopy. CT colonographic examinations were acquired using a low-dose MDCT protocol. Three observers interpreted the CT colonographic datasets separately and independently using a primary two-dimensional technique. Initial conventional colonoscopy was performed by one of two staff endoscopists unaware of CT colonographic findings. A second colonoscopy was performed within two weeks and served as reference standard. The sensitivities of CT colonography and initial colonoscopy were calculated both on a per-polyp and per-patient basis. For the latter, specificities, as well as positive and negative predictive values, were also calculated.

Results: Per-polyp sensitivity was 62% and 84% for MDCT colonography and initial colonoscopy, respectively. The sensitivity for detection of polyps ≥ 6 mm was 85.6% and 83.8% for MDCT colonography and initial colonoscopy respectively. Initial colonoscopy missed a total of 16 polyps; of these, six were correctly detected by MDCT colonography. With regard to per-patient analysis, MDCT colonography had a sensitivity of 80.4% (93.5% for initial colonoscopy); a specificity of 74.6% (100% for initial colonoscopy); a positive predictive value of 77.6% (100% for initial colonoscopy); and a negative predictive value of 77.7% (93.3% for initial colonoscopy).

Conclusion: Low-dose MDCT colonography compares favorably with colonoscopy for the detection of colorectal polyps ≥ 6 mm, with a marked decrease in performance for the detection of polyps ≤ 5 mm.

B-693 14:27

Prospective evaluation of extracolonic findings at contrast enhanced CT colonography in daily clinical practice

A. Spreng, P. Netzer, C. Quattropani, J. Mattich, H.-P. Dinkel, H. Hoppe; Berne/CH

Objective: To prospectively assess the frequency and clinical importance of extracolonic findings at contrast enhanced CT colonography in symptomatic patients in daily clinical practice.

Patients and Methods: CT colonography was performed in 102 symptomatic patients using contrast enhanced multidetector CT followed by conventional colonoscopy on the same day. Study analysis was embedded in clinical practice. Extracolonic findings were classified as of high, moderate, or low clinical importance. To determine the impact of extracolonic findings on further workup and patient treatment, patient records were reviewed.

Results: At CT colonography 89% (91/102) of patients had at least one extracolonic finding. In 32% (33/102) of all patients extracolonic findings of high clinical importance were detected, such as a hepatic lesion (n = 9), aortic aneurysm (n = 8), adrenal mass (n = 7) and enlarged lymph nodes (n = 7). Therefore, 40% (13/33) led to further workup or had an impact on therapy. In 45% (46/102) of patients findings of moderate importance were found such as gallstones (n = 14), pleural effusion (n = 11), ascites (n = 10) and cardiomegaly (n = 5). In 71% (72/102) of patients findings of low importance were seen, such as aortic sclerosis (n = 33), renal cysts (n = 27) and hepatic cysts (n = 15).

Conclusions: Using contrast enhanced CT colonography important extracolonic findings led to additional diagnostic or therapeutic considerations in 23% (23/102) of patients. In our study, the high number of patients with extracolonic findings is most likely due to IV contrast application and a symptomatic patient cohort.

B-694 14:36

CT colonography ("virtual colonoscopy"): Comparison of a new colon dissection software and a conventional endoluminal view software

M.S. Juchems¹, T.R. Fleiter², S. Pauls¹, S.A. Schmidt³, A.J. Aschoff¹, H.-J. Brambs¹; ¹Ulm/DE, ²Baltimore, MD/US, ³Stuttgart/DE

Purpose: To determine whether a new visualization software for CT colonography using a "colon dissection mode" has a better sensitivity and specificity in detection of colorectal lesions and is less time consuming.

Materials and Methods: We preselected 24 patients from our collective of whom 21 had either colon polyps or colon cancer. 3 patients were matched who had no findings. All patients received conventional colonoscopy after CT-colonography. CT-colonography was performed using a 4x- multi detector row (MDR) - CT (Philips

Scientific Sessions

MX 8000) in 13 cases and a 16x-MDR-CT (Philips MX 8000 IDT) in 11 cases. An experienced, blinded reader thereafter evaluated the data with both software systems on a dedicated CT workstation (Philips MxView).

Results: Conventional colonoscopy revealed 37 colonic lesions in 21 patients. 17 lesions were smaller than 5 mm, 16 lesions were 5-10 mm and 4 lesions were 10 mm or larger. The colon dissection software had an overall per-lesion sensitivity of 47.1% for lesions smaller than 5 mm, 56.3% (5-10 mm) and 75.0% for lesions larger than 10 mm. The endoluminal view software had an overall per-lesion sensitivity of 35.3% (< 5 mm), 81.5% (5-10 mm) and 100.0% for lesions larger than 10 mm. The average time consumption for evaluation with the colon dissection software was 10 min vs. 38 min with the endoluminal view software.

Conclusion: The "colon dissection" mode provides a significant time advantage during evaluation of CT colonography data sets. With "colon dissection" high sensitivities can be achieved. It is especially superior in detecting lesions smaller than 5 mm.

B-695 14:45

Value of multiplanar reconstruction in multidetector CT for preoperative staging of colorectal cancer: ROC analysis

K.-N. Jin¹, S.-H. Kim¹, J.-M. Lee¹, K.-S. Shin², J.-K. Han¹, B.-I. Choi¹, J.-Y. Lee¹;

¹Seoul/KR, ²Dae-Jeon/KR

Purpose: We hypothesized that multiplanar reconstruction (MPR) images have an additional role in preoperative staging of colorectal cancer.

Materials and Methods: Fifty-five patients with colorectal cancer underwent enhanced CT colonography using multidetector CT (MDCT). Interval reviews for both axial datasets without and with coronal and sagittal MPR images were performed independently by two radiologists. They were requested to determine the TNM-staging of colorectal cancer. Radiologists' performances in the context of identifying T4 versus ≤ T3, N0 versus ≥ N1, M0 versus M1 were evaluated by ROC analysis. Overall accuracy of the TNM-staging were calculated and compared between axial images only versus the combination of axial and MPRs. Interobserver agreement was also analyzed.

Results: By histology, pT2 in 5 patients, pT3 in 45, pT4 in 5, pN0 in 26, pN1 in 17, pN2 in 10, pN3 in 2, pM0 in 42 and pM1 in 13 were identified. When MPR images were added, ROC analysis revealed a significant improvement for differentiating N0 and ≥ N1 and marginal improvement for differentiating T4 and ≤ T3 for both reviewers. Overall accuracies were also significantly improved from 60% and 36.4% to 80% and 63.6% for T and N staging respectively. Accuracy for M-staging was improved in combined interpretation than in axial images alone, but the difference was not significant. Furthermore, for T-staging, good interobserver agreement was achieved for combined interpretation whereas fair agreement was achieved for axial images alone.

Conclusion: Combined interpretation of axial and MPR MDCT images for colorectal cancers significantly improves the local staging of the tumors.

B-696 14:54

Polyp measurement and size categorisation by CT colonography:

Agreement with colonoscopy and effect of observer experience

D. Burling, ESGAR CT colonography study GROUP investigators;

St. Mark's Hospital, London/UK

Purpose: To compare agreement between CT colonography and colonoscopy estimates for polyp size measurement and per-patient categorization, and to examine effects of observer experience.

Materials and Methods: 28 observers (3 groups: 9 experts, 9 radiologists, 10 technicians) from 9 European centres were asked to read 40 CT colonography cases from a dataset of 51 containing 12 large and 4 small polyp cases. Non-expert groups had no prior experience but were trained with 50 validated cases. Each observer categorised cases according to the largest lesion seen: cancer, large polyp, small polyp, normal. To distinguish large (≥ 1 cm) and small polyps (6 to 9 mm) observers measured the maximal 2D diameter using software callipers. Bland-Altman statistics were used to assess level of agreement between observer and colonoscopic reference measurement; differences between observer groups were assessed using Kruskal-Wallis and for polyp categorization using Chi-squared statistics.

Results: 375 (283 large, 92 small) polyp cases were read by 28 observers. Of these, 167 (45%) polyps were detected. The mean difference between observer measurements and colonoscopic reference size was -2.1 mm for experts (95% limits of agreement -9.4 to 5.2), -2.8 mm for radiologists (-13.3 to 7.7) and -2.2 mm for technicians (-11.1 to 6.6). There was no significant difference in either measurement variability ($P = 0.39$) or frequency of correct size categorization ($P = 0.28$) between the groups.

Conclusion: Training with 50 cases enabled inexperienced observers to measure and categorise polyps with a facility similar to experts. CT colonography appears to underestimate polyp size compared to a colonoscopy.

B-697 15:03

A multi-centre project of teaching CT colonography in Belgium: Work in progress

P. Lefere¹, S. Grayspeerdt¹, W. Roelandt², P. Van Wettere², L. Verhaeghe³, K. Ramboer³, P. Moons⁴, L. Djoa⁴, V. Herpels⁵, B. De Deurwaerder⁵, ¹Roeselare/BE, ²Oostende/BE, ³Bruges/BE, ⁴Tiel/BE, ⁵Kortrijk/BE

Purpose: To set up a teaching project in several radiology departments who are starting with CTC.

Materials and Methods: The teaching starts with a 4 hour-instruction course. The teaching period consists of performing 50 CTC followed by conventional colonoscopy. The colon is prepared by fecal tagging with barium and a reduced cathartic cleansing with magnesium citrate and bisacodyl. CTC is performed in the "novice" department. After smooth muscle relaxation the colon is inflated with CO₂ using an automated CO₂-injector. The colon is examined with multi-slice CT technique and with dual positioning. The data sets are read on a dedicated workstation by both the novice readers and the teachers. The preparation and colonic distention are graded by all readers. The detected polyps are recorded. The results of the novice readers are blinded to the teachers. The teachers give advise on the quality of the exam and on polyp detection and on how to avoid imperfections.

Results: Up to now 42 CTC were performed. At the time of the symposium more extensive results will be communicated. So far the preparation was adequate in all patients. Improvement of distention was possible in 15 patients. One patient presented with a lot of motion artefact. Fifteen lesions ≥ 6 mm were detected on conventional colonoscopy including one carcinoma. The teachers detected all lesions. The novices missed four 8 mm-polyps.

Conclusion: This multi-centre teaching project is an attempt to teach CTC to novice radiologists how to perform and read CTC using a standardized method.

B-698 15:12

Virtual colon dissection tool used in CT colonography: Comparison with conventional endoscopy results. A preliminary study

M. Cadi, R. Chollet, O. Lucidarme, P. Grenier; Paris/FR

Objective: The aim of this study was to determine the ease and accuracy of virtual colon dissection software to detect colonic polyps in CT colonography.

Methods and Material: To date, 60 patients, who underwent same day CT colonography and endoscopy, were studied using virtual colon dissection software. This commercially available software (Autodissection®, GEMS) dissects and unfolds the colon along its longitudinal axis to display the entire colonic surface with a 360° angle view. Hence, the entire inner surface of the colon can be studied at a glance without the need for navigation. Imaging findings were compared with conventional endoscopic results and the reading time of each examination was recorded.

Results: Four patients are excluded because of inadequate bowel preparation. Among the 56 remaining patients conventional endoscopy revealed 40 lesions. Using virtual colon dissection as primary tool to seek out polyps, the per-lesion sensitivities were 86.3%, 80.1% and 50.3% for polyps greater than 10 mm, 6-9 mm and smaller than 5 mm respectively. There was one false positive result for polyps greater than 10 mm as well as for polyps of 6-9 mm and 6 false positives for polyps smaller. Average time to display and analyse the entire inner surface of the colon was 14 minutes.

Conclusion: Virtual colon dissection software is a complementary tool to analyse CT colonography data that provides a good sensitivity for detection of colonic polyps in a short time.

B-699 15:21

Clinical impact and prevalence of incidental findings in a mixed population undergoing CT colonography

F. Iafrate, A. Laghi, M. Rengo, V. Panebianco, V. Martino, P. Paolantonio, M. Di Martino, R. Passariello; Rome/IT

Purpose: The aim of our study was to prospectively determine the frequency and clinical importance of extracolonic findings in patients undergoing CT colonography.

Material and Methods: 183 patients underwent CT colonography for several reasons. 133 patients (81 screening, 17 diverticulosis, 16 abdominal pain and cramping and 29 incomplete colonoscopy) performed the examination without

Scientific Sessions

i.v. administration of contrast agent. In 50 patients an additional i.v. contrast administration was performed based on the clinical indication for the examination (36: staging of neoplastic lesion, 14: follow-up). Helical CT from the diaphragm to the symphysis was performed in the supine and prone positions after rectal air insufflation. Two radiologists reviewed the CT images for extracolonic pathology and findings were classified as having major, moderate or minor clinical importance. **Results:** A total of 173 extracolonic findings were detected in 110 (60.1%) of the 183 patients. Of these, 43 (24.8%) were highly significant, 36 (20.8%) were moderately significant and 94 (54.33%) were of poor significance. In 72(39.34%) patients no extracolonic findings were observed. The most common highly significant lesions were mesenteric lymphadenopathy (n.18), aortic aneurysm and liver metastases (n. 6), peritoneal carcinomatosis and pulmonary nodules (n. 4). 32 of these 43 (74.4%) highly significant findings were new, and in 15 (34.88%) these abnormalities resulted in further diagnostic examinations.

Conclusions: CT colonography can detect highly significant extracolonic findings. Although extracolonic lesions were common, only a small proportion of patients required further diagnostic examinations. This finding must be considered when CT colonography is considered for routine workup or screening.

Hyperpolarized ^3He apparent diffusion coefficient MR imaging of the lung: Reproducibility, clinical correlation and safety

S. Diaz¹, P. Åkeson¹, I. Casselbrant¹, E. Pitulainen¹, G. Pettersson¹, P. Magnusson¹, P. Wollmer¹, B. Peterson², ¹Malmö/SE, ²Groton, CT/US

Purpose: The Apparent Diffusion Coefficient (ADC) reflects the size of the structures that compartmentalize the gas, in this case the size of the alveoli within the lung. The aim of this study was to examine the reproducibility of the ADC of hyperpolarized (HP) ^3He -inhalation MR imaging to assess emphysema and to verify its clinical application and safety.

Methods and Materials: 8 healthy volunteers and 16 emphysema patients (8 with Chronic Obstructive Pulmonary Disease (COPD) and 8 with alpha-1-antitrypsin deficiency (A1AT)) were imaged with HP ^3He -gas mixed with nitrogen. Each subject was imaged on 3 separate days with 5 different volumes of gas. Mean ADC per slice and per subject, histograms of the ADC values and ADC-maps were calculated. Comparison was made with lung function tests.

Results: The mean ADC values per subject showed very small intra-individual variation both in volunteers (mean 0.195-0.247 cm²/sec; SEM 0.000385-0.00516) and patients (mean 0.268-0.505 cm²/sec; SEM 0.001-0.006). The inter-individual variation was small in healthy volunteers (mean 0.210 cm²/sec; SD 0.020). A positional gradient was seen in all volunteers. Apical emphysema in COPD-patients, basal in A1AT-patients was seen. Comparison with Diffusion Capacity of Carbon Monoxide (DLCO) showed a good correlation ($R^2 = 0.626$). No correlation was found with FEV₁. No serious adverse events occurred.

Conclusion: The reproducibility over time was excellent in both groups. A difference in ADC between healthy volunteers and patients and between patient groups was found. The method seems to be sensitive and safe. Detection and monitoring of early emphysema and small changes should be possible.

B-701 14:09

Diffusion weighted ^3He -MR imaging in the assessment of pulmonary emphysema

K.K. Gast¹, T. Stavgaard², J.M. Wild³, A.E. Morbach¹, L. Vejby Soegaard⁴, A. Dahmen¹, H.-U. Kauczor⁵, E.J.R. van Beek⁶, C.-P. Heussel¹; ¹Mainz/DE, ²Copenhagen/DK, ³Sheffield/UK, ⁴Hvidovre/DK, ⁵Heidelberg/DE, ⁶Iowa, IA/US

Purpose: Diffusion weighted ^3He -MR imaging is a new method for quantitative assessment of lung microstructure. This study intends to investigate the usefulness of diffusion weighted ^3He -MR imaging in different forms of pulmonary emphysema in comparison with healthy volunteers.

Methods and Materials: In a European multicenter trial 79 patients with pulmonary emphysema and 37 healthy volunteers were included. All subjects underwent diffusion weighted ^3He -MR imaging, high resolution computed tomography (HR-

CT) and pulmonary function tests (PFT). Mean apparent diffusion coefficient (ADC) was calculated from diffusion weighted ^3He -MR imaging, emphysema index (EI) from HR-CT and the FEV1/VC ratio was determined by PFT.

Results: A total of 87 data sets from diffusion weighted ^3He -MR imaging were evaluable (patients, n = 58, volunteers, n = 29). Mean ADC showed higher values in patients (median, 0.28 cm²/s) than in healthy volunteers (median, 0.17 cm²/s, p < 0.001). Correlation between mean ADC and computed tomography was r = 0.52. Correlation between mean ADC and pulmonary function tests was r = -0.75. Correlation between PFT and HR-CT was r = -0.45 (n = 105).

Conclusion: Diffusion weighted ^3He -MR imaging differentiated well between volunteers and patients with pulmonary emphysema. Correlation of ^3He -MR imaging to HR-CT was fair. ^3He -MR imaging correlated significantly better with PFT compared with CT. The ADC determined from ^3He -MR imaging obviously does not simply describe morphology of the lung. Its good correlation to PFT emphasizes the functional character of ^3He -MR imaging. Diffusion weighted ^3He -MR imaging is an evolving method to quantitatively determine the extent and the regional distribution of pulmonary emphysema.

Acknowledgements: The ^3He project is supported by the European Commission ("PHIL") and the German Research Council (DFG, FOR474).

Quantitative analysis of regional airways obstruction using dynamic hyperpolarized ^3He MR imaging: Preliminary results in children with cystic fibrosis

P. Koumellis, E. van Beek, C. Hill, N. Woodhouse, S. Fichele, C. Taylor, J. Wild; ^{Sheffield/UK}

Purpose: Dynamic MR imaging of hyperpolarized ^3He can provide striking cine movies of lung ventilation in humans. This study aimed to examine the degree of pulmonary involvement and to quantitatively evaluate patterns of gas flow in lung regions in children with CF in comparison with spirometry.

Materials and Methods: The study population consisted of 8 children with CF aged 6-15 y (mean age 11.4 y). All of them had undergone recent spirometry. Imaging was performed on a 1.5 T whole body MR imaging system using a dynamic radial projection sequence described in [1]. A total of 7 ROI's were taken, three in each lung field and one in the trachea. Since all gas passes via the trachea, the tracheal signal intensity was used as a form of 'input function' to normalise for input flow effects.

Results: The low flow rate in the upper lobes was a pattern observed in all of the patients and is characteristic for CF, which has a preferential distribution in the upper lobes. When the flow measurements from the peripheral ROI's were averaged to give an index of flow in the peripheral lung these showed a good correlation (p < 0.005) with the forced expiratory volume (FEV1) from spirometry.

Conclusion: These results suggest that a quantitative measurement of localised airways obstruction in the early stages of CF may be obtained from dynamic ^3He MR imaging by using the slope of the signal rise as a measure of air flow in to the peripheral lung.

Oxygen-enhanced MR imaging in the assessment of smoking-related pulmonary emphysema: Preliminary results

F. Molinari, O. Pantalone, G. Corbo, S. Valente, T. Pirroni, L. Bonomo; ^{Rome/IT}

Purpose: To demonstrate the capability of oxygen-enhanced MR imaging to assess smoking-related pulmonary emphysema.

Method and Materials: 12 consecutive patients (age range 39-58) with smoking-related bullous emphysema (DLCO/Va ratio < 70% of predicted value) and 10 healthy non-smoking volunteers (age range 24-36) underwent measurements of lung volumes, forced expiratory flows (FEV1%, FEV1%/VC, FEV1%/FVC), diffusing capacity of the lung (DLCO%) and oxygen-enhanced MR imaging. Arterial blood gases and cutaneous oxymetry during 6 min walking test were also obtained in the patient group. Oxygen-enhanced MR imaging was performed with a cardiac synchronized inversion recovery single-shot fast spin echo sequence (TE = 26 ms/ TI=1200 ms) using a 1.5 T MR scanner. Oxygen-enhanced MR images were obtained in the coronal planes. Oxygen-enhancement was determined on a pixel-by-pixel basis with parametric maps of correlation coefficient (CC-maps), with parametric maps of activation magnitude (AM-maps), and by averaging oxygen-enhancements in spatially defined regions of interest (ROIs) in both lungs (overall oxygen-enhancement). To evaluate the capabilities of oxygen-enhanced MR imaging for the assessment of smoking-related pulmonary emphysema, overall oxygen-enhancement was correlated with DLCO%, alveolo-arterial PO₂-difference, maximal arterial desaturation during exercise, and severity of obstructive impairment (FEV1%/VC). CC-maps, AM-maps and overall oxygen-

Scientific Sessions

enhancements of non-smoking subjects were also compared with those of emphysematous patients (Mann-Whitney's test).

Results: Overall oxygen-enhancement had good correlation with DLCO%, alveolo-arterial PO₂-difference, maximal arterial desaturation during exercise and FEV1%/VC ($r > 0.5$, $p < 0.01$). CC-maps, AM-maps and overall oxygen-enhancement results were statistically different between the two groups ($p < 0.05$).

Conclusion: Oxygen-enhanced MR imaging is a useful imaging technique for the assessment of smoking-related pulmonary emphysema.

Assessment of pulmonary hypertension by MR imaging in patients with severe obstructive lung disease: Correlation with pulmonary function test

S. Ley, J. Zaporozhan, R. Eberhardt, M. Eichinger, C. Fink, S. Yubai, S. Erdugan, F. Herth, H.-U. Kauczor; Heidelberg/DE

Purpose: Assessment of hemodynamic changes in patients with severe emphysema due to chronic obstructive pulmonary disease (COPD) using MR imaging and evaluation of a relationship between decrease in pulmonary function and decrease in pulmonary hemodynamics.

Material and Methods: 17 patients (4f, 13m; mean age 61 years) with severe emphysema (mean FEV1/VC=35%) underwent pulmonary function test (PFT; ITGV=intrathoracic-gas-volume; FEV1=forced-expiratory-volume-1 s; RV=residual-volume, VC=vital-capacity) and phase-contrast flow measurements in the aorta and pulmonary trunk (PT) using a 1.5 T MR imaging. Most PFT and MR imaging were performed on the same day (± 20 days). For correlation, 15 healthy volunteers (4f, 11m, mean age 26 years) were examined using MR imaging. Examinations were performed in inspiratory breath-hold and the following parameters were assessed: peak velocity[cm/s](PV), bloodflow/min, acceleration time (ACT), delta cross sectional area (systole vs. diastole), systemic to pulmonary shunt (SPS).

Results: Patients showed significant lower hemodynamic values in the PT than volunteers for PV ($p = 0.01$, 67 vs. 80 cm/s), bloodflow/min ($p = 0.04$, 4 vs. 5 l), delta area ($p = 0.004$, 1.6 vs. 2.8 cm²) and ACT ($p = 0.048$, 142 vs. 215 ms). The vessel area ratio between aorta and PT was significantly ($p = 0.006$) higher in patients (1.3) than in volunteers (1.0). There was no SPS in patients or volunteers. There were no linear correlations between PFT data and hemodynamic values of the patients ($r < 0.4$).

Conclusion: Patients with severe COPD showed a reduction of hemodynamics in the pulmonary vasculature indicating pulmonary hypertension, but without correlation to PFT values.

B-705 14:45

Influence of different emphysema size classes visualized by quantitative MDCT-analysis on MRA lung perfusion in patients with chronic obstructive pulmonary disease

J. Zaporozhan¹, S. Ley¹, R. Eberhardt¹, O. Weinheimer², C. Fink¹, F. Herth¹, H.-U. Kauczor¹; ¹Heidelberg/DE, ²Mainz/DE

Purpose: Severe emphysema due to COPD is associated with reduced oxygen uptake. Our aim was to examine which pattern of structural loss of lung parenchyma is most associated with a reduction in pulmonary perfusion.

Material and Methods: 13 patients (mean 61 years) with severe emphysema underwent inspiratory MDCT (slice thickness 1/0.8 mm) and MRA with high-temporal-resolution (1.5 T; 3.5x9x4 mm³; 20 phases, each TA 1.5 sec). CT data were analysed with a self-written software for detecting and quantifying emphysema. In each patient, four clusters of emphysema with different volumes (up to 2, 8, 65 and 120 mm³) were analysed and visualized by colour coding. On a double monitor system, the distribution of emphysema clusters and perfusion patterns were analysed for 3 lobes on each side. A 4-point-score was used (1: smallest to 4: large emphysema clusters) on CT and on MRA (1: normal to 4: no perfusion).

Results: 78 lobes were evaluated. With CT, the score was 1 for 6 lobes, 2 for 22, 3 for 31, and 4 for 19 lobes. With MRA, the score was 1 for 6 lobes, 2 for 22, 3 for 32, and 4 for 18 lobes. In 65 lobes, the score was identical for CT and MRA (weighted Kappa = 0.83). The score was higher on CT in 7, and higher on MRA in 6 lobes.

Conclusion: Large emphysema clusters are correlated with a severe reduction or a complete loss of perfusion. Moderate emphysema clusters presented perfusion defects of varying size. With small structural changes, perfusion is not or only moderately reduced.

B-706 14:54

Correlation between inspiratory and expiratory lung attenuation on HRCT, pulmonary function tests, and smoking history in healthy smokers

B. Rodríguez-Vigil, I. Torres, J. Echeveste, F. García Río, S. Serrano, M. Pardo; Madrid/ES

Purpose: To evaluate inspiratory and expiratory lung attenuation on high resolution CT in healthy smokers and to correlate these findings with pulmonary function tests (PFT) and smoking history.

Materials and Methods: Thirty-six healthy subjects, 30 smokers (12 mild, 18 heavy) and 6 non-smokers underwent HRCT following a standardised protocol. The mean number of cigarettes/day was 28 ± 7 (packs/year = 34 ± 12). Images were obtained during deep inspiration and expiration at two different lung levels. The mean expiratory increase in lung attenuation was measured. Air trapping was semiquantitatively calculated and visually classified into 4 degrees (none, lobular, mosaic, extensive). Smoking habit was assessed by the Brinkman index, Glover-Neelsen and Fagerström scores. Lung function was evaluated by spirometry, plethysmography and carbon monoxide transfer factor. Lung attenuation at the upper and lower lobes was compared to PFT and smoking history by the Mann-Whitney and Wilcoxon tests, and correlated by the Spearman coefficient.

Results: Healthy smokers showed a significantly lower inspiratory and expiratory attenuation both in upper and lower lobes compared to healthy nonsmokers. Heavy smokers showed a lower expiratory upper lobe attenuation compared to mild smokers ($p = 0.027$). A significant relationship between expiratory upper lobe attenuation and FEV1 ($r = 0.453$, $p = 0.039$), FEV1/FVC ratio ($r = 0.486$, $p = 0.026$), mesoexpiratory flows ($r = 0.521$, $p = 0.018$), residual volume/total lung capacity ratio ($r = -0.560$, $p = 0.046$) and diffusion capacity ($r = 665$, $p = 0.013$) was found in smokers.

Conclusion: A significant decrease in the expiratory upper lobes attenuation on HRCT is noted in healthy heavy smokers. This alteration is related to airflow calibre, static volumes and diffusion capacity of the lungs.

B-707 15:03

Low-dose MDCT in the evaluation of pulmonary emphysema: What is the minimum radiation dose?

A.R. Larici¹, M.L. Storto¹, A.G. D'Agostino¹, F. Palladino², A. Canadè², L. Bonomo²; ¹Chieti/IT, ²Rome/IT

Purpose: To determine the minimum radiation dose which does not impair the quality of MDCT examination in the quantitative and qualitative evaluation of pulmonary emphysema.

Methods and Materials: 24 patients with a clinical diagnosis of COPD underwent two consecutive MDCT scans of the chest (1-mm collimation, 5 and 1.25 mm slice thickness) at standard (100 mAs) and low dose (40 mAs in 12 patients and 20 mAs in the remaining 12). Lung volume and mean attenuation values as well as volume and attenuation values of emphysematous areas were calculated on both standard and low-dose 5-mm thick images using a commercial software. A chest radiologist and a third-year resident independently evaluated both standard and low-dose 1.25-mm thick images for the presence and extent of emphysema, according to a 4-point scale visual score.

Results: No significant differences were found between lung volume and density values automatically calculated on standard dose and low-dose images ($p > 0.05$). For the expert reader, the visual score results were significantly lower on 20 mAs images than on 100 mAs ($p < 0.05$). For the second reader, the visual score results were significantly lower on both 40 mAs and 20 mAs images ($p < 0.05$). Interobserver agreement was good on 100 mAs images ($K = 0.74$) and moderate on 40 mAs images ($K = 0.58$).

Conclusions: Although radiation dose does not affect the automatic quantitation of pulmonary emphysema by MDCT, it seems to impair the visual grading of emphysema when doses < 40 mAs are used. Less experienced readers may underestimate the extent of emphysema on low-dose images.

B-708 15:12

Instability of the central airways: Comparison of end expiratory to dynamic expiratory volumetric MDCT acquisitions

G.R. Ferretti, L. Aubaud, J. Pépin, N. Choury, M. Coulomb; Grenoble/FR

Purpose: To evaluate the role of dynamic expiratory imaging using multidetector CT (MDCT) in comparison to end expiratory imaging in patients with suspected tracheomalacia.

Material and Methods: 23 consecutive patients (15 men) were prospectively evaluated with MDCT. 3 acquisitions of the central airways were obtained (120 kV,

Scientific Sessions

40 mA): 1) end of inspiration; 2) end of expiration; 3) during dynamic expiration. (Mean acquisition time: 4.5 sec). Percentage changes in cross-sectional area at 3 levels in the trachea (upper, middle, and lower trachea), right and left main stem bronchus were calculated.

Results: 12 of 23 patients had instability of the central airways (localized, n = 4; diffuse, n = 8); maximum mean percent change in cross-sectional area during dynamic expiration was 78% as compared to 42% at the end of expiration ($p = 0.02$). In control patients, the figures were 21% and 16%, respectively (NS).

Conclusion: MDCT during dynamic expiratory acquisition is more effective than end expiration acquisition to demonstrate instability of the central airways.

B-709 15:21

Diagnosis of tracheal instability with dynamic CT

Y.V. Marchenkova, T.N. Vesselova, A.G. Chuchalin, T.L. Pashkova; Moscow/RU

Background: Cough is one of the most common symptoms of chronic obstructive pulmonary diseases (COPD). It is well known that severe cough can induce dynamic instability of trachea in COPD. Some studies have shown an important role of dynamic CT in diagnosis of dynamic instability of the upper respiratory tract (trachea) in COPD patients suffering from severe cough.

Aim of the study: To compare the diagnostic efficacy of different diagnostic methods (both imaging and functional ones) in assessment of dynamic tracheal instability in COPD patients.

Materials and Methods: Two groups of patients have been studied. Group 1 consisted of 20 COPD patients (14 females, 6 males, mean age 60.9 ± 7.9 years) with dynamic tracheal instability, diagnosed on fibrobronchoscopy. Group 2 consisted of 10 COPD patients (2 females, 8 males, mean age 55.2 ± 4.8 years) without bronchoscopic signs of dynamic tracheal instability. Stage of COPD, duration of smoking and body mass index were similar in both groups. Patients were studied with spirometry (flow-volume curve), impulse oscillometry, fibrobronchoscopy, and electron-beam tomography (EBCT). EBCT was performed in dynamic multislice cine mode. Tracheal cross-sectional area was measured across the whole respiratory cycle.

Results: Comparing with results of fibrobronchoscopy which was regarded as a gold standard, sensitivity and specificity of pulmonary function tests were, correspondingly, spirometry 55% and 90%, impulse oscillometry 85% and 60%, dynamic EBCT 90% and 80%.

Conclusion: EBCT has shown the highest sensitivity specificity in detection of dynamic tracheal instability in COPD patients comparing with impulse oscillometry and flow-volume curve.

Multislice-spiral computed tomography (MSCT) versus Gd-BOPTA-enhanced magnetic resonance imaging (Gd-BOPTA-MRI) in the detection and characterization of hepatocellular carcinoma

I. Sansoni, A. Laghi, M. Celestre, C. Miglio, M. Di Martino, L. Coletta, M. Rengo, R. Passariello; Rome/IT

Purpose: To compare diagnostic accuracy of tetraphasic multislice-spiral computed tomography (MSCT) and Gd-BOPTA-enhanced magnetic resonance imaging (Gd-BOPTA-MRI) in detecting and characterizing hepatocellular carcinoma (HCC) suspected lesions.

Methods and Materials: Sixty-five patients with chronic hepatitis were referred for CT and MRI hepatic evaluation. CT was performed using a 4-slice scanner with tetraphasic acquisition protocol (unenhanced phase, and contrasted arterial, portal venous and equilibrium phases). MR-study was performed on 1.5 T-scanner using the following acquisition protocol: pre-contrast T2-weighted and T1-weighted; dynamic Gd-BOPTA T1-weighted at arterial, portal, equilibrium phases; hepatobiliary (60 min) T1-weighted sequence. CT and MRI were evaluated for the presence, number and characterization of lesions. The number of lesions at final diagnosis was considered to be equal to CT plus MR detected lesions. Image data were compared with histopathological studies of surgical specimens and/or follow-up imaging.

Results: 5 patients were excluded from study because of claustrophobia in MR or allergy to contrast in CT. Among the remaining 60 patients, 17 were negative for HCC suspected lesions in both modalities and 43 were positive in at least 1 technique with 73 lesions (35 HCCs, 17 Dysplastic Nodules, 3 FNH, 18 Shunts). Both MSCT and Gd-BOPTA-MR imaging detected 66/73 (90.41%) HCC suspected lesions ($20 \geq 2$ cm, $46 < 2$ cm). Lesion characterization was correct in 52/66 (78.79%) cases at CT and in 58/66 (87.88%) at MR.

Conclusion: No statistically-significant difference between MSCT and Gd-BOPTA-MRI was observed in terms of lesion detection rate, independent of lesion size. Findings of MSCT and Gd-BOPTA-MRI in characterizing lesions were comparable. Both are valuable advanced techniques for cirrhotic liver screening.

B-711 14:09

Detection and characterization of focal hepatic lesions: Comparative study of MDCT and current MR techniques

H. Lee¹, J. Lee¹, S. Kim¹, K. Shin², J. Lee¹, J. Han¹, B. Choi¹; ¹Seoul/KR, ²Daejeon/KR

Purpose: To compare the diagnostic performance of MDCT and Gd-BOPTA-enhanced MR imaging for the detection and characterization of focal liver lesions.

Methods and Materials: We evaluated fifty-nine patients with 118 solid and 91 nonsolid lesions who underwent MDCT and MR imaging within a 1-month period (77 of malignant, and 132 of benign lesions). MR images were obtained as T2-weighted turbo spin-echo and T1-weighted gradient-echo before and after 0.1 mmole/kg Gd-BOPTA administration. Multiphasic multi-detector row helical CT was performed except ten cases of metastasis. In part I, two reviewers did a direct paired comparison of CT and MR images for the assessment of liver lesions in consensus. Differences in detection and characterization with CT and MR images were assessed with the two-sided Wilcoxon signed rank test. In part II, two independent and blinded reviewers assessed the CT and MR images separately and evaluated diagnostic performance of each image modality using ROC curve analysis.

Results: In a direct comparison of images, the reviewers showed better results in the performance of MR imaging than CT in solid lesion detection and lesion characterization (solid lesion detection, $p = 0.002$; lesion characterization, $p \leq 0.001$ and $p = 0.001$ for benign and malignant lesion). However, in the ROC analysis, areas under the ROC curves are not significantly different (solid lesion detection, $p = 0.862$ and $p = 0.281$ for each reviewer, non-solid lesion detection, $p = 0.916$ and $p = 0.284$, lesion characterization, $p = 0.125$ and $p = 0.426$).

Conclusions: In the detection and characterization of focal liver lesions Gd-BOPTA-enhanced MR and MDCT show a similar diagnostic performance.

B-712 14:18

Focal liver lesion detection and classification on multi detector-row computed tomography (MDCT) and SPIO-enhanced magnetic resonance imaging (MRI): Could awareness of the patients clinical history influence the reader's diagnosis?

R. Cianci, A. Filippone, E. Grassetto, F. Di Fabio, C. Colosimo; Chieti/IT

Purpose: To determine the influence of clinical data on reader's diagnostic accuracy in liver lesion detection and classification with MDCT and non-enhanced and ferucarbotran-enhanced MRI.

Materials and Methods: 87 oncology patients with focal lesions underwent MDCT and MRI within 1 week. Image analysis was performed for each diagnostic method by two experienced radiologists in two different reading sessions. The first session was carried out without knowledge of the clinical data and for the second one readers were aware of the data. The degree of diagnostic confidence was expressed according to a four point scale for detection (1: Certainly absent; 2: Probably absent; 3: Probably present; 4: Certainly present) or for classification (1: Certainly benign; 2: Probably benign; 3: Probably malignant; 4: Certainly malignant). The overall diagnostic accuracy and receiver operating characteristic curves analysis (ROC) for each reading session and each reader were calculated.

Results: Awareness of clinical data significantly improved the lesion detection rate ($p < .05$), mostly of small sized lesions (< 1 cm) for MDCT and for MRI. There wasn't any statistically significant difference between the two reading sessions regarding MDCT overall diagnostic accuracy and Az values because there was an associated increase in the number of false-positive findings with awareness of clinical data. Conversely, SPIO-enhanced MR diagnostic accuracy and Az values significantly increased with awareness of clinical data, thanks to a reduction in false negative cases without an increase in false positive cases.

Conclusions: Knowledge of clinical data does not influence the reader's overall accuracy for MDCT although it improves reader's overall accuracy for MRI in the diagnosis of focal liver lesions.

Identifying resectable hilar cholangiocarcinoma: Mutidetector CT (MDCT) versus MR imaging

E.-S. Cho; Seoul/KR

Purpose: To compare the capability of MDCT and MR imaging in identifying patients who have resectable hilar cholangiocarcinoma.

Materials and Methods: Fourteen patients with suspected hilar cholangiocarcinoma underwent contrast-enhanced MDCT (using 4- and 16-slice scanners with a high resolution protocol and MPR reconstruction), MR imaging (with T1W axial, T2W axial, and MRCP images) and direct cholangiography. 7 of 14 patients underwent surgical resection. Two radiologists evaluated bile duct extension on MDCT and MR imaging according to the Bismuth classification and the results were correlated with pathologic findings (n = 7) or direct cholangiographic findings (n = 7). They evaluated lymph node metastasis and vascular involvement on MDCT and the results were correlated with pathologic findings (n = 7).

Results: In terms of bile duct invasion, the diagnostic accuracy of MDCT was 78.6% (11 of 14), whereas that of MR imaging was 42.9% (6 of 14). On MDCT, two cases were overdiagnosed and one was underdiagnosed. On MR imaging, six cases were overdiagnosed and two were underdiagnosed. On MDCT, the diagnostic accuracy of lymph node metastasis was 71.4% (5 of 7), that of hepatic arterial involvement was 85.7% (6 of 7) and that of portal vein involvement was 85.7% (6 of 7).

Conclusions: MDCT was superior to MR imaging in the evaluation of bile duct invasion. MDCT was accurate in the diagnosis of lymph node metastasis and vascular invasion. Therefore, MDCT provides more comprehensive preoperative information in hilar cholangiocarcinoma than MR imaging.

B-715 14:36

Comprehensive assessment of metastatic spread in patients with malignant melanoma by whole-body MR imaging with high-resolution

C. Müller-Horvat, P. Radny, J. Schäfer, C. Pfannenberg, S. Khorchidi, T. Nägele, C.D. Claussen, H.-P. Schlemmer; Tübingen/DE

Aim: Individual Therapy of patients with malignant melanoma considerably depends on information about tumor spread. Magnetic resonance imaging (MRI) has the distinct advantage to provide high resolution information, but state-of-the-art MRI of the whole body was so far impractical within one single examination. The aim was to investigate the clinical feasibility of a novel whole-body MRI system for comprehensive assessment of metastatic spread in clinical routine.

Methods: Initial feasibility study including 48 patients with malignant melanoma with known metastatic spread. MRI and conventional spiral CT of the whole body were performed between February 2, 2004 to August 8, 2004. Whole-body MRI and CT were assessed by two independent radiologist and findings were finally compared in consensus.

Results: Whole-body MRI was successfully performed in 48 subjects requiring a total room time < 60 min. Metastases not detected on CT were found in following locations (cerebral, n = 3; bone, n = 10; muscle, n = 4; subcutaneous metastases, n = 3; spleen, n = 2; liver, n = 2). In 3 patients therapy had to be modified. Pulmonary nodules smaller 5 mm were detected only on CT in 3 patients. Tumor spread to brain, abdominal and pelvic organs, lymph nodes and bone was otherwise correctly visualized compared to CT.

Conclusion: High-resolution whole-body MRI is feasible in clinical routine within one single examination and may have important impacts on management of patients with malignant melanoma.

B-716 14:45

The clinical impact of FDG PET on the management of patients with colorectal liver metastases and comparison with conventional imaging.

Evaluation with evidence based practice techniques

J.J. Sheehan, C.A. Ridge, E.V.M. Ward, S.E. Harte, G.J. Duffy, C.D. Collins, D.E. Malone, S.J. Skehan; Dublin/IE

Purpose: Using evidence based practice techniques we determined that PET with a sensitivity of 90% was the most sensitive imaging modality for detecting colorectal carcinoma liver metastases (CRCLM). All patients being considered for liver resection underwent a PET. This study retrospectively evaluated the clinical impact of using PET to stage colorectal liver metastases pre-operatively in our practice.

Materials and Methods: We selected consecutive patients with colorectal

carcinoma who had PET prior to liver resection. Radiologists reviewed PET images and compared these with conventional imaging (CT/MRI). Patients records were reviewed to establish surgical intentions before and after PET.

Results: From July 2002 to Dec 2003, 40 patients (M=25 and F=15) met the inclusion criteria. 95%(n = 38) had abnormal PET results. Of these, 47%(n=18) underwent hepatic resection. Diagnostic Impact: Discordance between PET and conventional imaging 64%(n = 24), which was predominately tumour upstaging (70%) by PET. Management Impact: Management change after PET 35% (n = 14), planned surgery cancelled 78% (n = 11). Surgical findings correlated with PET findings in 89% (n = 16). The discordances 11%(n = 2), (1 patient with tumour adherent to the diaphragm, 1 young patient with an equivocal PET result) were unresectable at laparotomy. 24%(n = 5) patients with limited extrahepatic disease on PET underwent laparotomy and CRCLM resection. Illustrative PET images will be shown and correlated with conventional imaging.

Conclusions: PET has a major impact on staging and surgical management of CRCLM. Extrahepatic metastases are not an absolute contraindication to liver resection.

B-717 14:54

Detection of tumor and metastatic disease by MR imaging vs PET-CT: Value of a new whole-body MR scanner

G.P. Schmidt, A. Baur-Melnyk, K. Hahn, M.F. Reiser, S.O. Schoenberg; Munich/DE

Purpose: To compare the accuracy for detection of malignant disease by whole body-MR imaging using parallel imaging and whole-body dual-modality PET-CT.

Materials and Methods: Preliminary results from a prospective study are presented, in which 20 patients with different oncological diseases underwent whole body dual modality-FDG-PET-CT screening for tumor staging or in case of suspected metastatic disease. All patients also underwent whole-body MR imaging with the use of parallel imaging. Coronal T1W- and STIR-sequences, axial T2W imaging of lung/abdomen (HASTE), contrast-enhanced dynamic and static T1W-sequences of liver, brain and abdomen were performed. Using a 32-channel MR imaging scanner with a total FOV of 205 cm and free table movement, complete patient anatomy was covered in one examination. Two experienced radiologists read the MR imaging-scans, one radiologist and nuclear scientist read PET-CT scans, each in consensus in a clinical setting. Presence of primary tumor, lymph node involvement and degree of metastatic disease was assessed using PET-CT as the gold standard for tumor staging.

Results: Metastasis from gastrointestinal tumor (25%) and breast cancer (25%) were the most common diagnoses. 4 patients had detectable primary tumor and 2 patients recurrent tumor. 124/140 malignant lesions were detected with MR imaging, resulting in a sensitivity of 89% and a specificity of 86%. In malignant lymph node detection sensitivity of MR imaging was 83% and specificity 85%.

Conclusion: Whole-body MR imaging is a reliable alternative in the detection of primary tumor and metastatic disease, although sensitivity in lymph node detection is impaired. With parallel imaging, high-resolution whole-body MR imaging is possible within reasonable scan times.

B-718 15:03

Preinterventional whole-body PET-CT in patients with malignant liver tumors: Influence on patient management to RF ablation therapy

H. Kuehl, G. Antoch, S. Rosenbaum, P. Veit, J. Barkhausen, A. Bockisch; Essen/DE

Purpose: Preinterventional imaging of patients with malignant liver tumors is mandatory to exclude extrahepatic tumor manifestation prior to RF ablation. The influence of whole-body PET-CT on management decision is evaluated.

Methods and Materials: 43 patients with hepatic malignancies (HCC 17, colorectal mets 14, other mets 12) were examined in PET-CT prior to planned intervention. CT was read alone by radiologists and the PET data evaluated by nuclear medicine physicians, each blinded to the others results. The PET-CT fusion data were read in consensus. The impact on the decision was analysed for the single imaging modalities as well as for the fusion data.

Results: 33 of 43 patients underwent RF ablation after whole-body PET-CT. The remaining 10 patients were not regarded as candidates for RF-ablation. In one patient CT showed complications of previous treatment and the patient was operated upon. In three patients negative PET results pointed to benign liver lesions which was then verified during follow-up. In the 6 remaining patients, whole-body scans revealed extrahepatic tumor spread, which was identified in 4 of 6 cases with CT and in all 6 cases with PET. PET/CT proved to be superior to PET alone in 5 of the 6 cases. Therapeutic regimen in 6 of the 10 patients not eligible for RF ablation was changed to systemic chemotherapy.

Scientific Sessions

Conclusions: The combination of whole body morphologic and metabolic imaging reliably identifies patients not suitable for local ablative therapy. PET-CT can be regarded as beneficial for patients planned for local ablative treatment with curative intention.

US-guided prostate biopsy: Is antibiotic prophylaxis necessary?

P. Bermudez Bencerray, J. Puig Domingo, A. Darnell Martin, A. Malet Munté, D. Gil Bello, A. Martin Olariz, M. Prieto Del Rei; Sabadell/ES

Purpose: To assess infectious complications in US-guided transrectal biopsy of the prostate comparing two groups of patients: one group with antibiotic prophylaxis and the other without prophylaxis.

Methods and Materials: A total of 1018 US-guided transrectal biopsies were performed in our centre from April 1996 to July 2003 with 16 G (n = 212) or 18 G (n = 806) core needles. Antibiotic prophylaxis was given in 404; the rest (614) received no antibiotics. Complications of the procedure were assessed at outpatient urologist visits between 1 week and one month after the procedure in the 212 first procedures and by telephone interview in the remaining 806.

Results: A total of 284 complications were found, including 41 major complications and 243 minor ones. Major complications were septic shock requiring admittance to the Intensive Care Unit (n = 3), sepsis (n = 3), Fournier gangrene (n = 1), urinary tract infection (n = 2), and fever requiring hospitalisation (n = 32). Minor complications were infection (n = 37), including 29 with fever that did not require admittance, prostatitis (n = 6), and epididymitis (n = 3). A total of 79.5% of all infectious complications occurred in patients without antibiotics and 20.5% in patients that received antibiotic prophylaxis. Of all major infectious complications, 73.2% occurred in the group without antibiotic prophylaxis, versus 26.8% in the prophylaxis group.

Conclusion: US-guided transrectal biopsy of the prostate has a statistically significant higher risk of infectious complications without antibiotic prophylaxis.

B-720 14:09

Comparison of the efficacy of three different anaesthetic regimens for transrectal ultrasound guided prostate biopsy (TUPB)

B.C. Anil Kumar, R.I. Doull; Dundee/UK

Purpose: TUPB is an increasingly common procedure performed using different anaesthetic techniques. This is a retrospective analysis of patient perceived pain during TUPB using three different regimens involving local intrarectal lignocaine gel (LILG) and Periprostatic lignocaine infiltration (PLI).

Materials and Methods: 241 patients who underwent TUPB between May 2001 and July 2004 were given a questionnaire to complete following their biopsy. Group A-(51 Patients, May 2001-December 2001) LILG 5 minutes before biopsy. Group B- (99 patients, January 2000-December 2002) LILG 5 minutes before and PLI 2 minutes before biopsy. Group C -(91 Patients, September 2003- July 2004) LILG 20 minutes prior and PLI 2 minutes before biopsy. Patients were asked about pain during the procedure, complications following the procedure and willingness to undergo repeat procedure if clinically indicated.

Results: 88% (45/ 51) in group A, 81%(81/ 99) in group B and 88% (80/91) in Group C responded. 88.5% in group A, 85% in group B and 96.2% in group C reported the procedure "easily tolerable" or "tolerable" which was statistically significant ($P < 0.018$). 11.5% in group A, 15% in group B and 4% in group C reported the procedure "barely tolerable" or "intolerable". Comparing groups A and B, there was no statistical difference in pain perception whereas there was significant statistical difference between Group B and C ($P < 0.046$).

Conclusion: LILG alone is as effective as LILG plus PLI for TUPB. LILG application 20 minutes before is more effective than application 5 minutes before the procedure.

B-721 14:18

Washout dynamic contrast enhanced versus T2 weighted MR imaging prior to transrectal ultrasound biopsy in patients at high risk for prostate cancer

M.A. Haider¹, A. Toi¹, J. Sweet¹, A. Kale¹, N. Bloch², J. Trachtenberg¹; ¹Toronto, ON/CA, ²Boston, MA/US

Purpose: Elevated PSA and prostatic intraepithelial neoplasia (PIN) are prostate cancer risk factors that can lead to repeated transrectal ultrasound biopsy (TRUSBx). The purpose of this study was to compare washout dynamic contrast enhanced MR imaging (WDCEMRI) to T2 weighted MRI for localization of prostate cancer in high risk patients.

Methods: In this prospective study, 33 patients with elevated PSA (> 4 ng/ml) and/or a prior diagnosis of PIN underwent WDCEMRI with an endorectal coil using a 1.5 T system (GEMS, Milwaukee, WI). Axial and coronal T2 weighted images and axial dynamic T1 contrast enhanced images were performed (3DFSPGR, 256x192, 3/0 mm, TR/TE 11.1/4.2 ms, flip angle 20deg, gadodiamide [Omniscan, Amersham, Princeton, NJ], 0.01 mg/kg at 4 ml/s, 9 phases, 7 post-contrast). Dynamis images were analyzed using a mono-exponential decay model. A washout decay constant threshold was used for cancer detection. Following MRI systematic TRUSBx biopsy was performed in 13 zones, 10 in the peripheral zone [PZ]. Pathologic diagnosis from the cores was used as a reference standard. Analysis was limited to the PZ.

Results: WDCEMRI accurately localized cancer in 11 of the 15 positive cores for a sensitivity of 73% versus 53% (8/15) for T2. Specificity was 73% (232/315) for WDCEMRI versus 79% (250/315) for T2. WDCEMRI was superior to T2 in providing useful localization for TRUSBx in 6/10 patients and T2 was superior in 0/10.

Conclusion: WDCEMRI has better regional sensitivity for prostate cancer than T2 weighted imaging and thus may be helpful in directing TRUSBx in patients who have had repeated negative biopsies.

B-722 14:27

Prostate biopsy in supine position in a standard 1.5 T scanner under realtime MR-imaging control using an MR-compatible endorectal biopsy device. First results

K. Engelhard¹, H.-P. Hollenbach², B. Kiefer², A. Winkel³, D. Engehausen², ¹Nürnberg/DE, ²Erlangen/DE, ³Schwerin/DE

Purpose: To investigate a biopsy device (MR imaging Devices Daum GmbH, Schwerin, Germany) for MR imaging-guided transrectal prostate biopsy.

Method and Materials: 20 patients with elevated PSA levels, negative tumor results in transrectal ultrasound (TRUS) and episodes of prior tumor negative prostate biopsies underwent MR imaging guided prostate biopsy in a 1.5 T scanner (Siemens Medical Solutions, Erlangen). After localisation of tumor suspected areas using a combination of an endorectal and two body-phased-array coils (one anterior, one posterior) the endorectal coil was replaced by the biopsy device. The needle guide was filled with a MR-visible fluid to control positioning of the needle using a real-time TrueFisp and a T2-TSE sequence observed with an in-room monitor. Core biopsies were taken manually in the magnet in supine position of the patient.

Results: The biopsy needle could be visualized and correctly positioned in all cases. Tumor suspected lesions with a diameter < 10 mm could be successfully punctured. In cases of histological confirmed cancer a good correlation was found between tumor location on the MR-images and tumor location at histology. The whole examination time was 60 minutes. No complications more than those associated with TRUS-guided biopsy were observed.

Conclusions: The demonstrated biopsy technique performed in a supine position of the patient can be a valuable tool for obtaining MR imaging-guided biopsies based on MR-images showing suspicious areas, which were not identified on TRUS-imaging.

B-723 14:36

Prospective evaluation of a routine protocol for combined magnetic resonance and ¹H-spectroscopic imaging of the prostate in patients prior to radical prostatectomy

A. Wetter, T. Engl, D. Nadjmabadi, T. Lehnert, W.-D. Beecken, D. Jonas, T.J. Vogl; Frankfurt a. Main/DE

Purpose: To prospectively evaluate a routine protocol for combined magnetic resonance and ¹H-spectroscopic imaging of the prostate in patients prior to radical prostatectomy.

Methods: 25 patients were examined prior to radical prostatectomy with our combined protocol, which consisted of T2-weighted turbo-spin-echo sequences

Scientific Sessions

and a transverse T2-weighted fat-sat TSE-sequence. For spectroscopy, we used a 3D-CSL-SE-sequence with a scan time of 10:45 minutes. Image reading was performed by two radiologists, tumors were classified in consensus according to the TNM classification. Voxels were classified as tumor-suspect, when the ratio of Cho+Crea/Cit was greater than 1.1, according to a previous work of our group. Imaging and spectroscopic results were compared and correlated to the results of the pathologic examination of the whole prostate.

Results: Examination time of the combined protocol was 20 minutes, a time feasible for routine use. Imaging alone resulted in a sensitivity and specificity regarding exact T-staging of 71% and 83%, respectively. Adding of spectroscopy could not enhance staging accuracy, in terms of a better differentiation between unilateral (T2a, T2b) and bilateral (T2c) involvement, as proved by comparison with the histological specimens. Also regarding T2 versus T3, the results of imaging and spectroscopy did not differ significantly. A disadvantage of spectroscopy was the long postprocessing time, taking in average 45 minutes per patient into account.

Conclusion: A combined examination with MR imaging and spectroscopy is possible in 20 minutes examination time and feasible for routine use, but cannot enhance sensitivity and specificity significantly.

B-724 14:45

Potential value of diffusion-weighted echo-planar magnetic resonance imaging in differentiating malignant from benign nodules in prostate cancer

S. Reinsberg, E. Scurr, J. Brewster, D. Dearnaley, A. Horwich, N.M. deSouza; Sutton/UK

Purpose: To determine the potential of diffusion-weighted magnetic resonance imaging (DW-MRI) in differentiating benign from malignant nodules by comparing the diffusion coefficients of low signal intensity nodules seen on T2-weighted images within the peripheral zone (PZ) with that of the central gland (CG).

Methods: Sixteen patients 48-80 years (median 71 years) with prostate cancer (Prostate Specific Antigen levels 11.3 ± 1.2 IU) were imaged using an endorectal receiver coil and echo-planar DW-MRI sequences with 4 diffusion values ($b = 0, 300, 600, 800$ s/mm 2). Image parameters were 2500/69 msec [TR/TE], 96x128 matrix, 200 mm field of view, 4 mm slice thickness. Apparent diffusion coefficients (ADC's) from regions of interest encompassing 20 nodules within the PZ (median ROI size 53 mm 2) with positive biopsies, and the whole CG (median ROI size 289 mm 2) were measured. In addition, patients in whom all three or four biopsies from one side were benign had ADC values measured in non-malignant PZ (median ROI size 63 mm 2).

Results: ADC values from CG were 1530 ± 110 (mean \pm sd) while those from malignant PZ nodules were 1310 ± 190 . Values from non-malignant PZ were 1690 ± 220 . Differences between all three regions were statistically significant. 95% confidence intervals of the means differences and p-values are 112 to 330 and $p = 0.0004$ (CG vs malignant PZ), 55 to 515 and $p = 0.02$ (malignant PZ vs non malignant PZ), 21 to 295 and $p = 0.03$ (CG vs non malignant PZ).

Conclusion: DW-MRI may be a useful adjunct to conventional T2-weighted sequences for increasing sensitivity of prostate cancer detection. Diffusion is restricted in malignant compared to benign prostatic nodules.

B-725 14:54

USPIO-enhanced T2* images at 1.5 T and 3 T: Initial results

R.A.M. Heesakkers¹, J.J. Futterer¹, A. Hövels¹, H.C. van den Bosch², T.W.J. Scheenen¹, J.O. Barentsz¹; ¹Nijmegen/NL, ²Eindhoven/NL

Purpose: To explore the ability to perform ultrasmall superparamagnetic particles of iron oxide (USPIO)-enhanced MR imaging at high field strengths (3 T) and to compare the image quality at 1.5 T and 3 T, in patients with prostate cancer.

Methods and Materials: 23 consecutive patients with prostate cancer were administered USPIO. 24 Hours after administration T2* images of the obturator area were acquired at 1.5 T and 3 T MR scanners, using a PPA coil, with an in-plane resolution of 0.56x0.56x3.00 mm and 0.50x0.50x2.50 mm, respectively. For both sequences 3 echo trains were used. Scanning parameters and type of scanner were not visible for the readers.

All images were evaluated on muscle-fat contrast, vessel-fat contrast, lymph node border, number of nodes and total image quality by 2 readers. All positive nodes were counted and compared.

Results: T-test showed significant difference in the results of the muscle-fat contrast, vessel-fat contrast, lymph node border and total image quality in the benefit of 3 T ($p < 0.05$). All positive nodes found at 1.5 T were also found at 3 T. In 3 patients an additional positive node was found at 3 T which was not visible on 1.5 T and which was outside of the usual resection area.

Conclusion: USPIO-enhanced techniques can be used at high field strengths and a high in plane resolution can be obtained. This may result in improved performance.

B-726 15:03

3D multiplanar TRUS with power Doppler in detecting prostatic fossa recurrences following radical prostatectomy

V. Gazhonova, A. Chepurov, A. Zubarev; Moscow/RU

Purpose: To identify the US features of local tumor progression with 3D PD TRUS in patients with rising PSA levels after radical prostatectomy (RP) for prostate cancer.

Methods and Materials: 14 pts with rising (more than 0.3 ng/ml) PSA following RP (range 3 to 10 years, mean 38 months) underwent 3D PDTRUS study for identification of local tumor recurrence. 3DUS images were evaluated for the presence of focal lesions, residual tissue volume, vascularity degree (VD) of the residual tissue. US finding were considered suspicious if any unusual hypoechoic tissue was present adjacent to the bladder neck, retro-trigone or perianastomotic site with an increase in the VD present.

Results: Of 14 pts, 9 had positive TRUS. Target biopsies revealed cancer in 8 of 14 pts (2-T2bNoMo, 4-T3aNoMo, 2-T3bNoMo). The mean volume of identified tissue in the prostatic fossa was higher in the cases with tumor recurrence than in normal cases ($p < 0.05$). There were significant differences for VD values between local recurrence areas than in non-cancerous zone ($p < 0.001$). The echogenicity was found to be lower in the region of malignancy ($p < 0.001$). Hyperechoic foci were characteristic of malignant tissue in 33% of cases. The overall accuracy, sensitivity and specificity of tumor recurrence detection after RP using 3D TRUS in were 93%, 89%, 83%, respectively.

Conclusions: 3D TRUS with PD appears to be clinically feasible and added anatomic information from the coronal plane for better detection of the recurrent tumor. Increase in the vascularity degree in the prostatic fossa could be used as criteria for diagnosis of tumor recurrence.

B-727 15:12

Multi-detector row CT cystoscopy in the evaluation of urinary bladder neoplasms

A.C. Tsili, C. Tsampoulas, F. Katzioti, D. Giannakis, A. Silakos, N. Sofikitis, S.C. Efremidis; Ioannina/GR

Purpose: To evaluate the utility of multi-detector row CT urography in the detection of urinary bladder tumors.

Materials and Methods: Twenty-one patients presented with hematuria and abnormal findings at conventional cystoscopy, underwent CT cystoscopy. The patients were examined in supine and prone positions, after bladder distention with room air. We used a detector configuration of 16x0.75 mm and pitch 1.2. We evaluated the transverse tomographic slices, the sagittal and coronal reformatted images. Virtual images were created using volume rendering technique. The results were compared to those of conventional cystoscopy, operative and pathology findings.

Results: CT cystoscopy detected all bladder lesions (43), as seen with conventional cystoscopy. The size of the lesions ranged from 0.3 to 8.2 cm in diameter (mean size: 2.4 cm). Fifteen lesions were smaller than 0.5 cm in diameter.

Conclusion: Multi-detector row CT cystoscopy is a highly accurate technique for the detection of urinary bladder neoplasms. With this technique the identification of lesions smaller than 0.5 cm seems promising.

B-728 15:21

Lymph node staging in patients with cervical cancer: Accuracy of integrated FDG PET/CT in correlation to histopathologic findings

S. Sironi, A. Buda, M. Picchio, C. Messa, F. Fazio; Monza/IT

Purpose: To prospectively determine the accuracy of integrated PET/CT for evaluating lymph node metastasis in patients with cervical cancer, using histopathologic findings as the reference standard.

Materials and Methods: Forty-eight women (mean age, 45.3 years) with clinical stage IA, IB, or IIA carcinoma of the uterine cervix were included in the study. All the 48 patients enrolled were scheduled for radical hysterectomy with pelvic lymph node dissection. Before surgical treatment, all of them underwent fluorodeoxyglucose (FDG) PET/CT imaging. At PET/CT studies, eight lymph node sites in the pelvis bilaterally were assessed for data analysis; paraaortic lymph node site was also evaluated. In all cases, imaging findings were compared with results of histopathologic examination. Fisher exact test and Cohen kappa test were used for statistical analysis.

Results: Ten (21%) of 48 patients had metastatic lymph nodes at histopathology, and thirty-eight (79%) of 48 had no histologically confirmed node metastasis. Of the total 864 lymph nodes sampled, 17 (2%) were found to be positive for malignant cells at histopathology, of which 15 were from pelvic and two from paraaortic

Scientific Sessions

sites. A good correlation was found between PET/CT and histopathologic diagnoses ($k = 0.67$). The overall lesion-based sensitivity, specificity, positive predictive value (PPV), negative value (NPV), and accuracy of PET/CT were 47%, 88%, 62%, 80% and 76%, respectively. The overall patient-based sensitivity, specificity, PPV, NPV, and accuracy of PET/CT were 50%, 95%, 71%, 88% and 85%, respectively.

Conclusion: PET/CT is accurate in depicting lymph node metastasis in cervical cancer.

Radiofrequency ablation of small breast cancer with a dedicated cooled tip needle electrode

G. Simonetti, G. Manenti, C. Pistolese, E. Cossu, O. Buonomo, A. Orlando; Rome/IT

Purpose: To evaluate the uniformity and reproducibility of thermal lesion ablation on selected breast tumors ≤ 2 cm and quantify the volume of tissue destruction induced with a new available radiofrequency ablation device and RF-generator.

Methods and Materials: A new cooled-tip electrode was realized to induce wide thermal lesions in eight swine breasts *in vivo* and in 12 resected pre and post-menopausal mammary glands from human surgical mastectomy. Five patients with biopsy proven non-palpable invasive breast carcinomas underwent sonographically guided RFTA of their breast tumors under general anesthesia followed by a 15 days delayed resection. Endpoints were technical success, completeness of tumor kill, marginal clearance, skin damage and patient reports of pain and procedural acceptability.

Results: In resected mammary glands the mean diameter of the radiofrequency-induced lesion was 3.7 ± 0.4 cm which correspond to approximate volume of 26.67 ± 9.59 cm^3 . *In vivo*, the mean diameter was 3 ± 0.4 cm corresponding to an approximate volume of 11.16 ± 3.65 cm^3 . The procedure was complete in all patients without any residual pathology and disease free margins histopathologically examined by using eosin hematoxilin and nicotinamide adenine dinucleotide diaphorase stains. The ablation procedure was well tolerated without skin and thoracic wall damages.

Conclusions: US-guided percutaneous ablation of small selected invasive breast carcinoma with dedicated device is a feasible and reliable technique because of the higher energy deposition due to the cooling of the needle electrode.

B-730 14:09

Galactography-guided stereotactic wire localization of intraductal lesions

M.H. Fuchsäger, R.S. Cárcilia, C.C. Riedl, M. Rudas, D. Flöry, T.H. Helbich; Vienna/AT

Purpose: Diagnostic galactography allows concise preoperative determination of number, location and extent of the lesions causing nipple discharge. Stereotactic targeting through galactography may provide further guidance to the surgeon and increase the likelihood of the causative lesion being found. The purpose of this study was to assess the feasibility of galactography-guided stereotactic wire localization in intraductal lesions.

Methods and Materials: 46 patients (mean age 58.7 years) with nipple discharge and galactographically verified intraductal lesions were included in this prospective trial. Galactography-guided stereotactic preoperative wire localization was performed in 47 lesions. Surgery and histologic work-up were performed in all cases.

Results: 14 (29.8%) lesions were malignant and 33 (70.2%) benign. 10 of 14 malignant lesions were ductal cancers *in situ*, three invasive ductal cancers and one invasive lobular cancer. 25 of 33 benign lesions were papillomas (five with atypia) and eight fibrocystic changes. In all patients nipple discharge ceased after open surgery (follow-up of at least 18 months).

Conclusion: Galactography-guided stereotactic wire localization is an accurate, safe, simple and time-saving method. This technique can be offered as an alternative to current surgical techniques in patients with galactographically verified intraductal lesions.

B-731 14:18

MR imaging guided localisation of breast lesion

J. Veltman, C. Boetes, J. Blickman, J.O. Barentsz; Nijmegen/NL

Purpose: To evaluate the accuracy of localisation wire placement using an open breast coil with mammography intervention aid and software (OBC, MIA&S).

Methods and Materials: Lesions only detectable on MR imaging were pre-operatively located using OBC and MIA&S (Machnet, Netherlands) and a double hook wire (DHW). Lesions were visualised using conventional FLASH3D pre and post gadolinium contrast subtraction images. DHW placement was done based on software output. Placement accuracy was evaluated by measuring the distance in three directions (AP, CC and LR) from the centre of the lesion and the tip of the DHW to the skin. Measurement differences were analysed. Time needed to perform a procedure was also recorded.

Results: 24 patients were included with a total of 26 lesions. Mean lesion size was 9 mm (range 4-35 mm). In AP direction the DHW was placed with a mean difference of 2.9 mm from the lesion centre (range 0-27 mm). In CC direction this was 1.2 mm (range 0-4 mm) and in LR direction 2.3 mm (range 0-5 mm). The largest difference in AP direction (27 mm) was due to technical limitations; the lesion was out of range for the device. Mean difference in AP direction, without this 1 problematic lesion, was 1.8 mm (range 0-4 mm). Procedure time varied between 25 and 50 minutes with an average of 33 minutes.

Conclusion: Localisation of breast lesions are accurate using the OBC with MIA&S and can be performed within acceptable time.

B-732 14:27

False-negative results after stereotactically-guided vacuum biopsy

D. Peter, J. Gruenhagen, R. Wenke, I. Schreer, M. Heller; Kiel/DE

Purpose: Detection of false-negative (FN) results after vacuum biopsy (VB) to differ retrospectively between misjudgement of a representative biopsy or an incidental occurrence of malignancy.

Methods and Materials: 343/668 patients, who underwent VB in our institution between 03/1999 and 12/2002 turned out to be benign. Those patients were followed to determine the FN rate of VB.

Results: The mean length of follow-up was 29.8 months for 1999 (25, 8 month for 2000, 23, 6 month for 2001 and 13 month for 2002). 44 patients (12.8%) were lost to follow-up. 7 cases (2%) showed progression, so that re-biopsy or open surgery had to be performed. 5/7 turned out to be malignant. Four cases must be considered retrospectively as not representative: One mass was obscured by hematoma on postinterventional mammography, three other cases with microcalcifications showed more than one lesion. These lesions remained because they were misinterpreted as being benign too.

Conclusion: The FN rate of 1.2% (4/343) is lower than the rate after needle localisation and open surgery. Correlation between histology and radiologic appearance is of highest importance, particularly if there is more than one group of microcalcifications. In 3 cases the diagnosis of malignancy was delayed because the remaining lesions were not removed. Furthermore patients must be strongly advised to take part in follow-up investigations for 3 years to finally exclude FN biopsy.

B-733 14:36

Vacuum-assisted breast biopsy (VAB): A study of cost-effectiveness

S.H. Heywang-Köbrunner¹, K. Bernerth², K. Rotter³, C. Perlet¹; ¹Munich/DE, ²Halle/DE, ³Leipzig/DE

Purpose: To examine cost effectiveness of percutaneous VAB.

Methods and Materials: The data of 244 patients with 288 single foci biopsied during 6 consecutive months were evaluated. 52 malignancies and 7 ADH were verified.

Results: Patients were split up into patients with single, two or 3 foci. Costs were calculated according to the diagnostic or therapeutic path which they had to follow based on their disease according to the usual treatment. The costs of vacuum biopsy were compared with the costs of open surgical biopsy (assuming that the lesions were too small or uncharacteristic for percutaneous biopsy (=correct selection)). Compared to surgical biopsy the costs for an average benign case were 67%, when VAB was used. For an average malignant case the costs using VAB also amounted to 67% of the costs of a merely surgical approach. Cost savings of malignant cases were due to the fact that fewer operations were needed to achieve clear margins and lymph node surgery, where needed.

Conclusion: With the correct selection (masses and larger lesions can undergo CNB) VAB is cost-effective.

Scientific Sessions

Clip migration after 11-gauge vacuum-assisted stereotactic breast biopsy with lateral approach: Retrospective review of 447 clips deployed after completion of breast biopsy

C. Chaveron, L. Ceugnart, F. Bachelle; *Lille/FR*

Purpose: To assess clip migration after vacuum-assisted breast biopsy with lateral approach and explain mechanisms of migration. We suggest options to localize the biopsy site before surgery in case of clip migration.

Methods and Materials: Retrospective review was performed of 447 lesions that underwent clip placement after stereotactic vacuum-assisted breast biopsy with an 11-gauge probe. The clip was placed when images obtained after biopsy suggested a complete removal. Postbiopsy mammography in two orthogonal planes was performed 8 days later.

We compared pre- and postbiopsy mammograms and measured the distance between the clip and biopsy site.

Results: The distance from clip to lesion site was more than 20 mm on at least one post-biopsy image in 60(13.4%) of 447 lesions that underwent clip placement. Marker clip misplacements are mainly attributed to an accordion effect along the axis of compression; in theory, this effect decreases with lateral approach of probe. Other mechanisms can explain: Delayed accordion effect, bleeding during or after the procedure, movement of the breast. A few options are suggested: Sonographically research of postbiopsy scar, sonographically clip placement a few days after biopsy....

Conclusion: Clip migration after vacuum-assisted breast biopsy does exist and is a practical concern. For surgical cases, repeat craniocaudal and 90° mediolateral mammograms should be obtained routinely on the day of pre-operative localization. We try to identify the percutaneous biopsy site in the excised specimen and to correlate histologic findings in the surgical specimen with those at vacuum-assisted biopsy to determine if the correct tissue was removed at surgery.

B-735 14:54

A new BiomarC tissue marker for breast biopsy: Clinical evaluation in ultrasound, mammography, cat scanning and breast MR imaging

M.T. Nelson, M. Garwood, S. Meisamy, P.J. Bolan, A. McIntosh; *Minneapolis, MN/US*

Purpose: To evaluate the clinical use of BiomarC tissue marker in image guided breast biopsies using MR imaging, mammography, and ultrasound.

Methods and Materials: Forty BiomarC breast markers were placed after breast biopsy using stereotactic mammography (11 markers), ultrasound (25 markers) and MR imaging placement (4 markers). The BiomarC tissue marker is a sterile, single patient use, pyrolytic carbon coated zirconium oxide discrete marker that is visible on standard radiographs (X-ray, mammography, stereotatic imaging and digital breast imaging) ultrasound and MR imaging at up to 4.0 Tesla field strength. All of the BiomarC tissue markers were placed through existing biopsy needles or through a 10 gauge trocar.

Results: All 40 BiomarC's were placed within 4 mm of the original biopsy site. Follow-up at 6 months on 10 benign biopsy patients showed no migration of the BiomarC tissue marker. The BiomarC was successfully placed under MR imaging guidance using a titanium trocar 140 mm. Four patients also had a 4 T MR imaging research study completed for follow-up neoadjuvant chemotherapy and the BiomarC tissue marker did not interfere with magnetic resonance imaging or magnetic resonance spectroscopy.

Conclusion: 40 BiomarC tissue markers were placed under image guidance using ultrasound, stereotactic mammography and MR imaging. All of the BiomarCs were in excellent position on post biopsy imaging and there is no evidence of breast marker migration on 6 month follow-up imaging. The BiomarC breast tissue marker does not interfere with magnetic resonance imaging or magnetic resonance spectroscopy studies.

B-736 15:03

A validation study for ultrasound guided 14-gauge large core breast biopsy

S. Jaromi¹, R. Mallek¹, M. Memarsadeghi¹, M. Fuchsjaeger¹, L. Liberman², T.H. Helbich¹; ¹*Vienna/AT*, ²*New York, NY/US*

Purpose: To determine the false-negative rate of ultrasound guided 14-gauge large core breast biopsy in a validation study of lesions that had subsequent surgical excision.

Methods and Materials: Retrospective review was performed of 722 lesions that underwent ultrasound guided 14-gauge large core breast biopsy and subsequent surgical excision. Biopsies were performed by five experienced radiologists. Medical records, imaging studies, and histologic findings were reviewed and

compared for agreement. A false-negative cancer case was defined as a pathologically proven cancer in which biopsy yielded benign results (except high-risk lesions).

Results: False-negative findings were encountered at ultrasound guided 14-gauge large core breast biopsy in 1.5% (7/468) of pathologically proven cancers. All false-negative findings could be prospectively identified due to imaging-histologic discordance. Ultrasound guided biopsy underestimated 46.4% (32/69) of the high-risk lesions. Ultrasound guided biopsy yielded benign results in 217 lesions. In ten of those 217 lesions (4.6%) the ultrasound guided benign biopsy result was not in agreement with the benign result of subsequent surgical excision.

Conclusion: Ultrasound guided 14-gauge large core breast biopsy had a false-negative rate of 1.5%. This 1.5% false negative rate is comparable to the previously published false-negative rate of needle localization and surgical biopsy.

B-737 15:12

Sonographically-guided percutaneous biopsy using two different vacuum biopsy systems

S.H. Heywang-Köbrunner¹, C. Perlet¹, A. Heinig², A. Bernhardt²; ¹*Munich/DE*, ²*Halle/DE*

Purpose: To evaluate the use of sonographically-guided percutaneous breast biopsy in lesions with uncertain histology and/or small size and to compare two vacuum-biopsy systems.

Methods and Materials: 34 patients were examined between July 2002 and August 2003. Patients were selected for large-volume percutaneous sonographically-guided vacuum assisted biopsy either by small size of the lesion or by its uncharacteristic features, which indicated a probably unspecific histology. Vacuum biopsy was performed with Mammotome HH (Ethicon) or Vacu Flash (BIP) through a coaxial needle.

Results: 2 invasive cancers (6, 10 mm) and one DCIS, 2 fibroadenomas, 1 papilloma, 1 fat necrosis, 1 inflammatory cyst and another 26 unspecific histologies resulted. 32/34 cases were considered representative due to removal of most of the lesion. One open biopsy and one MR imaging were recommended. The Vacu Flash system is handled easier, the Mammotome is faster but requires more skill. It shows advantages in case of bleeding.

Conclusion: Both systems are useful and reduce open biopsy in selected doubtful cases with unspecific histology. Study supported by Dt. Krebsliga and Dresdner Bank: Schleicher-Stiftung.

Comparison of ferumoxtran-10 and ferumoxytol for MR imaging of experimental arthritis

G.H. Simon, J. von Vopelius-Feldt, M.F. Wendland, Y. Fu, K.V. Berejnoi, H.E. Daldrup-Link; *San Francisco, CA/US*

Purpose: To detect and characterize inflammatory processes in an animal model of antigen-induced arthritis using MR imaging enhanced with two different USPIOs.

Methods and Materials: A monoarthritis was induced in the right knee of 12 Sprague Dawley rats by subcutaneous injections of Freund's adjuvant and intraarticular injections of methylated bovine serum albumin. Saline was injected into the left knee as a control. Both knees underwent MR imaging at 2 T before and 3-120 min and 24 h after injection of 200 micromolFe/kg Ferumoxtran-10 (n = 6) or Ferumoxytol (n = 6). Pulse sequences comprised T2-weighted multiecho-2D-SE 100/20, 40, 60, 80/90 (TR/TE/flipangle), T2*-3D-SPGR 100/15/38 and T1-3D-SPGR 50/1.7/60 sequences. USPIO induced signal intensity changes of arthritic and contralateral knees were determined. A paired t-test was used for statistical analyses. Joint specimens were processed for histopathologic correlation.

Results: The synovium of the arthritic joints showed a marked and progressive

Scientific Sessions

positive enhancement on T1-weighted images and a negative enhancement on T2-TSE and T2*-GE images after administration of either USPIO up to 120 min p.i. After 24 h, the T1-enhancement disappeared and a remaining negative T2-enhancement was observed. This enhancement in arthritic knees was significantly different from normal knees, which showed no or minimal enhancement ($p < 0.05$). No significant differences were observed between the two USPIOS ($p > 0.05$). Prussian blue histopathology confirmed iron oxide accumulation within the synovium of the arthritic joints, but not in the contralateral normal joints.

Conclusion: Inflammation in antigen-induced arthritis can be equally detected and characterized with Ferumoxtran-10 and Ferumoxytol. This imaging approach may prove clinically useful to target and grade inflammatory processes.

B-740 14:09

Evaluation of neck and body nodal metastases with ferumoxtran 10-enhanced MR imaging: Phase III safety and efficacy study

A. Saleh¹, F. Caseiro-Alves², C. Weber³, W. Schima⁴, ¹Düsseldorf/DE, ²Coimbra/PT, ³Roissy/FR, ⁴Vienna/AT

Purpose: To determine the safety and efficacy of magnetic resonance (MR) imaging with ultrasmall particles of iron oxide (USPIO) for nodal staging in oncologic patients.

Methods and Materials: 193 patients were examined by MR imaging before and after intravenous administration of the USPIO contrast agent ferumoxtran 10 (Sinerem®; Guerbet, Roissy, France and Combidex®; Advanced Magnetics, Boston, USA). 160 patients were evaluable for the efficacy analysis. The diagnostic accuracy for nodal staging of pre- and postcontrast MR imaging was compared with the use of McNemar's test. Imaging results were correlated with histopathological findings.

Results: The performance of ferumoxtran 10-enhanced MR imaging for nodal staging was significantly superior to non-enhanced studies ($p = 0.001$). In the patient-by-patient analysis, sensitivity, specificity and accuracy of precontrast MR imaging improved from 56%, 93%, and 70%, respectively, to 84%, 80%, and 83%, respectively, with ferumoxtran 10-enhanced MR imaging. In the node-by-node analysis sensitivity, specificity and accuracy were 23%, 99% and 63%, respectively, with precontrast MR imaging and 98%, 72% and 84%, respectively with ferumoxtran 10-enhanced MR imaging. Accuracies of ferumoxtran 10-enhanced MR imaging in patients with carcinomas of the head and neck (91), lung (25), breast (20) and the abdomino-pelvic area (24) were 88%, 76%, 80% and 54%, respectively. Back pain, increased sweating, nausea, rash and flushing each occurred in 2-3% of patients.

Conclusions: Ferumoxtran 10 is a safe and effective iron oxide contrast agent. Iron oxide-enhanced MR imaging is significantly more accurate compared to non-enhanced MR imaging for nodal staging in oncologic patients.

B-741 14:18

USPIO-enhanced GRE T2*W sequence versus TSE T2W sequence in T-staging evaluation of uterine malignancies: A comparison study with surgical and histological staging

P. Paolantonio, A. Laghi, C. Miglio, M. Rengo, V. Vergari, M. Di Martino, A. Guerrisi, R. Passariello; *Rome/IT*

Purpose: USPIO administration provides a significant decrease of SI of normal myometrium with higher C/N between neoplastic lesions and normal myometrium on GRE-T2*W sequences. The aim of our study was to compare the accuracy on T-staging of uterine carcinoma of USPIO-enhanced-GRE T2*W sequence versus TSE T2W sequence.

Methods and Materials: Thirty consecutive female patients referred for gynecological carcinomas, 19 with corpus uterine cancer and 11 with cervical carcinoma, underwent MR examination. TSE T2W sequence (TR/TE/matrix/acq. time: 3000 msec/132 msec/230x512/5.3 min) were acquired on axial and sagittal planes and GRE T2*W sequences (TR/TE/FA/matrix/acq. time: 1800 msec/15 msec/30°/230x512/13.51 min) were acquired on axial and sagittal planes before and 24 hours after iv administration of 2.6 mg/kg of body weight of USPIO (Sinerem, Guerbet, Paris, France). Image analysis was performed by consensus by two radiologists, assessing the T-staging of uterine malignancies on both USPIO-enhanced-GRE T2*W and TSE T2*W images and results were compared with the surgical and histological staging.

Results: No differences between the T-Staging obtained on USPIO-enhanced-GRE T2*W and TSE T2W images were observed. MR T-stage was confirmed in 28 cases after surgery. In two patients the T-stage obtained on both USPIO-enhanced-GRE T2*W and TSE T2W sequences resulted underestimated at histology.

Conclusions: T-stage of uterine malignancies obtained on USPIO-enhanced-

GRET2*W images was comparable with the one obtained on TSE T2W images. Therefore in patients with uterine malignancies that undergo iv USPIO administration for the N-staging assessment the T-stage may be obtained by only acquiring USPIO-enhanced-GRE T2*W sequence.

B-742 14:27

Whole body MR imaging in the evaluation of marrow disease employing intravenous iron contrast agent (Resovist)

C.J. Johnston, C. Gillan, J. Mc Hugh, P. O Gorman, S.J. Eustace; *Dublin/IE*

Purpose: To describe whole body MR imaging enhanced by intravenous superparamagnetic iron contrast agents (ferucarbotran) in the assessment of marrow based pathology: Preliminary experience.

Methods and Materials: 13 patients with proven marrow based disease (7 patients multiple myeloma, 6 patients metastatic disease) underwent whole body MR imaging. In each case patients underwent pre contrast, immediate and delayed (30 minutes) T2 weighted whole body scans with fat suppression after injection of 1.4 ml ferucarbotran (equivalent to 39.2 mg iron). Images were evaluated independently by 2 experienced readers and scored at a dedicated workstation.

Results: No difference in lesion detection was documented on pre- and immediate post-contrast scans. In 7 of 13 patients, documented marrow lesions were recorded as being more conspicuous on side by side comparison by both readers on the delayed (30 minute) scans. In 1 patient, additional lesions detected were detected.

Conclusion: Preliminary results using iron contrast agent enhanced whole body MR imaging shows promise for increasing lesion conspicuity in both myelomatous and metastatic marrow infiltration.

B-743 14:36

Experimental MRA investigations of atherosclerosis using ultra-small superparamagnetic particles of iron oxide at 3 T

A.N. Priest, H. Ittrich, C.L. Jahntz, H. Kooijman, C. Weber, G. Adam; *Hamburg/DE*

Purpose: To investigate the uptake by aortic plaques of an experimental USPIO contrast agent using MR imaging. Previous studies using a similar agent have demonstrated strong magnetic susceptibility effects impinging on the bright vessel lumen.

Methods and Materials: USPIOs (DDM43/34, Schering) were administered to six Watanabe rabbits at doses between 0.1 and 1.0 mmolFe/kg. Parasagittal MR angiography scans were acquired at 5 time-points during the subsequent 5 days. The contrast agent first reduced and then enhanced the blood signal over ~2 days following administration. At later time-points, additional bright-blood scans were acquired during gadopentate dimeglumine (Magnevist, Schering) infusion. Histological follow-up was performed for two animals, using HE, Prussian blue and RAM-11. MRA was performed with a 3 T clinical scanner (Philips) and head array-coil using two 3D gradient-echo sequences with acquired isotropic resolutions of 0.7 and 1.0 mm.

Results: Widespread susceptibility artifacts indicated USPIO uptake in bone marrow and liver. In the aorta, some one-sided lumen distortions were seen resulting from uptake in nearby ribs and spine, but surprisingly there were no artifacts suggestive of vessel wall uptake. Little USPIO uptake was seen in two animals histologically, despite the presence of active plaques.

Conclusions: Results of USPIO-enhanced scans of suspected atherosclerosis should be interpreted with caution. It is clear that the absence of susceptibility effects does not necessarily rule out the presence of plaque, even with the increased sensitivity to susceptibility at 3 T. The differing influences of USPIO agents and pulse sequences should be explored further by future studies.

B-744 14:45

Evaluation of CH3-DTPA-Gd (NMS60) as a new MR contrast agent: Early phase II study in brain tumors and dual dynamic contrast-enhanced imaging

M. Ito¹, H. Oshima¹, N. Shiraki¹, H. Ogino¹, Y. Shibamoto¹, H. Kasai¹, M. Mase¹, Y. Kawamura², T. Miyati³; ¹Nagoya/JP, ²Fukui/JP, ³Kanazawa/JP

Purpose: A newly developed contrast material CH3-DTPA-Gd (NMS60), a trimer containing 3 Gd³⁺ atoms per molecule has been shown to offer greater enhancement and longer vascular retention than Gd-DTPA in animals. We report on our experiences with an early phase II study on NMS60 in brain tumor patients together with our own additional investigations.

Methods and Materials: The longitudinal relaxation rate ($R_1=1/T_1$) and the transverse relaxation rate ($R_2=1/T_2$) of NMS60 and Gd-DTPA were determined at 20 °C in water at 1.5 T. An NMS60 dose of 0.1 or 0.2 mmolGd/kg was randomly

Scientific Sessions

assigned and administered to 10 patients (5 women, 5 men, mean age: 49 years) with brain tumors. Safety and contrast-enhancing ability of NMS60 were evaluated. Dual dynamic contrast-enhanced T₁ and R_{2'} studies (DUCE imaging) were also carried out in 2 patients.

Results: Regarding the relaxivity per Gd, R₁ and R_{2'} of NMS60 were 9.8 and 11.0 (mmol/L-s)⁻¹, respectively, compared to 4.9 and 8.0 (mmol/L-s)⁻¹ for Gd-DTPA. Although a transient slight increase of alanine aminotransferase was observed in 1 case, no other adverse reactions were observed after administration of NMS60. Contrast enhancement by NMS60 was excellent at both concentrations, and when tumor detectability was assessed with a 5-point scale, the diagnostic usefulness was 4 or higher in all cases. In DUCE imaging, NMS60 showed apparently higher signal intensity as compared with Gd-DTPA.

Conclusion: NMS60 had a stronger contrasting effect than Gd-DTPA in both fundamental and clinical studies, and thus is expected to be clinically useful.

B-745 14:54 ♀

Quantitative evaluation of SHU-555A (Resovist-Schering) enhancement in normal liver parenchyma and benign/malignant focal hepatic lesions

L. Santoro¹, S. Colagrande¹, A. Filippone², E. Grassedonio², G. Belli¹, N. Villari¹; ¹Florence/IT, ²Chieti/IT

Purpose: To quantify signal intensity (SI) enhancement (E) of liver parenchyma and focal lesions after bolus administration of contrast media (CM) Resovist in order to improve nodular masses characterization.

Methods and Materials: 10 normal subjects and 31 patients (16 male, age 58 ± 12) with definite nodular hepatic lesions (8 haemangiomas, 7 FNH, 18 metastases, 6 HCC; non haemangiomas have histological demonstration), underwent MR imaging examination on 1.5 Tunit (Gyrosan ACS NT, Philips). Axial 7 mm thick sections, respiratory gated TSE T2W, free breath SS T2W and breath-hold FFE T1W sequences were obtained. T1W sequences were repeated 20°, 50° and 180° after CM; both T1/T2W sequences were performed again at 10°. SI of normal liver and focal lesions were measured in each sequence and normalized to muscle in order to avoid rescaling phenomenon; E was calculated as (SI post-CM - SI pre-CM / SI pre-CM) × 100. Statistical analysis of E was performed by Anova/paired t-test.

Results: The only statistically significant SIE mean values were observed at T2/T1W 10° images: Respectively, normal liver -59 ± 9 and +2 ± 12%; haemangiomas -50 ± 15 and +70 ± 30%; FNH -45 ± 17 and -7 ± 19%; metastases -8 ± 14 and +10 ± 17%; HCC +13 ± 18 and +16 ± 18%. T2 SIE of benign lesions ranged from -30 to -70%, mean -46%, whereas T2 SIE of malignant from -20 to +15%, mean -3%. Haemangiomas had T1 SIE always higher than +40%; other lesions had T1 SIE always lower than +30%.

Conclusion: In our cases, after Resovist administration, we observed statistically significant differences in T2 SIE percentage of benign/malignant lesions without any overlap.

B-746 15:03

Hepatocellular carcinoma: Comparison of a macromolecular contrast agent vs gadobutrol and gadobenate dimeglumine in an experimental animal MR imaging study

S. Schindera¹, D. Semela¹, C. Redaelli¹, J. Fröhlich², P. Vock¹, C. Stoupis¹; ¹Berne/CH, ²Zürich/CH

Purpose: To compare MR imaging enhancement characteristics of a macromolecular blood-pool agent (Vistarem™) with those of gadobutrol and gadobenate dimeglumine for HCC detection.

Methods and Materials: 17 American Cancer Institute rats were implanted with HCC (1 mm³), using a subcutaneously grown Morris hepatoma cell line. Axial non-enhanced VIBE 3D T2 and T1 (contiguous slices: 1 mm) and dynamic contrast enhanced axial images were acquired on a 1.5 T system. Jugular vein injection of gadomelitol (Vistarem™, Guerbet, France) was performed in 11 animals, of gadobutrol (Gadovist®, Schering, Germany) in 3 animals and of gadobenate dimeglumine (MultiHance®, Bracco Imaging, Italy) in 3 animals. Signal intensity time curves and the contrast to noise ratio (CNR) were assessed for the centre and the rim zone of the tumor and normal parenchyma. MR findings were prospectively compared with histopathology.

Results: In all cases, compared to non-enhanced scans, a better tumor delineation after Vistarem™ administration was observed. Compared with gadobenate dimeglumine and gadobutrol, Vistarem™ showed a significantly higher ($p < 0.05$) and substantial stable CNR between parenchyma and HCC for all time points. Histology demonstrated reduced vascular structures within the tumor compared to the parenchyma, explaining the behaviour of Vistarem™. The long standing, constantly stable tumor-liver contrast of Vistarem™, compared to the extracellular

agents, demonstrates the little intratumoral vessel permeability of this agent through imaging time.

Conclusion: MR blood-pool agent Vistarem™ demonstrates an improved HCC delineation compared to extracellular agents, which suggests its potential for tumor characterization, targeting the differences in liver-lesion vascularization and permeability.

B-747 15:12

Delayed Gd-BOPTA MR imaging (Gd-BOPTA-MRI) phase: Different timing between normals and hepatopathics

I. Sansoni, A. Laghi, M. Celestre, C. Miglio, M. Di Martino, M. Rengo, L. Coletta, R. Passariello; Rome/IT

Purpose: The aim of our study was to assess the optimal timing of delayed phase of Gd-BOPTA-MRI of liver for patients with normal and impaired hepatic function.

Methods and Materials: Forty-one patients (28 hepatopathics, 13 normals) underwent MR examinations on 1.5 T-scanner using the following acquisition protocol: Basal T2-weighted HASTE sequence and T1-weighted FLASH sequence acquired before and after i.v. administration of Gd-BOPTA (0.2 mM/kg) at 15 seconds, 55 seconds and 135 seconds. Delayed T1-weighted FLASH hepatobilary phases were acquired at 40, 120 and 180 minutes after i.v. administration of Gd-BOPTA. Signal intensity (SI) measurements of hepatic parenchyma, bile and lesions were recorded for each Gd-BOPTA-enhanced acquisition. From the measured SI, liver and bile signal-to-noise ratio (SNR) and lesion to liver contrast-to-noise ratio (CNR) were calculated, and related behaviour curves were obtained. **Results:** Bile SNR in three delayed phases was progressively increasing in normal patients, whereas it was almost constant in hepatopathic patients, and this difference between the patient groups was statistically significant ($p < 0.05$). Concerning the liver SNR, the two curves have similar morphology, but cirrhotics one has lower values, related to reduced parenchyma functionality. Finally, in normal patients, the more delayed is the phase, the higher is the lesion/liver CNR value, while in hepatopathics, delayed phases don't allow significant increasing of lesion/parenchyma CNR, which moreover remains stable at three delayed phases.

Conclusion: Biliary excretion and delayed hepatic enhancement are decreased in cirrhotic patients. In hepatopathics, lesion/liver CNR is stable at three different delayed phases and is not statistically significantly different compared with the CNR of the equilibrium phase.

B-748 15:21

Imaging characteristics of hepatocellular carcinoma using the hepatobilary contrast agent Gd-EOB-DTPA

G. Jung¹, J. Breuer², U. Mödder¹; ¹Düsseldorf/DE, ²Berlin/DE

Purpose: To evaluate the ability of contrast-enhanced magnetic resonance imaging with Gd-EOB-DTPA in comparison with non-enhanced imaging and spiral computed tomography to provide additional information for classification and characterization of hepatocellular carcinoma.

Methods and Materials: 40 patients with histopathology proven hepatocellular carcinoma were selected for this subgroup analysis from a phase-III multicenter study in 235 patients with known or suspected liver lesions. The primary analysis was the comparison of the proportion of hepatocellular carcinoma correctly classified and characterized by combined pre-/post-contrast magnetic resonance imaging compared with pre-contrast magnetic resonance imaging alone or with spiral computed tomography. All images were evaluated on-site, and in a blinded reading by three independent readers off-site.

Results: In the on-site evaluation, the lesions were correctly classified as a malignant tumor with combined magnetic resonance imaging in 90.3%, with pre-contrast imaging alone in 82.9% and with spiral computed tomography in 87.8%. The proportion of correct characterization (lesion type diagnosis) with combined magnetic resonance imaging was 85.4%, 75.6% for pre-contrast imaging, and 77.5% for spiral computed tomography (n.s.), respectively.

In the blinded reading, one reader showed a significant increase in the proportion of correctly characterized lesions by 27% ($p < 0.05$). The other two readers showed a reduction in the proportion of correct characterization by 12% and 15%, respectively (n.s.).

Conclusion: Although the results of the blinded reading are equivocal, within a clinical setting Gd-EOB-DTPA seems to have a potential to improve the classification and characterization of hepatocellular carcinoma.

Visualization of the coronary arteries in children: A comparison between 2 MR sequences

N.D. Abolmaali¹, A. Esmaeili¹, M. Schmitt², R. Hofstetter¹, T.J. Vogl¹;
¹Frankfurt a. Main/DE, ²Erlangen/DE

Purpose: To compare conventional 2d T1-w SE sequences (T1SE) with 3d T2*-prepared true-FISP sequences (3dTfi) for the visualization of the main coronary arteries in children.

Methods and Materials: 8 children (1.5 to 10 years) with different cardiac diseases were examined in a 1.5 T system (Sonata). In addition to their routine imaging protocol they received either T1SE or 3dTfi for the visualization of the course of the main coronary arteries (CA). In three children, coronary anomalies were already suspected.

Results: As long as the sedation worked well, both sequence types produced adequate results. The proximal course of the main coronary arteries was visible with both techniques. Due to the small amount of epicardial fat in children, the CA were visualized more clearly and for a longer distance using the 3dTfi. Because of the higher spatial resolution, the CA were visible up to a length of 6.5 cm using 3dTfi. The following anomalies were visualized: Kawasaki disease, coronary course variants, and post-operative injury. The use of a minute amount of intravenous contrast material (Gd-DTPA) will increase the imaging quality of 3dTfi. **Conclusion:** For the visualization of the coronary arteries in children, 3dTfi offers higher quality than T1SE. Better and longer visualization is possible as compared with T1SE. The major prerequisite for both techniques is adequate sedation.

B-750 14:09

Contrast-enhanced low-dose 16-multislice CT (MSCT) in children with tracheal stenosis due to vascular compression: Initial results

D. Honnepf, J.E. Wildberger, A.H. Mahnken, M. Das, H. Schnöring,
J. Vázquez-Jiménez, R.W. Günther, G. Staatz; Aachen/DE

Purpose: To evaluate contrast-enhanced low-dose 16-MSCT in children for suspected vascular induced tracheal stenosis.

Methods and Materials: 8 children (1 newborn, 6 infants and 1 preschool child (13 days to 3 years, mean 0.8 years; 1.2 kg to 13.5 kg body weight; 6 male) with bronchoscopically suspected vascular tracheal stenosis were examined by contrast enhanced 16- MSCT (SOMATOM Sensation 16, Forchheim, Germany). Examination parameters were used as follows: beam collimation 16x1.5 mm resp. 0.75 mm, 120 kV resp. 80 kV, 18-50 effective mAs, tube rotation time 0.5 sec, i.v. contrast media application according to body weight (1.5 ml/kg body weight). In addition to conventional axial slices MPRs, VRTs and virtual bronchoscopy were additionally calculated.

Results: Dose adapted 16-MSCT revealed in all cases the cause of the bronchoscopically suspected vascular tracheal stenosis: double aortic arch (1), left main bronchus wedged between pulmonary artery stem and ascending aorta (1), compression due to brachiocephalic trunk (5), lusorian artery (1). In 3 patients further thoracic anomalies, such as tracheobronchial (2), vascular (1) and vertebral (1) anomalies were found. In 5 patients subsequent vascular surgery was performed due to the findings of the CT-examination.

Conclusion: Our preliminary data suggests that contrast enhanced low-dose 16-MSCT is favourable for the detection of vascular induced tracheal stenosis in newborns and infants.

B-751 14:18

Comparison of true FISP, HASTE, SSTSE and postcontrast T1w sequences in pediatric MR urography

M. Raissaki, N. Papanikolaou, V. Hatzimanoli, E. Drakonaki, M. Bitsori,
N. Gourtsoyiannis; Iraklion/GR

Purpose: To compare true FISP, HASTE and SSTSE sequences in delineating anatomical structures and identifying morphological abnormalities during MR

urography in neonates and children. To assess any additional diagnostic value on post contrast T1w sequences.

Methods and Materials: 19 consecutive patients, aged 4 days-9 years (mean 26.4 months) underwent MR urography in a 1.5 T unit. Coronal and/or axial true-FISP, HASTE sequences and projectional SSTSE images were acquired following intravenous administration of furosemide and were separately evaluated by 3 readers deciding by consensus. Depiction of morphology was assessed using a 5-point grading scale. The level of confidence for the presence and characterization of an abnormality was evaluated with a 3-point scale for each of the above sequences and for the turbo-FLASH sequence 0, 5, 15 minutes following intravenous contrast administration. Statistical analysis was performed using the Wilcoxon rank test.

Results: Renal parenchymal abnormalities were found in 7 renal units, ectopies and/or rotating anomalies in 5, agenesis in 3, duplicated systems in 5, dilatation in 17, and ureterocele in 1 unit. Visualization of the ureter was better with SSTSE compared to cross-sectional sequences, not reaching statistical significance. For pelvicalyceal systems and bladder, all T2-weighted sequences performed equally. Delayed post-contrast scans provided significantly higher ($p < 0.01$) diagnostic value compared to HASTE and true FISP sequences.

Conclusion: In pediatric MR urography, SSTSE sequences in combination with either HASTE or true FISP sequences provide excellent anatomical delineation of urinary tract collecting systems including the renal parenchyma. Delayed post-contrast T1w sequences may provide additional diagnostic information.

B-752 14:27

Contrast-enhanced MR cholangiography using mangafodipir trisodium for evaluation of neonatal jaundice

H.-K. Ryeom, B.-H. Choe, J.-Y. Kim; Taegu/KR

Purpose: To determine the feasibility and accuracy of contrast-enhanced magnetic resonance cholangiography (CEMRC) with Mangafodipir trisodium (Mn-DPDP) to exclude biliary atresia (BA) as the cause of neonatal jaundice.

Methods and Materials: Thirty-six jaundiced infants with suspected BA were prospectively evaluated using CEMRC and magnetic resonance cholangiopancreatography (MRCP) 1-5 days prior to ^{99m}Tc-DISIDA radionuclide scans. For the CEMRC, sequential magnetic resonance (MR) images were obtained one, two, and three hours after the administration of intravenous Mn-DPDP with a T1-weighted spoiled gradient-echo sequence. The possibility of biliary atresia was excluded if bowel excretion of the contrast material was noted in the CEMRC. The diagnostic specificity and accuracy of CEMRC was compared with those of conventional MR cholangiography, a ^{99m}Tc-diisopropyliminodiacetic acid (DISIDA) scan, and ultrasonographic triangular cord sign.

Results: The CEMRC was used to accurately distinguish biliary atresia ($n = 6$) from other cholestatic liver diseases ($n = 30$) without any false-positive results. Meanwhile, the conventional MR cholangiography, ^{99m}Tc-DISIDA scans, and ultrasonographic triangular cord sign showed 47% (14/30), 39% (11/28), and 7% (2/30) false-positive results in non-biliary atresia patients, respectively.

Conclusion: Accordingly, the current results suggest that CEMRC using Mn-DPDP is feasible and more accurate than MRCP, ^{99m}Tc-DISIDA scans, or ultrasonography for the exclusion of BA. As such, CEMRC using Mn-DPDP would appear to be a promising modality in the early exclusion of BA as the cause of neonatal cholestasis.

B-753 14:36

Diagnostic imaging in children with Crohn's disease: MR imaging with true-FISP as a new gold-standard?

C. Hohl, P. Haage, G.A. Krombach, T. Schmidt, M. Ahaus, R.W. Günther,
G. Staatz; Aachen/DE

Purpose: To evaluate the impact of MR imaging with true-FISP sequences in the evaluation of inflammatory bowel wall changes in children with Crohn's disease.

Materials and Methods: 24 children aged between 7 and 21 years with suspected or known IBD underwent MR imaging on a 1.5 T scanner. 1 hour after 1 l-mannitol solution was given orally, MR imaging was performed using coronal HASTE-M2D, coronal fat-suppressed T2-TSE, axial dynamic T1-weighted GE sequences before and after i.v.-contrast (Gd-DTPA) and true-FISP sequences before and after i.v.-contrast in coronal and axial planes. MR images were correlated with endoscopy and clinical findings. In 14 patients a recently performed conventional X-ray enteroclysis was available. The MR imaging sequences were evaluated by three experienced radiologists regarding sensitivity and specificity in the detection of inflammatory bowel wall changes. In addition the image quality was assessed regarding the different tissue contrasts and susceptibility to artifacts. Finally, patients' acceptance for the MR imaging examination was recorded.

Scientific Sessions

Results: With a sensitivity in the detection of inflammatory small-bowel changes of 93.3% and 100% the true-FISP outnumbers the other performed sequences (T1 = 80%, HASTE = 13.3% and T2-TSE = 53.3%). The true-FISP sequences revealed a significant superiority regarding soft-tissue differentiation in comparison to all other performed MR sequences. The distension of the bowel wall was good in all children. The patients acceptance of the MR imaging-examination was eminent.

Conclusion: Small-bowel MR imaging examination is appropriate for children and with use of true-FISP sequences it is a convincing method with an outstanding sensitivity in the diagnosis of IBD. MR imaging ought to replace conventional enteroclysis as a gold standard for IBD diagnosis in children.

B-754 14:45

Apparent diffusion coefficients of paediatric mass lesion with free-breathing diffusion-weighted MR imaging

O.E. Olsen, N.J. Sebire; London/UK

Purpose: To assess the distribution of apparent diffusion coefficients (ADC) within high and low cellularity mass lesions in the paediatric chest, abdomen and pelvis.

Methods and Materials: Thirteen children were scanned with a standard diffusion weighted MR sequence ($b = 0$ and 1000 s/mm^2). ADC maps were calculated. Subsequent histological specimens were categorised as high, intermediate or low cellularity. Lesion pixel values from the central three slices of the ADC maps were analysed and compared to histopathology.

Results: Median ADC for high cellularity lesions was 0.83 (25/75 centiles = 0.74/0.85) and low cellularity lesions 2.01 (25/75 centiles = 1.43/2.45) $\times 10^{-3} \text{ mm}^2/\text{s}$ (Kruskal-Wallis test, Chi-Square = 9.519; $p = 0.023$).

Conclusion: ADC mapping is feasible in imaging of paediatric mass lesions in the chest, abdomen and pelvis with standard clinical equipment. The distribution of ADC values within a mass lesion may be determined by its cellularity.

B-755 14:54

Functional MR imaging (BOLD) at 3 Tesla in the brain of fetal sheep: The relation to maternal blood oxygenation during hypoxia and methodological aspects

U. Wedegärtner, M. Tchirikov, S. Schäfer, A. Priest, H. Schröder, G. Adam; Hamburg/DE

Purpose: To quantify the dependence of the fetal brain BOLD signal on maternal blood oxygenation (MatSO₂) and to investigate the influence of position of Regions Of Interest (ROI).

Material and Methods: The brains of singleton fetuses of five anaesthetized (isoflurane/O₂/N₂O) sheep were subjected to rapid sequences (single-shot EPI) of BOLD measurements (3 T MR scanner). MatSO₂ and maternal heart rate were recorded continuously. After a normoxic phase, hypoxia was induced by reduction of oxygen in the ventilated gas mixture. ROI were placed in the cerebrum and in the cerebellum. BOLD SI% were calculated from mean values of steady state BOLD signal intensities (SI) of control and hypoxic plateaus: BOLD SI% = S_{hypoxia}/S_{control} × 100. BOLD SI% were correlated with MatSO₂, and linear regression analysis (slope) was performed. Additionally, ROI were varied slice level and position within the slice. Differences in BOLD SI% for ROI placements were calculated.

Results: Control MatSO₂ was 89%O₂ (80-96) [mean (95%CI)]. During hypoxia MatSO₂ was reduced to 62%(50-75) and fetal BOLD SI% decreased to 64% (44-85) in the cerebrum and significantly stronger to 56%(32-80) in the cerebellum. Correlation and regression ($p < 0.001$) between BOLD SI% and MatSO₂ were: cerebrum: $r^2 = 0.84$; slope = 1.27 SI%/MatSO₂ (1.17-1.36); cerebellum: $r^2 = 0.83$; slope = 1.54 (1.44-1.63). BOLD SI% was 4% less in the slice above. Variations of BOLD SI% for different ROI positions were in the range of 0-12%.

Conclusions: The depletion of oxygen supply is reflected by distinct decreases of fetal brain BOLD signal intensities which are faster in the cerebellum than in the hemispheres. BOLD SI% is influenced only slightly by ROI position.

B-756 15:03

Magnetic resonance imaging (MRI) of the perinatal thyroid gland

P.C. Brugger, D. Prayer; Vienna/AT

Purpose: As little information is available on the MRI signal characteristics of the normal perinatal thyroid gland (TG), we studied its signal characteristics in a series of fetuses, preterm neonates, term neonates and infants.

Methods and Materials: The series comprised 130 MRIs of fetuses imaged in utero (19th-38th gestational weeks), 100 term neonates and infants until the 5th month of postnatal life, and 25 preterm infants born between 24-33 weeks of

gestation which were imaged 8-200 days after delivery. Protocols included T2- and various T1-weighted sequences in frontal or sagittal planes. Signal intensity of the thyroid was measured.

Results: On T2-weighted images the TG was detectable only by its topographical relationships. In contrast, the fetal TG displayed T1-weighted hyperintensity from the 20th gestational week onwards which was also characteristic to term neonates. This hyperintensity then gradually disappeared to become isointense to muscle by the 3rd postnatal month (as in adults). In preterm neonates these signal changes took a similar temporal course, so no pronounced hyperintensity as was present at term. The relative and absolute signal intensities of the TG took the same course as the anterior pituitary.

Conclusion: T1-weighted hyperintensity of the TG is a normal finding in fetuses and neonates that disappears after birth following a temporary course, which parallels the decrease in signal intensity of the anterior pituitary gland. This is independent of gestational age at birth and may reflect changes associated with the maturation of the pituitary-thyroid axis in the postnatal period.

B-757 15:12

A new look at the fetus: Thick-slab T2-weighted sequences in fetal MR imaging

P.C. Brugger, C. Mittermayer, D. Prayer; Vienna/AT

Purpose: While magnetic resonance imaging (MRI) of the fetus may be considered as an established adjunct to fetal ultrasound, an overall impression of the fetus is hardly provided by stacks of slices alone. The present study evaluates the use of thick-slab T2-weighted images to obtain a three dimensional impression of the fetus using MRI.

Methods and Materials: A thick-slab T2-weighted sequence (TR: 8000/TE: 800-400) was added to the routine protocol in 100 fetal MRIs made for different clinical indications (19th-37th gestational weeks) on a 1.5 T magnet using a five-element phased-array surface coil. Slice thickness adapted to fetal size and uterine geometry varied between 25 and 50 mm, as did the field of view (250-350 mm). Acquisition of one image took less than one second.

Results: Thick-slab T2-weighted images visualize fetal anatomy in a more comprehensive way than is possible with a series of 3-4 mm thick slices. They facilitate the assessment of the whole fetus, surface structures, extremities and fetal proportions. Fetal pathology may be captured in one image. Lower TEs enhance the transparency of the skin and allow recognition of normal fluid-filled organs and pathologies associated with fluid accumulations.

Conclusion: Thick-slab T2-weighted imaging provides additional information that is difficult to gain from a series of images. It is a valuable adjunct to conventional 2D imaging and an alternative to three dimensional reconstructions. Moreover it facilitates communication with those not familiar with cross-sectional anatomy.

B-758 15:21

The use of magnetic resonance imaging in the evaluation of vascularization of porous ocular implants

A. Álvarez Luque, A. Royo, T. Berrocal, M. Fernández-Velilla, A. Fernández-Zubillaga, J. Abelairas; Madrid/ES

Purpose: To assess the utility of MR imaging in detecting fibrovascular tissue growth within porous implants used in orbital reconstruction following evisceration or enucleation.

Methods and Material: 39 children who had received a porous orbital implant (29 a hydroxyapatite, 10 a high-density polyethylene implant) were prospectively evaluated with MR imaging. T1-weighted sequences with fat saturation were acquired before and after Gd administration, and 3-mm thickness axial and sagittal reformations were obtained. MR imaging was evaluated for the degree of Gd-uptake by the implant (quantified as 0, 1/4, 1/4-2/4, 2/4, 2/4-3/4, 3/4, 4/4 enhancement); type of enhancement (homogeneous or heterogeneous); area of initial enhancement (anterior or posterior); extraimplant Gd-uptake indicating infection; and presence of lines in the prosthesis suggesting fissures. MR imaging findings were compared with the state of the implant during the surgical act of peg placement.

Results: The Gd-uptake was zero in three prosthesis, 1/4 in three, 1/4-2/4 in two, 2/4 in three, 2/4-3/4 in four, 3/4 in 12, and 4/4 in 12. The enhancement started in the posterior region in 22 cases (81.4%), was homogeneous in 21 (77.7%) and extraimplant enhancement occurred in 4 (18%). Lines suggesting fissures were observed in 4 prosthesis (14.8%), confirmed at surgery. The Gd enhancement on MR imaging and the surgically proven vascularization was similar in 34 implants (85%). MR was inconclusive in one case (3%). There was no correspondence between the MR findings and those of surgery in 5 cases (12%).

Conclusion: MR imaging is a reliable technique in detecting fibrovascular tissue growth within porous ocular implants.

Endovascular treatment of brain AVMs using Onyx: Preliminary results of a prospective, multicenter study

C. Cognard¹, A. Januel¹, D. Herbreteau², X. Barreau³, J. Drouineau⁴, L. Pierot⁵; ¹Toulouse/FR, ²Tours/FR, ³Bordeaux/FR, ⁴Poitier/FR, ⁵Reims/FR

Purpose: To evaluate the safety and the efficacy of Onyx in the endovascular treatment of brain arteriovenous malformations (AVMs).

Methods and Materials: From May 2003 to July 2004, 38 patients (21 females/17 males; age: 16 to 64 years; mean: 30 years) harboring brain AVMs were treated using Onyx. Clinical presentation was intracranial hemorrhage in 19 cases, epilepsy in 10 cases, headaches in 5 cases, progressive neurological deficit in 1 case and other in 3 cases. AVMs were located in the cerebral hemispheres (33 cases), in the corpus callosum (3 cases), in the basal ganglia (1 case) and in the cerebellum (1 case).

Results: A total of 80 sessions of embolization was performed (1 to 8 sessions/patient; mean: 2.11). The technical way of using Onyx is described (selective catheterization, injection of Onyx and withdrawing of the microcatheter). The duration of injection was between 5 to 68 mn (mean: 35 mn) and the volume injected by session was between 0.3 and 5.5 ml (mean: 1.5 ml). Technical problems and clinical complications are reported. The final degree of occlusion and the complementary treatment, if needed, are described.

Conclusion: The preliminary results of this prospective, multicenter study demonstrate the great efficacy of Onyx in the treatment of brain AVMs. The technical way of using Onyx should be very precise to avoid some complications.

B-760 14:09

Endovascular treatment (EVT) in first intention in the management of ruptured intracranial aneurysm: Prospective consecutive series

C. Cognard, M. Mejdoubi, A. Januel, P. Tall, J. Albucher, F. Chollet, M. Gigaud, M. Tremoulet; Toulouse/FR

Purpose: Since January 1998 the neurovascular multidisciplinary team has decided to use embolisation as the first intention treatment of ruptured aneurysms. Our goal is to review the results of this therapeutic strategy.

Materials and Methods: From January 1998 to December 2002 (5 years), 401 patients were admitted with a subarachnoid hemorrhage (SAH). Seventy three patients had a sine materia hemorrhage (18%). Among the 328 patients with aneurysmal SAH, 28 were unexplored (8.5%), 28 untreated (8.5%), 272 had their ruptured aneurysm treated (83%). Embolization was performed in 222 of the 272 cases (82%) and surgery in 50 cases (18%). The reason why surgery was performed was: failure of EVT in 8 cases (2.9%), intracranial hematoma in 16 cases (5.7%), aneurysm morphology unsuitable for EVT in 15 cases (5.4%), absence of the interventional neuroradiologist in 11 cases (4%). EVT was successful in 96.8% of attempted procedures (243/251). Remodeling technique was used in 11.4% for broad based aneurysms. Clinical evolution was without any clinical complication in 69% of the cases. Thirty-two patients out of 222 (14%) died, 8 of them due to treatment complications (3.6%).

Conclusion: This series shows that embolization as a primary treatment in aneurysmal SAH is justified and can be performed routinely. Nevertheless, increasing the number of specialized neuro-interventionists and dedicated angiogram equipment is required. Patient and case selection must be discussed by a well-trained multidisciplinary neurovascular team. Creating hemorrhagic stroke centre recommendations is mandatory to promote global management of patients with intracranial bleeding.

B-761 14:18

Double microcatheter technique for endovascular coil embolization of large, wide-necked intracranial aneurysms

H.-J. Choo, T. Lee, H. Jeong, H. Choi, H. Kim, T. Moon, C. Choi, S. Lee; Pusan/KR

Purpose: To assess the feasibility, safety, and effectiveness of the double microcatheter technique in endovascular coil embolization of large, wide-necked intracranial aneurysms.

Methods and Materials: Between September 2002 and June 2004, 55 patients with 60 intracranial aneurysms were treated with endovascular coil embolization. The initial attempts at embolization failed in ten cases because evidence of coil instability within the aneurysm or significant impingement of coil loops on the parent artery were observed. Among these 10 cases, three were located in the anterior communicating artery, three in the middle cerebral artery bifurcation, two in basilar tip, one in the posterior communicating artery, and one in the superior hypophyseal artery. The 10 cases were treated with double microcatheter technique. Advancement of a second microcatheter into the aneurysm allowed two coils to be braced across the aneurysmal neck before the detachment of either coil. We retrospectively analyzed the feasibility and effectiveness of the technique.

Results: The double microcatheter technique permitted successful coil embolization in all 10 cases. The angiographic results were 6 complete, 2 small neck remnant, and 2 incomplete occlusion. There were no technique-related complications.

Conclusion: The double microcatheter technique might be feasible, safe, and effective when there is evidence of coil instability or parent vessel compromise during embolization of large, wide-necked aneurysms. The increased technical demands and potential for complications necessitate that clear indications be present before this adjunctive technique is considered.

B-762 14:27

Urgent recanalization using stents for acute internal carotid artery occlusion in progressive stroke syndromes with contralateral internal carotid stenosis or occlusion

H.-J. Choo, T. Lee, H. Jeong, H. Choi, K. Park, S. Sung, H. Kim, S. Lee; Pusan/KR

Purpose: To assess the feasibility, safety, and effectiveness of urgent recanalization using stents for acute internal carotid artery occlusion in the progressive stroke syndromes with chronic contralateral carotid stenosis or occlusion.

Methods and Materials: Between January 2004 and June 2004, urgent recanalization using stents for acute ICA occlusion was performed in 5 progressive stroke patients. Three patients had chronic occlusion and two patients had severe stenosis of the contralateral ICA. There were 3 men and 2 women with a mean age of 51.4 years. A 0.014-in microwire was placed into the distal ICA or middle cerebral artery, crossing the occluded segment. The stent was then advanced over the microwire and deployed in the lesion. We retrospectively analyzed the feasibility and effectiveness of the urgent recanalization using stents for acute ICA occlusion in the progressive stroke patients with chronic contralateral ICA stenosis or occlusion.

Results: We successfully completed recanalization using stents in all patients. All patients showed rapid improvement of neurological signs and favorable clinical outcomes. There were no procedure-related complications; patients were neurologically stable on clinical follow-up (mean 2 months, range 1-6 months). Angiographic follow-up after 3 months revealed no in-stent restenosis in 3 patients.

Conclusion: Urgent recanalization using stents for acute internal carotid occlusion may salvage the vessel and promise better clinical outcome in progressive stroke patients with contralateral chronic ICA stenosis or occlusion. Further studies are necessary to define the correct management of this catastrophic event.

B-763 14:36

MR angiography vs. digital subtraction angiography in the follow-up of clipped and coiled intracranial aneurysms

A. Hochmuth, U. Hubbe, S. Ziyeh, V. Vougioukas, A. Berlis; Freiburg/DE

Purpose: To evaluate the reliability of Time-of-Flight-MRA in comparison to digital subtraction angiography in the follow-up of endovascular and surgically treated ruptured intracranial aneurysms.

Methods and Materials: Between May 1998 and October 2003, in 62 patients with 73 treated aneurysms 96 MRA and 76 DSA examinations were performed to assess the occlusion rate and/or recurrence of coiled or clipped aneurysms. DSA and MRA were performed within one week.

Scientific Sessions

Results: 51/73 aneurysms were coiled (two of them later clipped and excluded from evaluation), 4 of them showed artifacts in MRA which hindered interpretation. 45/49 (91.8%) were well or sufficiently assessable. Residual flow was found or presumed in 20 and confirmed by DSA in 17 cases. Seven were partially thrombosed, which affected evaluation in 2. Sensitivity and specificity in detecting residual flow or persistent aneurysm neck were 90% and 93.5%, respectively. Of the 24 clipped aneurysms, only 2 were evaluable, 22 showed severe artifacts.

Conclusion: MRA is a valuable tool in the evaluation of coiled aneurysms, especially in rating residual flow or flow due to coil compaction. Problems may arise in partially thrombosed aneurysms due to hyperintense thrombus. Neurosurgical clips produce such intense artifacts, that MRA seems to be meaningless in the follow-up of clipped aneurysms.

B-764 14:45

Follow-up of coiled cerebral aneurysms: Comparison of 3D-TOF MRA at 3 T with 3D-TOF and contrast-enhanced MRA at 1.5 T

N. Anzalone, C. Righi, L.S. Politi, A. Iadanza, M. Cadioli, G. Scotti; Milan/IT

Purpose: To compare 3D-TOF-MRA of coiled aneurysms at 3 T with 3D-TOF-MRA and ultrafast contrast-enhanced MRA (CE-MRA) at 1.5 T.

Methods and Materials: Twenty-three patients treated with detachable coils for cerebral aneurysms underwent examinations at 3 T and 1.5 T separated by 24 hours. 3D-TOF-MRA at 3 T was performed with a head T/R coil and an axial acquisition (TR/TE = 23/3.2). At 1.5 T, a sensitivity encoding head coil was used; a 3D-TOF axial acquisition was performed first (SENSE factor 2, TR/TE = 23/3.6), followed by an axial 3D ultrafast (21 sec) gradient echo sequence (SENSE factor 2, TR/TE = 6.1/2.1) enhanced with 0.1 mmol/kg Gd-BOPA (MultiHance). Source images as well as MIP and SSD reconstructions targeted on the vessel of interest were evaluated.

Results: Twenty-four aneurysms were evaluated. The presence of coil artefact was equally evident on 3D-TOF at 3 T and 1.5 T but was not apparent on CE-MRA. The parent artery was identifiable in 22 cases after 3D-TOF-MRA at 3 T and CE-MRA at 1.5 T but in only 20 cases after 3D-TOF-MRA at 1.5 T. Patency of the residual aneurysm was demonstrated in 9 cases after 3D-TOF-MRA at 1.5 T, but in 12 cases after 3D-TOF-MRA at 3 T and CE-MRA at 1.5 T; in each case CE-MRA permitted superior demonstration of residual patency. Comparison of the 3D-TOF acquisitions revealed higher signal and a sharper definition of the parent vessel and residual patency at 3 T.

Conclusion: MRA follow-up of coiled aneurysms is feasible at 3 T and is better than at 1.5 T; nevertheless greater definition of residual patency is achieved with ultrafast CE-MRA at 1.5 T.

B-765 14:54

Multislice CT angiography (MSCTA): A comparison with digital subtraction angiography (DSA) in the postoperative evaluation of clipped aneurysms

S. Binaghi, M. Colleoni, A. Dehdashti, L. Regli, A. Uské; Lausanne/CH

Purpose: To evaluate the accuracy of MSCTA in the postoperative workup of clipped intracranial aneurysms compared to DSA.

Methods: Forty-two patients harbouring 52 aneurysms (34 ruptured, 18 unruptured) who underwent surgical clipping were included in this study. Postoperative MSCTA and DSA were simultaneously performed for each patient. Two independent neuroradiologists reviewed every DSA and MSCTA. The criteria that were applied were the occlusion of the aneurysmal dome, the presence of a residual neck, and the lack of stenosis on the parent vessels near the clip. The mean duration of MSCTA and DSA was respectively 15 and 45 minutes.

Results: The quality of MSCTA was good in 83% of cases, moderate in 9% and poor in 7%. MSCTA results were unclear in 7 patients (13%) due to clip-related artefacts in 5 patients, and to failed contrast injection in 2 patients. MSCTA showed complete exclusion of all treated aneurysms, whereas DSA revealed a residual neck in 2 aneurysms. Retrospectively, MSCTA identified these residual necks. The sensitivity of MSCTA was therefore 96% and the specificity was 100%.

Conclusion: MSCTA is a valuable and non-invasive method for postoperative control of clipped aneurysms. However, DSA should be performed when MSCTA results are doubtful or in presence of abnormalities which need further endovascular treatment.

B-766 15:03

Silent cerebral ischemic lesions revealed with diffusion weighted MR imaging (DWI) in patients submitted to thromboendarterectomy (CEA), protected and unprotected carotid artery stenting (CAS)

M.C. Michelassi, M. Cosottini, M. Puglioli, I. Trivelli, S. De Cori, G. Parenti, C. Bartolozzi; Pisa/IT

Purpose: Carotid endarterectomy (CEA) is a proven standard treatment of high-grade carotid artery (CA) stenosis. Carotid artery stenting (CAS) has gradually been established as an alternative method to CEA. Diffusion-weighted MR imaging (DWI) demonstrates new cerebral lesions during revascularization that is supposed to indicate the occurrence of cerebral microemboli. The purpose is to assess the prevalence of cerebral ischemic insults detectable with DWI during CEA and CAS and the role of cerebral protection during CAS as a method of reducing the number of cerebral ischemic events.

Materials and Method: We prospectively evaluated 76 unselected patients with high grade internal CA stenosis that underwent CEA (group I) and CAS (52 patients) with cerebral protection device in 30 patients (group II) and without in 22 (group III). All patients underwent to MR examination before and within 7 days after the procedure to assess the number of silent ischemic lesions.

Results: The incidence of new ischemic lesions in patients treated with CEA or CAS was 8% and 30% respectively. The total number of lesions and the lesions ipsilateral to the treated vessel were significantly higher in patients of group III compared to group II ($p = 0.02$ and 0.01). The number of lesions contralateral to the treated vessel was not different in the two groups.

Conclusion: Silent ischemic lesions are more frequent in patients treated with CAS than with CEA. The protection device during CAS seems to reduce the number of microembolic events. Contralateral lesions probably source from the procedural manoeuvres in the aortic arch.

B-767 15:12

MR imaging of brain embolism in patients with carotid stenosis before and after percutaneous angioplasty with distal protection

A. Koren; Ljubljana/SI

Purpose: To estimate the size, localization and incidence of brain embolism with MR imaging (MR) in 31 patients with hemodynamically important carotid stenoses discovered by ultrasound who were candidates for percutaneous transluminal carotid angioplasty with stenting and distal protection (PTAF).

Methods: The study was prospective and nonrandomized. We analyzed MR lesions in time windows of 24 hours before and after PTAF and describe correlations with clinical data and ultrasound properties of stenosis and plaques.

Results: 77.5% of lesions were smaller than 1 cm before PTAF. The number of lesions greater than 1 cm was statistically different between groups of asymptomatic and symptomatic patients for both hemispheres (R: $p < 0.05$, L: $p < 0.01$). We discovered new lesions after PTAF in 9.7% of all patients: 75% of lesions were smaller than 1 cm and in a site related to the treated carotid. No patients with embolism had new neurological symptoms after the procedure; most of them had lipid plaques and neurological deficit before PTAF.

Conclusions: Most patients with brain embolism had lipid plaques. We didn't discover any correlation between severity of stenosis or plaque type and morphology and site of brain lesions before PTAF. The majority of patients with new lesions after PTAF had stenoses greater than 90% and neurological symptoms before the procedure.

B-768 15:21

Changes in cerebral blood flow before and after carotid endarterectomy: Evaluation by acetazolamide-challenge ^{123}I -IMP SPECT

I. Sakuma, N. Tomura, S. Takahashi, T. Otani, T. Nishii, K. Sasaki, J. Watara; Akita/JP

Purpose: Hyperperfusion syndrome is now recognized as a disastrous complication after carotid endarterectomy (CEA). The present study investigated cerebral blood flow (CBF) changes after CEA.

Materials and Methods: In 16 patients (17 ICAs), CBF and cerebral vasoreactivity (CVR) were assessed before and 7-9 days after CEA using acetazolamide (ACZ)-challenge ^{123}I -IMP single photon emission CT (SPECT). CBF and CVR were measured by placing regions of interest (ROIs) in bilaterally symmetrical regions of the middle cerebral artery territory. Asymmetry index (AI) of CBF was also calculated in 12 patients without severe ICA stenosis on the contralateral side. To estimate presence or absence of hyperperfusion phenomena immediately after surgery, ^{99}mTc -HMPAO SPECT was also performed within 3 days after CEA.

Results: CBF of the ipsilateral hemisphere did not significantly change after CEA.

Scientific Sessions

However, CVR of the ipsilateral hemisphere was increased after CEA ($51.5 \pm 29.7\%$) compared to before CEA ($33.9 \pm 33.8\%$). Although no significant alteration of resting AI was seen, ACZ-challenge AI was significantly higher after surgery ($94.6 \pm 13.2\%$) compared to before CEA ($79.1 \pm 15.3\%$; $P < 0.05$). In 5 ICAs (29.4%), hyperperfusion of the ipsilateral hemisphere was seen on $^{99m}\text{Tc-HMPAO SPECT}$. Of these, severe stenosis of the contralateral ICA was present in 3 patients. Hyperperfusion after CEA was noted in 5 patients, and mean CVR before surgery was significantly lower in these patients ($18.1 \pm 23.9\%$) than in other patients ($40.5 \pm 36.0\%$).

Conclusion: CVR and ACZ-challenge AI improved after CEA. CVR before CEA can predict risk of hyperperfusion after CEA.

Multi-centre study to assess patient doses in interventional radiology in Belgium

K. Smans¹, H. Bosmans¹, L. Struelens²; ¹Leuven/BE, ²Mol/BE

Purpose: The Euratom directive 97/43 and the Belgian Royal Decree of July 20, 2001 impose today, the application of the ALARA principle, in particular in rooms for interventional radiology. Within this framework, a multi-centre study is started to assess the patient doses in interventional radiology and to prepare from these data potential future auditing parameters.

Methods and Materials: 20 Centers, spread over Belgium, are participating in this ongoing project. The activities include an extensive interview with the interventionalist regarding the working procedures, the verification of the data in at least 10 (detailed) patient cases, the registry of DAP values during one year and physical/technical tests of the equipment. DAP values were corrected for patient weight and were then used to set National Diagnostic Reference Levels (DRL). The influence of different parameters on the DAP was studied.

Results: First results show that there is a large spread in the DAP-values per procedure. This is partly due to different system-parameters (e.g. dose levels at the image intensifier), but it is mainly due to the way of working. In particular, the number of frames and series taken during digital subtraction differs a lot between the participating centres. Averaged DAP-values of some centres largely exceed the (preliminary) DRL. A series of guidelines for the optimisation of interventional procedures could be derived.

Conclusion: It was possible to select a minimal data set for interventional procedures that allows a directed feedback or interaction/cooperation between interventionalist and medical physicist, and that may be used for future auditing.

B-770 14:09

A six year follow-up of patient dose values: Transition from conventional to digital in projection radiography

E. Vano, J.M. Fernandez, J.I. Ten, C. Prieto, L. Gonzalez, R. Rodriguez; Madrid/ES

Purpose: To report the evolution of patient doses in projection radiography during the last 6 years in a large University Hospital that has moved from film-screen to digital radiology.

Methods and Materials: Entrance surface air kerma for patients were calculated from the radiographic techniques using the measured X-ray tube outputs. After implantation of digital techniques in 1999 (computed radiography -CR- and flat panel -FP-), an automatic system to gather dosimetric data was designed and installed. The system, working in real time, allows to detect relevant changes on patient dose. A database with more than 100,000 patient dose data has enabled computing the evolution during the last 6 years.

Results: Mean values of entrance air kerma (with backscatter) for chest PA and LAT were respectively 0.20 and 0.60 mGy before digital, 0.27 and 1.27 mGy during the transition and 0.11 and 0.64 mGy in 2003 (CR). For FP these values have been: 0.15 and 0.74 mGy in 2003. No statistical significant difference exists between CR and FP. For lumbar spine AP and LAT values have been: 4.4 and 8.6 mGy during the transition and 3.2 and 8.6 mGy in 2003. Mean values for

abdomen images were 2.9 mGy during the transition and 2.2 mGy in 2003. Sample sizes were between 1,000 and 10,000 data.

Conclusion: Patient dose values for projection radiography showed an increase (35 to 110% for chest images) during the implantation of digital techniques and a relevant decrease (roughly by 30%) once the patient audit system was installed.

B-771 14:18

Embryo/fetal doses and risks from fluoroscopically assisted kyphoplasty during pregnancy

N. Theocaropoulos, J. Damilakis, K. Perisinakis, G. Papadokostakis, A. Hadjipavlou, N. Gourtsoyiannis; Iraklion/GR

Purpose: Inadvertent or emergency fluoroscopic exposures of the spine during pregnancy are reasonably suspected for delivering considerable radiation doses to the conceptus. The purpose of the study was to provide normalized data for the determination of conceptus dose specific to gestational stage and treated spinal level and to estimate the conceptus radiation dose and risk associated with typical kyphoplasty treatment.

Methods and Materials: Direct measurement of conceptus doses from simulated fluoroscopic projections involved in surgery at different spinal levels for the three trimesters of gestation with use of anthropomorphic phantoms and thermoluminescent dosimetry. The normalized data were used for the calculation of conceptus radiation dose from typical kyphoplasty procedure. The associated radiogenic risk of fatal cancer during childhood and congenital malformation to the progeny of the unborn child was derived.

Results: Normalized conceptus doses vary by a factor of 4000 with gestational stage, fluoroscopic projection and vertebral level. Conceptus doses from a typical kyphoplasty procedure are smaller than 4 mGy, provided that the conceptus lies outside the primarily irradiated region. The corresponding fatal cancer risk during childhood is from 2 to 160 times lower than the natural incidence rate. When the embryo is primarily irradiated, mean conceptus dose can be as high as 105 mGy from a non-optimized exposure. At least 35 minutes of fluoroscopy are required for the induction of deterministic effects. Optimization of fluoroscopy protocols may reduce conceptus dose by a factor of 40.

Conclusions: Low dose fluoroscopy protocols should be available for treatments in advanced pregnancy.

B-772 14:27

Optically stimulated luminescent (OSL) dosimeters for use in diagnostic and therapeutic radiology

C.A. Perks¹, J.E. Gray², C. Reft³, B. Markey², M. Salasky², J. Leppert⁴, R. Ford², D. Gress⁵, ¹Kidlington/UK, ²Glenwood, IL/US, ³Chicago, IL/US, ⁴Indianapolis, IN/US, ⁵Victor, NY/US

Purpose: To describe the dosimetric properties of OSL materials including energy sensitivity, linearity, angular dependence and ease of use.

Methods and Materials: Aluminum oxide doped with carbon ($\text{Al}_2\text{O}_3:\text{C}$) has been used for personal dosimetry for 10 years. The material is available in patch, dot or strip form, and can be read-out with a relatively inexpensive dosimeter-reader (inert gas is not required). $\text{Al}_2\text{O}_3:\text{C}$ elements were used to make measurements with beam qualities from mammography through megavoltage energies, including photons and electrons. Patches (1.5 cm square) and dots (6 mm diameter) were used to characterize the dosimetric properties of the material. Strips of material (6 mm x 15 cm) were used to measure CT dose and profiles.

Results: $\text{Al}_2\text{O}_3:\text{C}$ provides measurements with a precision of better than 1.5% (1 standard deviation) over the energy range evaluated and is capable of measurements down to 10iGy. It can be read multiple times with signal reductions of approximately 0.2% for each reading. Energy dependence is within 10% for energies from 22 to 120 kVp. CT dose profiles are possible with a 0.1 mm sampling interval. The signal does not fade with time and the material is not affected by environmental conditions, e.g., heat or humidity. The OSL response is similar to that of TLD in terms of dose and dose rate, and the response is independent of energy for 6 to 20 MeV electrons.

Conclusions: $\text{Al}_2\text{O}_3:\text{C}$ in the OSL mode is very promising for many applications in both diagnostic and therapeutic radiation dosimetry.

B-773 14:36

A novel method to manufacture anatomically correct phantoms for projection radiography

W. van der Putten, J. Gallagher, P. Woulfe; Galway/IE

Purpose: Appropriate use of medical radiography requires tools to assess image quality and radiation dose. Anatomically realistic phantoms can be expected to

Scientific Sessions

be useful for this purpose and this study reports on a novel way to obtain such phantoms.

Methods and Materials: The manufacturing process involves 1) the acquisition of a digital image and 2) conversion of the digital pixel matrix into an input file for a Rapid Prototyping machine. This uses previously obtained calibration factors which convert pixel grey scale values into appropriate polymer thickness. The type of polymer is chosen both for its suitability in the Rapid Prototyping process and appropriate radiological thickness. This raw model is then machined to improve its appearance and provide protection.

Results: Phantoms have been manufactured based on clinical X-rays obtained during normal clinical operation. In order to evaluate the range of imaging parameters a chest X-ray was used (acquired with Computed Radiography) and a mammography image obtained from a Full Field Digital System. Testing of the phantoms has been performed through comparison of the original images with those obtained from the phantom based on European Quality Criteria for diagnostic images.

Conclusion: It has been demonstrated that Rapid Prototyping is a convenient manufacturing method to obtain high quality phantoms which produce clinical images at relevant exposure levels. The phantoms are suitable for their intended task as test phantoms. Suggestions for improvement in the RP method are made. Phantoms can be easily manufactured and can include pathology if required.

B-774 14:45

Evaluation of a high-speed high-resolution film/screen system for medical radiography

R.E. Dickerson, P.C. Bunch; Rochester, NY/US

Purpose: This paper discusses the evaluation of a high-speed high-resolution film/screen system that provides improved image quality and opportunities for dose reduction. A description of the technical aspects of this system is given. The film features novel silver-halide microcrystals and is dual coated using a split E-layer coating format that features gradient crossover control. The system can be exposed with existing intensifying screens and provide significant dose reductions without sacrificing image quality.

Methods and Materials: This paper describes details of the system's design and performance. The film includes: 1) a dual layer structure that provides high-speed and high-resolution imaging of chest and orthopedic images, and 2) high-sensitivity silver-halide microcrystals that provide high contrast and high resolution. Modulation transfer function (MTF) measurements were used to describe the resolution of various film/screen combinations and they are compared to existing state-of-the-art film/screen systems.

Results: Inverse-square sensitometry and MTF measurements, as well as phantom and clinical radiographs using this film/screen system, demonstrate several benefits. A significant dose reduction is possible without reducing image quality using standard intensifying screens. In addition, significant image quality improvements are possible in orthopedic imaging using high-resolution extremity-intensifying screens at conventional radiation doses.

Conclusions: We have designed, built and implemented a novel film/screen system for general-purpose radiography that provides high-resolution images with a potential for dose reduction or MTF improvement. Initial clinical evaluation of the system demonstrates a 2X reduction in dose without sacrificing image quality. In addition, significant improvements in resolution are possible at the conventional radiation doses.

Improvement of X-ray image quality for medical applications using synchrotron radiation monochromatic X-rays

K. Hyodo, M. Ando, S. Ohtsuka, I. Yamaguchi, T. Takeda; Tsukuba/JP

Purpose: We have been developing two-dimensional imaging systems for intravenous coronary angiography and micro-angiography using synchrotron radiation monochromatic X-rays. To improve the image quality obtained by the systems, new techniques were introduced.

Methods and Materials: The first four patient examinations for intravenous coronary angiography were performed in May 1996 under collaboration between the University of Tsukuba and KEK using two-dimensional Imaging System I at the beamline AR-NE1. After improvement of the imaging system, Imaging System II has been employed for clinical examinations since 2000. Images were obtained at above the K-edge energy of iodine (33.2 keV) using an image intensifier-television (II-TV) system. The system has an advantage in producing dynamic two-dimensional images. To improve the image quality obtained by the system, preliminary experiments on stereo-imaging were performed using vessel phantoms to evaluate the three-dimensional structure of arteries by (1) rotating the object

and (2) using a Laue crystal. To further improve the image quality, image enhancement of the clinical images obtained by the Imaging System II was performed using a digital filter that used the value of mean density and standard deviation in a local area of the image.

Results: The possibilities of the image quality improvement by the stereo-imaging methods and the digital filter were confirmed.

Conclusion: Those improvements, along with the high current and the long lifetime of the electron beam obtained by efforts of the accelerator group, more practical examinations will be possible.

B-776 15:03

Combining deterministic and Monte-Carlo methods in the simulation of X-ray attenuation and scatter

Y. Kyriakou, P. Deak, T. Riedel, L.v. Smekal, W.A. Kalender; Erlangen/DE

Purpose: A new hybrid simulation approach which combines deterministic computation of X-ray attenuation and single-scatter contributions with estimates of multiple scattering via Monte-Carlo (MC) methods.

Methods and Materials: We employed mathematically defined objects in simulations of various scanner geometries. For the primary signal, X-ray attenuation was computed along the direct rays from the focus to each detector element using a prototype software (ImpactSim, VAMP, Möhrendorf, Germany). In addition, by summing single Compton or Rayleigh scattering inside the object over all paths from the focus to all detector elements, we calculated the corresponding single-scatter contribution to the signal. Standard MC simulations were used to validate the deterministic method and to quantify the single and the total scatter signal. The simulations were compared to measurements on a flat panel detector C-arm system (Axiom Artis dFC, Siemens Medical Solutions, Forchheim, Germany).

Results: Results for the calculated single-scatter signal were in agreement to within 1-3% with MC simulations. The structure in the scatter images was mainly determined by the single scatter signal; the total to single scatter difference images therefore show little or no structure and can thus be estimated efficiently by an adapted coarse MC simulation. Simulated and measured findings were in generally good agreement.

Conclusions: The new hybrid simulation method allows to assess scatter contributions at low computational expense as compared to standard MC. Thereby it provides a potential basis for systematic scatter corrections in X-ray tomography.

CT image quality performance of a flat-panel detector C-arm system

T. Riedel¹, Y. Kyriakou¹, D. Schäfer¹, T. Brunner², W.A. Kalender¹; ¹Erlangen/DE, ²Forchheim/DE

Purpose: To evaluate the achievable CT image quality of a commercial C-arm system equipped with a flat-panel detector.

Methods and Materials: A commercial Axiom Artis dFC C-arm system (Siemens, Forchheim, Germany) was available for the evaluation. The detector consists of a photodiode array of amorphous silicon (a-Si) providing 960x960 pixels with a pixel size of 184 µm coupled to a 600 µm thick phosphor layer of Thallium-doped cesium iodide (CsI:Tl) for X-ray absorption. The system offers a scan range of 240° of rotation with angular steps from 0.6° to 1.5° corresponding to 400 to 200 projections. For the measurements the source-to-detector distance was varied between 105 and 120 cm, thereby producing a magnification of 1.4 to 1.6. Several phantoms for spatial and low-contrast resolution as well as clinical specimens were measured. Scan times were 15 s and reconstruction was performed with prototype software (VAMP, Möhrendorf, Germany). Deterministic simulations (ImpactSim, VAMP) were applied for validation and tests.

Results: For a focal spot size of 0.4 mm an isotropic spatial resolution better than 200 µm was determined and was also demonstrated visually in specimen measurements. Phantom and specimen measurements indicated that low contrast details of 10 HU and diameters of 10 mm were recognized with air kerma values of about 100 mGy.

Conclusions: The evaluation confirmed the feasibility of CT imaging applications for commercial C-arm systems with flat-panel detectors. The evaluated system provided a high contrast resolution superior to standard CT imaging. Even details with contrasts of 10 HU are detectable but at the expense of high exposure levels.

Imaging properties of a new dynamic large flat panel detector for DSA and 3D-rotational angiography (CT-mode)

R.W.R. Loose¹, M. Wucherer¹, B. Geiger², M. Mechtel¹, R. Adamus¹, E. Vano³; ¹Nürnberg/DE, ²Förchheim/DE, ³Madrid/ES

Purpose: To evaluate high- and low-contrast resolution of a dynamic CsI-aSi large flatpanel detector for DSA-mode and 3D-rotational angiography (CT-mode) for phantoms and clinical examinations.

Methods and Materials: Detail contrast detectability and high contrast resolution of a new DSA system with dynamic CsI-aSi flatpanel detector (FD) (AXIOM Artis-dTA) and an equivalent image intensifier (II) system (AXIOM Artis-FA) were compared with equivalent parameters (phantom dose and postprocessing). FD parameters are: detector size 30x40 cm, matrix 2480x1920, pixel size 154 µm. The diameter of the II was 40 cm. High contrast resolution was determined with a lead grid phantom at 42 cm/22 cm field of view (FOV) of the FD and 40 cm/20 cm of the II. Detail contrast detectabilities were determined with a CDRAD phantom and 20 cm PMMA with 20 different dose parameters for both systems. 3D-reconstructions (~400 slices, 0.3 mm thickness) were acquired with rotational angiography (CT-mode).

Results: The high contrast resolution of the FD was 25-38% better compared with the II (depending on magnification). For similar detail contrast detectability (51% of all objects) the Entrance Skin Air Kerma (ESAK) was 512 µGy for the FD and 818 µGy for the II. Reconstructed CT-images demonstrate a low contrast resolution of < 20 HU.

Conclusions: In comparison to an equivalent II, the FD demonstrates a significant higher contrast resolution and similar detail contrast detectability at 37% less dose. In clinical 3D-examinations a low contrast visualization of soft tissues is possible for the first time.

In vivo lymphocytes trafficking to tumor: A cellular magnetic resonance imaging approach for cell-based anticancer therapy

P. Smirnov¹, E. Lavergne¹, F. Gazeau¹, B. Doan², B. Gillet², C. Combadiere¹, B. Combadiere¹, O. Clement¹; ¹Paris/FR, ²Gif sur Yvette/FR

Purpose: Cellular imaging by MR imaging is potentially useful to track of injected cell-based therapy in vivo and estimate treatment efficiency against tumor growth. The aim of this study was the follow-up in vivo by MR imaging at 7 T of the infiltration of intravenously injected lymphocytes in implanted tumors in mice.

Methods and Materials: Cells were labelled with anionic nanoparticles, which are taken up by endocytosis pathway. OVA-specific lymphocytes (OT-1), labelled with 1.5 pg iron per cell, were adoptively transferred in C57BL/6 recipient mice with growing OVA-expressing EL-4 (EG-7) tumors. Injected OT-1 cells were tracked in vivo by 7 T MR imaging at 24, 48 and 72 h after transfer. Tumors were analyzed ex vivo by micro-MR imaging at 9.4 T.

Results: Images showed a significant negative enhancement of the spleen at 24 h. Between 48 and 72 h after labelled cells injection, a negative enhancement was observed in the tumor with heterogeneous signal. The presence of labelled cells in tumors was confirmed by ex-vivo studies on the 9.4 T high resolution imaging, and by iron histopathological staining. It suggests first the migration of lymphocytes into spleen followed by their recruitment by tumor site. Subsequently, we showed that labelled OT-1 lymphocytes kept their ability to induce in-vivo tumoral regression.

Conclusion: These results demonstrate that magnetic resonance tracking of lymphocytes is feasible. The ability to define the kinetics of CD8 antitumor migration is crucial for improving the efficiency of tumor rejection. Thus, high-resolution imaging method would have significant clinical and research applications.

In vitro cell labelling with SPIO and USPIO: A comparison

F.M.A. Kiessling¹, R. Sun¹, J. Bedke¹, R. Krueger¹, M. Bock¹, R. Huss², C. Seliger², H.-J. Gröne¹, W. Semmler¹; ¹Heidelberg/DE, ²Munich/DE

Purpose: The purpose of this study was to compare the labelling efficiency and toxicity of SPIO and USPIO for three cell lines.

Methods and Materials: Using human fibroblasts, immortalized rat progenitor cells and HEP-G2-hepatoma cells, dose- and time-dependency of SPIO and USPIO uptake were evaluated. The amount of intracellular SPIO and USPIO was monitored over two weeks by T2-magnetic resonance relaxometry, ICP mass spectroscopy (ICP-MS) and histology. Transmission-electronmicroscopy was used to specify the intracellular localization of the iron particles. Cell death-rate and proliferation-index were assessed as indicators of cell-toxicity.

Results: For all cell lines SPIO showed higher uptake rate than USPIO. With 3 mg Fe/ml growth medium highest uptake of SPIO was found in the HEP-G2 cells (110.1 ± 2.4 pg Fe/cell). However, intracellular iron contents in rat progenitor cells (13.7 ± 0.7 pg Fe/cell) and fibroblasts (7.2 ± 0.3 pg Fe/cell) were also capable of reducing T2-relaxation times in cell pellets below detection threshold after 5 h incubation with SPIO. While 4 days after re-cultivation of labelled cells a significant reduction of cellular iron oxide content was found by ICP-MS and histology for SPIO a strong MR-label was present for more than 6 days. For both particle types viability, apoptotic index and proliferation of labelled cells were not significantly different from unlabelled cells.

Conclusions: Our hematopoietic, mesenchymal and epithelial cell lines accumulated SPIO more efficiently than USPIO indicating SPIO to be better suited for cell labelling. Using SPIO labelled cells a suitable window of 6 days was available for in vivo MR tracking experiments.

B-781 14:18

Labelling of human mesenchymal stem cells with different iron oxide MR imaging contrast agents: Uptake, intracellular persistence and in-vitro imaging at 3 T

H. Ittrich, C. Lange, H. Dahnke, C. Nolte-Ernsting, G. Adam; Hamburg/DE

Purpose: In-vitro evaluation of cellular uptake and persistence of different types of superparamagnetic iron oxide nanoparticles ((U)SPIOs) in human mesenchymal stem cells (hMSC) as well as detection and quantification on MR imaging at 3 T.

Methods and Materials: hMSCs were incubated for 24 h with 4 dilutions of stock suspension (1:30-30.000) of 5 (U)SPIO contrast agents: Endorem, Resovist, citric acid coated magnetite cores of 7 nm (CMF3), 3 nm (CMF7) and cobalt ferrite cores (CoF) of 12 nm. Iron uptake, intracellular retention, detection and quantification in MR imaging were evaluated up to 5 weeks after incubation by histological analyses (Prussian blue), atomic absorption spectrometry (AAS) and T2*-MR-relaxometry (multiecho gradient echo sequence, 3 T Philips Intera) on homogenous solid gelatine phantoms of 5×10^4 labelled hMSCs/ml.

Results: An effective labelling of nearly all hMSCs was proven histologically by using Resovist, CMF7 and CMF3(1:30/1:300) with mean iron concentrations of 5.1/1.8, 1.9/1.4 and 1.5/1.0 pg/cell compared with 0.58/0.34 and 0.43/0.30 pg/cell (Endorem, CoF(1:30/1:300)) and 0.01 pg/cell for unlabelled control. Resovist showed best intracellular retention followed by CMF7 and CMF3. Detection of 5×10^4 labelled cells/ml in MR imaging was possible up the 5 weeks after incubation (Resovist, CMF7 and CMF3) with an increasing T2* time in contrast to Endorem and CoF-labeled cells (only 3 weeks). Correlation between cellular iron load and 1/T2* was shown ($R^2=0.76-0.98$).

Conclusion: Efficiency of labelling hMSCs with (U)SPIOs depends on coating, size and core compound of used particles. Long intracellular retention of (U)SPIOs offers the possibility of cell tracking and migration monitoring in a clinical 3 T Scanner and promising prospects for in vivo applications.

Relaxation determination of magnetically labelled macrophages

R. Trost¹, J. Reichenbach¹, I. Hilger¹, M.-R. Lisy¹, D. Schueler², J. Sedlack¹, A. Rauscher¹, W.A. Kaiser¹; ¹Jena/DE, ²Bremen/DE

Purpose: In vitro MR relaxation times of magnetically labelled macrophages were determined on a 1.5 T clinical magnet.

Methods and Materials: Human macrophages (cell line J774) were incubated with bacterial magnetosomes (\varnothing 42 nm) which were covalently bound to fluorochrome Dy676 (Dyomics, Jena). Multiple cell samples (each 0.5 ml) with

Scientific Sessions

different numbers of incubated macrophages (range: 10^6 - 10^7) were measured with a small surface coil in a 1.5 T clinical scanner. IR- and multi-echo spin-echo sequences were used to determine T1 and T2 relaxation times, respectively, based on a ROI evaluation. In addition, a multi-echo gradient-echo sequence was used to determine T2*.

Results: Samples with the highest cell labelling caused severe signal loss and image distortions and were not further analyzed. Both T1- and T2-shortening was observed with increasing cell labelling with magnetosomes. T1 was shortened from approximately 2340 ms for pristine macrophages embedded in agar down to approximately 1500 ms for a sample containing 2.5×10^6 macrophages. Similarly, T2 decreased from 67 ms down to 30 ms. In contrast, T2* was strongly shortened (< 5 ms) and could not reliably be determined.

Conclusion: Magnetosomes are promising probes to label macrophages magnetically. Further MR imaging studies are needed to characterize their full potential for applications in molecular imaging.

B-784 14:36

Fast T2/T2*-mapping at 3.0 Tesla for quantification of cellular iron-uptake

L. Matuszewski¹, R. Kuhlpeter¹, H. Dahnke², T. Persigehl¹, A. Wall¹, B. Tombach¹, W. Heindel¹, T. Schaeffter¹, C. Bremer¹; ¹Münster/DE, ²Hamburg/DE

Purpose: To quantify cellular iron-uptake by T2/T2*-mapping using fast multi-echo sequences at 3.0-Tesla.

Methods and Materials: Human lung carcinoma cells (CLL-185) were labelled with superparamagnetic iron oxides (SPIO) by a previously established lipofection-protocol. MR imaging measurements were performed on a 3 T scanner (Philips Intera) using fast multi-echo readout sequences. Agarose gel-phantoms were prepared containing (a) 1×10^5 cells with increasing amounts of cellular SPIO (1.0-5.0 mg Fe/ml in the medium), (b) different amounts of identically labelled cells (5×10^3 - 2.5×10^5 cells/ml agarose) and (c) free SPIO at identical concentrations as measured in (a) and (b). Cellular iron-load was qualitatively analyzed by light microscopy (LM) and quantified by Atomic Emission Spectroscopy (AES).

Results: With increasing iron concentration in the medium LM and AES showed a dose dependent uptake of SPIO-particles (e.g. [1.00 mg Fe/ml]: $4.37 \pm 0.07 \mu\text{g}/10^5$ cells; [5.00 mg Fe/ml]: $18.65 \pm 1.38 \mu\text{g}/100,000$ cells; $p < 0.05$). While all MR phantom studies showed a strong dose-dependent decrease of T2*-relaxation time the decrease in T2-relaxation time was more subtle (e.g. [1.0-16.0 µg Fe/ 10^5 cells]: T2*: 59.2-9.7 ms; T2: 63.3-57.9 ms). Compared to phantoms containing free SPIO T2*-effects were significantly higher ($p < 0.01$) and T2-effects significantly lower ($p < 0.05$) for iron labelled cells. R2*-values were linearly correlated with cellular iron-load ($r = 0.99$; $p < 0.0001$) or cell number ($r = 0.99$; $p < 0.0001$) respectively.

Conclusion: Estimation of cellular iron load and/or number of iron labelled cells in vitro can be achieved by fast T2/T2*-mapping. The comparison of T2- and T2*-relaxation properties allows to differentiate between cell-bound and free SPIO. Further studies are warranted to elucidate if this method is applicable for cell quantification in-vivo.

B-785 14:45

Diffusion weighted imaging for monitoring of anti-angiogenic tumor treatment

T. Persigehl¹, L. Matuszewski¹, A. Wall¹, C. Wülfing¹, H. Kooijman², B. Tombach¹, R. Mesters¹, W. Heindel¹, C. Bremer¹; ¹Münster/DE, ²Hamburg/DE

Purpose: The aim of this study was to evaluate diffusion weighted imaging (DWI) for non-invasive assessment of anti-angiogenic tumor treatment efficacy.

Methods and Materials: Two different human cancer cell lines (HT-1080, KU-19-19) were implanted in nude mice. Tumor bearing animals were treated either with a vascular targeting agent (VTA, n = 11), an endothelin-A-receptor-inhibitor (ETAR; n = 9) or saline (control; n = 20). Diffusion weighted imaging (DWI) was performed after treatment initiation using a multi-shot EPI and a single-shot TSE DWI sequence. Apparent diffusion coefficient (ADC) maps were calculated and ADC values were correlated with the vascular volume fraction (VVF) measured by iron oxide enhanced MR imaging. Moreover, tumor volume and grade of tumor necrosis determined by MR imaging or histology, respectively, were correlated with the ADC values.

Results: In our models the VTA treatment of HT-1080 xenografts revealed a significant reduction of tumor size while ETAR therapy of KU-19-19 was inefficient. Effective tumor treatment (VTA) resulted in a significant increase of the ADC compared to control (e.g. MS-EPI: $1.45 \pm 0.23 \text{ } 10^{-3} \text{ mm}^2/\text{sec}$ versus $0.79 \pm 0.1 \text{ } 10^{-3} \text{ mm}^2/\text{sec}$; $p < 0.01$). Inefficient therapy (ETAR) showed no significant effects on the ADC compared to tumors treated with saline (MS-EPI: $0.65 \pm 0.038 \text{ } 10^{-3} \text{ mm}^2/\text{sec}$ versus $0.72 \pm 0.07 \text{ } 10^{-3} \text{ mm}^2/\text{sec}$). The grade of tumor necrosis and the VVF correlated well with the ADC changes.

Conclusion: DWI may allow non-invasive and early differentiation of effective versus ineffective anti-angiogenic tumor treatment. Further studies are warranted to elucidate the clinical potential of this imaging approach.

B-786 14:54

Diffusion weighted imaging: An early predictor for therapeutic efficacy

J. Stojanovska¹, B.A. Moffat², T.L. Chenevert², B.D. Ross², A. Rehemtulla², D.E. Hall²; ¹Skopje/MK, ²Ann Arbor, MI/US

Purpose: To assess diffusion weighted MR imaging as an early surrogate marker for evaluating the therapeutic-induced cellular changes of experimental gliomas.

Methods and Materials: Intracerebral 9L tumors were induced in Fischer-344 rats. Two groups ($n = 12$) were established. First group received intratumoral injection of either 67 mg/ml BCNU or ETOH at 50% of the tumor volume under stereotactic guidance. Second group received systemic IP injection of 6.65 mg/kg, 13.3 mg/kg and 26.6 mg/kg of BCNU. The protocol consisted of T2WI and DWI prior to treatment and post treatment at 24 hrs, 48 hrs, 72 hrs and 3 times a week thereafter on a 7 T Varian imaging system. Isotropic ADC maps were calculated and ADC pixel value histograms were generated from tumor ROIs.

Results: Diffusion changes can be detected at BCNU IT group after 48 hrs and the tumor shrinkage between 5 and 7 days post treatment with mean ADC value $1.49 \times 10^{-3} \text{ mm}^2/\text{sec}$. The ETOH group showed diffusion changes after 48 hrs and slowly tumor growing in comparison with Control. Diffusion changes and tumor shrinkage can be detected for groups 26.6 mg/kg and 13.3 mg/kg BCNU at day 7 post treatment in comparison with 6.65 mg/kg group. The cell Log Kill mean for BCNU groups (IT and 26.6 mg/kg) indicates no tumor tissue left in comparison with control and 6.65 mg/kg BCNU where tumor tissue was present confirmed by histology.

Conclusion: Diffusion MR imaging can monitor early changes in tumor cellularity caused by treatment response and can help the physician in tailoring treatment protocol if a tumor is resistant to first-line therapies.

B-787 15:03

In vivo imaging of protease activity and marker gene expression through a fiberoptic catheter-based fluorescence detection system

M.A. Funovics¹, H.S. Su², R. Weissleder², U. Mahmood²; ¹Vienna/AT, ²Boston, MA/US

Purpose: Design, construction, and evaluation in vivo of a fiberoptic catheter-based imaging sensor for the intravital monitoring of molecularly sensitive near infrared fluorescent (NIRF) probes and optical marker genes.

Methods: An imaging device based on a miniaturized fiberoptic sensor (MIFS) was built in which the image created by a 2.7F fiberoptic catheter is relayed through a dichroic mirror, bandpass filter and on two independent cameras, permitting simultaneous recording of white light and fluorescent images. Spatial resolution and spectral transmissions were measured, and sensitivity was determined on a dilution series of a near infrared (NIR) fluorophore. In vivo testing was performed on nude mice bearing intraperitoneal tumors expressing green fluorescent protein (GFP), and on a mouse model of ovarian carcinoma with enzyme-activatable NIR probes sensitive to tumoral activity of the protease cathepsin B.

Results: The 18 G catheter showed a resolution of 7 line-pairs per mm, and a detection limit for the fluorochrome Cy5.5 of 1-10 pmol. Detection of endogenous GFP gene expression was feasible in tumor nodules of < 1 mm in size, with tumor SI of 153.26 ± 26.45 (mean \pm SD) compared to SI from adjacent non-tumoral tissue of 36.73 ± 11.69 (mean \pm SD; $p < 0.008$). Similarly, activation of the NIR-probe by tumoral cathepsin B could be detected in the peritoneal tumor seeds of the ovarian cancer model with tumor SI of 246.33 ± 7.77 (mean \pm SD) compared to SI from adjacent non-tumoral tissue of 41.56 ± 18.64 (mean \pm SD; $p < 0.001$). Combined NIR/white light images consistently revealed more tumors than white light examinations alone.

Conclusion: The proposed minimally invasive optical imaging system offers a method to obtain simultaneous white light and fluorescent images at high sensitivity, allowing the superimposition of anatomic and molecular information in real time. In vivo MIFS imaging of gene expression, enzyme activity and potentially other molecular events is feasible using both a transvascular approach as well as direct interventional access to several organs and body cavities.

In vivo assessment of gene expression ability after application of focused ultrasound

W. Hundt¹, S. Guccione², D. Mayer², M. Bednarski²; ¹Munich/DE, ²Stanford, CA/US

Purpose: Evaluation of gene expression changes of muscle tissue cells after treatment with focused ultrasound.

Methods and Materials: Muscle tissue of 25 Balb/c mice were transfected with a CMV_Luc plasmid. 10 days after the transfection focused ultrasound (Focus Surgery) using five different energy levels (4133 W/cm², 3067 W/cm², 2157 W/cm², 1401 W/cm², 802 W/cm²) was applied. After focused ultrasound application a MR imaging scan (1.5 T GE Signa) of all animals using a diffusion weighted steam sequence (TR = 6000 ms, TE = 30 ms, NEX=8, δ=9 ms, Δ=170 ms, b-values = 50, 250, 500, 750, 1000 (s/mm²)) was performed. The determination of the gene expression was done by an optical imaging system (Xenogen).

Results: At a intensity of 4133W/cm² the diffusion coefficients of the treated tissue was D=(0.30 ± 0.03) 10-3 mm²/s and the T2-time 117.49 ± 6.74 ms showing a 83% reduction of the Luciferase reporter gene activity. At an energy level of 2157W/cm² the diffusion coefficient was D=(0.78 ± 0.03)10-3 mm²/s and the tissue T2 time 63.91 ± 3.90 ms a 4 fold increase of gene expression was seen. At a intensity of 802W/cm² the mean diffusion coefficient was D=(0.74 ± 0.04)10-3 mm²/s and the T2= 46.34 ± 1.18 ms still leading to a higher gene expression of 2.5 fold compared to the reporter gene activity prior to the application of focused ultrasound (D=(0.68 ± 0.04)10-3 mm²/s; T2=(36.3403 ± 1.1827)ms).

Conclusion: Focused ultrasound can induce gene expression in muscle tissue. The diffusion coefficient D (mm²/s) and the T2 time (ms) of muscle tissue correlates with the reporter gene activity of the transfected muscle tissue.

In-vitro high-field (3 T) high-resolution MR imaging of the female pelvic floor anatomy in correlation with cadaveric cross-sections

K. Pinker, O. Preyer, M.C. Sora, A. Ba-Ssalamah, S. Trattning, V. Mlynarik, W. Umek; Vienna/AT

Purpose: The aim of this study was an anatomic-MR-comparison study using high resolution imaging of the regular female pelvic floor anatomy in-vitro with high-field MR imaging (3 T).

Methods and Materials: We isolated three female cadaveric pelvises of the Vienna Anatomy-Donation-program, cut to fit a standard MR headcoil. All MR images were acquired using a 3 T Bruker Medspec 30/80 Scanner and a head-birdcage transmit/receive coil with an actively shielded gradient system (maximum gradient strength 45 mT/m). A T2-RARE-sequence (TR/TE = 10.098/38.9 ms; matrix size 512x384; RARE factor=4, FOV 230x159 mm, TA 16 min) and a T2-MSME-sequence (TR/TE = 10.000/19 ms; matrix size 512x386; FOV 230x159 mm, TA 1 h 4 min, SI 2/4 mm) was used for high resolution axial images of the female pelvic floor anatomy. All images were carefully evaluated and compared with plastinated slices of the same orientation.

Results: High-field MR imaging depicted the female pelvic floor anatomy to anatomic detail. We could visualize the course and the fascicular structure of the levator ani muscle. The three layers of the urethra (two muscular, one endothelial) and the course of the muscle-fibres in the outer longitudinal and the inner circular layer of the urethra could be identified correctly. The neurovascular bundle was clearly visible.

Conclusion: High-field MR imaging depicts regular anatomy of the female pelvis to a level equal to plastinated macroscopic anatomic cross-sections.

B-790 10:39

Evaluation of female urethra and supporting ligaments with MR imaging

K.J. Macura, R.R. Genadry, D.A. Bluemke; Baltimore, MD/US

Purpose: One of the hypotheses for female stress urinary incontinence is that the sphincter deficiency results from decreased muscle volume and urethral hypermobility results from defects in the supporting ligaments. Our purpose was to evaluate the urethral sphincter in women with urinary incontinence and age-matched continent volunteers, and assess visualization of urethral ligaments with different MR techniques.

Methods and Materials: We evaluated urethral sphincter with intraurethral MR imaging in 10 incontinent women (mean age 59.7) and two groups of continent volunteers: 8 volunteers age-matched to the incontinent group (mean age 51.7), and 6 volunteers not age-matched, mean age 43.8. We measured the urethral sphincter muscle length and thickness and compared the sphincters between the incontinent patients and two groups of volunteers. We analyzed urethral support ligaments in 49 continent women. Twenty-patients (mean age 38.2) were imaged using 14 F endourethral MR coil, 29 women (mean age 40.1) were imaged using pelvic phased array coil. The visibility and symmetricity of three ligaments (periurethral, paraurethral, and pubourethral) were assessed.

Results: There was no significant difference in the urethral sphincter size when incontinent patients were compared to age-matched volunteers. The intact periurethral ligament was the most consistently visualized urethral support structure in continent population. With advancing age, urethral ligaments become thinner and asymmetric. Incontinent patients with urethral hypermobility have defects in periurethral ligaments.

Conclusions: Decrease in urethral sphincter volume is associated with normal aging. Defects in periurethral ligaments leading to urethral hypermobility can be well assessed with MR imaging.

B-791 10:48

Borderline tumors of the ovary: CT and MR features and tumor markers in differentiation from stage I disease

N.M. deSouza, R. O'Neill, R. Dina, W.P. Souter, G.A. McIndoe; London/UK

Purpose: To describe features of borderline ovarian tumours on CT and MR imaging in order to differentiate them from Stage I lesions.

Methods and Materials: We retrospectively reviewed preoperative CT and MR imaging of 38 ovarian tumours in 30 patients classified as borderline or Stage I at histopathology. Two radiologists in conference blinded to the histopathology noted tumour size, number and size of septations, nodules and vegetations, and presence of ascites.

Results: Nineteen borderline (17 patients) and 19 Stage I tumours (13 patients) were identified at histopathology. Borderline tumours were not significantly smaller than Stage I tumours (mean diameter 10.5 ± 5.4 cm versus 13.0 ± 5.3 cm). Although numbers of septations per mass were similar, there was a significant difference in their thickness between borderline and Stage I masses (mean \pm SD = 3.3 ± 1.5 mm vs. 5.1 ± 2.34 mm, $p = 0.04$). Also, although numbers of nodules/vegetations per mass were similar, borderline tumours had significantly smaller solid components than Stage I masses (mean \pm SD = 15.0 ± 9.8 mm vs. 32.0 ± 19.0 mm, $p = 0.003$). Areas under the Receiver Operating Characteristic curves were 0.75 and 0.68 respectively for these features, and a discriminant model resulted in correct classification of 78.6% of cases. Ascites was seen in 4 and 5 cases respectively. Tumour markers were marginally elevated in both groups with no significant differences.

Conclusion: Borderline ovarian tumours have imaging features similar to Stage I tumours. Although the thickness of septations and size of solid components may be helpful in predicting likelihood of Stage I disease, neither feature allows confident differentiation between these entities.

B-792 10:57

Comparison of clinical and MR imaging staging with pathologic evaluation in cervical carcinoma

T.M. Cunha, A. Félix, I. Cabral; Lisbon/PT

Purpose: To evaluate the accuracy of clinical and MR imaging staging in patients with cervical carcinoma.

Methods and Materials: 47 patients with histologically proven cervical carcinoma were included in this prospective study, between October of 1998 and April of 2004. The patients mean age was of 51.8 years (age range 30-77 years). All patients underwent preoperative pelvic MR imaging and MR imaging reports were revealed to the treating gynecologists. Clinical evaluation used FIGO staging. Clinical criteria for operability in our institution are: patients with stage \leq IB1 and IIA tumors \leq 4 cm with small vaginal invasion. Radical hysterectomy specimen histologic report was used as the gold standard of this study. MR imaging protocol: Axial T1- (TR/TE = 427/8), transverse, coronal and sagittal T2-weighted images (TR/TE = 5952/150), and a dynamic study (for small lesions) after 0.1 mmol/Kg Gd-DTPA intravenously in the sagittal plane were obtained with a Philips 1.0-T magnet, using a body coil. The mean elapsed time between MR imaging and surgery was of 36 days (Median = 33 days). MR imaging only found criteria for operability in 38 of the 47 cases. By pathological staging only 39 cases were eligible for surgical treatment accordingly with our protocol.

Results: In the 47 cases studied MR imaging obtained accuracy for surgical staging of 97.2%, and accuracy for staging of 97.5%. Clinical staging obtained accuracy for staging of 82.9%.

Conclusion: MR imaging is useful in the preoperative evaluation of early cervical carcinoma, especially when it is unclear from the clinical examination whether the choice of therapy is surgery or radiation therapy.

B-793 11:06

Pitfalls in MR imaging staging of cervical cancer

A. Sahdev, J.L. Hughes, R.H. Reznek; London/UK

Purpose: To appreciate potential errors and pitfalls in the interpretation of MR imaging during staging of cervical cancer. To learn strategies and techniques to avoid these potential errors.

Materials and Methods: MR scans of 132 women undergoing staging between 1994-2004 were retrospectively evaluated for potential pitfalls and errors. 81 patients underwent surgery allowing correlation of MR imaging and surgical findings.

Results: In 11 (14%) of 81 patients the tumour was not detected on MR imaging (false negatives). 8 of these 11 patients, had a pathological tumour less than 1 cm. In 2 patients residual tumour infiltrated the entire cervix without mass effect.

Scientific Sessions

or differential signal intensity. In the last patient co-existing endometriosis obscured the tumour. In 8(10%) patients MR tumour size was overestimated by 2-3 mm due to inflammatory changes. 4 (5%) patients had false positive MR diagnosis of parametrial invasion due to large exophytic tumours. In detection of nodal metastasis MR sensitivity was 63%, specificity 56% and accuracy 89%. Cystic change in metastatic nodes were a pitfall resembling ovarian tissue. Vaginal wall appearances are a further pitfall. Folding and post biopsy thickening lead to false impression of tumour invasion, upstaging the carcinoma.

Conclusions: We present pitfalls of staging MR in detection, size estimation of primary tumour and parametrial extension. These include technical inadequacies, anatomical variants, confusion by co-existent disease and effects of previous intervention. We describe alterations in MR techniques and protocols which avoid these pitfalls. Techniques and interpretation of lymph node specific contrast agents to assess nodal metastases are also discussed.

B-794 11:15

Uterine fibroids: Relationship between symptoms and MR imaging evaluation

Y. Fargeaudou¹, J.-P. Pelage², D. Jacob¹, M. Abitbol¹, O. Le Dref¹, R. Rymer¹; ¹Paris/FR, ²Boulogne/FR

Purpose: To determine the relationship between fibroid-related symptoms and fibroid volume/location evaluated using MR imaging.

Methods and Material: One hundred and sixteen consecutively seen women with symptomatic fibroids underwent pelvic MR imaging and clinical evaluation. Demographics and clinical presentation were recorded in all women who completed a questionnaire of fibroid-related symptoms. Special emphasis was given to heavy menstrual bleeding (duration of menses, presence of clots, number of pads/tampons used daily, hemoglobin level), bulk-related symptoms, pelvic pain and infertility precisely evaluated. All women had a pelvic MR imaging with axial and sagittal T1 and T2-weighted images. Location, number and volume of dominant uterine fibroids (submucosal, subserosal, intramural and full-thickness), uterine volume and the presence of adenomyosis were carefully recorded. Relationship between symptoms and fibroid volume/location was then computed.

Results: Black women were significantly younger and had multiple fibroid uterus more frequently than the others. Submucosal fibroids were associated with heavier menstrual bleeding than the other types (duration of periods, hemoglobin level, presence of clots). Women presenting with adenomyosis (with or without fibroids) had heavier menstrual bleeding than those with uterine fibroids only. Pelvic pain was more frequently observed in women with large uteri (> 500 cc) or in cases of intramural fibroids. There was a trend towards lower fertility in women with large uteri or multiple fibroids.

Conclusion: A significant relationship between menorrhagia and the presence of submucosal fibroids was found. Adenomyosis was also associated with bleeding symptoms.

The effectiveness of MR imaging in the non-invasive diagnosis of endometriosis: Can laparoscopy be replaced?

C. Alvey, S. Kennedy, C. Ang, D. Barlow, S.J. Golding; Oxford/UK

Purpose: Retrospective study was carried out to determine the accuracy, sensitivity and specificity of MR imaging in detecting lesions of endometriosis, compared to the gold standard investigation of laparoscopy.

Methods and Materials: 100 women (age range 20 - 59 years; mean 37.03) underwent MR imaging using a standardised protocol in a 1.5 Tesla Sigma System (General Electric Medical Systems). Examinations were reported by one radiologist, blinded to the findings of laparoscopy. Imaging findings were compared retrospectively with the findings at surgical investigation to determine presence or absence of disease.

Results: Analysis showed that MR imaging in our study had an accuracy of 91.1%, sensitivity of 88.8% and specificity of 93.1%. This yields a positive predictive value of 92.3% and a negative predictive value of 90%. A Chi-squared test yielded a result of 37.79, indicating a high degree of conformity between the MR imaging and surgical findings. Moreover, findings in this study suggested that laparoscopy may have a false negative rate of 3%. It was notable that 30 patients failed to proceed to surgical investigation at the discretion of the clinician, as the MR imaging findings were deemed to be sufficiently positive for medical treatment to ensue.

Conclusion: MR imaging offers an efficient and effective means of diagnosing endometriosis before patients proceed to surgical investigation and can prevent

a significant number of patients from having invasive investigation. Our findings indicate strongly there is a case for detailed cost-effectiveness study.

B-797 11:33

CT features of adnexal torsion

T. Sella, D. Aharoni, N. Hiller; Jerusalem/IL

Purpose: The clinical presentation of adnexal torsion can at times mimic nongynecological causes of acute lower abdominal pain. In these cases, CT may be the initial imaging study performed. The purpose of this study is to define the CT characteristics of adnexal torsion.

Materials and Methods: This retrospective review examined pelvic CT findings in 35 patients with surgically proven adnexal torsion. CT findings were correlated with sonographic, surgical and pathologic findings.

Results: Localized abdominal pain was found in 79% of patients, with an acute onset in 60%. Torsion was clinically suspected only in 26% of cases. The time interval between admittance and CT ranged from the same day to 1 week (mean 1 day). On CT, the involved adnexa was misplaced in 65%; of these, 34% were midline and 31% were in the contralateral pelvis. The uterus was diverted to the side of the involved ovary in 47%. The size of the involved adnexa ranged from 3 - 20 cm (mean 9.5 cm). An underlying ovarian mass was noted in 71% (pathologically confirmed). All adnexal masses had smooth margins; 80% of them had a cystic component, 50% showed mural thickening. Pelvic ascites was seen in 40%, and effacement of the pelvic fat in 29%, pathologically correlating with adnexal necrosis. The uninvolved ovary was visualized and was normal in 74%.

Conclusion: A smooth adnexal mass which is abnormally located in the pelvis, with ipsilateral deviation of the uterus should raise the suspicion of adnexal torsion. Inflammatory signs on CT suggest necrosis.

B-798 11:42

Selecting postmenopausal patients with abnormal uterine bleeding (AUB) to invasive assessment by transvaginal ultrasonography (TVUS)

S. Ciatto, S. Cecchini, A. Landini, A. Benvenuti, M. Zappa; Florence/IT

Purpose: Abnormal uterine bleeding (AUB) is a common symptom in the menopause, is associated to increased risk of endometrial carcinoma (EC), and in the past did prompt immediate invasive diagnostic assessment (dilatation and curettage, endometrial biopsy, hysteroscopy). As most first AUB episode are spurious and are not associated to EC, risk-based selection to invasive assessment has been advocated for these patients. Measuring endometrial thickness by transvaginal ultrasonography (TVUS) has been suggested as a proper criterium.

Materials and Methods: A consecutive series of 2693 postmenopausal women referring for AUB and undergoing TVUS from 1993 to 2000 has been linked with the local cancer registry database. The adopted protocol foresaw hysteroscopy in presence of a) suspicion for EC at TVUS morphology, and/or b) persistent (> 2 episodes) AUB, and/or thickness (half layer) > 4 mm; 63 of 64 EC cases were correctly suspected according to these criteria.

Results: Endometrial thickness showed a significant association to EC: a cut off of 2 mm (half layer) was associated with a 94.9% sensitivity and a 68.2% specificity (68.2% of subjects could be spared unnecessary invasive assessment on this basis).

Conclusion: Endometrial thickness measured at TVUS is a safe criterium to select subjects at their first AUB episode to invasive assessment. A cut off of 2 mm (half layer) seems a reasonable and reliable clinical reference standard.

An update on the use of ultrasound in osteomyelitis and the importance of power Doppler

A.K. Nath, A.U. Sethu; Muscat/OM

Purpose: An update study with 200 patients of our previously published paper from 1992 looking into the use of ultrasound in osteomyelitis.

Scientific Sessions

Materials and Methods: Plain radiographs of the affected area and sonography along with power doppler of the affected area and the opposite normal area was performed in 200 patients clinically suspected of having osteomyelitis. Sonograms were obtained using 7.5 to 11 MHz phased array linear transducer on Power vision 6000 Toshiba unit. Needle aspiration or surgery was performed to confirm diagnosis.

Results: 120 of the 200 patients had osteomyelitis, sonographically revealing fluid in contact with the bone with no intervening soft tissue. The fluid proved to be pus. 120 osteomyelitis patients had (a) radiograph and ultrasound positive - 50 patients (b) radiograph normal initially but ultrasound positive - 70 patients. 50 patients had following findings-30 patients had soft tissue abscesses, 10 patients had cellulitis and 10 were normal. Limitations of ultrasound in remaining 30 patients will be highlighted, as seen in sickle cell disease (10 pts), septic arthritis (10 pts), epiphyseal osteomyelitis (7 pts) and Brodie's abscess (3 pts). Color Doppler helped in showing increased blood supply to infected periosteum, adjacent infected bone and soft tissue.

Conclusion: Ultrasound and color Doppler is useful in 1) Predicting osteomyelitis 2) differentiating osteomyelitis from soft tissue abscesses 3) localizing the lesions 4) limitation of ultrasound in the disorders mentioned above help to resort to direct methods like aspirations to make the diagnosis of osteomyelitis 5) Power Doppler was useful as stated above.

B-800 10:39

Ultrasound of the reflection pulley of the long biceps tendon

L. Bacigalupo¹, C. Martinoli¹, Y. Morag², J.A. Jacobson², A.S. Miller², S. Bianchi³; ¹Genoa/IT, ²Ann Arbor, MI/US, ³Chene-Bougeries/CH

Purpose: To describe the US appearance of the coraco-humeral and superior gleno-humeral ligaments (forming the reflection pulley) in normal subjects and patients with pulley tears associated with rotator cuff pathology and biceps tendon instability.

Methods and Materials: A correlative US-anatomic study was performed on freeze-frozen cadaveric shoulders and correlated with the normal US appearance of the reflection pulley in 20 healthy volunteers. Then, 12-5, 15-7 and 17-5 MHz US images were obtained in n = 21 consecutive patients with pulley lesions confirmed on MR-arthrography. Patients with massive rotator cuff tears and biceps tendon rupture were excluded.

Results: High-resolution US was reliable to image the reflection pulley system in normal subjects. In the patients group, pulley lesions occurred in isolation (n = 1) or combined with either subscapularis (n = 11) or supraspinatus (n = 9) tendons tears. Main US signs of reflection pulley lesions included hypoechoic thickening (n = 3), discontinuity (n = 7) and non-visualization (n = 11) of the coraco-humeral ligament. Pulley thickening was associated with subscapularis tears but not with an abnormal biceps tendon position. Biceps tendon subluxation was observed over the subscapularis in patients with pulley rupture combined with anterior tears of the supraspinatus (n = 9) or superior tears of the subscapularis (n = 3). In complete tears of subscapularis (n = 5), the biceps was dislocated.

Conclusion: US is valuable in detecting lesions of the ligamentous structures forming the reflection pulley regardless of the associated cuff pathology. US allows differentiation of a pulley lesion from an isolated tear of the anterior border of the supraspinatus and superior border of the subscapularis.

B-801 10:48

Comparison of ultrasound and radiography in detecting tendon calcifications around the elbow, and differentiating them from enthesophytes

K. Motamed, L.L. Seeger, J. Kim, J.P. DiFiori; Los Angeles, CA/US

Purpose: To demonstrate the advantage of ultrasound over plain radiography in the detection of elbow calcific tendonitis, and in differentiation of elbow calcific tendinitis from enthesophytes.

Materials and Methods: A single sports medicine physician referred all patients for localized elbow pain. Ultrasound images and radiographs of 21 tendon attachment sites (olecranon, medial or lateral humeral epicondyle) in 13 elbows were reviewed by two musculoskeletal radiologists by consensus. A trained musculoskeletal sonographer performed dynamic ultrasound studies under the supervision of a musculoskeletal radiologist. The radiographic studies consisted of frontal, lateral and bilateral oblique views. The interpretations of the ultrasound images and radiographs were performed independently, and the radiologists were blinded to the results of the correlative studies.

Results: Ultrasound images revealed positive findings at 12 sites out of the possible 21 (57%). Of these positive cases six showed enthesophytes, and seven showed calcium deposits in the substance of the tendons at their attachment to bone (one site showed both). Radiographs demonstrated only four positive sites,

all felt to represent enthesophytes (19%). Two of these four were sonographically proven to be calcium deposits embedded entirely within the substance of the tendon at the attachment site.

Conclusion: Elbow ultrasound was shown to be superior to radiography in detecting elbow tendon calcifications, and differentiating them from enthesophytes.

B-802 10:57

Role of US in the evaluation of dorsal scapholunate ganglion cyst

M. Scialpi, C. Malaspina, B. Boranga, G. Scalera, F. Crusco, L. Lupattelli; Perugia/IT

Purpose: To assess the role of ultrasonography (US) in the demonstration of symptomatic occult dorsal scapholunate ganglion cysts.

Methods and Material: One hundred and forty-nine consecutive patients were examined over a period of 12 months with high-resolution US (13 MHz linear-array transducer). Validation of US findings was obtained with surgery in sixty-one patients and with MR imaging in the remaining ones. Topography of the lesion, evaluation of articular pedicle and the relationship with scapholunate ligament were recorded.

Results: In the detection of dorsal occult ganglion cysts, we reported a sensitivity of 98%, a specificity of 89% and a positive predictive value of 95.3%.

Conclusion: US is a useful diagnostic technique in the study of dorsal ganglion cyst. It is helpful in demonstrating occult cysts in symptomatic patients, in selecting treatment options and in post-operative follow-up.

B-803 11:06

Patients with suspicion of gout: Should the first metatarsophalangeal joints be additionally investigated if clinical symptoms are located in other regions? Evaluation with US

T. Rettenbacher, J. Hoflehner, M. Daniaux, M. Herold, D. zur Nedden; Innsbruck/AT

Purpose: Ultrasound (US) is a sensitive method to reveal urate deposits. The purpose of the study was to investigate, if US investigation of the clinical silent first metatarsophalangeal (MTP-I) joints in addition to the US investigation of the site of clinical symptoms can improve the detection rate of gout.

Methods and Materials: In a prospective study, 26 patients with clinical suspicion of gouty inflammation in a location other than the MTP-I-joints underwent high resolution US of the site of clinical symptoms and additionally of both MTP-I-joints. US-findings suggestive of urate deposits were stippled, bright foci and hyperechoic areas within joint effusions, within synovia, or around the joints. Definite diagnoses were established by microscopy of aspirates and/or by characteristic clinical and laboratory findings.

Results: Thirteen patients had gout, 9 were diagnosed having other types of arthritis, and 4 had a definite diagnosis of arthrosis. US revealed signs of urate deposits at the site of clinical symptoms in 9 of 13 patients with gout (69%) and at the clinical silent MTP-I-joints in 12 of those patients (92%). US investigation of the MTP-I-joints in addition to the site of clinical symptoms increased the US detection rate of urate deposits from 69% (9 of 13 patients) to 100% (13 of 13 patients) in our series.

Conclusions: US investigation of the clinical silent MTP-I-joints in addition to the regions of clinical symptoms markedly improved the detection rate of gout and should therefore always be additionally investigated.

B-804 11:15

US of the rotator cuff tendons in "pulse subtraction" mode: Are longitudinal intra-tendinous tears finally visible?

H. Guerini, A. Feydy, J.-L. Drapé, A. Chevrot; Paris/FR

Purpose: Intratendinous longitudinal tears remain the weakness of shoulder ultrasonography because they are considered invisible by this technique. Our purpose was to assess their visibility and to describe the pattern of longitudinal tears of the supra- and infraspinatus tendons using US with "pulse subtraction" mode.

Materials and Methods: Prospective study of 52 patients with a suspicion of tendinous lesions underwent US before a CT- or MR-arthrogram, or a CT-bursography. The examination was carried out with an 8-16 MHz probe in tissue harmonic mode ("pulse subtraction"). The diagnostic criterion for a longitudinal tear was an intratendinous hypoechoic line prolonging a partial or complete tendon tear. US images were correlated with CT and MR arthrograms findings.

Results: Ten cases of longitudinal tears were described at ultrasonography against 18 visible on the CT and MR arthrograms. The US false-negatives were related to poor patient echogenicity (4 cases), very retracted tendons (2 cases) or post-

Scientific Sessions

operative patients (2 cases). Sensitivity, specificity, positive predictive value and negative predictive value were 52%, 92%, 83% and 80%, respectively. Longitudinal tears accompanying complete tendon tears were more difficult to detect (5/11) than those accompanying partial tears (5/6). The "pulse subtraction" mode improved considerably the contrast between normal tendon and tears. Mobilization of the arm sometimes allowed a better visualization.

Conclusion: Contrary to the generally accepted idea, our results show that longitudinal tears can be detected with US. Nevertheless, the sensitivity remains insufficient, especially in cases accompanying full thickness tendon tears, in post-operative and poorly echogenic patients.

B-805 11:24

US morphology of the supraspinatus tendon in basketball players: Correlation with main pathologic models of impingement syndrome in young overhead athletes. Preliminary report

R. Girometti, A. De Candia, M. Sbuelz, F. Toso, C. Zuiani, M. Bazzocchi; Udine/IT

Purpose: To assess the normal and pathologic US morphology of supraspinatus tendon and its correlation with main pathologic models of secondary shoulder impingement syndrome in a population of young overhead athletes.

Methods and Materials: 10 basketball players, age range 19-22, professionals for at least 3 years, and a control group of 10 non-athlete patients of the same age range were investigated using a high resolution 5-12 MHz linear transducer. Static and dynamic standardized morphological study of supraspinatus tendon was performed. We evaluated tendon morphology, thickness of the subacromial bursa and width of the subacromial space.

Results: 6 of 10 players were asymptomatic for shoulder impingement and/or functional limitations, with no US evidence of impingement, except for 2 cases in which right subacromial space is reduced in comparison with contralateral, non-dominant side (6.0 vs. 7.4 mm and 6.6 vs. 7.9 mm). 4 of 10 players showed clinical and US findings of impingement syndrome: 2 players were symptomatic for right shoulder instability and present right (5.3 vs. 7.7 mm) or bilateral (5.2 vs. 6.0 mm) subacromial space reduction. 2 remaining players presented with moderate clinical impingement signs respectively at the left non-dominant shoulder (subacromial space: 6.8 vs. 7.4 mm) and at right shoulder (with bilateral US subacromial space reduction: 6.4 vs. 6.0 mm). Control group subjects were asymptomatic and presented normal tendon morphology according to selected US criteria.

Conclusion: These initial pathological findings seem to be due to different etiologies of secondary shoulder impingement according to the "continuum instability-impingement" model.

B-806 11:33

US diagnosis of talocalcaneal coalition

F. Pugliese¹, M. Valle¹, S. Bianchi², U. Rossi¹, P. Tomà¹, C. Martinoli¹; ¹Genoa/IT, ²Chene-Bougeries/CH

Purpose: To determine the value of high-resolution US in patients with talocalcaneal coalition.

Methods and Materials: A group of n = 10 patients with CT-proved talo-calcaneal coalition and n = 40 healthy subjects with no coalition used as controls underwent 12-5 MHz US of the medial ankle. In each examination, coronal scans over the medial aspect of the subtalar joint were obtained on each side keeping the patient's limbs in a frog-leg position. US images were reviewed by two observers who had neither prior knowledge of the cases nor access to previous radiographic examinations. Each observer reviewed the cases for signs of talo-calcaneal coalition and then decided if coalition was present.

Results: High-resolution US was reliable to image talo-calcaneal coalition based on an absent or markedly diminished subtalar joint space. US sensitivity and specificity for talo-calcaneal coalition ranged from 88% to 100% without false-positive results. The different type of coalition (synostosis, synchondrosis, syndesmosis) did not influence the US diagnosis. In 2/10 cases, the coalition was bilateral.

Conclusion: High-resolution US is valuable in detecting congenital talo-calcaneal coalition. It may help in the selection of patients with suspected disease to be submitted to other imaging modalities after an inconclusive radiographic study and may avoid axial and oblique views of the foot as part of the radiographic foot series. US may also be valuable in cases in which coalition might not be suspected clinically and in patients with atypical symptoms.

B-807 11:42

Feasibility and accuracy of US-guided sacroiliac joint injection: Preliminary experience

A. Klauser, B. Moriggl, M. Schrimmer, F. Frauscher, D. zur Nedden; Innsbruck/AT

Purpose: To assess the feasibility of ultrasound (US)-guided injections in the sacroiliac joint.

Materials and Methods: Twenty-two US-guided sacroiliac joint injections were performed in 11 human cadavers. US was performed with a 2.5 MHz curved array transducer (Esaote Technos MPX or Acuson Sequoia 512). 22-gauge spinal needles were used for injections. We injected 1 ml non-ionic contrast material (Iomeron, Bracco). Three different transverse scanning approaches for needle placements (1. level of L5; 2. level of S1, and 3. level of S2) were evaluated. Computed tomography (CT) was used to confirm the proper placement of the injections.

Results: Of 22 sacroiliac joint injections, 17 (77%) were intraarticular. The injections were repeated in 10 (45%) sacroiliac joints under CT guidance because of improper needle placement. The highest success rate was found using the most caudal (level of S2) approach.

Conclusion: Our preliminary findings suggest that US-guided injection using the most caudal located approach (level of S2) is an appropriate method for sacroiliac joint injection.

Dynamic videofluoroscopic assessment of the pseudoarthrosis of the scaphoid in decision making for surgical therapy

C.E.M. Hannig, P.H. Hellerhoff, A.C. Wuttge-Hannig, A. Schoppmann, K.-D. Werber, E.J. Rummey; Munich/DE

Purpose: In cases of pseudoarthrosis of the scaphoid (PAS) CT and MR imaging are excellent tools for the demonstration of bone structure and localisation of fragments. MR imaging can detect early stages of osteonecrosis. But for the surgeon it is of crucial interest to differentiate between stable fibrotic fixation, partially unstable fibrotic fixation and completely unstable pseudoarthrosis. The aim of our study was to find out how dynamic videofluoroscopy can contribute solutions for this problem.

Material and Methods: In the last 10 years we performed 1020 dynamic videofluoroscopic studies of carpal structures. 220 patients with PAS underwent dynamic videofluoroscopy. Radio-ulnar and dorso-palmar movements were registered. In 116 patients of them, arthroscopy and / or surgery were performed based on MR imaging and videofluoroscopic results. Arthroscopic and / or intraoperative findings were considered as gold standard. Mean age was 20.2 years, male: female ratio was 10:1.

Results: Distribution of videofluoroscopic findings was: stable fibrotic fixation n = 42; partially instable fibrotic fixation n = 22; complete instable n = 52. All cases of unstable fixation of PAS underwent surgery (Herbert-screw Matti-Russe intervention). Arthroscopic and intraoperative findings matched to 100% the videofluoroscopic diagnosis. The completely unstable PAS were frequently associated with other carpal instabilities like scapho-lunar dissociation, DISI or other ligamentous lesions.

Conclusion: Dynamic videofluoroscopy turned out to be a reliable tool in surgical decision making for the right functional therapy. Slow motion and frame-by-frame analysis allows a reliable diagnosis of the instability. Additional information is supplied by MR imaging.

Somatic findings in globus pharyngus: Results of a follow-up study before and after therapy

C.E.M. Hannig, P.H. Hellerhoff, A.C. Wuttge-Hannig, H. Stein, E.J. Rummey; Munich/DE

Aim of Study: To detect specific morphologic and functional alterations of the pharynx and esophagus in patients with the sensation of globus.

Scientific Sessions

Material and Methods: Between 1999 and July 2004, 668 patients were referred to our interdisciplinary consulting staff with the diagnosis of typical globus sensation. (Mean age 53.5 years, male:female ratio 1: 1.1) Diagnostic work-up was based on videofluoroscopy. Additional endoscopy, 24 h-pH-monitoring including manometry and ENT examinations were also performed. 450 patients showed up for follow-up study after therapy.

Results: 81.2% of the patients showed somatic findings. 61.2% suffered from gastro-esophageal reflux disease (GERD) proven by 24 h-pH-monitoring (gold-standard) and/or endoscopy. In 89.2% of these patients videofluoroscopy revealed a dysfunction of the upper esophageal sphincter (UES). Mostly we found delayed opening frequently associated with motor disturbances of the tubular esophagus. UES dysfunction was also responsible for the development of early Zenkers diverticula, oropharyngeal pouches due to an increase in intrapharyngeal pressure during deglutition with retention of saliva. The follow-up of the GERD group revealed a complete disappearance of UES dysfunction in patients sufficiently treated with anti-reflux medication or surgery. The remaining 20% with unproven GERD showed reduction of symptoms after treatment of the UES dysfunction (dilatation-therapy or UES myotomy). 18.8% showed no pathologic findings at first examination and in follow-up.

Conclusion: GERD was a predominant finding in our patient-population with globus pharyngus. Globus sensation disappeared in cases of adequate anti-reflux therapy. Videofluoroscopy is the method of first choice in the assessment of pharyngo-esophageal motor disturbances and could best demonstrate therapy effects.

B-810 10:39

Respiratory patterns associated with swallowing

O. Ekberg, M. Bülow, R. Olsson; *Malmö/SE*

Purpose: The pharynx is a common canal used for air during respiration and for food during swallowing. It is important that no part of the bolus reaches the airways. This is achieved by closure of the airways during swallowing and thereby by an interruption of respiration. We wanted to evaluate the timing of bolus transportation through the pharynx and apnea time during swallowing as well as the coordination between bolus transport and respiration.

Method and Materials: We used videofluoroscopy of the pharynx taken in a lateral projection during swallowing of thin liquids and paste. We simultaneously measured airflow through the nostrils with a silicon mask placed over the nose. The tracing of respiration was integrated on the fluoroscopy monitor. Therefore, bolus transportation and respiration could be assessed simultaneously. We examined 12 healthy adult volunteers. Each volunteer was examined during 6 swallows.

Results: We found that in 65% of the swallows expiration preceded pharyngeal swallowing, while in 35% an inspiration preceded. In 83% of the swallowings an expiration followed pharyngeal bolus transit. Pharyngeal transit time (PTT) of the bolus was less than 1 second. The apnea time during the bolus passage through the pharynx was also 1 second or less. There was no correlation between PTT and the apnea time.

Conclusions: In normal adults most swallowing occurs during expiration. However in about 20% of swallows an inspiration follows the swallowing. Pharyngeal transit time is short as is the apnea time during bolus transport.

B-811 10:48

Visualization of swallowing using real-time cineTurboFLASH sequence and a positive oral contrast agent: A feasibility study

P. Paolantonio, A. Laghi, M. Rengo, A. Guerrisi, V. Vergari, V. Panebianco, R. Passariello; *Rome/IT*

Purpose: The aim of this study was to evaluate the ability of cineTurbo FLASH sequence in depicting the oesophageal swallowing process using a positive oral contrast agent in healthy volunteers.

Methods and Materials: Ten healthy volunteers underwent MR imaging of the oesophagus during swallowing of a mixture of semolina pudding and Gd-DTPA as oral positive-contrast agent. All the examination were performed on 1.5 T magnet (Magnetom Vision; Siemens, Erlange, Germany) equipped with a phased-array coil. Single-slice imaging was performed in the median sagittal plane while subjects were in a prone position. Thirty serial images were obtained using cineTurbo FLASH (TR: 416 msec TE: 1.2 msec TI: 200 msec FA: 8° matrix: 90x128 acq. time: 0.57 sec) for an overall temporal acquisition time of 17 sec during swallowing. The images were reviewed by two gastrointestinal radiologists on a off-line console using a cine-view system.

Results: The semolina pudding and Gd-DTPA mixture showed optimal properties in terms of signal intensity, viscosity and density. The image quality was optimal

in all cases. The turbo-FLASH sequence provided optimal temporal resolution and sufficient spatial resolution during motion.

Conclusion: The depiction of swallowing using cine-turbo-FLASH sequence and oral positive contrast agent is a feasible technique representing a promising approach for the investigation of the oesophageal swallowing process and is expected to be of value for the documentation of functional disturbances in patients with dysphagia.

B-812 10:57

Outcome after endoscopic surgical therapy for Zenker's diverticula

A.C. Wuttge-Hannig, H. Feussner, C.E.M. Hannig; *Munich/DE*

Aim of the study: Myotomy of the upper esophageal sphincter (UES) in Zenker's diverticula is widely accepted in the surgical therapy for smaller diverticula of the type Brombart I-III. In stages III and IV myotomy was usually combined with diverticulectomy. Due to new developments in endoscopic equipment for minimally invasive surgical therapy, the dissection of the sphincter alone is now performed more in the higher stages of diverticula especially in the elderly. This leads to a new radiologic appearance of post-surgical cases.

Material and Methods: We examined 36 patients with advanced stages of Zenker's diverticula before and after minimally invasive endoscopic intervention. (Mean age: 67.7 yy, male:female = 25:9). Examination was performed by videofluoroscopy. Because of a high incidence of regurgitation and aspiration we used iso-osmolar lotrolan.

Results: Generally, the post-surgical appearance of the diverticula did not change very much due to the lack of resection. The neck of the diverticula appears much broader in the 21 cases with a good outcome. Also, the emptying of the diverticulum after therapy was faster with less retention. Preoperatively diagnosed regurgitation was not seen. In the 15 cases with poor outcome the leading finding was an incomplete dissection of the UES with retention, regurgitation and even aspiration. In the group, a high incidence of untreated GERD could be identified.

Conclusion: Videofluoroscopy is the best tool for the pre-/and postoperative assessment of Zenker's diverticula to identify a dysfunction, or incomplete dissection of the UES, sometimes caused by scarring.

B-813 11:06

Real-time high-resolution MR imaging for the assessment of gastric motility disorders

W. Ajaj¹, S.C. Goehde¹, C. Kuehle¹, N. Papanikolaou², M. Forsting¹, J. Barkhausen¹, T.C. Lauenstein¹; ¹*Essen/DE*, ²*Crete/GR*

Introduction: Disturbances of gastric motor function are believed to play a key role in the development of symptoms in patients with functional gastrointestinal disorders (FGID). Thus FGID represent a major burden to society and to affected patients. The aim of this study was to evaluate whether patients with increased or decreased gastric motility can be differentiated from healthy volunteers by means of real-time MR imaging.

Material and Methods: Ten healthy volunteers, ten patients with gastroparesis and ten patients with functional pylorospasm/peptic pyloric stenosis underwent real-time MR imaging. All patients were examined on two separate days one time prior to therapy and second time after adequate therapy. Antral motility was quantified by calculating a gastric motility index.

Results: Patients with gastroparesis showed a lower motility index (mean 1.5 mm²/s) compared to the reference volunteer group (mean 2.5 mm²/s), while the mean motility index of the patient group with pylorospasm was more than three times as high as the reference value of the volunteer group (mean 9 mm²/s). However, the gastric motility index in the patient group with gastroparesis increased and in the group with functional pylorospasm/peptic pyloric stenosis decreased statistically significantly after therapy.

Conclusion: Real-time MR imaging is a reliable tool for the assessment of gastric motion. Furthermore, the difference in gastric motility index in patients, whether with increased or decreased gastric motility, could be evaluated and quantified. Due to the non-invasive character of MR imaging, this imaging modality can be an attractive alternative to conventional invasive diagnostic tools for gastric motility disorders and therapeutic monitoring.

B-814 11:15

Sonographic comparison of gastric emptying of broth and water: Is there a promoting cephalic factor?

J.F. Pedersen, J.F. Pedersen; *Glostrup/DK*

Purpose: To examine the emptying times of broth and water, and explore the possibility of a cephalic influence on gastric emptying.

Scientific Sessions

Methods and Materials: On different days, each of twelve healthy volunteers had meals of either 350 ml water or 350 ml broth. The antral area was determined at sonography five times before the meal as a baseline, and every 1-4 minutes after the meal. The time until the antral area had decreased to 150% of baseline (T150) was determined and used as surrogate expression of gastric emptying time. In the second part of the study T150 was measured in ten volunteers who had meals of either water alone or water followed by sham feeding with broth.

Results: The mean T150 was for water 20.3 min (range 12-40), and for broth was significantly shorter at 12.6 min (5-21), $P = 0.0020$. In the subsequent series the mean T150 was 28.5 min (18-49) for water and significantly shorter for water followed by sham feeding, 22.8 (14-40), $P = 0.0078$.

Conclusion: Broth empties faster from the stomach than plain water, probably because of a "cephalic phase" stimulation of gastric motility via the vagus nerve.

B-815 11:24

Visualization and quantification of large bowel motility by the use of functional cine-MR imaging

S. Buhmann, C. Kirchhoff, C. Wielage, T. Mussack, M. Reiser, A. Lienemann; Munich/DE

Introduction: The aim of our study was to develop a method to visualize and quantify large bowel motility using MR imaging.

Material and Methods: 15 healthy individuals (8 male, 7 female, 25-40 years) were twice examined at 6 a.m. after a minimum starving phase of 8 hours. Two blocks of repeated measurements of the entire abdomen were performed using a 1.5 T MR imaging system with T2-weighted HASTE sequences (Matrix 256 + 207; FOV400 mm; 9-11 slices; SL6 mm) anatomically adjusted to the large bowel with a navigator technique for respiratory gating before and after the oral application of sennate versus intravenous erythromycin.

The diameter D (cm) of a bowel segment at 5 given positions in the ascending (AC), transverse (TC) and descending colon (DC) was set as the parameter for motility-measurement.

Results: D of the bowel lumen was estimated as median and the variance ratio as percentage before and after use of the prokinetics was calculated. After application of both drugs a significant ($p < 0.05$) increase of median D in all bowel regions was found. AC: 3.41 cm to 3.69 cm(ST); 3.52 cm to 3.59 cm(E). TC: 3 cm to 3.4 cm(ST); 3.3 cm to 3.42 cm(E). DC: 2.67 cm to 2.9 cm(ST); 2.86 cm to 2.97 cm(E). The variance ratio of the diameter 104%(AC), 69.1%(TC) and 103%(DC) was measured for ST while for E a ratio of 115.9%(AC), 90.4%(TC) and of 112%(DC) was calculated. Thus for E a greater variance and a greater bowel activity was considered.

Discussion: For the first time we developed an adequate non-invasive method to visualize and quantify large bowel motility. By comparing two prokinetic drugs to enhance motility, E was proofed to be the prepotent drug.

B-816 11:33

Functional cine MR imaging for the assessment of implanted synthetic mesh in patients after incisional hernia repair

T. Fischer, A. Ganghofer, S. Bensler, R. Ladurner, T. Mussack, A. Lienemann; Munich/DE

Purpose: The aim of our study was to develop a method that allows the visualization and evaluation of implanted meshes in patients after incisional hernia repair, with MR imaging. Furthermore we assessed problems typically related with mesh implantation like adhesions and muscular atrophy.

Methods and Materials: We enrolled 16 patients after incisional hernia repair, in each of 8 patients the mesh implantation was done by laparoscopy (ePTFE mesh) resp. laparotomy (polypropylene mesh). All patients had a clinical and ultrasound abdominal examination. Functional MR imaging was performed on a 1.5 T system in supine position. Sagittal and axial TrueFISP images of the entire abdomen were acquired with the patient repeatedly straining. Evaluation included: correct position and intact fixation of the mesh, visceral adhesions, recurrent hernia and atrophy of the rectus muscle.

Results: Time range between operation and examination was 6 to 36 months. In all patients with laparoscopy the ePTFE mesh was visible, the polypropylene mesh was not detectable in any case. In 5 of the 8 ePTFE meshes the fixation was not intact, 1 was crumpled, in 3 cases a recurrent hernia was detected. 13 of 16 patients had adhesions of the intestinum to the anterior abdominal wall, in 5 mobility of the abdominal wall was reduced, 8 showed an asymmetric atrophy of the rectus muscle.

Conclusion: Functional cine MR imaging is a suitable method for follow-up studies in patients after hernia repair. ePTFE meshes can be directly visualized and typical complications like intestinal adhesions and abdominal wall dysmotility can be assessed.

B-817 11:42

Pattern analysis of defecography in patients with chronic constipation: Analysis and its predictive value for the responsiveness of biofeedback therapy

H. Yang, A. Kim; Seoul/KR

Purpose: To determine diagnostic value of defecography in predicting the responsiveness of biofeedback therapy in patients with chronic constipation.

Materials and Methods: Over a two-year period, among patients medically diagnosed with chronic constipation (ROME II), 92 patients underwent defecography and biofeedback therapy. Two blinded readers analyzed and classified into five patterns; I = normal, II = hypertonic anal sphincter (poor opening of anus due to persistent contraction), III = dyskinetic puborectal sling (inadequate laxity), IV = spastic pelvic floor syndrome (persistent contraction of both puborectal sling and anal sphincter), V = unclassified. Also, the degree of rectal contraction during defecation was analyzed with scoring (grade0 to 3). Biofeedback therapy showed therapeutic response in 71 out of 92 patients (77%). In these two groups, responsive or non-responsive group to biofeedback therapy, we evaluated if the morphologic pattern of defecogram or the degree of rectal contraction predicts responsiveness of biofeedback therapy.

Results: On defecograms, type IV was most common (50 out of 92 patients, 54%), followed by II (21/92, 23%), III (12/92, 13%), and V (9/92, 10%). However, there was no significant difference in defecographic type between the responsive and non-responsive groups ($P = 0.630$). Defecograms showed rectal contraction in 78 patients (85%) and moderate to vigorous contraction (more than grade2) was seen in 66 patients. Most of the biofeedback-responsive group showed rectal contraction (66 out of 72 patients, 92%) with statistical significance ($p < 0.001$). **Conclusion:** There was no difference in morphologic types of defecogram between the responsive and non-responsive biofeedback groups. However, the presence of rectal contraction during defecation was highly associated with therapeutic response after biofeedback therapy.

B-818 11:51

Prospective assessment of interobserver agreement for defecography in fecal incontinence

A.C. Dobben¹, T.G. Wiersma², L.W.M. Janssen³, R. de Vos¹, M.P. Terra¹, C.G.M.I. Baeten⁴, J. Stoker¹; ¹Amsterdam/NL, ²Arnhem/NL, ³Utrecht/NL, ⁴Maastricht/NL

Purpose: Primary aim was to determine the interobserver agreement of defecography in diagnosing enterocele, anterior rectocele, intussusception and anismus in fecal incontinent patients. Subsidiary aim was to evaluate the influence of different levels of experience on reading defecographies.

Methods: Defecographies were performed in 105 consecutive fecally incontinent patients. Observers were classified by different levels of experience and were compared to the findings from an expert radiologist. Quality of the expert radiologist was evaluated by an intra-observer agreement procedure.

Results: Intra-observer agreement was good to very good except for anismus: incomplete evacuation > 30 seconds (kappa 0.55), puborectalis impression (kappa 0.54). Interobserver agreement for enterocele and rectocele were good (kappa both 0.66) and fair for intussusception (kappa 0.29). Interobserver agreement for anismus: incomplete evacuation > 30 seconds was moderate (kappa 0.47) and fair for puborectalis impression (kappa 0.24). Agreement in grading of enterocele and rectocele were good (kappa respectively 0.64 and 0.72) and for intussusception fair (kappa 0.39). Agreement separated by experience levels was very good for rectocele (kappa 0.83) and grading of rectoceles (kappa 0.83) and moderate for intussusception (kappa 0.44) at the most experienced level. For enterocele and grading different experience levels did not influence the reproducibility.

Conclusions: Reproducibility for enterocele, anterior rectocele and severity grading are good, while fair to moderate for intussusception. For anismus the diagnosis incomplete evacuation > 30 seconds is more reproducible than puborectalis impression. The level of experience seems to play a role in diagnosing anterior rectocele and its grading and in diagnosing intussusceptions.

Estimation of radiation exposure in 16-detector row multislice computed tomography (MSCT) of the heart and comparison with calculation programs

C. Hohl¹, A.H. Mahnken¹, M. Das¹, C. Leinendecker², T. Schmidt¹, R.W. Günther¹, J.E. Wildberger¹; ¹Aachen/DE, ²Erlangen/DE

Purpose: To evaluate the defacto administered organ-dose in MSCT of the heart and compare it to calculated values.

Materials and Methods: A female Alderson-Rando-Phantom was equipped with thermoluminescent dosimeters (TLD) in five different positions to assess the organ-doses of five representative organs (thyroid, thymus, oesophagus, pancreas, liver). Radiation exposure was performed on a 16-row-MSCT scanner (Sensation 16, Siemens-Medical-Solutions, Forchheim, Germany) with seven different routine scan-protocols: Two 120 kV CT-Angiography-(CTA)-protocols with different collimation, a 100 kV CTA-protocol, two 120 kV Ca-Scoring-(CS)-protocols with different collimation and two 80 kV CS-protocols in different collimations. Each scanning-protocol was repeated five times. The ECG was simulated using a ECG-simulator (Laerdal Medical GmbH, Munich, Germany) with fixed heart rate of 80 bpm. The measured organ doses were compared with the values calculated by a commercially available computer program (ImpactDose, IMP, Erlangen, Germany).

Results: Directly irradiated organs such as thymus received organ-doses between 27 mSv (CTA 120 kV), 16 mSv (CTA 100 kV) and 7 mSv (CS 80 kV). Organs receiving only scattered radiation such as the thyroid collected organ-doses between 2.7 mSv (CTA 120 kV), 1.7 mSv (CTA 100 kV) and 0.6 mSv (CS 80 kV). The calculated values for the thymus were in good agreement with the measured doses. The calculation program underestimated depending on the scanning-protocol the measured organ doses by a factor between 1.8 and 3.5 for the thyroid. Due to different location of liver-dome and pancreas the measured organ-doses were 10 times higher than the calculated.

Conclusion: 100 kV-CTA-protocols lead to a 60% dose-reduction compared to 120 kV-CTA-protocols. Depending on the scanning protocol organ-doses are rather underestimated by the dose calculating program.

B-820 10:39

Measurements of spatial and temporal resolution for ECG-gated 16-row multidetector CT using a dynamic cardiac phantom

P.G.C. Begemann, U. van Stevendaal, R. Manzke, A. Stork, F. Weiss, C. Nolte-Ernsting, M. Grass, G. Adam; Hamburg/DE

Purpose: To measure spatial and temporal resolution for ECG-gated 16-row MDCT at various heart rates, pitches and rotation times using a beating heart phantom.

Methods and Materials: A resolution phantom with rows of cylindrical holes from 0.4-3.0 mm is mounted to a cardiac phantom, which simulates the motion of a beating heart. Stationary and moving data acquisition is performed at various heart rates (HR, 60-120 bpm), table pitches (0.15-0.30) and scanner rotation times (RT, 0.42 and 0.50 s for 70 bpm). Raw data are reconstructed using a multi-cycle real cone beam reconstruction algorithm at multiple phases of the RR-interval. Multi-planar reformations (MPR) are generated and analyzed. Temporal resolution and cardiac cycles used for image reconstruction are calculated.

Results: In 97.2% (243 / 250) of all data obtained with the stationary resolution phantom, the complete row of cylindrical holes with 0.6 mm in diameter is visible. These results are independent of heart rate, pitch, scanner rotation time and phase point of the reconstruction.

For the dynamic phantom, spatial resolution is determined during phases of minimal motion (116/250). In 40.5% (47/116), resolution is 0.6 mm and in 37.1% (43/116) 0.7 mm. Temporal resolution varies between 63 ms and 205 ms, using 1.5 to 4.37 cardiac cycles for image reconstruction.

Conclusion: With the stationary measurements, the stability of the cone-beam reconstruction algorithm can be proven. In the measurements during movement, the maximum spatial resolution is 0.6 mm, the maximum temporal resolution 63 ms. In phases of maximal motion, MPRs cannot be evaluated.

B-821 10:48

Dynamic cine-mode imaging of the mitral valve with 16-channel MDCT.

A feasibility study

H. Alkadhi, S. Leschka, B. Baumert, A. Plass, D.A. Bettex, B. Marincek, T. Boehm, S. Wildermuth; Zürich/CH

Objective: Our aim was to assess the feasibility and image quality of dynamic cine-mode imaging of the mitral valve using retrospectively electrocardiography-gated 16-channel MDCT.

Materials and Methods: Contrast material-enhanced MDCT was performed in 37 patients having a normal mitral valve, as demonstrated by transesophageal echocardiography. 20 CT data sets covering the valve apparatus were reconstructed every 5% step of the R-R interval. Multi-planar reconstructions were performed in the parallel short-axis and perpendicular long-axis of the left ventricle. Two independent, blinded readers evaluated the image quality for dynamic cine-mode visualization of the valve components in systole, diastole, and during transition phases in-between.

Results: Inter-observer agreements for image quality ratings of valve components in all cardiac cycle phases ranged from good to excellent. Image quality for visualization of valve leaflets, apposition zone, commissures, and mitral annulus (ranging from adequate to excellent) was significantly superior on perpendicular than on parallel planes for all cardiac phases ($p < 0.05$). Tendinous cords were visualized on both perpendicular and parallel planes with bad to adequate quality, whereas papillary muscle visualization was adequate to excellent on both imaging planes. Visualization of each valve component was superior in systole and diastole in both imaging planes as compared to the transition phases ($p < 0.001$).

Conclusions: Non-invasive cine-mode imaging of the mitral valve by using retrospectively electrocardiography-gated MDCT is feasible and allows an accurate visualization of the moving valve. Perpendicular long-axis reconstructions yield superior image quality when compared to the short-axis, and enable a determination of its functional morphology.

B-822 10:57

Assessment of left ventricular parameters using 16 slice computed tomography. Evaluation of a new software for endocardial and epicardial border delineation

T. Schlosser, K. Pagonidis, C.U. Herborn, P. Hunold, K.-U. Waltering, J. Barkhausen; Essen/DE

Purpose: To quantify left ventricular function and mass derived from 16 detector row computed tomography coronary angiography data sets using a new analysis software.

Materials and Methods: Multiplanar reformations in the short axis orientation were calculated from axial contrast enhanced CT images in 18 patients referred for CT coronary angiography. End-diastolic volume (EDV), end-systolic volume (ESV), ejection fraction (EF) and left ventricular mass (LVM) were analyzed with a recently developed imaging software (CT Mass, MEDIS, Leiden, The Netherlands) using an automated contour detection algorithm of left ventricular endo- and epicardial contours and by manual tracing. The data were compared to MR imaging measurements as standard of reference.

Results: EDV, ESV, EF and LVM derived from automated contour detection algorithm were not statistically significantly different compared to manual tracing (CT_{auto} vs. CT_{manual}: EDV = 137.1 ± 45.7 ml vs. 134.2 ± 39.9 ml, ESV = 58.8 ± 34.2 ml vs. 58.1 ± 30.1 ml, EF = $59.2 \pm 13.7\%$ vs. $58.1 \pm 12.0\%$, LVM: 130.9 ± 29.1 g vs. 133.7 ± 33.2 g; $p > 0.05$). However, EDV (118.7 ± 43.6 ml), ESV (50.1 ± 33.5 ml) and LVM (142.8 ± 38.4 g) as calculated based on MR data sets were statistically significantly different in comparison to CT ($p < 0.05$), whereas EF ($59.9 \pm 14.4\%$) did not differ significantly from both CT algorithms ($p > 0.05$).

Conclusion: Automatic and manual analysis of data acquired during CT coronary angiography using a 16 detector row-CT scanner allow for a reliable assessment of left ventricular ejection fraction and a rough estimation of left ventricular volumes and mass.

B-823 11:06

Time resolution and phase time resolution in ECG gated reconstruction using multislice CT

K. Tsujioka, N. Akino, Y. Takahashi, M. Niwa, Y. Uebayashi; Toyooka-city Aichi/JP

Purpose: Evaluating time resolution is important in ECG gated reconstruction methods using multi slice CT. However, in the past, evaluations were made according to the unit of time, even when changes in heart rate occurred. In practical terms, however, a higher heart rate means a shorter time between heartbeats,

Scientific Sessions

and motion artifact is more likely to occur in the time resolution. In this report we will propose the phase time resolution method to evaluate ECG gated reconstruction.

Method and Materials: We measured the time resolution of multi slice CT using our original rotating phantom, and also observed heart movement by an X-ray TV system excelling in time resolution. We determined the rate at which images are available within one heartbeat, and we regarded this outcome as the phase time resolution.

Results: A higher heart rate resulted in a shorter time resolution of CT images. However, the phase time resolution's performance improved when the heart rate was low.

Conclusions: Phase time resolution is an important factor in determining the image quality of ECG gated reconstruction. Even with a shorter time resolution, a shorter heartbeat time results in a larger value of the phase time resolution as well as occurrence of artifact. On the other hand, in the case of a longer time resolution, a longer heart beat time results in a smaller value of the phase time resolution, and thus causes no artifact to occur. From this investigation we obtained knowledge of the most appropriate parameter for scanning in clinical inspections.

Does thin slice multidetector CT (MDCT) improve stent patency and in-stent restenosis evaluation?

G. Ligabue, F. Fiocchi, S. Ferraresi, R. Rossi, L. Rossi, M.G. Modena, R. Romagnoli; Modena/IT

Purpose: To assess the value of 16 slice CT in non-invasive evaluation of stent patency.

Methods and Materials: We performed MDCT evaluation of stent patency in 88 patients (142 stents): 48 by means of 4 detector MDCT using 1.25 mm slice thickness, the remaining with 0.6 mm 16 detector MDCT. The comparison was based on: accuracy in stent patency assessment; accuracy in intra-stent restenosis detection and capability of visualization of the vessel lumen inside the stent. Coronary Angiography (CA) was considered gold standard.

Results: CA identified significant restenosis in 9/72 (12.5%) of stents evaluated with 1.2 mm protocol VS 8/70 (11.4%) with 0.6 mm protocol. Stent occlusion was detected respectively in 3/72 (4.1%) VS 4/70 (5.7%). Stent patency was correctly assessed in all cases with both techniques by means of detection of contrast material proximal and distal to the stent. Significant in-stent restenosis was never detected with 1.25 mm scanner while it was correctly diagnosed in 2/8 cases (25%) with 16 slice MDCT. Thin slice also allows a better visualization of the stent's lumen especially of the ones with < 3 mm diameter (12/14 [85.7%] VS 15/15 [100%]; p < 0.005) and the ones in the RCA (11/21 [52.4%] VS 14/18 [77.8%]; p < 0.005).

Conclusion: Although the stent lumen can be visualized in most stents with sub-millimeter MDCT, a reliable evaluation of in-stent restenoses is not feasible even if it is possible to detect this correctly in a few more cases. Nevertheless, for stent patency evaluation 16 slice MDCT might provide precious clinical information.

B-825 11:24

Cardiac imaging at 3 Tesla: Comparison of different sequences and the use of parallel imaging between 1.5 and 3 T

B. Spors, F. Patrick, K. Klimes, M. Grothoff, R. Noeske, M. Gutberlet, R. Felix; Berlin/DE

Purpose: To compare image quality, signal-to noise ratio (SNR), and contrast-to noise ratio (CNR) of different MR imaging sequences and the use of parallel imaging at 1.5 and 3 T in volunteers.

Method and Materials: We examined 20 volunteers (33 ± 8 years) with a 1.5 Twin Speed Excite and 3 T Signa V/I (GE Medical Systems) using a 4-element phase array surface coil. Fast Spinecho (FSE) T1 (Double-TR), T1-STIR (Triple-IR) and T2 sequences were performed in transverse orientation. Steady State Free Precession (SSFP) sequence was obtained in a 4-/2-chamber long and short axis view for functional analysis. At 3 T the flip angle used for the SSFP sequences was reduced from 45° to 30° . A Tagging sequence was performed in a 2-chamber short axis view. All sequence parameters apart from the flip angle remained constant for 1.5 and 3 T.

Results: Mean SNR was remarkably increased ($p < 0.05$) in all cardiac sequences at 3 compared to 1.5 T. At 3 T the SNR increased by 160% (T2), 123% (T1 STIR) and 91% (T1). CNR showed a similar increase. Mean SNR of SSFP sequences was more than doubled at 3 T (150%), without any significant effect on CNR. By using parallel imaging acquisition time, SNR and CNR was reduced by half. Using the tagging sequence, the grids were longer visible at 3 compared to 1.5 T.

Conclusion: Cardiac FSE sequences at 3 T demonstrated an increase of SNR

and CNR in comparison to 1.5 T without any major changes of sequence parameters. The increased SNR allows the use of parallel imaging with a reduction of imaging time.

B-826 11:33

MR evaluation of the anisotropic diffusion properties of human heart muscle in vivo using MRDTI with parallel acquisition techniques

X. Zhao, K. Li, Y. Li, C. Yu; Beijing/CN

Purpose: To evaluate the anisotropic diffusion properties of human heart muscle tissues with MR diffusion tensor imaging (MRDTI).

Methods: Ten healthy volunteers were enrolled in the study group. The subjects underwent cardiac MRDTI using singleshot EPI sequence with parallel acquisition techniques (iPAT). Data acquisition was performed along the midventricular short axis. The acquisition timing was performed at 100 ms, 200 ms, 300 ms, 400 ms, 500 ms, 600 ms, respectively representing different stages in the cardiac cycle. From the DTMR imaging images, the anisotropic diffusion parameters (FA, RA, VR) in different cardiac stages were calculated with post-processing tools.

Results: The cardiac MRDTI image quality was sufficient for processing in all 10 subjects. The measurements of FA, RA in 600 ms were significantly larger ($P < 0.001$) than those of the other cardiac stages; the measurements of VR in 600 ms were significantly smaller ($P < 0.001$) than those of other cardiac stages. There were no significant differences between the measurements of the other groups except 600 ms. No significant correlation between different groups could be found. The use of parallel acquisition techniques (iPAT) allowed for a substantial improvement in breath-related artifacts and image distortion. Intra- and interobserver variability were sufficiently small in the measurements of the anisotropic diffusion parameters.

Conclusion: Cardiac MRDTI techniques with iPAT can be used quantitatively to measure the anisotropic diffusion properties of human heart muscle tissues in vivo.

B-827 11:42

Multi-slice MR first-pass myocardial perfusion imaging: Impact of the receiver coil array

M.H.K. Hoffmann, F.T. Schmid, M. Jeltsch, A. Wunderlich, B. Schmitz, A.J. Aschoff; Ulm/DE

Purpose: Comparison of a new 12-element body phased-array coil with a conventional 4-element surface receiver coil array to provide increased signal-to-noise ratios for cardiac steady state free precession (SSFP) perfusion imaging.

Materials and Methods: 13 consecutive patients were included in the study. Patients were examined both with a 4-element surface coil array and a 12-element body coil array. First-pass myocardial perfusion imaging using saturation recovery SSFP was acquired during antecubital injection of Gd-DTPA. Imaging parameters: TR 2.8 ms/TE 1.3 ms, Flip Angle 50°, Bandwidth 960 Hz/pixel and Half-Fourier Acquisition. Signal-to-noise (SNR) ratio was calculated using 6 regions of interest (ROI) for the myocardial perfusion scans. Calculations of corresponding ROIs using the two different coil setups were compared using ANOVA analysis. Semi-quantitative perfusion parameters were calculated for both groups.

Results: The mean SNR in myocardial perfusion imaging increased by 21% using the 12-element coil setup ($p < 0.001$) when compared to the 4-element coil. ROI comparisons revealed an increased signal inhomogeneity with the 12-element coil when compared to 4-element coil experiments. Absolute normal range values of semi-quantitative perfusion parameters were consistently higher using the 12-element coil setup ($p < 0.001$).

Conclusions: The 12-element coil array provides higher SNR, but these improvements come with trade-offs in image homogeneity. Increased SNR translates into higher semi-quantitative perfusion values and offers the potential for improved detection of perfusion defects.

B-828 11:51

Quantification of aortic valve stenosis in MR imaging: Comparison of steady state free precession and fast low angle shot sequences

T. Schlosser, M. Jochims, M. Nasser, P. Hunold, K.-U. Waltering, T. Bartel, J. Barkhausen; Essen/DE

Purpose: To assess aortic valve areas by planimetry using two different MR sequences (steady state free precession (SSFP) and gradient-echo fast low-angle shot (FLASH)) in comparison to transesophageal echocardiography (TEE).

Methods: 27 patients with known aortic stenosis were imaged with MR and echocardiography. MR was performed on a 1.5 T MR scanner using a cine SSFP sequence (TR = 2.9 ms, TE = 1.3 ms, FA = 65°, temporal resolution = 19 ms,

Scientific Sessions

spatial resolution = 1.3 mm x 1.3 mm) and a cine FLASH sequence (TR = 8 ms, TE = 3.3 ms, FA = 20°, temporal resolution = 33 ms, spatial resolution = 1.9 mm x 1.3 mm). The imaging plane for planimetry was perpendicular to the aortic root. Planimetry was performed in cross-sectional images in systole by a radiologist blinded to the results of the TEE.

Results: MR planimetry could be performed in all patients. Mean aortic valve area measured by TEE was 0.97 mm², 1.00 mm² for SSFP and 1.25 mm² based on FLASH images. Good correlation was found between aortic valve areas measured on SSPF images and by TEE. The mean difference between the valve areas assessed based on SSFP and TEE images was 0.15 ± 0.13 cm² (FLASH vs. TEE: 0.29 ± 0.17 cm²).

Conclusion: Measurements of the aortic valve area based on SSPF images correlate better with TEE compared to FLASH images. The higher spatial and temporal resolution and the improved image contrast must be considered as major advantages of the SSFP images.

The impact of prior mammograms in mammography screening

A.J.J. Roelofs¹, N. Karssemeijer¹, N. Wedekind², S. van Woudenberg¹, C. Beck², J.H.C.L. Hendriks¹, M. Rosselli del Turco³, H. Junkermann², C.J.G. Everts²; ¹Nijmegen/NL, ²Bremen/DE, ³Florence/IT

Purpose: To investigate the impact of prior mammograms on mammography screening reading performance.

Methods and Materials: Twelve radiologists experienced in screening mammography each read 160 digitized screening cases twice on a soft-copy reading station (MeVis BreastCare), once with and once without previous-round mammograms. In half of the cases breast cancer was detected at a later stage; the other half were complicated normals, and benign cases. In about 50% of the positives the lesion was found in the next screening round, and in 50% during the screening interval. In retrospect all abnormalities were visible. For all cases mediolateral oblique images were available, for some also crano-caudal images. Readers annotated potential abnormalities, and estimated their likelihood of malignancy. Also, for every mammogram they assessed the priors as needed, helpful or not needed. CAD system markings for microcalcifications were accessible. Cases were displayed in a balanced order, regarding the availability of prior mammograms. Between the two readings of a case was a minimal period of two weeks. All readers participated in soft-copy reading training before starting the study. Effects of prior mammograms on detection performance were determined using LROC analysis.

Results: Reading performance was significantly better when prior screening mammograms were available. Results of displaying prior mammograms on request were significantly worse, but still better than when priors were not shown at all. With priors the referral rate can be reduced by 40% without loss of sensitivity.

Conclusion: The availability of prior mammograms has a significant effect on detection performance in screening mammography.

B-830 10:39

The impact of training on radiologists' performance in softcopy reading:

A study from the European SCREEN-TRIAL project

N. Wedekind¹, A.A.J. Roelofs², C. Beck¹, D. Boehm¹, J.H.C.L. Hendriks², P. Skaane³, N. Karssemeijer², C.J.G. Everts¹, H.-O. Peitgen¹; ¹Bremen/DE, ²Nijmegen/NL, ³Oslo/NO

Purpose: The purpose of this study was to evaluate the effect of appropriate training on radiologists' softcopy reading performance of FFDM.

Method and Materials: Eighteen radiologists from five different European countries participated in this 3-phase study. All of them were experienced in mammography screening, but novel to softcopy reading. In phase 1, participants received an initial training in operation and diagnostic reading skills on softcopy reading workstations before they read 150 FFDM cases (20% cancer) in hardcopy and softcopy, each with a time limit of 2 hours for 75 cases. During phase 2 of the

study, the radiologists read 500 to 1000 cases in softcopy during a six-months self-training period. Finally, in phase 3, the 150 cases were read again in softcopy. Sensitivity, specificity and reading speed were determined to allow for a quantitative comparison of the performance of softcopy and hardcopy reading as well as softcopy reading before and after the self-training period.

Results: After a short introductory training the radiologists' sensitivity and specificity for softcopy reading were already at a high level and were accordingly not significantly improved by training. Solely the initial reading speed was lower after the switch-over to softcopy reading. However, the average reading speed increased during the training, and was eventually on an equal or higher level as compared to hardcopy reading.

Conclusion: In conclusion, it is possible to increase the reading speed in softcopy reading by an appropriate training while keeping the sensitivity and specificity at a high level.

B-831 10:48

The imaging follow-up of ACR category 3 lesions in screening work-up

S.-Y. Ham¹, S. Chung¹, B.-K. Ko², I. Yang¹, H.-D. Kim¹; ¹Seoul/KR, ²Ulsan/KR

Purpose: To evaluate the imaging findings of ACR category 3 lesions, follow-up results and cancer incidence in screening breast evaluation. We aimed to analyze the percentage of women with a diagnosis of breast cancer 1 year after a short-interval follow-up recommendation.

Methods and Materials: We performed retrospective analysis of 6,901 screening mammograms and sonograms for last five years. The purpose of the evaluation is mostly asymptomatic screening in 73% (5,037/6,901) of the cases. Total 386 (5.6%) lesions had assigned to Breast Imaging Reporting and Data System (BI-RADS) category 3 for non palpable, probably benign lesions. At least six months follow-up imaging were reviewed and compared with the initial study.

Results: Ninety-four percent (363/386) were stable on follow-up sonography. Twenty-three lesions (6%) had minimal interval changes (ten were interval growth, seven were decreased dimension, six had disappeared). The number of breast cancers detected in category 3 was two (one ductal carcinoma in situ and one invasive ductal carcinoma). The frequency of cancer detection after a recommendation for short-term follow-up on subsequent examination was 2/386.

Conclusion: Most of the category 3 lesions (94%) are stable in follow-up imaging. However, the cancer detection rate is 0.52% (2/386) in category 3 lesions with at least six months follow-up study and is not trivial, so the recommendation for follow-up and patients compliance are important factors to increase the significance of screening.

B-832 10:57

A prospective study of computer aided detection in the United Kingdom

National Breast Screening Programme

L.A.L. Khoo, P. Taylor, R.M. Given-Wilson; London/UK

Purpose: We evaluated computer aided detection (CAD) prospectively in UK routine screening.

Methods and Materials: Films from 6,111 women, aged 50 and over, receiving three-yearly mammographic screening were analysed (R2 ImageChecker - V5.0). Films were independently double read. Readers recorded an initial evaluation, viewed CAD prompts then recorded a final evaluation. Assessment recall was decided following arbitration. Relative sensitivities were calculated for single reading, single reading with CAD and double reading.

Results: Total cancer detection rate 1.0% (62 cancers in 61 women). CAD prompted 84% (51/61) of detected cancers. Nine of 12 cancers missed on single reading were correctly prompted, but seven prompts were over-ruled by the reader. Sensitivity of single reading was 90.2% (95% CI: 85% to 95%), single reading with CAD 91.5% (95% CI: 86%-97%), double reading without CAD 98.4% (95% CI: 95%-100%). Acting on seven missed but prompted cancers would have given 97.5% sensitivity for single reading with CAD. Recall to assessment rate 6.1% with an increase of 5.8% due to CAD. Average time, per reader, to read a case was 25 seconds without CAD and 45 seconds with CAD.

Conclusion: Compared to single reading, CAD increases sensitivity by 1.3% and double reading by 8.2%. If all correct CAD prompts were actioned, sensitivity would be comparable to double reading. However, 78% of prompts on missed cancer were over-ruled. This may be because of low prompt specificity in the screening environment. Single reading with CAD increases radiologists' time required, compared to double reading, because of increased recall rates.

Opportunistic breast cancer early detection in Tyrol, Austria 1996-2004. Do we really want or need a mammography screening program in Tyrol?
T.E. Frede; Innsbruck/AT

Purpose: Statements made in a recently published OeBIG feasibility study for a mammography screening program for Austria according to European Union guidelines commissioned by the Austrian Ministry for Health and Women have raised many questions.

Methods and Materials: This author has examined the state of breast cancer early detection in Tyrol. A comprehensive review of all available data and results based on 3,160 primary biopsy recommendations between 1996 and 2004 at our breast center was performed.

Results: Early detection has been improved by organizing the existing opportunistic screening through a true team approach, incorporating not only the clinic's specialties, but also the private radiologists and referring physicians. This year our center will make the definitive diagnosis in over 75% of the 340 primary breast cancers occurring yearly in Tyrol with 65% being discovered by routine examination. Over 75% stem from second-opinion examinations. About 94% of our primary biopsies are now performed minimally invasive with an overall 47.6% (1303/2740) malignancy rate. Pathological TNM-staging was obtained in over 96% of women under 70 years of age. 54.2% (61.8% in 2004) of all discovered cancers were TNM-stage 1 or better lesions (75.2% in our routine patients). With an overall participation of about 70% of our target group (women over 34 years), it is women under the age of 50, who most consistently follow our recommendations resulting in an above average rate of 57.9% TNM-stage 1 and better lesions.

Conclusions: A mammography screening program as proposed by the OeBIG would only represent one giant leap backwards for Tyrolean women-kind!

B-834 11:15

Screening US in mammographically normal dense breasts
H.-S. Choe, E. Ko, Y.-A. Bae, G.-H. Kim, Y. Lee, S.-Y. Chung; Anyang/KR

Purpose: To evaluate the value of additional US examination for screening in asymptomatic women who showed normal dense breast on screening mammography.

Materials and Methods: From January 1999 to June 2004, 513 women with normal mammographic findings and dense breast compositions underwent US examination. We analyzed the results of US examinations, and evaluated the cases that additional US examinations altered the managements of the patients.

Results: Age distribution of patients was from 26 to 70 (20 s: 19, 30 s: 148, 40 s: 275, 50 s: 58, over 60: 13). After the additional US examinations, final assessments were normal in 308 patients, changed to benign in 122 patients, to probably benign in 76 patients and to suspicious malignancy in 8 patients. Five out of 8 patients with suspicious malignant lesions underwent biopsy, and only one patient was diagnosed as mucinous carcinoma. Other four cases were fibrocystic changes, fibroadenomas(2), and focal ductal dilatation and sclerotic stroma. US examinations diagnosed additional category 3 or 4 lesions in 16% of all patients. Category 4 lesions were found in 2.6% of patients in 36 - 50 years old, and one 27 year-old woman. But breast carcinoma was diagnosed in only one case of total additional breast US examinations.

Conclusion: Additional US examination for screening can help the diagnosis of category 3 or 4 lesions, especially in late thirty and forties. But screening US examinations in all patients with normal dense mammography was not effective in the diagnosis of breast cancer.

B-835 11:24

Assessment of suspicious lesions in mammography screening by minimally invasive biopsy

H. Junkermann, I. Junkermann, M. Borowski, P. Hanisch, U. Bonk, W. Böcker; Bremen/DE

Purpose: Minimally invasive biopsies are standard for pathological assessment in the German model projects for mammographic screening. The results of this approach in the Bremen project are analyzed and compared to the standards of the European Guidelines for Mammographic Screening.

Methods and Materials: From June 2001 to 31st March 2004, 37574 women have taken part (34604 first round participants, FRP; 2967 second round participants, SRP). 5.6% of FRP and 4.5% of SRP have been invited for assessment. After clinical assessment, ultrasound and additional mammography, invasive assessment has been done in 591 FRP (=1.7%) and 36 SRP (= 1.2%).

Results: In 629 lesions, a minimally invasive biopsy and in 45 lesions, a primarily open biopsy was performed. 51% of the minimally invasive biopsies had a

malignant result. 359 lesions (=57%) had been biopsied under ultrasound guidance, 68% of these had been malignant. 34% of 140 stereotactically guided core biopsies and 22% of 130 stereotactically guided vacuum biopsies had been malignant. Routine use of minimal invasive biopsies allowed a preoperative diagnosis in 93% of malignant lesions (EU-guidelines optimal > 90%) and a low number of open benign biopsies (benign to malignant ratio 0.27:1; EU-guidelines optimal < 0.5:1).

Conclusion: The routine use of minimally invasive biopsies allowed preoperative diagnosis in carcinomas and a benign:malignant ratio according to optimal EU standards.

B-836 11:33

Core needle breast biopsy: An alternative to short-term follow-up in probably benign breast lesions (BI-RADS™ 3)?

S. Jaromi, G. Pfarl, D. Floery, C.C. Riedl, W.K. Matzek, M. Rudas, T.H. Helbich; Vienna/AT

Purpose: To assess if stereotactic or ultrasound-guided core needle breast biopsy (CNBB) can be used as an alternative to short-term follow-up in non palpable, probably benign breast lesions (BI-RADS 3™).

Methods and Materials: From 1994 to 2004, stereotactic or ultrasound guided CNBB were performed in 288 lesions which were prospectively assigned as BI-RADS™ 3. Stereotactic CNBB was performed with either spring loaded (needle size 14-g, n = 37) or directional vacuum-assisted biopsy devices (needle sizes 14-g; n = 85; 11-g, n = 90). Sonographically guided biopsies were performed with an automated gun and a 14-gauge needle (n = 76). Following CNBB, patients underwent either surgical excision (n = 204) or mammographic follow-up (n = 84) for at least 20 months. Histological results of CNBB were compared with those of surgical biopsy.

Results: There were 185 masses, 68 calcifications, 14 masses with calcifications, 16 asymmetric densities and five asymmetric densities with calcifications. A diagnosis of malignancy was found at CNBB in 1/288 (0.35%) [ductal carcinoma in situ (DCIS)]. Atypical ductal hyperplasia (ADH) was found at CNBB in 13/288 (4.5%) cases, of which 2 (0.75%) were underestimated. Thus, surgery revealed malignancy in 3/288 (1%) [3 cases of DCIS]. The remaining 285 lesions revealed a benign histology at surgery or were stable during follow-up.

Conclusions: The low number of carcinomas does not favor CNBB as an alternative to short-term follow-up in non palpable, probably benign breast lesions (BI-RADS 3™).

B-837 11:42

MR imaging breast tumor characteristics of BRCA1 and BRCA2 gene mutation carriers

J. Veltman¹, C. Boetes¹, T. Kok², I. Obdeijn³, R. Manoliu⁴, P. Besnard⁴, H. Zonderland⁵, J. Blickman¹, J. Barentsz¹; ¹Nijmegen/NL, ²Groningen/NL, ³Rotterdam/NL, ⁴Amsterdam/NL, ⁵Leiden/NL

Purpose: To evaluate breast tumors in gene mutation carriers (GMC) using MR imaging in order to detect potential misleading characteristics more frequently present in this group on mammography.

Methods and Materials: Retrospectively, MR imaging tumor characteristics of 25 GMC were evaluated. Results were compared with a control group (CG) of 25 breast cancer patients who underwent pre-operative breast MR imaging. Tumors were evaluated on lesion morphology, delineation, internal morphology and kinetics. Statistic comparison of characteristic spread between both groups was done using the Pearson Chi-Square test and multivariate analysis.

Results: 24 lesions were detected on MR imaging in the carrier group, 26 in the control group. In the GMC 19 cases had IDC, 5 DCIS, and 2 ILC. In the control group this was respectively 18, 5 and 3. Tumor size in the CG was significantly larger compared to the carrier group for both pathology and MR imaging measurements. The Pearson chi-square test resulted in $\chi^2 = 11.7$ ($p = 0.001$) for lesion morphology, $\chi^2 = 8.2$ ($p = 0.02$) for internal morphology, $\chi^2 = 5.0$ ($p = 0.08$) for delineation and $\chi^2 = 1.2$ ($p = 0.28$) for kinetics. Using the multi-variate analysis the most different characteristic was tumor shape.

Conclusion: Breast tumors in GMC often present as a rounded lesion with rim enhancement and a type 3 curve. On MR imaging detected rounded lesions in GMC should therefore closely be evaluated for rim-enhancement and kinetics. Both these parameters are essential in not evaluating these rounded lesions as benign.

Mammographic, ultrasonographic, histologic and immunohistochemical features in patients with breast cancer and BRCA1 or BRCA2 gene mutation

C. Miro, M. Tomas, P. Pastor, E. Vazquez, A. Arjonilla, E. Ramiro, J. Contreras; Madrid/ES

Purpose: To analyze mammographic and ultrasonographic findings, morphology and immunohistochemical patterns in hereditary breast carcinomas in BRCA 1 and BRCA 2 mutation carriers.

Methods and Materials: Of 44 patients with hereditary breast carcinoma, BRCA 1 mutation was found in ten patients and BRCA 2 in seven. Fifteen of these seventeen patients were females aged 29 to 54 and two males that were 67 to 77 years old.

Results: The most common finding was a well defined nodule with size ranging from 0.5 to 3.5 cm in a dense breast (14 of 17 patients). In the other three cases microcalcifications were found. The most common histologic type was invasive ductal carcinoma (70% of cases in both groups). In two cases with BRCA 1 mutation histologic type was medullary carcinoma. One patient with BRCA 1 mutation showed bilateral involvement at the time of diagnosis. Three patients showed recurrences in the ipsi- or contralateral breast during follow-up. Two patients had also ovarian cancer. Two patients with BRCA 2 mutation were males. All of them were poorly differentiated carcinomas with an immunohistochemical pattern of poor prognosis. 50% of cases showed nodal involvement.

Conclusion: Patients with BRCA 1 mutation are relatively young women with nodules in dense breasts and aggressive immunohistochemical patterns. Bilateral involvement is common as well as early recurrences and association with ovarian cancer. Medullary carcinoma is more common (20%) in BRCA population than in sporadic breast cancer. In the BRCA 2 group the involvement of males stands out.

Real-time MR imaging of the thorax: Experience in 1100 examinations

A. Kluge, C. Mueller, G. Bachmann; Bad Nauheim/DE

Purpose: To assess the value of Real-time MR imaging (RT-MRI) in both emergencies and in dedicated cardiovascular questions.

Materials and Methods: From June 2001 to July 2004, 1132 RT-MRI examinations using TrueFisp sequences have been performed. Indications for this technique and its role in the diagnostic process have been evaluated retrospectively.

Results: 919 RT-MRI examinations did not apply either cardiac or respiratory gating. 180 sequences served for general anatomical overview of thoracic structures. 382 sequences were used as a first-line diagnostic technique in cases of suspected pulmonary embolism, and aortic dissection was suspected in 98 patients. 309 sequences served to assess suspected thoracic pathology, most of them after cardiac surgery. 163 RT-MRI were additionally applied to visualize incidental findings detected with other MRI techniques. RT-MRI was the sole MRI technique applied in 96 examinations. As most of the cases were non-emergencies, other sequences could be added, most of them being contrast enhanced MR angiography and T1-weighted non fat-saturated sequences. Retrospectively, the correct diagnosis could be established with RT-MRI alone in 86% of the examinations, and it shortened examination time in the other cases. 48 CT examinations were added to confirm and to further differentiate non-vascular thoracic RT-MRI findings.

Conclusion: RT-MRI was 100% reliable in emergencies and shortened the examination time in complex situations after cardiac surgery. The inherent T2-weighted contrast makes it well suited for vascular pathologies. Although 38 malignant neoplasms have been diagnosed, CT has to be used in these cases.

B-840 10:39

Comparison of whole-body PET/CT and whole-body MR imaging in patients with newly diagnosed non-small cell lung cancer: Initial results

F.M. Vogt, P. Veit, L. Freudenberg, S.G. Rühm, J. Barkhausen, G. Antoch; Essen/DE

Purpose: To assess the accuracy of whole-body PET/CT and whole-body MR imaging for staging non-small cell lung cancer (NSCLC).

Materials and Methods: 28 patients with newly diagnosed NSCLC underwent whole-body [¹⁸F]-2-Fluoro-2-deoxy-D-glucose (FDG) PET/CT and whole-body MR imaging for tumor staging. Images were evaluated by two different, blinded reader teams and diagnostic accuracies of both imaging procedures for assessing the TNM stage were compared. Histology and a mean clinical follow-up of 250 days served as standards of reference. Differences between both staging procedures were tested for statistical significance by McNemar's test.

Results: The overall TNM tumor stage was correctly determined in 23/28 patients (82%) with PET/CT and in 18/28 patients (64%) with MR imaging ($p = 0.1797$). PET/CT had a direct impact on patient management in 3 patients compared to MR imaging, while MR imaging did not change the therapy regimen compared to PET/CT. Separate assessment of the T-stage was limited to histologically verified cases ($n = 12$). PET/CT showed accurate T-staging in 12/12 of these patients (100%) whereas MR imaging allowed correct assessment of the T-stage in 7/12 of these patients (58%) ($p = 0.0625$). The N-stage was correctly determined in 27/28 of the patients (96%) with PET/CT and in 20/28 patients (71%) with MR imaging ($p = 0.0125$). Both imaging procedures showed a similar performance in detecting distant metastases.

Conclusion: Although no statistically significant difference was found for overall TNM-stage evaluation, there is a firm tendency for more accurate staging results with PET/CT. Assessment of larger patient cohorts will be required.

B-841 10:48

Can FDG-PET/CT replace mediastinoscopy or operative biopsy in patients with lung tumors?

P. Fencl, O. Belohlavek, J. Schutzner, P. Fiala, P. Pafko, P. Zatloukal; Prague/CZ

Purpose: FDG-PET/CT investigation enables exact anatomical localisation of hypermetabolic foci, thus it has the ability to evaluate neoplastic lymph node (LN) involvement with respect to topography. We performed a pilot study to determine whether this hybrid imaging modality could replace mediastinoscopy or per-operative biopsy.

Methods and Materials: 39 patients underwent FDG-PET/CT examination before planned lung surgery. LNs were classified as small (S, less than 10 mm) or large (L, larger than 10 mm) according to CT, and cold (C) or hot (H) according to PET. All primary tumours and 64 LNs in 32 patients were examined histologically after mediastinoscopy or thoracotomy. Only histologically confirmed specimens were included in the evaluation.

Results: There was one false negative and one false positive PET in diagnosis of primary tumours (sensitivity=96%, specificity=89%, accuracy=94%). In total 14 LNs were affected by neoplasm: 6 of 7 H/L LNs, 1 of 4 H/S LNs, 1 of 9 C/L LNs, 5 of 43 C/S LNs, and one LN was directly invaded by tumor. Assessment of LN involvement based separately on PET and CT, resulted in sensitivity of 50% and 50%, specificity of 92% and 82%, accuracy of 83% and 75%, respectively. Assessment of LNs based on FDG-PET/CT resulted in sensitivity of 43%, specificity of 96% and accuracy of 84%.

Conclusion: FDG-PET/CT is an accurate modality for differential diagnosis of primary lung tumours. Positive LN findings could reduce the number of patients for whom surgery is indicated. Negative LN findings, however, cannot replace mediastinoscopy or operative biopsy.

B-842 10:57

Multislice CT for detection pulmonary embolism after lung surgery for cancer

A. Lemmi, T. Lombardi, P. Corneli, M. Chiodi, M. Scialpi, L. Lupattelli; Perugia/IT

Purpose: The incidence of pulmonary embolism (PE) in patients undergoing lung surgery for cancer remains unclear. In these patients the risk for venous thromboembolism is potentially high due to the combination of prothrombotic effects of cancer, extensive surgery, prolonged immobilization and parietal or endothelial local alteration consequent to surgery. The aim of our study was to assess the incidence of PE after lung surgery for cancer using a multislice CT (MSCT).

Scientific Sessions

Materials and Methods: Thirty-four patients (mean age, 65 years; range, 48-78 years) undergoing major surgery for lung cancer were included in this study. Diagnosis of cancer was confirmed in all cases. Twenty-three patients underwent a lobectomy, 9 a pneumonectomy, and the remaining 2 a wedge resection. To detect PE we performed MSCT at 7-15 days after surgery. The diagnostic criteria for PE were a partial or total intraluminal filling defect. Patients were scheduled to receive pharmacological prophylaxis for venous thromboembolism at the discretion of the attending physician.

Results: MDCT showed PE in 7 out of 34 patients; of these two were asymptomatic. Of these 2 PE involved the stump of resection, 3 arteries (mainstream n = 1, lobar n = 1, and segmentary n = 1), and subsegmentary arteries" with "PE involved the stump of resection (n = 2), main artery (n = 1), lobar artery (n = 1), segmental artery (n = 1), and subsegmental arteries (n = 2).

Conclusions: Despite antithrombotic prophylaxis, PE is a common complication in patients undergoing lung surgery for cancer. MSCT is a reliable method to detect PE after lung surgery for cancer.

B-843 11:06

Does core lung biopsy with large needle (≥ 18 G) increase pneumothorax incidence?

A. Oikonomou, G. Patlakas, M. Mantatzis, L. Panagiotidou, D. Bouros, P. Prassopoulos; *Alexandroupolis/GR*

Objective: To evaluate the complication rate and diagnostic accuracy of core lung biopsy (CLB) with needles ≥ 18 G in patients with focal lung lesions.

Materials and Methods: Fifty-three consecutive patients with focal lung lesions (0.8-9.3 cm) underwent CT and CT-guided CLB (mean age: 65.7 yrs, range: 29-81 yrs) with the single-needle technique. 14 G, 16 G and 18 G needles were randomly selected for biopsy. The incidence of pneumothorax and catheter insertion was correlated with histology result, size and depth of the lesion, presence of emphysema, needle size and needle passes. The final diagnosis was established on histopathology after surgical resection or on follow-up and response to treatment.

Results: 14 G, 16 G and 18 G needles were used in 20, 40 and 21 passes, respectively. In 28 procedures two needle passes were performed including four cases where two different needle sizes were used. Pneumothorax occurred in 6 of 53 procedures (11.32%), 4 being in two passage procedures. Drainage was needed in 4 procedures (7.54%). Sensitivity, specificity and negative predictive value of CLB were 93.6, 100, and 63% respectively. None of the parameters examined were found to predict the incidence of pneumothorax ($p > 0.1$).

Conclusions: CLB with needles ≥ 18 G provide high diagnostic accuracy and a pneumothorax rate comparable with the best results reported in the literature for fine needle biopsy. This contradicts perceptions that the risk for pneumothorax increases with larger needles.

B-844 11:15

Modified CT-bronchoscopy as a guidance tool for bronchoscopic needle aspiration. A phantom study

G.M. Weiner¹, B. Geiger², K. Schulze¹, J. Bilger¹, P. Krebs¹, K.-J. Wolf¹, T. Albrecht¹; ¹Berlin/DE, ²Princeton, NJ/US

Purpose: During transbronchial needle aspiration, axial CT-slices are usually used for orientation. To improve the hit rate, a software tool was developed to visualize the target through a semitransparent wall in virtual bronchoscopy. This guidance tool was tested against the customary method in a phantom study.

Methods and Materials: To evaluate the software, an airway phantom with 16 "peribronchial" targets was scanned and examined by three bronchoscopists. In a first pass the targets were bronchoscopically punctured in the traditional way, with knowledge only of the axial CT images. In a second pass, the virtual bronchoscopy was used interactively in real time for guiding the intervention. In addition to the feature of three-dimensional display, measurements could be performed simultaneously to determine the puncture site. CT-scans with metal spots representing the puncture sites were used to analyze the number of hits or the distance and angle between puncture site and target.

Results: Using exclusively axial CT-sections for needle positioning, 14 out of 48 punctures hit the target. Guidance by virtual bronchoscopy increased the hit rate to 32 out of 48. Each investigator at least doubled the hit rate with the virtual guidance. When the target was missed the distance and angle between target and puncture site were significantly smaller applying the new method.

Conclusion: Despite its simplicity, the new virtual guidance tool shows a significant increase in yield, compared to the conventional type of orientation when performing TBNA. It could be a promising tool in clinical practice.

B-845 11:24

Evaluation of the bronchial suture in lung transplant recipients with virtual bronchoscopy

W.F.M. De Wever, I.M. Van Mieghem, I. Van Breuseghem, J.A. Verschakelen; *Leuven/BE*

Purpose: To compare virtual bronchoscopy (VB) with fiberoptic bronchoscopy (FB) in the evaluation of the bronchial suture in lung transplant recipients.

Material and Methods: 37 patients entered the study. Diameter and wall irregularity of the bronchial suture were graded independently using both techniques. Evaluation of VB was performed by 3 radiologists with consensus reading. Evaluation of FB was performed by the pulmonologist. The diameter was graded on a 4-point scale from 0=normal to 3=complete stenosis. Wall irregularity was scored between 0=normal and 2=severely irregular.

Results: There was a high correlation between VB and FB scores of the diameter ($r_s = 0.85$, $p < 0.05$); however the distribution of both scores was significantly different ($p < 0.05$) which was related to an overestimation of the constriction with VB in 29% cases. Correlation between VB and FB scores of wall irregularity ($r_s = 0.33$, $p < 0.05$) was moderate but significant; the distribution of both scores was not significantly different ($p = 0.6$) due to a high incongruence rate between VB and FB scores (48%).

Conclusion: VB can play an important role in the evaluation and follow-up of bronchial sutures in lung transplant recipients and is a very good alternative to the more invasive FB.

B-846 11:33

ECG gated 64 slice CT angiography for the differential diagnosis of acute chest pain

T.R.C. Johnson, C.R. Becker, B.J. Wintersperger, K. Nikolaou, C. Rist, S. Paul, A. Knez, M.F. Reiser; *Munich/DE*

Purpose: To evaluate the usefulness of an ECG-gated 64 slice CT angiography protocol for the assessment of pulmonary arteries, coronary arteries and the aorta in the differential diagnosis of acute chest pain.

Methods and Materials: ECG-gated 64 slice CTA was performed with a Siemens Somatom Sensation 64 CT scanner in 32 patients suffering from chest pain. Heart rates were 70.5 ± 12.2 /min. A Medrad Stellant dual head power injector was used for contrast media administration; volume and flow rate were adapted to the scan length, mean values were 143.1 ± 19.0 ml and 4.4 ± 0.5 ml/sec, respectively; scan time was 23.1 ± 3.3 sec. Bolus tracking in the ascending aorta was used with a delay of 6 seconds. Collimation was 64×0.6 mm, rotation time 0.33 sec; retrospective gating was used for reconstruction. Density measurements and visual assessment of motion artefacts were performed to evaluate image quality.

Results: Sufficient opacification of the pulmonary vessels, the coronary arteries and the aorta could be achieved in all individuals. There was minor blurring in seven patients and one examination with non-diagnostic images of the coronary arteries, whereas only slight motion artefacts of the pulmonary arteries were seen in two patients. Diagnoses included pulmonary embolism (n = 9), high grade coronary stenosis (n = 3) and aortic aneurysm (n = 4).

Conclusion: With current techniques, an ECG-gated CT angiography of the whole chest is feasible with very good image quality. The protocol proved to be helpful in the differential diagnosis of acute chest pain.

B-847 11:42

Endobronchial tuberculosis: Evaluation with multislice spiral CT

J.-Q. Yu¹, X.-H. Zhu², Z.-G. Yang¹; ¹Chengdu/CN, ²Shanghai/CN

Purpose: To explore the diagnostic value of multislice spiral CT with thin collimation, scanning the entire thorax with image post-processing, in endobronchial tuberculosis.

Materials and Methods: Ninety-eight patients with endobronchial tuberculosis diagnosed by bronchoscopy, microbiology and pathology were scanned using a multislice spiral CT, scanning the entire thorax with 3 mm collimation within one breath-hold. 3D image reconstructions including MIP, CVR and CTVE were used. The CT features, findings of fiberoptic bronchoscopy and pathology in these cases were evaluated.

Results: On CT images, bronchial abnormalities were found at 136 sites in 98 cases, including bronchial occlusion in 13(13/136, 9.6%) lesion sites, uniform stricture of bronchi in 27(27/136, 19.8%) and irregular stricture of bronchi in 96(96/136, 70.6%). Thirty-one lesions (31/136, 22.8%) were located in a main bronchus, 81 (81/136, 59.6%) in a lobar bronchus and 24 (24/136, 17.6%) in a segmental bronchus. Multiple lesions occurred in 56 (56/98, 57.1%) cases. Strictures of bronchi manifested as wall thickening (27/123, 22.0%) uniform or irregular stenosis

Scientific Sessions

(96/123, 78.0%). Using the results of fiberoptic bronchoscopy and pathology as diagnostic criteria, reviewers diagnosed endobronchial tuberculosis by the multislice spiral CT correctly in 84.6%, with 89.8% sensitivity, 63.2% specificity. **Conclusion:** Multislice spiral CT scan is a fast, effective and non-invasive diagnostic method. The use of thin section scans and 3D reconstruction will be useful in improving diagnosis of endobronchial tuberculosis.

CT-guided percutaneous radiofrequency ablation in patients with inoperable malignant lung tumors: Safety and efficacy

S.F. Lin, J.H. Chen, S.B. Wang; Shantou city Guangdong Province/CN

Purpose: To evaluate therapeutic safety and efficacy of percutaneous radiofrequency ablation (PRFA) for inoperable malignant lung tumors by contrast-enhanced dynamic CT.

Methods: CT-guided PRFA was performed on 81 patients with stage III or IV inoperable malignant lung tumors, in a total of 128 foci. Contrast-enhanced dynamic CT was performed before the PRFA, immediately after, 3 months and 12 months after the PRFA, respectively. The therapeutic safety and efficacy was evaluated by the complications of PRFA, CT scan, and survival rate. Fifty matched patients with a total of 75 foci were taken as the control group, undergoing chemotherapy but no PRFA.

Results: Immediately after PRFA, the margin of all foci were blurred; of 128 foci, density reduction was found in 73 (57%) foci; small air bubble signs were found in 64 (50%) foci. Of all foci at 3 months after PRFA, 4 (3%) foci were found to have almost completely disappeared; 68 (53%) foci had shrunk and 37 (29%) foci were expanded, while 19 (15%) foci remained unchanged. Continued follow-up in 67 patients in a total of 104 foci showed that 4 (4%) foci were found to have almost completely disappeared; 22 (21%) foci had shrunk and 63 (61%) foci were expanded; and 15 (14%) foci remained unchanged. Moreover, the median survival duration was significantly longer in PRFA group than in control group (15.2 months vs 8.7 months, $p < 0.01$).

Conclusion: CT-guided PRFA is a safe and effective treatment for inoperable malignant lung tumors. Contrast-enhanced dynamic CT is a useful modality for assessment of therapeutic efficacy.

Quantification of hepatic iron by MR: Body or surface coil?

L. Martí-Bonmatí, M. Pastor Juan, F. Peñaloza, J. Olalla Muñoz, M. Martínez Pérez; Valencia/ES

Objective: The quantification of hepatic iron concentration from MR signal intensity (SI) measurements has a high predictive value for iron overload. The University of Rennes Web site (<http://www.radio.univ-rennes1.fr/Sources/EN/Hemo.html>) allows calculation of iron concentration by means of SI measurement obtained from MR sequences. The use of a volume body coil is mandatory in these calculations. The purpose of our study was to evaluate whether SI measurements from MR images obtained with the surface coil and parallel imaging have the same values as those obtained with the body coil.

Materials and Methods: A total of 10 patients (2 women and 8 men; mean age, 49 years) were prospectively included. MR imaging involved gradient-echo sequences with different weightings (120/4/90; 120/4/20; 120/14/20; 120/21/20). These sequences were obtained with both the body and a phase-array surface coil. SI measurements were obtained from each sequence by means of ROIs placed in the liver (3) and paraspinal muscle (2). Hepatic iron concentration is expressed in $\mu\text{mol/g}$.

Results: Seven patients had iron overload, between slight and moderate levels. There was no statistical difference (t student, $p = 0.3$) comparing quantifications obtained with the body coil (76 ± 72) and surface coil (79 ± 74). The correlation between measurements was excellent ($R^2=0.98$, $p = 0.000$). The mean difference between body and surface coil measurements per patient was -3 ± 9 (range, -9 to 3). No patient was classified in a different group of iron overload.

Conclusions: MR images with surface coils and parallel imaging allow an accurate quantification of hepatic iron concentration with shorter acquisition time and better resolution.

Diffusion-weighted MR imaging in differential diagnosis of adrenal masses.

Work in progress

V. Zampa, I. Bargellini, S. Ortori, F. Odoguardi, C. Bartolozzi; Pisa/IT

Purpose: To assess the usefulness of diffusion-weighted MR imaging (d-MRI) in providing an objective value to increase diagnostic accuracy in the differential diagnosis of adrenal masses.

Materials and Methods: Six patients (8 lesions) were enrolled with US or CT diagnosis of an adrenal mass (diameter range: 2.5-6 cm) and clinical and laboratory findings suggestive for pheochromocytoma. Conventional MR imaging (C-MRI, 1.5 T) was performed with: FSE-T2W with and without fat suppression (breath-holding or respiratory triggering), double-echo in- and out-of-phase GRE. d-MRI (single-shot echo-planar) was performed in breath-holding using two different b gradient factor values (500 and 1000 sec/mm²) in the three axes. Apparent diffusion coefficient (ADC) was calculated. All patients underwent surgical excision and histologic analysis of the mass. As a control group, d-MRI and C-MRI were performed in 10 patients (16 lesions) with adrenal adenoma ($n = 8$), hyperplasia ($n = 6$), myelolipoma ($n = 1$) and metastasis ($n = 1$), confirmed by clinical, laboratoristic and imaging follow-up.

Results: In all 6 patients the surgical specimens confirmed the diagnosis of pheochromocytoma. C-MRI was highly suggestive of pheochromocytoma in 5/8 lesions. Using $b = 500$, ADC was significantly higher ($P = .03$) in pheochromocytomas (mean ADC $2.26 \times 10^{-3} \text{ mm}^2/\text{sec}$) than in controls (mean ADC $1.69 \times 10^{-3} \text{ mm}^2/\text{sec}$); the difference was not statistically significant using $b = 1000$. By ROC curves (Area-Under-the-Curve = 0.734) an ADC cut-off value of $2.20 \times 10^{-3} \text{ mm}^2/\text{sec}$ (with $b=500$) was identified for the diagnosis of pheochromocytoma (specificity 87.5%, sensitivity 75%, PPV 75%, NPV 87.5%).

Conclusions: Although larger series are required, d-MRI using $b = 500 \text{ sec/mm}^2$ provides an objective value to distinguish pheochromocytomas from other adrenal masses with high diagnostic accuracy.

B-851 10:48

Black-blood-EPI sequences for the evaluation of focal liver lesion:

Comparison to a standard T2-weighted sequence

C.J. Zech¹, K.A. Herrmann¹, O. Dietrich¹, M.I. Menzel², M.F. Reiser¹, S.O. Schoenberg¹; ¹Munich/DE, ²Erlangen/DE

Purpose: To evaluate the feasibility of diffusion-weighted black-blood (BB)-EPI-sequences with parallel imaging for detection of focal liver lesions in comparison to a standard T2-weighted sequence.

Materials and Methods: 20 patients with known or suspected focal liver lesions underwent a diffusion-weighted fat-saturated BB-EPI-sequence (TR 2200 ms, TE 50 ms, b-value = 50 s/mm², 2 averages, 18 seconds breath-hold, Matrix 192x162) and a standard fat-saturated T2-W-sequence (TR = 2800; TE = 107, 1 average, 3 x 17 seconds breath-hold, Matrix 320x320) with 6 mm slice thickness on a 1.5 T MR imaging-system (Magnetom Avanto, Siemens Medical Solutions). Both sequences used parallel imaging with an acceleration factor of 2. Overall image quality and degree of artifacts were compared with help of a five-point scale with 5 being the most desirable score. The detection rate and the level of confidence with regard to lesion detection were evaluated for both sequences in comparison to a contrast-enhanced (gadolinium and /or SPIO) MR examination, which was used as a standard-of-reference.

Results: The diffusion-weighted BB-EPI-sequence showed significantly ($p < 0.05$) improved overall image quality (average score 4.1 versus 3.5) and fewer artifacts (average score 4.15 versus 3.3) in comparison to the T2-W-sequence. Lesion detection was 83% versus 61% superior in the BB-EPI sequence. The level of confidence for the detection of focal liver lesions was also superior for the BB-EPI-sequence.

Conclusion: Diffusion-weighted BB-EPI-sequences within a single breath-hold for liver imaging are feasible with parallel imaging and show excellent image quality. They might contribute to easy and confident lesion detection in comparison to T2-W-sequences.

Scientific Sessions

B-852 10:57

Diffusion-weighted MR imaging in the differentiation of benign and malignant focal liver lesions

C. DellaPina, R. Lencioni, D. Cioni, L. Crocetti, S. Montagnani, J. Lera, A. Conti, E. Batini, C. Bartolozzi; Pisa/IT

Purpose: To evaluate the ability of diffusion-weighted MR imaging to differentiate benign and malignant focal liver lesions.

Methods and Materials: Twenty-two patients 21-72 years old with 34 focal liver lesions were included in an on-going, prospective clinical trial. All patients were examined using a 1.5 T MR scanner and a phased-array torso coil. The MR protocol included T2-weighted FRFSE respiratory-triggered images, T2-weighted FRFSE breath-hold images, breath-hold diffusion-weighted echoplanar images ($b = 500$), breath-hold unenhanced and contrast-enhanced T1-weighted fat-suppressed FSPGR in the arterial (30 seconds), portal-venous (80 seconds) and delayed phase (180 seconds) after bolus injection of 0.2 ml/kg of paramagnetic contrast agent (MultiHance; Bracco, Milan, Italy). Apparent diffusion coefficient (ADC) values were evaluated. The t-test was used to compare the mean ADC values of benign and malignant liver lesions. The gold standard was provided by pathology ($n = 9$) or follow-up MR imaging for at least six months ($n = 13$).

Results: Final diagnoses included hemangioma ($n = 14$), focal nodular hyperplasia ($n = 9$), metastasis ($n = 6$) and hepatocellular carcinoma ($n = 5$). Lesion size ranged from 1.2-8.5 cm. Mean ADC value was 2.3×10^{-3} mm 2 /sec for hemangiomas, 1.6×10^{-3} mm 2 /sec for focal nodular hyperplasia, 0.8×10^{-3} mm 2 /sec for metastases and 1.1×10^{-3} mm 2 /sec for hepatocellular carcinoma. The difference between ADC values of benign and malignant liver lesions was statistically significant ($p < 0.05$).

Conclusion: Preliminary results suggest that diffusion-weighted MR imaging and ADC maps provide valuable information in the differentiation of benign and malignant liver lesions.

B-853 11:06

Diffusion weighted imaging of liver metastases: A study of the relative lesion conspicuity compared to conventional sequences

P. Cowley, J. MacLachlan, J. Tibballs, N. Davies, J. Bell; London/UK

Purpose: Little published data is available to support claims that diffusion weighted imaging (DWI) is highly sensitive for liver metastases. Since Aug 2003 we have included DWI in our standard MR liver protocol. This study retrospectively examines all cases involving liver metastases and quantitatively evaluates conspicuity on DWI compared to conventional sequences.

Method: Studies performed on one Tesla magnet with uniform protocol. Sequences evaluated are T2W TSE axial, STIR & DWI (b -factor 50). Lesion to liver signal intensity ratio (SIR) calculated on all sequences. Comparative analysis of data taking account of primary disease and size of deposits.

Results: 75 scans (59 cases) examined which identify 204 lesions. Primary diseases consist of carcinoid (106), colorectal (72), breast (10) and other (16). On average breast metastases DWI SIR is 62% greater than STIR (STD 0.69) and 86% greater than T2W (STD 0.67). Colorectal DWI SIR are 13% greater than STIR (0.29), 37% greater than T2 (0.37). Carcinoid DWI SIR are 6% greater than STIR (0.32), 25% greater than T2W (0.46).

Conclusion: DWI is indeed a highly sensitive sequence for liver metastases, in some cases indicating lesions otherwise overlooked. Lesions not visible on conventional sequences cannot be included in the quantitative comparison reducing the power of the study and the quantitative estimate of relative lesion conspicuity. Homogeneity of background liver is a further factor where DWI has advantages over STIR and T2W imaging.

B-854 11:15

Optimization of contrast enhancement for pancreatic CT imaging using multi-detector row CT: Effect of different scan delays on arterial, venous, pancreatic and hepatic enhancement

S. Lee, W. Lee, Y. Yim, J. Choi, D. Choi, H. Lim, J. Lim; Seoul/KR

Purpose: To evaluate the effect of different scan delays (SDs) on 3-phase pancreatic CT imaging; early arterial phase (EAP), pancreatic parenchymal phase (PPP), and portal venous phase (PVP), using multi-detector row CT (MDCT) for determining the optimal SDs for each phase.

Materials and Methods: During 8 months, 100 patients underwent 3-phase CT by using MDCT (8 and 16 slice CT). The SDs were determined as 5 s, 10 s and 15 s after the aortic initial enhancement (AIE) for EAP, as 20 s, 25 s and 30 s after the aortic peak enhancement (APE) for PPP and at 70 s, 80 s and 90 s postinjection for PVP. 120 mL of Ultravist 370 was injected at a rate of 4 mL/s. HU

of ROI was measured at the segment 8 for hepatic enhancement (HE), the pancreatic head for pancreatic enhancement (PE), the aorta, hepatic artery and SMA for arterial enhancement (AE), and the portal vein and SMV for venous enhancement (VE) at all three phases, and were compared for evaluating the effects of different SDs.

Results: During EAP, all of AE, PE, VE and HE revealed to be maximal at the 15 s-SD, but no significant difference between the 10 s- and 15 s-SDs in AE and between the 5 s-SD and 10 s-SDs in VE. During PPP, AE, PE, VE and HE were maximal at the 20 s-SD ($p = 0.001$), 25 s-SD ($p = 0.245$), 25 s-SD ($p = 0.037$) and 30 s-SD ($p = 0.001$), respectively. During PVP, AE, PE, VE and HE were maximal at the 70 s-SD ($p = 0.090$), 70 s-SD ($p = 0.657$), 80 s-SD ($p = 0.230$) and 70 s-SD ($p = 0.139$) postinjection, respectively. PE was maximal in PPP in SDs ($p = 0.000$).

Conclusion: The optimal SDs of EAP, PPP and PVP for pancreatic CT were 10 s SD after AIE, 25 s SD after APE and 70 s SD respectively.

B-855 11:24

Optimization of iodine concentration for the diagnosis of focal liver lesions in MDCT

R. Hammersting¹, P.J. Valette², D.M. Regent³, T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Lyon/FR, ³Vandoeuvre-les-Nancy/FR

Purpose: To optimise iodine concentration in multidetector CT (MDCT) of liver tumors.

Method and Materials: In this multicenter, double blind, randomised, parallel group comparison clinical Phase IV study, 91 patients with the diagnosis of abdominal tumors were included and 60 patients were suspicious of liver tumors. All patients underwent MDCT using a bi-phasic contrast-enhanced technique. Iomeprol was administered intravenously in three concentrations (300, 350, 400 mg iodine/ml). The overall iodine dose (36 g) was equal within the groups; administration of contrast was obtained in a dual mode [4 ml/sec for arterial, 2 ml/sec for portal venous phase imaging (equal for all three groups)]. The absolute contrast between lesions and surrounding tissue as well as contrast densities were analysed by summary statistics and an exploratory Kruskal-Wallis test.

Results: Contrast density of normal liver parenchyma was 61.3, 64.8 and 72.7 HU for Iomeprol 300, 350 and 400 ($p = 0.01$) in the arterial phase. The highest concentration led to higher densities for the enhancement of normal liver tissue. Median contrast density of lesion-surrounding tissue tended to be higher for Iomeprol 400 than for the other groups at arterial (74 HU versus 64 and 66) and portal-venous phase (113 HU versus 99 and 102). Higher contrasts of Iomeprol 400 were measured versus 300 and 350 for subgroups of patients with certain lesions: HCC (45, 48 and 71 HU), CCC (64, 65 and 84 HU).

Conclusions: High concentration contrast medium shows advantages in demarcation and delineation compared to lower iodine-concentrated contrast agents for the diagnosis of liver tumors especially of hypervascularized lesions.

B-856 11:33

Computer-assisted evaluation of small hepatocellular carcinoma (HCC) by multiphase dynamic imaging using multidetector helical CT (MDCT)

F. Yan¹, P. Xu¹, W. Cheng¹, G.-Q. Wei², X. Zeng², J.-Z. Qian², L. Fan²; ¹Shanghai/CN, ²Princeton Junction, NJ/US

Purpose: The increased data volume from MDCT poses challenges to clinical workflow. This work is to evaluate the feasibility of computer assistance for the diagnosis of small HCCs (< 30 mm) from MDCT scans, by employing tools of synchronized visualization of multiphase scans and automated quantification of lesion size and enhancement patterns.

Materials and Method: Tri-phase MDCT scans of 40 patients were acquired at pre-contrast, arterial and portal venous phases. The scans were evaluated for the diagnosis of small HCCs using a computer tool (EDDA Technology, Inc). The tool automatically finds corresponding locations of a marked lesion in scans at other phases, and allows synchronized scrolling and visualization of tri-phase scans. Lesion size and attenuation pattern are automatically quantified, with enhancement curve across tri-phases plotted together with that of the normal parenchyma.

Results: 80 small HCCs, ranging between 4.8-28 mm (mean, 15 mm), were diagnosed. With the registration tool, 66.3% of HCCs were quantified as having the "iso/hypo_hyper_hypo" attenuation pattern across the tri-phases. Their corresponding average differences in HU as compared to normal parenchyma were -13.7 ± 9.5 HU, $+22 \pm 9.7$ HU and -20 ± 13.8 HU respectively. 22.5% manifested the pattern of "iso/hypo_hypo_hypo". Their average differences in HU compared to normal parenchyma were -10.6 ± 5.8 HU, -10 ± 8.4 HU and -12 ± 4.6 HU respectively. The remaining HCCs had atypical attenuation patterns.

Scientific Sessions

Conclusions: The automatic registration of lesions across multiphase scans and the quantification of their enhancement patterns objectively reflected the contrast characteristics of small HCCs. The synchronized visualization and quantification tools improve the workflow efficiency and provide visual and quantitative information that aids diagnostic accuracy.

B-857 11:42

Quadruple-phase MDCT of the liver in patients with suspected HCC: Effect of contrast material flow rate

W. Schima¹, T.J. Vogl², C. Catalano³, L. Marti-Bonmatí⁴, E.J. Rummeny⁵, F. Tardagüila Montero⁶, ¹Vienna/AT, ²Frankfurt a. Main/DE, ³Rome/IT, ⁴Valencia/ES, ⁵Munich/DE, ⁶Priego/ES

Purpose: To evaluate the effect of contrast material flow rate (3 ml/s vs 5 ml/s) on the detection and visualization of HCC at MDCT.

Materials and Methods: In a prospective, randomized multi-center trial, 97 patients suspected of having HCC underwent quadruple-phase (double arterial, portal-venous, delayed phase) MDCT. Patients were randomized to receive the iso-osmolar contrast medium iodixanol 320 mg I/ml (1.5 ml/kg b.w.) at a flow rate of 3 or 5 ml/s (48 vs 49 patients). Qualitative (lesion detection, visualization, image quality) and safety assessment were performed.

Results: Overall, 100 and 145 HCC were detected in the 3 and 5 ml/s group, respectively ($p < .05$). More lesions < 1 cm were detected at 5 ml/s (33 vs 16 lesions). The late arterial phase showed significantly more lesions than the early arterial phase at both injection rates (133 vs 100 lesions and 96 vs 67 lesions, respectively, $p < .0001$). There was no difference between both groups in subjective visualization of HCC and in overall image quality, but hyperattenuating HCC were better visualized in the late arterial phase using the higher flow rate (excellent: 54% vs 27%). No differences between 3 ml/s and 5 ml/s were reported for the rate of patient discomfort ($p = 1.0$) and contrast media-related adverse events ($p = .62$). Most discomforts were of mild intensity and none was severe.

Conclusion: For detection of HCC with MDCT a higher flow rate of 5 ml/s is recommended. Visualization of small HCC is improved without increasing the rate of discomfort or the risk of adverse events.

Liver hemangiomas: Pattern-based classification scheme for enhancement speed at arterial phase CT

M. Scialpi¹, A. Rotondo², M. Scaglione², A. Ragazzino², L. Lupattelli¹, ¹Perugia/IT, ²Naples/IT

Purpose: To present a classification scheme for classifying liver hemangiomas on the basis of the enhancement speed patterns that they exhibit in the arterial phase on helical Computed Tomography (CT).

Methods and Materials: Triphasic helical CT scans in 54 non cirrhotic patients with 100 hemangiomas were retrospectively reviewed. On arterial phase enhancement the speed of all lesions were classified as follows: rapid (> 75% of tumor volume), intermediate (25%-75% of tumor volume), and slow (< 25% of tumor volume). Differences in mean size among the hemangiomas with slow, intermediate, and rapid enhancement were analysed. A P value of less than 0.05 was considered statistically significant.

Results: Slow enhancement was observed in 61 of the 100 hemangiomas (61%), intermediate enhancement was seen in 11 (11%), and rapid enhancement was seen in 28 (28%). A significant differences in mean size ($P < .001$) was seen among hemangioma with speed and intermediate enhancement. Temporal peritumoral enhancement was most frequently encountered in rapid enhancing hemangiomas (13 of 28 [46.4%]) than in those with intermediate (1 of 11 [0.9%]) and slow (0 of 61 [0%]) enhancement ($P < 0.001$).

Conclusion: Different phases of enhancement on helical CT facilitates the diagnosis of liver hemangiomas. Our classification scheme may be useful for the interpretation of the arterial phase on helical CT.

Natural history of incidental testicular masses ≤ 0.5 cm detected by US

L. Pallwein, H. Steiner, A. Klauser, F. Frauscher; Innsbruck/AT

Purpose: To evaluate the natural history of incidental testicular masses ≤ 0.5 cm detected with ultrasound (US).

Methods and Materials: Fifteen patients (mean age: 39.3 years; range, 27 - 61 years) with urological problems such as prostatitis, epididymitis, infertility, and lower abdominal pain but without suspicion of testicular tumor, underwent scrotal US using a transducer with a frequency of 12.0 MHz (Acuson Sequoia, Mountain View, Cal.). In the 15 patients 16 unilateral testicular masses were found. All patients underwent an organ-sparing frozen-section-guided approach. The US findings were compared with the histological findings.

Results: Tumor size varied from 0.15 - 0.5 cm (mean: 0.35 cm). Histological analysis revealed pure seminoma in 3 cases (18.8%), Leydig cell tumor in 9 cases (56.3%), Leydig cell hyperplasia in 3 cases (18.8%), and fibrotic pseudotumor in 1 case (6.6%). US findings showed in all cases a well-defined mainly hypoechoic mass with peripheral and central flow pattern on color Doppler US. Tumor markers were within normal range in all subjects.

Conclusion: US is highly sensitive in the detection of small testicular tumors. Since the majority of the tumors ≤ 0.5 cm were malignant, exploratory surgery remains the best therapeutic approach. Removal of a testicle can be avoided by an organ-sparing frozen section-guided approach.

Are renal perfusion parameters reliable without deconvolution analysis?

M.I. Dujardin, S.P. Sourbron, R. Luypaert, P. Van Schuerbeek, F. Deridder, D. Verbeelen, S. Makkat, T. Stadnik; Brussels/BE

Purpose: To investigate whether measures for renal blood flow, blood volume and mean transit time, obtained by T1-DCE perfusion MR imaging, are reliable without deconvolution analysis.

Materials and Methods: 12 normal patients underwent single-slice perfusion on a 1.5 T MR imaging. During the first pass of 20 ml Gadolinium (at 2 cc/s) one axial 4 mm slice was acquired using a Turboflash sequence (TR 4.4 ms, TE 2.2 ms, FA 50°, temporal resolution 0.3 s). Post-processing included conversion to tracer concentrations and deconvolution with an aorta AIF. Parametric maps (maximum time course, area under the curve and the ratio of both) were calculated before (rRBF, rRBV and rMTT) and after deconvolution (RBF, RBV and MTT). Average cortical values were obtained from whole cortex ROIs. Results were evaluated by visual image inspection and by non-parametric correlation analysis.

Results: Image inspection showed that in 4/12 patients rMTT values were lower in medulla than in cortex, contrary to expectations based on physiological considerations. For MTT and RBF no such discrepancies were observed. rRBV and RBV maps are essentially identical with proper scaling. Intersubject comparison of ROI data provided strong evidence for a complete lack of correlation between MTT and rMTT ($r = 0.16$, $p = 0.34$), and between RBV and rRBV ($r = 0.09$, $p = 0.54$). RBF and rRBF were weakly but negatively correlated ($r = -0.28$, $p = 0.056$).

Conclusion: Renal perfusion parameters are unreliable without a deconvolution analysis. Interpreting these parameters in terms of physiological quantities such as RBF or MTT may lead to erroneous conclusions.

B-861 10:48

Does a deconvolution analysis remove the dependency of renal perfusion parameters on injection dose?

M.I. Dujardin, S.P. Sourbron, R. Luypaert, P. Van Schuerbeek, C. Ernst, S. Makkat, T. Stadnik; Brussels/BE

Purpose: To determine whether a deconvolution analysis of T1-weighted dynamic contrast enhanced MR imaging produces values of renal blood flow (RBF), blood volume (RBV) and mean transit time (MTT) independent of injection dose.

Scientific Sessions

Materials and Methods: Perfusion measurements were performed on 14 normal humans using a 1.5 T MR imaging. During the first pass of Gadolinium, 4 mm single-slice axial images were obtained using a Turboflash sequence (180° preparatory pulse, TR 4.4 ms, TE 2.2 ms, FA 50°, matrix 128/256, acquisition time 0.3 s). A dose of 10 ml Gadolinium was injected in 6 patients (group 1) and of 20 ml in 7 patients (group 2). Injection rate was 2 cc/sec in both cases. Mean age was 52 years for group 1 and 51 for group 2. Using in-house built software, signals were converted to tracer concentrations and deconvolved with an AIF selected manually in the aorta. Whole cortical ROI measurements of RBF, RBV and MTT were obtained and compared between patient groups using non-parametric Mann-Whitney statistics.

Results: For group 1 we found mean cortical values for RBF (/ml/min/ml), MTT (/sec) and RBV (/ml/ml) of 1.7 ± 0.7 , 17 ± 9 and 0.5 ± 0.7 respectively. For group 2 the mean values were 1.3 ± 0.3 , 18 ± 4 and 0.4 ± 0.1 respectively. The difference between groups was not statistically significant ($p > 0.05$) for any of the parameters.

Conclusions: A deconvolution analysis of T1 weighted dynamic contrast enhanced MR imaging of the kidney leads to RBF, RBV and MTT values which are independent of injection dose.

B-862 10:57

Protective role of pancreas and successful islets transplantation on transplanted kidney of type I diabetic uremic patients: Clinical and color Doppler ultrasound (CDU) assessment in 234 patients

C. Losio, M. Venturini, P. Fiorina, E. Angeli, A. Secchi, A. Del Maschio; Milan/IT

Purpose: In type I diabetic uremic kidney-transplanted patients, diabetes and immunosuppression can reduce kidney-graft function. Simultaneous pancreas or successful-islets transplantation determine resolution of diabetes. Our purpose was to retrospectively evaluate the transplanted kidneys of Kidney-Alone (KA), Kidney-Pancreas (KP) and Successful-Kidney-Islets (KIS) transplanted patients.

Materials and Methods: From 1991 to 2004 the transplanted kidneys of 166 KP, 24 KIS and 44 KA patients were evaluated with CDU (Ansaldi-Esaote AU590/ATL-Philips HD15000); the mean resistance index (RI) of three intraparenchymal arteries and renal size (distance between the upper and lower poles) were measured. Urinary albumin excretion (UAE), Serum creatinine (SC) and glycated hemoglobin (HbA1c) were also evaluated. All data were recorded baseline, 2, 4 and 6 years from transplantation.

Results: The KP and KIS groups only showed a significant reduction of RI (KP-baseline: 0.74 ± 0.01 ; KP-6 years: 0.68 ± 0.01 ; KIS-baseline: 0.72 ± 0.02 ; KIS-6 years: 0.69 ± 0.02 , $p < 0.05$; KA-baseline: 0.76 ± 0.02 ; KA-6 years: 0.76 ± 0.04). Despite all groups showing an increase in graft size after the transplant, only in the KP group did renal hypertrophy persist at 6 years from transplantation. An increase of UAE was evident only among KA patients (KA-baseline: 31.4 ± 9.0 mg/L; KA-6 years: 82.9 ± 33.6 mg/L). A significant increase in SC was found at 6 years only in KA group, not in KP and KIS (KA-baseline: 1.58 ± 0.08 mg/dL; KA-6 years: 2.78 ± 0.44 mg/dL, $p < 0.05$). HbA1c levels at 6 years were significantly lower in KP than KA (KP-6 years: $5.9 \pm 0.1\%$; KD-6 years: $8.1 \pm 0.4\%$, $p < 0.05$).

Conclusion: CDU allows quantitative and reproducible measurements of transplanted kidney. Pancreas and successful-islets transplantation, restoring good glycometabolic control, exert a protective role on function, hypertrophy and microcirculation of kidney-graft.

B-863 11:06

Microscopic hematuria and pelvic congestion syndrome: A late sequela of cirrhosis

E.K. Lang, R. Thomas, M. Brammer, S. Joshi; New Orleans, LA/US

Purpose: To investigate the relationship of hematuria and pelvic congestion syndrome to collateral flow and pressure related changes in the left renal vein as consequence of cirrhosis and demonstrated on dynamic helical CT.

Methods and Materials: 40 patients, 29 male, 11 female, age 38-73 years, with the diagnosis of cirrhosis presented with microscopic hematuria ($n = 32$), pelvic congestion syndrome ($n = 8$) and varicoceles ($n = 2$). Patients were studied by multiphasic helical CT pre-enhancement, late arterial-early cortico-medullary, parenchymal and excretory phase sequences, 1.25 - 3.8 mm collimation.

Results: Advanced cirrhosis, hepatitis C, ($n = 14$) alcoholism or nutritional, ($n = 26$) was confirmed in all 40 patients. The early cortico-medullary and parenchymal phase CT demonstrated huge splenorenal shunts in all patients. In 17 of 18 patients elevated left renal vein pressure was confirmed by left renal vein catheterization. 8 of the female patients showed massive dilation of the ovarian vein communicating to dilated pelvic veins and causing a pelvic congestion syndrome, 2 male patients demonstrated left varicoceles, a consequence of retrograde flow in the dilated left gonadal vein.

Conclusions: Massive splenorenal anastomoses to the left renal vein cause elevation of left renal vein pressure and are likely responsible for microscopic hematuria. Retrograde flow from the left renal vein into the gonadal and ovarian veins cause pelvic vein congestive syndrome in the female and varicoceles in the male.

B-864 11:15

MR urethrography in complete posterior urethral stricture: Comparison with retrograde and/or voiding urethrography

D. Sung, S. Cho, Y. Kim, K. Chung, D. Moon, J. Kim; Seoul/KR

Purpose: The purpose of this study is to evaluate the usefulness of magnetic resonance (MR) urethrography in complete posterior urethral stricture.

Materials and Methods: Twelve patients with complete posterior urethral strictures were studied preoperatively with axial and sagittal TSE T2, sagittal T1 and contrast-enhanced sagittal T1-weighted images with 3 mm thickness covering the entire urethra by 1.5 T MR scanner. Before MR scanning, aseptic lubricant was infused through the external urethral meatus to dilate the distal urethra up to the stricture. To determine which method accurately estimate the stricture length, each imaging result was compared to surgical specimen or finding.

Results: At MR imaging, the strictured segment manifesting as low signal intensity on T1WI and T2WI was seen just proximally to the dilated distal urethra in all patients without contrast enhancement. MR imaging was able to show the periurethral extent of fibrosis and the prostatic displacement. Two patients with prostatic displacement and long strictures of 3 cm needed the combined perineal and transpubic approach at surgery. For MR versus retrograde and/or voiding urethrography, the mean measurement errors were 0.33 ± 0.26 cm and 1.69 ± 0.97 cm. MR measurement of the stricture length demonstrated significantly lower errors ($p < 0.05$) and better linear fit compared with the conventional urethrography ($R^2: 0.85$ vs 0.03).

Conclusion: MR imaging of the dilated urethra with aseptic lubricant, which we call "MR urethrography" is an effective tool in the evaluation of complete posterior urethral stricture. It can be particularly helpful in the surgical planning.

B-865 11:24

Diagnosis of epididymo-testicular disjunction on gadolinium-enhanced MR imaging in patients with cryptorchidism

A.E. Mahfouz, H. Sherif; Doha/QA

Purpose: To assess the value of magnetic resonance imaging in diagnosis of epididymo-testicular disjunction in patients with cryptorchidism.

Methods and Materials: Fifty children with cryptorchidism (44 unilateral and 6 bilateral) were examined by MR imaging. The patients were examined by coronal T2-weighted and proton density images as well as transverse T1-weighted images of the scrotum, inguinal region, and pelvis, followed by transverse and coronal fat-saturated T1-weighted GRE images before and after intravenous injection of Gd-DTPA. Maximum intensity projection (MIP) of the coronal gadolinium-enhanced fat-saturated T1-weighted images has been performed. All patients underwent surgical treatment. MR imaging and surgical findings were compared.

Results: Out of the 56 undescended testes included in the study, 52 testes could be identified on MR imaging, 30 intraabdominally and 22 within the inguinal canal. Epididymo-testicular disjunction could be demonstrated in 12 testes on MR images as enhancing soft tissue structure (representing the elongated epididymis) or vascular structures (representing the looping spermatic vessels) preceding the undescended testis through the inguinal canal into the scrotum. Compared to the gold standard of surgical exploration, MR imaging has sensitivity of 57%, specificity of 100%, negative predictive value of 80%, positive predictive value of 100%, and accuracy of 84% for the diagnosis of epididymo-testicular disjunction.

Conclusion: MR imaging has high specificity for the diagnosis of epididymo-testicular disjunction in patients with cryptorchidism.

B-866 11:33

An anatomical study of retro-renal peritoneal extension and implications for safe percutaneous renal intervention

R. Vikram, C. Ripley, I. Zealley; Dundee/UK

Purpose: Retro renal peritoneal reflections have been implicated in grave intraperitoneal complications following percutaneous renal interventions. We attempted to determine the prevalence and extent of this anatomical variant by studying CT scans on patients with ascites.

Materials and Methods: CT images of 105 consecutive patients with free intraperitoneal fluid were evaluated by two reader consensus. The angle between a horizontal line through the kidney and another line joining the most posterior

Tuesday

Scientific Sessions

extent of the peritoneal reflection and the epicentre of the infra-hilar portion of each kidney was measured.

Results: On the right (n = 105) the peritoneal reflection extended posteriorly to between 0° - 30° from the horizontal in 60.5%, between 31° - 60° in 24%, between 61° - 90° in 2% and beyond 91° in 1%. It did not extend posterior to the horizontal line in 12.5%. On the left (n = 88) it extended posteriorly to 0° - 30° in 48% and to 31° - 60° in 9% and did not extend posterior to the horizontal in 48%.

Conclusions: Retro-renal extension of the peritoneal reflection is surprisingly common and much more common on the right. During percutaneous renal interventions the kidneys are usually approached at an angle between 30° and 60° from the horizontal. Between these angles the likelihood of traversing the peritoneal cavity is substantially higher on the right (27% vs 9% p < 0.05). Where there is a choice, we suggest that percutaneous renal interventions be performed on the left side to minimize the risk of intraperitoneal hemorrhage.

B-867 11:42

Terminal stage pelvic malignancy with bilateral obstructive uropathy: Is there a role for percutaneous intervention?

D. Souftas, M. Mantatzis, P. Prassopoulos; *Alexandroupolis/GR*

Purpose: Patients with terminal stage pelvic malignancy and bilateral ureteric obstruction have a very short life expectancy. The purpose of this study is to evaluate the expediency of percutaneous nephrostomy (PN) -with or without ureteral stenting- in these cases.

Materials and Methods: PN was performed in 75 patients with obstructive uropathy, due to terminal stage pelvic malignancy, under imaging guidance. Percutaneous ureteral stenting was attempted in 38 patients, where guidewire passed through the obstruction, and was successful in 35. The patients' clinical improvement and quality of life after PN and/or stenting were objectively evaluated according to the Karnofsky-scale. Patients with painful bone metastases were not included in the study.

Results: In 60 (80%) of the patients urea and creatinine levels were restored to normal, in 9 (12%) there was improvement and in 6 (8%) no difference was noticed. Twenty-one (28%) patients could go back to usual personal activities, 11 (14.6%) needed minimal support, and 12 (16%) continued to need full support, despite clinical improvement. There was no clinical improvement in 31 (41.3%) patients (elderly, with ascites - limb edema and non painful metastatic bone disease). The patients died in a period between 48 h and 37 months post PN (median survival 7.2 months).

Conclusion: PN with or without stenting for management of obstructive uropathy in terminal stage pelvic malignancy is justified in terms of significant prolongation of survival, clinical improvement in the majority of cases and better quality of life in about half of the patients.

B-868 11:51

Percutaneous radiofrequency ablation (RFA) of small renal carcinoma D. Breen¹, B. Stedman¹, E. Rutherford¹, J. Cast²; ¹*Southampton/UK*, ²*Hull/UK*

Purpose: Small renal tumours are increasingly found incidentally in elderly patients. This group often have significant co-morbidity and may be unsuitable for major surgery. RFA offers a less invasive therapeutic option. This study aims to assess the safety, efficacy and medium term outcome of RFA in the management of small RCC.

Method and Materials: 41 patients (mean age 76.8 yrs, range 54-89) underwent RFA of 45 tumours (mean 3.5, range 1.5-6.8 cm) between November 1999-2004. 46 treatment sessions were performed, 32 under intravenous sedation and 14 under GA. Treatments lasted 12 to 24 minutes and were ultrasound (31) or CT (15)-guided. All patients were followed clinically, biochemically and with 6 monthly CT.

Results: Complete tumour necrosis was seen in 38 of the 45 tumours. Five tumours required further CT guided treatment for residual viable crescents of tumour. Two elderly patients (87, 88 years) have been treated conservatively despite traces of tumour on follow-up CT. Only minor complications have been identified. Self limiting macroscopic haematuria was seen with a large central tumour. No significant rise in mean serum creatinine has been noted (mean rise 5.8 mmol). One patient with VHL syndrome had 4 tumours treated in a solitary kidney with complete response, however metachronous nodules developed during follow-up and she died of metastatic renal carcinoma. Follow-up (mean 14.8 months, range 1-58 months) revealed no evidence of local or distant recurrence in 38 of 41 patients.

Conclusion: Medium term experience suggests RFA is a safe, well tolerated and minimally invasive therapy for small renal tumours.

The early results of transhepatic hemodialysis catheters

C. Andic, S. Yilmaz, T. Sindel, E. Lüleci; *Antalya/TR*

Purpose: To assess the early results of transhepatic hemodialysis catheter placement in patients who have exhausted traditional sites of venous access.

Materials and Methods: Nine patients (seven men and two women aged 35-77 years; mean age, 56 years) underwent placement of 11 transhepatic hemodialysis catheters. Transhepatic catheters were placed in the absence of an available peripheral venous site (3 patients) or for preservation of the single remaining venous site for arteriovenous fistula and arteriovenous graft (6 patients). Patient follow-up was performed by reviewing dialysis records and maintaining communication between the patients and the radiologist.

Results: Technical success was achieved in all patients. The mean time of the catheters in situ was 34.6 days (range, 1-67 days). Because of catheter tip dislocation, two patients required catheter repositioning to achieve optimal blood flow in hemodialysis. Two patients required catheter exchange because of early device failure. There were three complications in the 11 catheter placements (%27.3) in 9 patients including unilateral (right) hemothorax (1 patient), venous-biliary-peritoneal fistula (1 patient) and massive intraperitoneal hemorrhage (1 patient). Catheters were removed after maturation of a functioning arteriovenous fistula (3 patients) and because of the complications (3 patients). One catheter dislodged prematurely due to pulling of the catheter by patient. Two patients still had functioning catheters in 42nd and 63rd days when this manuscript was submitted.

Conclusions: Despite the limited available literature and complications risks of the procedure, transhepatic hemodialysis catheters offer a viable option to patients who have exhausted traditional sites of venous access.

B-870 10:39

Treatment of renal cystic diseases: Use of minocycline hydrochloride as soft sclerosing agent

F.M. Danza, V. Marino, A. Magistrelli, A. Bernardini, S. Costanzi, E. Bock, L. Bonomo; *Rome/IT*

Purpose: To describe percutaneous treatment of renal cystic diseases, using a new sclerosing agent permitting a procedure with lower discomfort for patients and better handling for the operator.

Methods and Materials: 62 patients (54 simple cysts, 8 autosomic polycystic renal disease [APRD]) were treated with this soft method instead of classic alcoholization. After percutaneous extraction of half content of the cyst, a solution of minocycline hydrochloride (1 mg per ml of native volume of cyst) was introduced and left into the cavity (single-shot technique). For the absence of effects on excretory system of the sclerosing agent a previous opacification of cystic lumen is not required. Follow-up was performed at 3, 6, 9 and 12 month after treatment.

Results: In simple cyst the treatment was successful in 90% at 6 months (volume reduction over 50%). In 10% of cases a retreatment was needed, with a total success rate of 100%. No recurrence was noted. In APRD a significative reduction in renal volume was obtained, while no definitive signs of improvement of renal function or hypertension are demonstrated.

Conclusion: This method is superior to alcoholization: the discomfort for patient is minimal, results are better, without risks in accidental extravasation. The procedure is rapid and less expensive (catheter set not required). For simple cysts the method is superior to alcoholization. The application of this new kind of sclerosis in APRD has a promising, low cost role in reducing abdominal volume, but bigger experience and longer follow-up is needed.

Scientific Sessions

B-871 10:48

Partial endovascular embolisation of thyroid gland: Initial experience

K. Brzozowski, P. Zukowski, B. Jaron, P. Twarkowski; Warsaw/PL

Purposes: We have three current therapies for patients with hyperthyroidism: antithyroid drugs, radioiodine and surgery treatment, but it is exist a group of patients who cannot use these therapies. In this study we check the partial embolisation of thyroid gland as an alternative for patient who tolerate current therapies.

Material and Methods: Between January 2004 to August 2004 we perform partial embolisation of thyroid gland in six patients with hyperthyroidism. First we performed selective arteriography for evaluate the blood supply of thyroid gland and next we embolized two or three thyroid arteries by means of mixture of histoacryl and lipiodol. Next we use post embolisation angiography to evaluate the affectivity of embolisation.

Results: At the end of the follow-up period all six patients were euthyroid and the size of thyroid gland had decreased. We have no complication.

Conclusion: The clinical follow-up after embolisation suggest that this procedure is an effective, minimally invasive and safe method for the treatment for patients with hyperthyroidism.

B-872 10:57

Pregnancy outcome following uterine artery embolisation

W.J. Walker, T.T. Carpenter; Guildford/UK

Purpose: We present pregnancy course and outcome of 45 pregnancies in 37 women following Uterine Artery Embolisation. This being the largest reported series world wide of pregnancy post Uterine Artery Embolisation.

Materials and Methods: Cases identified by screening questionnaires and database, direct conversation and hospital delivery notes.

Results: 25 Live births, 5 Ongoing pregnancies (all past 2nd trimester), 2 Terminations, 10 Miscarriages, 1 Ectopic Pregnancy, 1 - 33 week still birth (True Knot in Cord), Uterine Volume on ongoing and successful pre-pregnancies varied from 59.95 cc - 1808.4 cc, 24 Successful deliveries after 24 weeks gestation, 18 by Caesarean section, Pre-term delivery rate 5/25 (20%), 2 Successful pregnancies complicated by bleeding first trimester, 2 Cases proteinuric hypertension, 2 Cases pre-term spontaneous rupture of membranes, 3 Cases primary post partum haemorrhage, Mean birth weight term babies 3.256 kg, One case of fetal growth restriction, Updated demographic and more detailed complication data will be presented.

Conclusion: When demographics of patient population in question is considered there does not appear to be an obvious excessive obstetric risk following Fibroid Embolisation.

B-873 11:06

Transcather embolization of male varicocele with Fibro-Vein mousse infusion: Experience with 260 patients

R. Gandini, V. Pipitone, M. Chiocchi, C. Reale, D. Konda, G. Simonetti; Rome/IT

Purpose: The aim of the study was to evaluate efficacy and safety of the Fibro-Vein mousse in the treatment of male varicocele.

Materials and Methods: From January 2000 to March 2004, 260 patients (mean age: 28.2 years; range 15-44) were treated by sclerotherapy of the pampiniform plexus venous dilatation. All patients had infertility, pain or both; the diagnosis was routinely obtained by physical examination and Doppler ultrasound. Phlebography was performed under local anesthesia with access through the basilic vein using 4 Fr Simmons II catheter. In all patients embolization was performed with mousse of Fibro-Vein 3% and air (ratio 1:4). Follow-up was routinely performed by Doppler ultrasound and clinical examinations.

Results: A technical success was obtained in all but 26 patients (10%); of the 73 patients (28.1%) with infertility 34 (46.6%) became again fertile; of the 153 (58.8%) patients with pain 132 (86.3%) had pain relief, of the 34 (13.1%) patients with pain and infertility, 27 (79.4%) had a pain relief and improvement of sperm count alteration, while 7 (20.6%) patients had relief of pain but still sperm count alteration.

Conclusion: Male varicocele treatment by Fibro-Vein mousse and air is safe and very effective technique that allows an easy pampiniform plexus sclerotherapy.

B-874 11:15

Bulbar urethral strictures treated with allium temporary covered stents:

First clinical experience

Z. Markovic¹, B. Markovic¹, D. Yachia², R. Levy², H. Maksimovic¹, O. Vojvodic¹; ¹Belgrade/YU, ²Hadera/IL

In August and October 2003, a new generation of urethral stents ALLIUM, produced in Israel, were inserted in 18 patients with chronic stricture of bulbar urethra. The indications for insertion were determined according to well-known and recognized therapeutic protocols. The stent is made of nitinol wire with polyurethane cover. Stent inserted under local anesthesia by a special self-expandable system that may be fixed or flexible. The stents are available in three lengths. Radioscopically-assisted insertion was performed over formerly placed metal guide. Balloon-catheter dilatation of stricture matching the stent width was carried out. Preinsertion urethrotomy was performed in one case. The insertion technique is simple presupposing the knowledge of interventional radiology and endoscopic urology techniques. The check-up was done according to a priori established protocol. Due to stent migration, the "stent over stent" technique was applied in one case, while reposition by balloon-catheter upward traction was performed in two cases of caudal migration. No irritative discomfort was reported in the first 4 months after stent dwelling. Uroflowmetric control verified at least four times better results than before the insertion. On behalf of flexibility, low radial force and conical shape of the posterior part of stent, no lesion of the external urethral sphincter were manifested. The stents withdrawn after 6-12 months by outward traction using the forceps. The first clinical experience are very favorable and ALLIUM stent may be expected to be the stent of choice for chronic bulbar strictures.

B-875 11:24

MR-guided galvano-therapy in patients with prostate cancer: Technique and first clinical results

S. Zangos¹, H. Mayer², F. Mayer¹, A. Wetter¹, K. Eichler¹, M.G. Mack¹, W. Schwarz¹, T.J. Vogl¹; ¹Frankfurt a. Main/DE, ²Regensburg/DE

Purpose: To examine the feasibility of MR-guided galvano-therapy (electrochemical treatment) in patients with prostate cancer.

Material and Methods: Sixteen patients (mean age 72 years) with histological proven prostate cancer were prospectively treated with galvano-therapy. Two MR compatible electrodes were positioned in the prostate under MR guidance with a transgluteal approach in an low field MR imaging-system (0.2 T, MR Concerto, Siemens). A maximum of 350 coulomb was applied with 3 treatments and an interval of 1 week. Follow-up was performed 3, 6 and 12 months with clinical examination, PSA values and MR-spectroscopy.

Results: The treatment was well tolerated by all patients. After the treatment 9 patients had a reversible urinary dysfunction and in 3 patients a hematuria emergent. One patient developed a prostatitis which had to be treated with antibiotics. In 9 patients a stable disease and in 2 patients a response could be observed in the follow-up. In 3 cases no success could be achieved. 3 patients died in the course of follow-up, whose dead could not be attributed to the prostate cancer or the treatment.

Conclusion: MR-guided galvano-therapy of the prostate gland is considered as a new and promising treatment option for prostate cancer.

Early experience with the self-expanding plastic stent (Polyflex) in oesophageal cancer

F.G. Irani, J.P. Morales, T. Sabharwal, R. Salter, R. Dourado, A. Adam; London/UK

Purpose: To present our early experience with the use of self-expanding plastic endoprosthesis (retrievable) in oesophageal cancer.

Material and Methods: A total of six stents (Polyflex) were placed in six patients (3 male, 3 female), mean age 64 years (range 48-77). Five had oesophageal cancer and required weight gain before surgical intervention. The remaining patient had a malignant fistula between the airway and the oesophagus. Stents were deployed using radiological guidance and conscious sedation in the interventional suite.

Results: In all patients successful deployment of stents was achieved (100%). No case of stent migration was noted. No major complications were seen. All the patients booked for surgical treatment improved their quality of life and dysphagia score at least in 1 grade. Weight gained was satisfactory prior to surgery. Immediate exclusion of the fistula was observed in the patient with the tracheo-oesophageal fistula.

Scientific Sessions

Conclusion: Our early experience would suggest that the use of the new self-expanding plastic stent is a feasible and safe option in palliative treatment for weight gain while awaiting surgery. Furthermore, the Polyflex should be considered a good option for the management of tracheo-oesophageal fistulae, and would also be suitable for use in refractory benign oesophageal strictures.

B-877 11:42

Human growth factor (HGF) evaluation before liver intervention:

A prognostic significance for liver regeneration

T. Lehnert, A. Gazis, A. Wetter, S. Zangos, R. Hammerstingl, A. Thalhammer, W.-O. Bechstein, T.J. Vogl; *Frankfurt a. Main/DE*

Purpose: To evaluate and compare the complexity of liver regeneration in correlation with the regeneration factor HGF, post liver resection and MR-guided laser induced thermotherapy (LITT).

Material and Methods: 40 patients were evaluated, 21 patients post surgical liver intervention and 19 patients post ablation (LITT). During a subsequent monitoring period of 12 months the effects of therapy on the cytokine HGF were evaluated and compared to the initial, pre-interventional HGF value. In addition, the effects on liver volume after surgical and interventional radiological procedure was evaluated using unenhanced and contrast enhanced MR imaging and CT. Volumetric examination (CT-volumetry) of liver parenchyma pre and post intervention was accomplished and the dynamics of liver regeneration and regional growth of liver segments were evaluated.

Results: A significant influence on the HGF process could be confirmed on loss of liver parenchyma resulting from surgery or LITT induction. Pre-interventional HGF-values < 1500 pg/ml (n = 23) led to a significant increase of liver volume (115-584 ml). Patients with initial HGF-values > 2000 pg/ml (n = 11) showed a decrease of liver volume (5-409 ml) after intervention. Pre-interventional HGF-values between 1501 pg/ml and 1999 pg/ml (n = 6) showed no definite reaction of liver parenchyma. All patients younger than 55 years showed stronger dynamics than 55+ year old patients.

Conclusion: Human growth factor (HGF)-value, pre-interventional, has a significant impact on the liver regeneration post MR-guided laser induced thermotherapy (LITT) and surgical resection. Pre-interventional low HGF-values correlate with increased liver regeneration and stronger regeneration dynamics.

B-878 11:51

Laser-induced thermal ablation of lung metastases: CT findings in a follow-up study

N. Hosten, C. Rosenberg, C. Weigel; *Greifswald/DE*

Purpose: Laser-induced thermal ablation of pulmonary metastases is a new option in multimodal cancer therapy. Preliminary results from patients of an ongoing study are presented.

Materials and Methods: 45 lesions in 34 patients were treated (CT fluoroscopy, Monocath 5.5 F water-cooled applicator, MeoMedical, Germany; maximal 14 W for up to 15 min, 1 to 3 applicators per lesion). Different primaries, mainly colorectal carcinomas (12 / 34 patients), had caused metastatic disease. Lesion size ranged from 6 to 64 mm, median 22 mm. Follow-up CT was performed the first 3 months each, then all 3 and 6 months, respectively. Median follow-up was 6 months (1 to 52 months).

Results: Ablative therapy was technically successful in 43 / 45 patients. In 5 cases therapy was completed after 2, in 3 cases after 3 sessions. An initial increase in size of the visualized correlate was seen in 13 cases, secondary cavity in 5 cases. 26 patients showed marked size reduction of the imaging correlate in further follow-up. These patients were diagnosed successfully treated. Residual CT findings were ground-glass opacity or cystic defects. Consecutive pneumothoraces (47%) needed drainage in 9% of the cases, hemorrhage (22%) was self-limited in all cases. Complications showed no significant difference to diagnostic lung biopsies.

Conclusion: Laser-induced thermal ablation is a promising option in multimodal therapy of non-resectable lung metastases. First results show differences in feasibility correlated to localization of the targeted lesion. Therapy success evaluation demands an interval of at least three months.

Nephrotoxicity after renal arteriography with "low" and "iso-osmolar" iodine and gadolinium contrast media (CM) in an experimental model

B.A. Elmståhl, U. Nyman, P. Leander, K. Golman, T. Almén, R. Pehrson, C.-M. Chai; *Malmö/SE*

Purpose: To compare the nephrotoxic effect of the "iso-osmolar" CM iodixanol (150 and 320 mg I/mL), "low-osmolar" CM iopromide (150 mg I/mL) and two gadolinium CM, 0.5M gadodiamide and 1.0 M gadobutrol, in an ischemic porcine model.

Methods and Materials: Following left-sided nephrectomy each test solution was injected in 8 animals at a rate of 20 mL/min (dose 3 ml per kg) into the right renal artery distal to an occluding balloon at the start of a 10-minute period of ischemia. The plasma half-life elimination times of the CM one to three hours post-injection were used to compare the effects of the different test solutions on glomerular filtration rate. Longer half-life means lower GFR.

Results: The median plasma half-lives following injection were: Iodixanol 150 mgI/mL - 144, iodixanol 320 mg I/mL - 142, iopromide 150 mg I/mL - 138, 0.5M gadodiamide - 237 and 1.0 M gadobutrol - 1583 minutes.

Conclusion: The "iso-osmolar" CM iodixanol and "low-osmolar" iopromide appeared less nephrotoxic than the two gadolinium CM. According to this experimental study iodixanol 320 mg I/mL is the agent of choice for renal arteriography and/or angioplasty procedures resulting in a far better X-ray attenuation than the other agents.

B-880 10:39

Effects of intravenous iomeprol on common carotid and brachial artery blood flow and shear stress

S. Tamburini, C. Irace, D. Barresi, S. De Franceschi, A. Gnasso; *Catanzaro/IT*

Purpose: Radiographic iodinated contrast media (CM) induce vascular tone and blood flow alterations. To evaluate hemodynamic modifications induced by CM, we measured blood flow and shear stress in the common carotid and brachial artery before and after intravenous iomeprol injection.

Methods and Materials: Thirty consecutive outpatients referred to our department of radiology for a thoracic or abdominal spiral CT scan were enrolled. The monomeric low osmolality iomeprol (iomeron 350) was injected. Common carotid and brachial arteries were studied by ultrasound and internal diameter and flow velocities were measured online. All subjects underwent a venous blood withdrawal for blood viscosity evaluation. Blood flow (BF), Pulsatility Index (PI) and shear stress (SS) were calculated.

Results: In the common carotid artery, no variation in vascular parameters was found. In the brachial artery, BF was significantly reduced (0.9 ± 0.4 vs. 0.6 ± 0.3 mL/s $p < 0.0001$) as well as SS (41.5 ± 13.9 vs. 35.3 ± 11.0 dynes/cm 2 $p < 0.002$), whereas PI significantly increased (5.0 ± 3.3 vs. 7.5 ± 5.3 $p < 0.001$).

Conclusion: The main finding of our study is that the intravenous injection of iomeprol causes a reduction in BF and SS at least in the brachial artery, but not in the common carotid artery. PI, a measure of peripheral vascular resistance, increases in the brachial artery and its change is related to BF. These modifications might be the consequence of the rigidification of erythrocytes following CM injection. Alternatively, endothelin release induced by CM, as described at renal level, might cause vasoconstriction of the small vessels distal to the brachial artery.

B-881 10:48

Contrast media inhibits oxygen consumption in proximal tubular cells from diabetic rats by inducing nitric oxide release

F. Palm, P.-O. Carlsson, A. Fasching, P. Hansell, P. Liss; *Uppsala/SE*

Purpose: Injection of iodinated contrast media (CM) is associated with increased risk for progressive renal dysfunction in diabetic subjects. The exact mechanism

Scientific Sessions

mediating the nephropathy is not known, but earlier studies have proposed alterations in the renal oxygen metabolism as a potential mediator. In this study, we compared the effect of ipromide on the oxygen consumption in isolated renal proximal tubular cells from normal and streptozotocin-induced (STZ)-diabetic rats. The involvement of nitric oxide (NO) was also studied, since the molecule interferes with oxygen consumption.

Methods and Materials: Renal proximal tubular cells were isolated from healthy and STZ-induced diabetic Sprague-Dawley rats weighing approximately 300 g. The in vitro oxygen consumption was measured in a sealed chamber. The influence of CM-induced NO-release was evaluated by pretreating the cells with the NO synthase inhibitor L-NAME.

Results: Iopromide decreased the oxygen consumption in the cells isolated from the diabetic animals, while no effect was seen in the cells from healthy normoglycaemic animals. Pretreatment of the cells obtained from diabetic animals with L-NAME did not effect the baseline oxygen consumption per se, but prevented the CM-induced decrease in oxygen consumption.

Conclusions: These observations suggest that CM selectively in renal tubular cells from diabetic subjects induce release of NO, which inhibits the cellular oxygen consumption. The consequence of intracellular ATP depletion in CM-induced nephropathy during diabetes remains to be established.

B-882 10:57

Evaluating the risk of contrast medium (CM) induced nephropathy (CIN) in relation to gram iodine dose and estimated glomerular filtration rate (eGFR)

U. Nyman¹, T. Almén², P. Aspelin³, M. Hellström⁴; ¹Trelleborg/SE, ²Malmö/SE,

³Stockholm/SE, ⁴Gothenburg/SE

Purpose: To make a preliminary meta-analysis of the risk of CIN in relation to CM-dose expressed as gram iodine (I) instead of simply volume and renal function as eGFR based on serum-creatinine (sCr), sex and weight instead of sCr alone.

Methods and Materials: A Medline search of reports containing definitions and frequencies of CIN, mean eGFR, mean dose of low-osmolality CM and using hydration as only prophylaxis identified ten randomised controlled trials and two cohort investigations, exclusively coronary examinations. The ratio "gram iodine/eGFR" (gram/mL x·min⁻¹) was correlated with the frequency of 1) unspecified CIN defined as rise of sCr of $\geq 44.2 \text{ } \mu\text{mol/L}$ or $\geq 25\%$ and 2) severe CIN defined as oliguria or need of dialysis.

Results: The linear correlation coefficient between the risk of CIN and the ratio "gram I-dose/eGFR" was 0.91 according to definition (1) and 0.84 according to definition (2). At a 1:1 ratio "gram I-dose/eGFR" the regression line indicated a 10% risk of unspecified CIN and a 1.5% risk of severe CIN. At a 3:1 ratio "gram I-dose/eGFR" the risk of unspecified and severe CIN increased to about 50% and 15%, respectively.

Conclusion: The ratio "gram iodine-dose/eGFR" may be an expedient way to predict the risk of CIN. Further studies are needed to define the safety of various ratios in relation to type of examination, type of CM, various risk factors and to reveal a possible exponential relation between CM dose, eGFR and the risk of CIN.

B-883 11:06

Development of water-soluble metallofullerenes as X-ray contrast media

A. Miyamoto, Y. Shibamoto, H. Okimoto, H. Shinohara; Nagoya/JP

Purpose: Although iodinated contrast media are very useful in diagnostic imaging, they can induce various side effects including allergic reaction. With the expectation to reduce the adverse effects, we tried to apply nanotechnology (especially, use of fullerene) to X-ray contrast media. Fullerenes have attracted much attention for various possibilities in recent years. We investigated whether fullerenes containing one or two atoms of heavy metals could be X-ray contrast media. By capsulating heavy metals in fullerene, it was expected to produce little side effects intrinsic to heavy metals.

Methods and Materials: Heavy metal atoms, such as Gd, Er and Eu were encapsulated into fullerene (C_{60}) and synthesized as polyhydroxyl forms ($Gd@C_{60}(OH)_n$, $n = 40$, Gd-fullerenols). They were dissolved in water at a maximum soluble concentration and subjected to CT number analysis. The CT numbers of the solutions were measured using a 16-row multidetector CT scanner. **Results:** The CT number of water-soluble metallofullerenes were 56.0 HU for $Gd@C_{60}(OH)_{40}$, 111.5 HU for $Er@C_{60}(OH)_{40}$, 100.9 HU for $Eu@C_{60}(OH)_{40}$ and 23.3 HU for $Gd_2@C_{60}(OH)_{40}$.

Conclusion: The CT numbers of the water-soluble metallofullerenes investigated in the present study were not high enough to be used clinically in place of iodinated contrast materials. However, if nanotechnology progresses in the near future, it may prove to have a possibility as an X-ray contrast material with little adverse effect.

B-884 11:15

Automatic injectors in magnetic resonance and computed tomography:

Pilot study on hygienic aspects

B. Buerke, A.-K. Sonntag, R. Fischbach, W. Heindel, B. Tombach; Münster/DE

Purpose: To evaluate hygienic conditions using automatic injectors in magnetic resonance (MR) and computed tomography (CT) during clinical routine.

Methods and Materials: Microbiological analysis of the surfaces of medical devices (e.g. control console) and the palm of technical and medical staff were performed by imprint before and after hygiene education. In addition, the microbiological contamination of spikes for contrast medium (CM) and saline following multiple (MR 14 h; CT 8 h) and single use and the potential of retrograde contamination along the tube by the patient were analysed separately.

Results: A bacterial contamination with typical dermal bacteria was documented for the analysed surfaces of medical devices, the palm of technical and medical staff and injections spikes following multiple use (MR: 10/10 CM spikes, 6/10 saline spikes; CT: 8/10 CM spikes, 5/10 saline spikes). Correct hand disinfection in combination with single use of spikes avoids bacterial colonization. Retrograde bacterial contamination from the patient was not observed.

Conclusion: Recurrent hygiene teaching sessions for technical and medical staff in MR and CT departments using automatic injectors are a matter of urgent necessity. Furthermore, multiple use of spikes has to be avoided until dedicated investigations on the potential of hygienical contamination of spikes in multiple clinical use according to time are performed.

B-885 11:24

High-concentration iomeprol in CT angiography: Aortic enhancement in anaesthetised swines

A. Napoli¹, C. Catalano¹, V. Lorusso², A. Morisetti², P.G. Nardis¹, F.A. Calabrese¹, R. Passariello¹; ¹Rome/IT, ²Milan/IT

Purpose: Iomeron® is a commercially available solution of iomeprol. Its highest marketed concentration is 400 mg iodine(I)/mL. However, it can be formulated in even more concentrated solutions. After positive cardiovascular safety assessment in rabbits, we tested the efficacy of a 500 mg (iodine)/mL formulation in a CT study in swines.

Material and Methods: Iomeprol formulations at 500 and 350 mg (iodine)/mL (Bracco SpA, Milan Italy) were injected at 3 mL/s in 8 female anaesthetised pigs (60-90 kg bw) at a dose of 0.5 g (iodine)/kg in a cross-over study design (at least 6 h elapsed time between the two administrations). CT examination (General Electric, HiSpeed DX) was performed with dynamic scans, starting 8 s after contrast medium administration; images were acquired every 3 s for 120 s. Each animal received 1 mL/kg of 500, and 1.43 mL/kg at 350 mgI/mL.

Results: Mean injected volume was 75 mL (60-86 mL range) for 500 and 107 mL (range 85-125) for 350 mgI/mL formulation. Mean aortic attenuation values achieved during 500 mgI/mL administration, across the arterial phase was significantly greater ($p < 0.03$) than that achieved during 350 contrast medium administration. Plotting enhancement over time, tests showed a contrast medium dynamic profile with a higher (mean arterial magnitude > 70 HU) and earlier arterial peak with iomeprol 500.

Conclusion: Iomeprol 500 favourably compares with lower concentrations, eliciting substantial HU enhancement, even in a small study population. Particularly, higher and earlier arterial peaks are promising features for small arterial imaging. Nevertheless, a further investigation with a larger study group is necessary.

B-886 11:33

Effect of iodine flow rate on parenchymal and vascular enhancement during contrast enhanced multiphasic abdominal multidetector row CT

H. Schoellnast, P. Brader, B. Georgieva, B. Oberdabernig, H.A. Deutschmann, M. Tillich; Graz/AT

Purpose: To assess the influence of iodine flow concentration on parenchymal and vascular enhancement during multiphasic abdominal multi-detector row CT (MDCT).

Methods and Materials: Fifteen patients underwent multiphasic abdominal MDCT with standard (group A) as well as with high concentration contrast media (group B) (paired study group), and 90 patients underwent abdominal MDCT either with standard (group A) or with high concentration contrast media (group B) (unpaired study group). In group A, 1.5 mL standard contrast media (300 mgI/ml) per kg was injected with a flow rate of 4 ml/sec while in group B 1.1 mL high concentration contrast media (400 mgI/mL) per kg was injected with the same flow rate. Measurements were performed for all groups in liver, spleen, pancreas, portal vein, inferior vena cava and abdominal aorta to compare enhancement.

Scientific Sessions

Results: Patients of group B showed higher aortal and pancreatic enhancement during the arterial phase than patients of group A. The mean difference in aortal enhancement was 60 HU in the paired and 70 HU in the unpaired study group ($p < 0.01$). The mean difference in pancreatic enhancement was 10 HU in the paired and 17 HU in the unpaired study group ($p < 0.05$ and $p < 0.01$, respectively). During the portal venous and hepatic venous phase no significant difference in parenchymal and vascular enhancement was observed between group A and B ($p > 0.05$).

Conclusion: A high iodine flow rate improves enhancement of the aorta and the pancreas during the arterial phase of multiphasic abdominal MDCT but does not influence later phases.

B-887 11:42

Influence of iodine flow concentration on vessel attenuation and visualization in multi-detector row CT angiography of the pulmonary arteries

H. Schoellnast, H.A. Deutschmann, G.A. Fritz, U. Stessel, G.J. Schaffler, M. Tillich; Graz/AT

Purpose: To assess the influence of iodine flow concentration on attenuation and visualization of the pulmonary arteries in thoracic multi-detector row CT angiography (MDCTA).

Methods and Materials: One hundred consecutive patients who were referred to our department with suspected acute pulmonary embolism underwent multi-detector row CTA of the pulmonary arteries either with 120 mL standard contrast media (300 mgI/mL) (group A) or with 90 mL high concentration contrast media (400 mgI/mL) (group B). The contrast media was injected with a flow rate of 4 mL/sec. The scan delay was determined using semiautomatic bolus tracking system in all examinations conducted with the same scanning parameters. Quantitative analysis was performed by region of interest measurements along the z-axis to compare the attenuation profile of both groups. Visual analysis of the attenuation of the fourth, fifth and sixth order arteries was performed to assess the difference in visualization of peripheral arteries between both groups.

Results: The mean enhancement along the z-axis was 268 ± 56 HU in group A and 344 ± 108 in group B. The difference of 77 HU was statistically significant ($p < 0.001$). The attenuation profile was similar in both groups. The detection rate of fifth and sixth order arteries was significantly higher in group B than in group A (94% compared to 91% and 72% compared to 60%, respectively, $p < 0.01$).

Conclusions: MDCTA of the pulmonary arteries with a high iodine flow concentration significantly increases the attenuation of the pulmonary arteries, thereby leading to an improved visualization of subsegmental pulmonary arteries.

B-888 11:51

Initial experience with the Artis dTA flat panel detector (FD) C-arm system: Optimizing hepatic contrast medium (CM) delivery

J.C. Hellinger, R. Fahrig, N. Strobel, D. Fleischmann, G. Glazer; Stanford, CA/US

Purpose: Three dimensional (3D) C-arm Computed Tomographic (CT) systems combine two dimensional (2D) angiographic imaging and 3D CT visualization. Streaming artifact can produce inhomogenous CT enhancement. The purpose of this work is to determine injection parameters which may be sufficient to overcome streaming artifact in the liver.

Methods and Materials: In a 36 kg porcine model, the common hepatic artery was selected using a Simmons 3 end-hole angiographic catheter. Conray 60(270 mgI/cc) was injected intra-arterially and angiographic (30 sec rotational acquisition, 70 kVp, 190 views) and CT (0.42 mm slice thickness) images were acquired with the FD system. Injection parameters included 1 cc/sec, 2 cc/sec and 3 cc/sec at 100% concentration and 4 cc/sec at 50% concentration. Image quality, enhancement values and signal to noise ratios (SNR) were recorded in right and left hepatic arteries as well as central and peripheral segmental arteries.

Results: Subjective image quality was highest with 3 cc/sec and 4 cc/sec injections. At 1 cc/sec, overall SNR was greater in right hepatic arteries as compared to the left (8 ± 4.6 vs 6 ± 2.7). Differential enhancement was observed in the right anterior (7 ± 4) and posterior segments (6 ± 2.8). Central SNR (7 ± 1.7) was greater than peripheral SNR (3 ± 1.3). 4 cc/sec injections at 50% concentration produced the greatest homogeneity for right (6 ± 3.0) and left (6 ± 2.4) lobes. Both 3 cc/sec and 4 cc/sec injections achieved more homogeneous SNR in right segmental anatomy. At 100% concentration, progressive increase in peripheral SNR was achieved with 2 cc/sec and 3 cc/sec injections.

Conclusion: With 3D C-arm CT systems, faster injection rates produce more homogenous vascular enhancement. At higher flow rates, lowering iodine concentrations can reduce the delivered iodine content without diminishing image quality.

Morphology of congenital diaphragmatic hernias studied with fetal MR imaging

P.C. Brugge, G.J. Kasprian, U. Rauhofer, D. Prayer; Vienna/AT

Purpose: To define morphology of congenital diaphragmatic hernias (CDH) using fetal magnetic resonance imaging (MRI).

Methods and Materials: 21 fetuses (19-39 gestational weeks) with ultrasound diagnosis of suspected CDH underwent 1-3 fetal MRI studies (total 31) on a 1.5 T magnet using a five-element phased-array surface coil and no sedation. Imaging protocols included T2-, T1-weighted and balanced-angiography sequences in different section planes.

Results: Fetal MRI identified two right-sided and 19 left-sided CDHs. In all left-sided CDHs the herniated content included stomach, small intestine and colon except for the descending and sigmoid. With the left colonic flexure in place, the course of the colon corresponded to the lateral extent of the defect. Meconium filling of the intrathoracic colon was variable. The extent of an intrathoracic left hepatic lobe (13/19) situated on the ventral thoracic wall was variable, and associated with more dorsally positioned stomach. The ipsilateral lung was recognizable in only 3/19 cases. Contralateral lung size corresponded to mediastinal shift which was more pronounced in cases with intrathoracic liver and associated with left heart compression. Real hernias presented with fluid beneath the pleural cupula, low-positioned colon, or lung within the dorsal costodiaphragmatic recess. Marked progression of the pathology was observed in one case. Associated malformations included isolated palatal cleft and CAM.

Conclusion: Detailed morphological description of CDH is possible with fetal MRI which may have a bearing on prognosis as MRI can also identify real hernias. Possible progression of the pathology underlines the importance of intrauterine follow-up.

Logistic regression analysis of mortality and necessity of ECMO therapy in fetuses with CDH based on MR imaging lung volume measurement

A.K. Kilian, E.M. Schütz, T. Schaible, C. Düber, K.W. Neff; Mannheim/DE

Purpose: To calculate mortality rate and necessity of extracorporeal membrane oxygenation therapy (ECMO) in patients with congenital diaphragmatic hernia (CDH) using logistic regression analysis based on MR imaging fetal lung volume (FLV) measurement.

Methods and Materials: 38 fetuses with CDH, diagnosed on ultrasound examination prior to 32 weeks gestation, underwent MR imaging FLV measurement (3D HASTE-imaging) within 34-36 weeks gestation. Based on logistic regression analysis, mortality and necessity of ECMO therapy was calculated by estimating the prenatal FLV in MR imaging. 18 healthy age-matched fetuses served as normal controls.

Results: Mean FLV of all fetuses with CDH was 20.5 ± 11.8 ml (range 5.1-41.6 ml). Mean FLV of controls was 77.7 ± 25.5 ml. Mortality decreases with increasing FLV from 80% for neonates with 7 ml prenatal FLV to 1% for children with 30 ml FLV. Higher FLV was associated with improved survival. Children with FLV of 5 ml show a mortality rate of 86% in comparison to FLV of 25 ml with a mortality of 4%. Similar results were found for the necessity of ECMO therapy. Probability of ECMO therapy decreases with increasing FLV from 80% with 8.3 ml FLV to 1% with 76.6 ml FLV. Children with FLV of 5 ml have a probability of ECMO therapy of 84% compared to FLV of 45 ml with only 14%.

Conclusion: Logistic regression analysis based on MR imaging fetal lung volume measurement is a potential predictor for clinical time course including mortality and necessity of ECMO therapy in children with CDH. High risk infants can be identified prenatally.

Scientific Sessions

Comparison between single and multidetector CT in the reduction of sedation rates, conventional angiograms, and patient motion artifacts in young children following liver transplantation

A.A. Lemos, J.M. Sternberg, F. Somalvico, F. Ferrari, M.M. Castelnovo, P.R. Biondetti; Milan/IT

Purpose: To determine whether the use of multidetector-row helical CT (MDCT) can decrease the need for sedation, the number of conventional angiograms and patient motion artifacts compared with single detector CT (SDCT) in young children after liver transplantation.

Methods and Material: Between January 1993 and March 2004, 126 young children underwent liver transplantation at our institution. For detection of post-operative complications, 84 of the 124 studies were performed by using SDCT with either a step and shoot or helical mode acquisition (group 1), whereas the remaining 42 studies were performed with a four array MDCT (group 2). The mean age was 3.2 years in group 1 (range 8 months-17 years) and 2.4 years in group 2 (range 17 months-12 years). We retrospectively reviewed sedation records, the number of conventional angiograms additionally required to confirm the diagnosis, and patient motion artifacts before and after the introduction of MDCT at our institution. Statistical comparison among the two groups was determined by using the Mantel-Haenszel Chi-square test.

Results: In group 1, 60.7% (51 of 84) patients required sedation and/or catheter angiography, whereas in group 2, 28.5% (12 of 42) required sedation and/or catheter angiography. Patient motion artifacts were present in eight cases in group 1, and in four cases in group 2. Regarding sedation rates and the number of conventional angiograms; there was a significant statistical difference ($p < 0.001$). No statistical difference was found regarding patient motion artifacts ($p > 1$).

Conclusion: Sedation rates and the number of conventional angiograms were significantly reduced with MDCT. A real reduction of patient motion artifacts should be evaluated in a larger number of patients.

B-892 10:57

Virtual colonography of the fetal colon

P.C. Brugger, C. Mittermayer, C.J. Herold, D. Prayer; Vienna/AT

Purpose: To evaluate the power of fetal magnetic resonance imaging (MRI) in assessing fetal colon anatomy and pathology with virtual colonography.

Methods and Materials: 130 fetuses from 19 to 39 gestational weeks (GW) were imaged on a 1.5 T magnet using a five-element phased-array coil and no sedation. A variety of T1-weighted sequences were acquired in frontal or sagittal planes and maximum intensity projections (MIP) and three dimensional reconstructions were made.

Results: All T1-weighted sequences selectively visualized the hyperintense meconium within the fetal colon from the 19th GW onwards. By the 24th GW the whole colon was meconium filled and MIPs allowed virtual colonography. The topography, flexures and parts of the fetal colon including the variable sigmoid can be identified. Hastra became apparent with advancing age. Considerable variation in the total amount of meconium was observed in fetuses of comparable ages. The normal development could be followed *in vivo*, and colon pathologies (malrotation, congenital diaphragmatic hernias, atresia) were easily recognized. Due to the large field of view the whole colon (and terminal ileum) may be visualized in the frontal plane even in larger fetuses.

Conclusion: Using meconium as a natural contrast media, virtual fetal colonography is possible with fetal MRI. This method offers great potential in the prenatal diagnosis of colon pathologies and postnatal management. In addition to morphology, the pattern of meconium distribution within the fetal colon and small intestine may provide further clues to the location of intestinal stenosis or atresia.

B-893 11:06

Investigation of normal renal development with fetal magnetic resonance imaging

L. Witzani, M. Hoermann, G. Kasprian, C. Balassy, P. Brugger, D. Prayer; Vienna/AT

Purpose: Understanding urinary tract development is essential for the early detection of its abnormalities. Hence the aim of this study is to investigate the development of the normal fetal kidney with magnetic resonance imaging (MRI).

Methods and Materials: 426 fetal MRI examinations were carried out, 33 were excluded because abnormalities of the kidneys were detected and therefore a total of 393 examinations were evaluated between the 16th and the 39th gestational weeks. T2 weighted scouts in axial, coronal and sagittal planes were obtained on a 1.5 T superconducting unit using a phased array coil. Imaging protocol included

T2 weighted SSFSE, T2 weighted balanced angiography and diffusion weighted sequences. Renal size, signal intensity, lobulation, differentiation of the collecting system and function by means of signal intensity on diffusion weighted images were assessed.

Results: The mean length of the kidneys correlated well with gestational age and ranged from 13 to 45 mm. Lobulation was already detectable in the 16th gestational week. The collecting system appeared hyperintense on T2 weighted images from the 16th week. Renal parenchyma showed intermediate signal on T2 weighted images. The kidneys were hyperintense on diffusion weighted imaging during the course of pregnancy, suggesting normal renal function.

Conclusion: Fetal MRI appears to be an excellent tool in the assessment of morphological development of the kidneys and can provide information about intrauterine renal function, which is of great clinical importance in the early detection of abnormalities of the urinary tract.

B-894 11:15

Voiding urosonography combined with fluoroscopic voiding cystourethrography in the diagnosis of reflux: Does the order matter?

J. Tzovara, F. Papadopoulou, A. Anthopoulou, E. Siomou, E. Arkoumani, S. Efremidis; Ioannina/GR

Purpose: Diagnostic imaging for vesicoureteral reflux (VUR) in children includes both fluoroscopic voiding cystourethrography (VCUG) and contrast-enhanced voiding urosonography with harmonic imaging (CE VUS HI). Many studies have shown a higher sensitivity for VUS compared to VCUG. Some investigators however, argue that this might be due to that VUS usually precedes VCUG when performed at the same session. The purpose of our study is to assess if the order of the examination affects the detection of VUR.

Methods and Materials: Two hundred and two children with 402 kidney-ureter-units (KUU) of mean age 2.7 years were prospectively studied for possible VUR. In all children VUS with 1-2 ml of a 2nd generation contrast agent (sulfur-hexafluoride microbubbles, SonoVue, Bracco, Italy) and VCUG with the standard technique were performed. In group A (108 children, 214 KUU) VCUG preceded VUS, while in group B (94 children, 188 KUU), the sequence was reversed. McNemar test was used for statistical analysis.

Results: In group A VUS and VCUG revealed VUR in 65(30.4%) and 41(19.2%) KUU respectively. In group B VUS and VCUG depicted 75(39.9%) and 43(22.8%) refluxing KUU respectively. Concordance of findings regarding the presence of VUR between VUS and VCUG was found in group A in 179/214(83.6%) KUU and in group B in 154/188(81.9%) KUU, ($p = 0.48$). In group A VUS depicted 29/70(41.4%) more refluxing KUU and missed 5/70(0.07%) compared to VCUG. In group B VUS disclosed VUR in 33/76(43.4%) more KUU and missed 1/76(0.01) refluxing KUU. No significant difference was found between group A and B in the detection of VUR by the two modalities.

Conclusion: The order of the examination does not influence the detection of VUR by VUS and VCUG.

B-895 11:24

Voiding urosonography harmonic imaging with 2nd generation contrast agent for the diagnosis of reflux

F. Papadopoulou, J. Tzovara, A. Anthopoulou, E. Siomou, E. Evaggelidou, S. Efremidis; Ioannina/GR

Purpose: Contrast enhanced voiding urosonography harmonic imaging (CE VUS HI) has been introduced recently as a sensitive method in both the diagnosis and follow-up of vesicoureteral reflux (VUR). The purpose of our study is to evaluate the reliability of CE VUS HI in the diagnosis of VUR using a 2nd generation contrast agent.

Methods and Materials: We evaluated 70 children (mean age: 2.2 years) with 137 kidney-ureter-units (KUU) -3 children had single kidneys- for possible VUR performing C-E VUS HI after introduction of 1-2 ml of sulfur-hexafluoride microbubbles (SonoVue, Bracco, Italy) using low mechanical index and Fluoroscopic Voiding Cystourethrography (VCUG) with the standard technique on the same session. For the statistical analysis we used Mc Nemar test.

Results: VUS and VCUG revealed VUR in 47/137 (34%) and 23/137 (17%) KUU respectively. Concordance in findings regarding the presence of reflux between VUS and VCUG was found in 113/137 (82.4%). VUR was detected only by VUS in 25 KUU (19 grade II, 6 grade III) and missed in only 1 KUU (grade I) which was detected by VCUG. Consequently, VUS disclosed VUR in 25 KUU out of the 48 refluxing KUU (52%). VUS upgraded reflux in 6 KUU compared to VCUG and VCUG in 5 compared to VUS. The difference in the detection rate of reflux between VUS and VCUG was statistically significant ($p = 0.000006$).

Conclusion: CE VUS HI with 2nd generation contrast medium has improved the diagnosis of VUR in children compared to VCUG.

Comparison of voiding urosonography harmonic imaging using 2nd generation contrast agent with direct radionuclide cystography for the diagnosis of reflux

A. Anthopoulou, A. Fotopoulos, J. Tzovara, J. Al Bokhrli, E. Siomou, I. Mantzios, F. Papadopoulou; Ioannina/GR

Purpose: The use of contrast-enhanced voiding urosonography harmonic imaging (CE VUS HI) for the diagnosis of vesicoureteral reflux (VUR) is gradually increasing. The purpose of this study is to determine the sensitivity of CE VUS HI using 2nd generation contrast agent in the diagnosis of VUR in children compared to direct radionuclide cystography (DRNC).

Methods and Materials: Twenty children (mean age: 3.3 years) with 41 kidney-ureter-units (KUU)-1 duplex kidney- were included in our prospective study for possible VUR, evaluated by CE VUS HI after introduction of 1-2 ml of sulfur-hexafluoride gas microbubbles (SonoVue, Bracco, Italy) using low mechanical index and DRNC using a maximum of 20 MBq of ^{99m}Tc DTPA. For the statistical analysis we used Mc Nemar test.

Results: VUS and DRNC detected VUR in 20/41 (49%) KUU and 11/41 (27%) KUU respectively. Concordance in findings regarding the presence of reflux between VUS and DRNC was found in 32/41 (78%). VUR was detected by VUS only in 9 out of the 20 (45%) refluxing KUU (8 grade II and 1 grade III). DRNC upgraded 1 KUU with grade I reflux into grade II. The difference in the detection rate of reflux was not significant ($p = 0.07$).

Conclusion: CE VUS HI with 2nd generation contrast medium has improved the diagnosis of VUR in children compared to DRNC. Our data seem to indicate a higher sensitivity of CE VUS HI compared to DRNC, although the number of our cases is still small.

B-897 11:42

Voiding cystourethrography versus low-dose contrast-enhanced harmonic voiding urosonography using the 2nd generation US contrast medium SonoVue

K. Darge, F. Schreiber, M. Beer, N. Gordjani, H. Riedmiller; Würzburg/DE

Purpose: To evaluate if low-dose contrast-enhanced voiding urosonography (VUS) using a 2nd generation US contrast medium (SonoVue®, Bracco, Italy) is comparable to voiding cystourethrography (VCUG).

Methods and Materials: In 40 patients (female = 30, male = 10; 1 month - 15 years), VUS was carried out. This comprised of a pre-contrast US of the urinary tract, catheterization of the bladder and administration of the US contrast medium, SonoVue®, at a volume of 1% of that of the bladder filling. This was followed by a repeat scan of the urinary tract including during voiding. The US study was conducted in fundamental and harmonic imaging modalities using a Sonoline Elegra® (Siemens, Germany) US machine. VCUG was subsequently performed in all patients.

Results: A total of 84 kidney-ureter units (4 duplex kidneys) were available for evaluation. In 25(30%) kidney-ureter units reflux was detected by one or both methods. In 76(90%) units the results were concordant. Discordance was present in 8(10%) kidney-ureter units as reflux was diagnosed in 5 and 3 units only with VUS and VCUG, respectively. Taking VCUG as the reference method the sensitivity and specificity of VUS were 85% and 92%, respectively.

Conclusion: The results of low-dose SonoVue® enhanced voiding urosonography point to a comparable diagnostic efficacy as that of VCUG. The volume of US contrast medium required for an examination is significantly less than that of the 1st generation US contrast medium, Levovist® (Schering, Berlin, Germany). This may bring about significant cost reduction for the examination.

B-898 11:51

Monitoring of Infliximab therapy in children with Crohn's disease (CD) with true-FISP MR-imaging

C. Hohl, M. Ahau, T. Schmidt, E. Berkemeier, R.W. Günther, G. Staatz; Aachen/DE

Purpose: Infliximab, as an Anti-TNF- α antibody agent, has been recently applied in children with severe CD. Because there is only little experience in treating children with Infliximab, short-term monitoring is essential. The purpose of our prospective study was to evaluate if true-FISP MR imaging is a suitable method for monitoring Infliximab therapy.

Materials and Methods: 5 children, aged 14-16 years, suffering from severe CD and not responding to corticosteroid therapy, were treated with Infliximab. Before and 1-2 weeks after Infliximab administration, all children underwent MR imaging of the small bowel on a 1.5-T-MR scanner. MR imaging was performed 1 hour

after 1 litre of a 2.5% Mannitol solution was given orally, with use of True-FISP sequences before and after i.v. contrast (Gd-DTPA) in coronal and axial planes. The activity of bowel inflammation was determined by assessment of bowel wall thickening and evaluation of extraintestinal inflammatory changes. The imaging findings were additionally correlated with the clinical symptoms of each child.

Results: True-FISP MR imaging enabled an excellent assessment of inflammatory activity in CD. 4 of 5 children showed a good response to Infliximab therapy with marked improvement of the inflammatory changes of the bowel wall and regression of extraintestinal inflammatory signs. The imaging findings of true-FISP MR imaging correlated well with the clinical findings and influenced the further therapeutic regimen.

Conclusion: True-FISP MR imaging of the small bowel enables short-term and precise monitoring of Infliximab therapy in children with CD.

CT angiography as a method of brain death confirmation

A. Pal, D. Ozretic, Z. Pavcec, H. Saghir, I. Zokalj, Z. Perhoc, B. Latin, M. Ozretic; Cakovec/HR

Purpose: After clinical diagnosis of brain death, Croatian legislature requires confirmation with one 'paraclinical' method (DSA, scintigraphy, TCD, evoked potentials, EEG). We explore the appropriateness of CT angiography, as a potential 'paraclinical' method.

Methods and Materials: From December 2002, 18 patients in coma after traumatic brain injury or nontraumatic SAH, aged 23-46, were evaluated as possible organ donors. Brain death was diagnosed according to clinical criteria (fixed dilated pupils, absence of bulbar reflexes, negative apnoea-test). Only 9 patients were later candidates for CT angiography. Exams were performed on single-slice scanner. An area from C1 to the lateral ventricle bodies was covered. Standard protocol was used: 100 mL of nonionic contrast medium (370 mg/mL) flow rate 4 mL/s, 1 mm slice thickness, pitch 1.5, scan delay up to 60 s. No visualization of great intracranial vessels and the absence of parenchymal attenuation increase after contrast administration due to cerebral circulatory arrest were criteria for brain death confirmation.

Results: In 7 patients there was no enhancement of vessels forming the Circle of Willis, and filling of ECAs and infracerebral ICAs was shown. In 2 patients there was slight enhancement of anterior circulation vessels (MCAs and ACAs) and in agreement with clinicians; exams were repeated 12 hours later when they were confirmatory. Eventually families allowed organ harvesting in 4 patients.

Conclusion: Rapid diagnosis of absence of intracranial arterial circulation is important for identification of potential organ donors. Results of CT angiography are comparable to other radiological 'paraclinical' methods, but further comparison studies are needed.

B-900 10:39

High resolution MR imaging of cervical artery dissection (CAD) at 3.0 T with a dedicated surface coil: New insights into the pathomorphology?

R. Bachmann¹, I. Nassenstein¹, H. Kooijman², H. Kugel¹, G. Kuhlenbaumer¹, S. Kraemer¹, W. Heindel¹; ¹Münster/DE, ²Hamburg/DE

Purpose: To assess in a prospective study the capability of high-resolution arterial vessel wall imaging at 3.0 T (HR-MRI) in pts with suspected CAD and to compare it to 1.5 T standard MRI.

Methods and Materials: 15 patients (5 m, 10 f, mean age 39 yrs) underwent cervical MRI at 1.5 T (T1w-TSE, T2w-TSE, CE-MRA) and HR-MRI at 3.0 T (Gyroscan Intera, Philips). HR-MRI was acquired using a phased array coil with four circular elements. HR-MRI-protocol consisted of: 1) bright blood 3D inflow MRA (TR/TE/FA = 25 ms/3.1 ms/16, 120 slices, reconstructed voxel size 0.3x0.3x0.8 mm); 2) black blood cardiac gated water selective T1w 3D spoiled GE (TR/TE/FA = 31 ms/7.7 ms/15, 36 slices, 0.3x0.3x1.0 mm); 3) black blood cardiac triggered fat suppressed T2w TSE (TR/TE/ETL = three heart beats/44 ms/7, 18 slices, 0.3x0.3x2 mm).

Scientific Sessions

Results: In 5 pts findings were normal at both studies. In 5 pts dissection diagnosed at 1.5-MRI was confirmed by HR-MRI. However, HR-MRI yielded much better delineation of internal and external vessel wall boundary and clearer distinction between intramural hematoma and thrombus. In 2 pts vessel occlusion was confirmed. In 2 pts an intramural hematoma was clearly visible at HR-MRI, not discernible at 1.5-MRI. In 1 pt a pseudoaneurysm of the vertebral artery was detected at HR-MRI, not visible at 1.5-MRI.

Conclusion: HR-MRI permitted excellent analysis of morphological features of CAD due to increased spatial resolution. Additional clinical relevant information could be gained in 3 pts. Thus, HR-MRI at 3.0 T is a promising tool for the assessment of vessel wall pathology in patients with CAD.

B-901 10:48

Comparison of stenosis quantification using 16-row MDCTA and contrast enhanced MRA in a phantom model simulating soft and calcified plaque material

K. Papke, K. Schliephake, M. Finke, M. Fruth, F. Brassel; Duisburg/DE

Purpose: To compare the precision of stenosis measurements using 16-row MDCTA and contrast enhanced MRA (ceMRA) in a phantom model simulating carotid artery disease with calcified and non-calcified stenoses.

Methods and Materials: 90 stenoses with lumens ranging from 0.5 to 2.5 mm were placed in tubes with a diameter of 5 mm, simulating stenoses from 50 to 90% according to the NASCET method. 45 stenoses consisted of PVC simulating calcified plaques, the other 45 of wax simulating plaques with high lipid content. The phantom tubes were filled with dilute contrast material and examined a) with a 16-row MDCT scanner (Siemens Somatom Sensation 16) and b) with a 1.5 T MR scanner (Siemens Magnetom Sonata), both with standard clinical examination protocols. With both methods, the stenotic residual lumen was measured independently of window settings using density profiles across the stenosis in a plane perpendicular to the vessel axis.

Results: Both methods demonstrated a high correlation between the measurement results and the gold standard with MRA performing slightly better than MDCTA ($r = 0.96$ for MRA vs. $r = 0.93$ for MDCTA, $p \leq 0.0005$). With MDCTA, the diagnostic precision was significantly lower in calcified stenoses ($r = 0.92$) as compared to soft stenoses ($r = 0.97$). In soft plaque stenoses, MRA and MDCTA did not differ significantly.

Conclusion: Although both methods provide excellent stenosis quantification, MRA is superior to MDCTA especially in calcified stenoses. Therefore, MRA should be used if precise stenosis quantification is crucial for therapeutic decisions, e.g., in carotid artery disease.

B-902 10:57

Imaging work-up in patients with suspected cervical artery dissection:

Diagnostic efficacy of a combined neck and head MR-imaging protocol

I. Nassenstein, T.-U. Niederstadt, S. Krämer, R. Dittrich, W. Heindel, R. Bachmann; Münster/DE

Purpose: To start immediate anticoagulant therapy the quick and reliable diagnosis of cervical artery dissection (CAD) and accompanying cerebral ischemia is of paramount importance. In this prospective study the diagnostic performance of a combined head and neck MR-imaging protocol in pts with suspected CAD was assessed.

Methods and Materials: 51 consecutive pts (24 m, 27 f, mean age 39.6 yrs) admitted to our stroke unit with suspected CAD and age < 56 yrs underwent a combined head and neck MR examination within 24 h (Gyrosan Intera 1.5 T, Philips). Neck-MR imaging consisted of ax T1w-TSE, T2w-TSE, contrast enhanced T1w-TSE and CE-MRA (imaging time 17 min). Head-MR imaging included DWI, Flair and TOF-angiography (12 min). Three radiologists assessed both studies in consensus with regard to the presence of CAD and acute ischemia.

Results: Mean time between onset of symptoms and scan was 7.3 days. In 18 pts neck and head MR imaging results were normal. In 15 pts acute ischemia was verified by head MR imaging, but neck MR imaging was normal. 6 pts presented with acute ischemia and specific findings of CAD. In 12 pts no acute ischemia was present but definite signs of CAD.

Conclusion: The proposed combined MR-protocol allows imaging work-up of pts with suspected CAD in approximately 30 min, giving conclusive information about the status of the intra- and extracranial vasculature and the presence of ischemia. The high incidence of pts with definite CAD lacking cerebral ischemia indicates the necessity of an early definite diagnosis in order to start timely anticoagulation to prevent development of stroke.

B-903 11:06

Improvement of CTA of the circle of Willis by using lower tube voltage

A. Waaijer, B.K. Velthuis, C.J.G. Bakker, G.A.P. de Kort, M.S. van Leeuwen; Utrecht/NL

Purpose: To compare using 90 kV for CT angiography (CTA) of the circle of Willis to the conventional 120 kV.

Materials and Method: Three patient groups were scanned: 30 with clipped cerebral aneurysms; 20 with acute subarachnoid hemorrhage (SAH) and 20 with a family history of cerebral aneurysms. Half of each group was scanned with 90 and half with 120 kV. Clipped patients were scanned with pitch 0.3 and effective tube current (mA_{eff}) was adjusted to keep radiation dose constant, resulting in 120 kV and 200 mA_{eff} or 90 kV and 450 mA_{eff}. The other groups were scanned with pitch 1, with 120 kV at 200 mA_{eff} and 90 kV at 330 mA_{eff} due to restricted tube load. Absolute CT values were measured in Hounsfield Units (HU) and contrast-to-noise ratio (CNR) was calculated. Two radiologists subjectively scored arterial visualization, detail visibility, noise, and hindrance from venous structures, SAH, or clip artifact on a five-point scale.

Results: Absolute vascular enhancement was significantly higher with 90 kV: mean 340 HU versus 247 HU ($p < 0.001$; 95% CI: 67.9-118.1). CNR increased with 20% in clipped and SAH patients, though insignificantly. Subjective analysis increased at 90 kV for arterial visualization with 0.9 points ($p < 0.001$) without increase in noise or venous enhancement. In SAH patients, hindrance of subarachnoid blood diminished at 90 kV with an increase of 0.6 points ($p < 0.01$).

Conclusion: This study shows that with 90 kV better image quality can be achieved for CTA of the circle of Willis at equal or lower radiation dose.

B-904 11:15

The application of MR perfusion-weighted imaging in patients with unilateral ICA stenosis or occlusion

J. Lu, K. Li; Beijing/CN

Purpose: To investigate the value of MR perfusion-weighted imaging (PWI) in patients who had unilateral ICA high-grade stenosis or occlusion and to assess the utility for evaluating cerebral hemodynamic changes before and after surgery or interventional therapy.

Methods: MR PWI (Siemens sonata) was performed on 62 patients with unilateral ICA high-grade stenosis or occlusion. rCBF, rCBV, rMTT and TTP were calculated. Surgery or interventional therapy was performed in 15 patients, among which 4 underwent STA-MCA anastomosis, 8 underwent PTAS and 3 underwent CEA. The perfusion findings before and after therapy were evaluated.

Results: The abnormal perfusion findings were depicted in 62 patients. The values of rCBV, rMTT and TTP of abnormal regions were statistically different between the affected and the contralateral side ($P < 0.01$). However rCBF was not statistically different ($P > 0.05$). There was a significant difference between the values of TTP, rCBV and rMTT and the degree of ICA stenosis. TTP and rMTT were higher in patients with ICA occlusion than stenosis ($P < 0.01$). Surgery or interventional therapy was performed in 15 patients; TTP and rMTT were decreased after therapy ($P < 0.01$). However, there was no statistical difference between rCBF and rCBV ($P > 0.05$).

Conclusions: PWI can objectively and clearly demonstrate the abnormal hemodynamic changes in patients with unilateral ICA high-grade stenosis or occlusion and can depict the improved situation of cerebral perfusion after surgery or interventional therapy.

B-905 11:24

Cerebral AVM: Hemodynamic characterisation by ultrafast contrast enhanced MRA and non-enhanced dynamic active tagging MRA

M. Essig, C. Fink, F. Giesel, J. Debus, M. Bock, H.-U. Kauczor; Heidelberg/DE

Purpose: To assess the hemodynamic characteristics of patients with angiographically proven cerebral AVMs we applied to 20 patients both an ultrafast, time resolved contrast enhanced MR-DSA technique (cMRA) as well as a non-enhanced dynamic tagging MR-DSA (dMRA).

Methods and Materials: The cMRA is based on an ultrafast 3D-FLASH acquisition after bolus injection of 10 cc of MultiHance® (Bracco Imaging, Milan, Italy) using parallel imaging techniques (IPAT) at a TR of < 2 ms and a TE of < 1 ms and a temporal resolution of about 250 ms. The dMRA sequence, with a temporal resolution of 100 ms, is based on the spin labeling sequence (STAR) in which a bolus of blood upstream from the AVM is tagged by an inversion pulse and imaged downstream at different time intervals after tagging (100 ms to 1200 ms) using also a 2D FLASH acquisition. For both techniques morphological and hemodynamic parameters were assessed and compared with the clinical presentation.

Scientific Sessions

Results: A hemodynamic assessment and a detailed analysis of the angiarchitectural of the malformation was possible with both techniques. Feeding arteries, AVM nidus, and draining veins were detected easily. The time resolution was better with dMRA, but suffers from a substantially longer acquisition. Artifacts are more pronounced on the dMRA while the cMRA proved to be robust.

Conclusion: Both cMRA and dMRA proved to be very helpful diagnostic tools in the assessment of the angiarchitectural and the hemodynamic changes of cerebral AVMs. The time resolved acquisition allowed interesting insights into the hemodynamics of such malformations.

B-906 11:33

CT and MR imaging features of cerebral cortical venous thrombosis

A. Stix, J. Simbrunner, A. Ruppert-Kohlmayr, G. Komatz, M. Feichtinger, G.E. Klein, F. Ebner, F. Ebner; Graz/AT

Purpose: Although thrombosis of the dural sinuses is increasingly recognised, the diagnosis of cortical venous thrombosis (CVT) remains challenging. The aim of this study was to describe the CT and MR imaging findings of CVT.

Methods and Materials: 15 patients (7 men and 8 women) with mean age 43 years (range 16-75) with CVT underwent CT and MR imaging. CTA was performed in 10, MRA in 11 and DSA in 4 patients. Scans were analysed by two radiologists retrospectively blinded for the diagnoses. The number of occluded cortical veins (CV) and sinuses was counted.

Results: 9 patients showed thrombosis of dural sinuses and CVT while 6 patients showed isolated CVT. CTA, MRA and DSA proved reliable in the detection of sinus thrombosis but MRA and DSA were inconclusive for CVT. Altogether unenhanced CT scans revealed 24 occluded CV, T1-weighted images 11 and T2-weighted images 2. T2-weighted gradient-echo images showed 32 occluded CV. Parenchymal lesions have been detected in 9 patients by CT and in 13 by MRT. **Conclusion:** Due to anatomical variations of cerebral cortical veins it is difficult to detect a CVT in MRA and DSA. Non-angiographic techniques are reliable in the diagnosis of CVT. Unenhanced CT scans and T2-weighted gradient-echo sequences have an especially high sensitivity in the detection of CVT.

B-907 11:42

Non invasive diagnosis with orbital color Doppler (OCD) of carotid cavernous sinus fistulas (CCSF): Personal experience in 20 cases

M. Venturini, F. D'Ascenzo, S. Bianchi Marzoli, F. Simonato, G. Scotti, A. Del Maschio; Milan/IT

Purpose: Several case reports have shown dilatation and modification of flow in the Superior Ophthalmic Vein (SOV) with OCD in CCSF. Our aim was to evaluate OCD in the diagnosis of CCSF, in a relatively large number of patients.

Methods and Materials: Both eyes of 20 patients with clinical suspicion of CCSF were examined with OCD (ATL-Philips HDI-5000 / 5-12 MHz linear-probe). Blood flow of the SOV, inferior ophthalmic veins (IOV), central retinal vessels and ophthalmic arteries was evaluated. The size of each vessel, the direction of blood flow and the following flow parameters were considered: maximum and minimum velocities for veins; peak systolic, end diastolic velocities and resistance indices (RI) for arteries. Positive diagnosis was based on the finding of SOV (and IOV) dilatation, with reversed, arterialized and low resistance (RI < 0.50) blood flow. Definitive diagnosis was based on digital angiography.

Results: CCSF was correctly diagnosed with OCD in 19/20 patients. SOV showed reversed, arterialized and low resistance blood flow in 19/20 cases, with bilateral orbital involvement in 4 cases. The SOV was dilated in 14/19 patients and not dilated in 5/19. The IOV was dilated with reversed and arterialized flow demonstrated in 8/20 cases (bilateral in 2 cases).

Conclusion: OCD provides an accurate and reproducible assessment of blood flow of retrobulbar vessels. An accurate and non invasive diagnosis of CCSF was obtained with OCD, due to SOV (and IOV) blood flow changes, and was also possible in non dilated orbital veins.

B-908 11:51

Application and efficacy of non-invasive spinal multidetector CT angiography in patients with suspected dural fistula with spinal drainage

P. Zabakis, C. Santosh, L.J. Walker, E. Teasdale; Glasgow/UK

Purpose: Multidetector CT has made a significant impact on intracranial vascular imaging. This study evaluates the technique and role of multidetector spinal CT Angiography (MDSCTA) in patients with possible spinal dural fistula.

Methods and Materials: 11 patients (9M) presenting with spinal symptoms and suspected by MR of harboring a fistula (DAVF) with spinal venous drainage, were studied by MDSCTA. All had spinal catheter angiography (DSA); 9 had contrast

enhanced spinal MRA; 5 had operative, 2 intravascular, and 1 combined treatment, while 3 had no intervention.

Results: DSA showed 5 typical spinal DAVFs; 2 cranial DAVFs with spinal drainage. In 2 cases it failed to demonstrate the fistula, and in 2 the results were equivocal. MDSCTA confirmed abnormal vessels in all cases and identified the DAVF level in 9 of the 11 patients. In 1 case MDSCTA failed to identify the level due to erroneous technique while in another case none of the imaging techniques (CTA, MRA, DSA) identified the level. MDSCTA identified the feeding vessel in 2 cases with negative/doubtful super-selective angiography (both were confirmed at surgery). Initial DSA failed to identify the level in 5 cases. In 3 of these cases, MDSCTA correctly guided the repeated DSA. In the 9 cases with both MRA and MDSCTA the DAVF level was correctly identified in 5 with MRA and 7 with MDSCTA.

Conclusion: MDSCTA is a feasible and effective diagnostic examination in DAVFs with spinal drainage, able to guide, limit and expedite DSA and surgery.

Radiographic role extension in fluoroscopy: The four tier structure in practice

S. Dyce, L.J. Abraham, G.P. Fitzgerald, C.J. Garvey; Liverpool/UK

Purpose: To illustrate the benefits of the four tier structure for radiographers providing a fluoroscopy service.

Methods: Rising demand and increased expectation have placed major pressure on radiology departments. A shortage of radiologists in the UK has resulted in existing radiologists devoting more time to cross-sectional imaging. Radiographers have assumed an increasingly important role in other areas, particularly in developing and running the GI fluoroscopy service. The four tier structure for radiographers currently being implemented in the UK offers significant opportunities for role redesign whilst ensuring appropriate competency and backfilling of more basic roles.

Results: Radiographers have become advanced practitioners through training in the performance of and, more recently, reporting barium enema studies, linked to local University programmes. Other developing areas include NG tube insertion, performing and interpreting contrast swallows and vetting requests for appropriateness. Backfilling of responsibilities has been done through the establishment of approved training programmes for assistant practitioners to perform basic duties including chest and extremity radiographs, venflon insertion and other duties previously performed by basic grade radiographers. Consultant radiographers are developing further skills including endoscopy along with research and audit programmes.

Conclusion: Role development for radiographers is advancing rapidly, especially in the area of GI fluoroscopy. Appropriate competency-based training programmes allow individuals to progress along assistant practitioner, practitioner and advanced practitioner grades. Roles for Consultant Radiographers in GI fluoroscopy are emerging and should be encouraged. Competency assessment is quite well advanced. More emphasis needs to be placed on research and audit.

Are digital images good enough? A comparative study of conventional film-screen vs digital radiographs on printed images of total hip replacement

K. Eklund, K. Jonsson, G. Lindblom, B. Lundin, J. Sanfridsson, M. Sloth, B. Sivberg; Lund/SE

Purpose: The aim was to evaluate the inter- and intra-observer variability and to find differences in diagnostic safety between digital and analog technique in diagnostic zones around hip prostheses.

Materials and Method: In eighty patients who had had a Total Hip Replacement (THR) for more than two years, a conventional image and a digital image were taken. Gruen's model of seven distinct regions of interest was used for evaluations. Five experienced radiologists observed the seven regions and noted in a protocol the following distances: stem-cement, cement-bone and stem-bone. All images were printed on hard copies and were read twice. Weighted kappa analyses has

Scientific Sessions

been used. The two most frequently loosening regions, stem-cement region 1 and cement-bone region 7, were closely analysed.

Results: In region 1 the five observers had an agreement of 86.75%-97.92% between analog and digital images in stem-cement, which is a varied weighted kappa 0.29-0.71. For cement-bone region 7 an agreement of 87.21%-90.45% was found, which is a varied weighted kappa of 0.48-0.58. All the kappa values differ significantly from nil.

Conclusions: The result shows that digital technique is as good as analog radiographs for diagnosing possible loosening of hip prostheses.

B-911 10:48

Strategy for redesigning workflow

R. Tjønneland, B. Lagesen, J. Andersen; Oslo/NO

Purpose: Presenting how we involved our staff to participate in redesigning the workflow, when changing our hospital RIS-PACS vendor.

Method and Materials: Reengineering of workflow was a highlighted topic and goal when purchasing RIS-PACS. The implementation process was established as a project task, with its own organisational team and leadership outside the department of Radiology. The project established a manager to organize user groups of different topics concerning workflow. These groups included employees of different occupations, who worked out executive principles. The management board of Radiology established reference groups to secure quality and anchor the suggested solutions among the users.

Results: *Strength:* The employees showed enthusiastic involvement in the process. The knowledge of our organization increased. This created an ownership among the employees to the workflow-solution and increased the power of accomplishment. *Weakness:* A big democracy process is time consuming. This kind of strategy might be difficult to manage, in order to find common solutions. *Possibilities:* The best solutions are made jointly. Where there were different interests of workflow solutions, the manager group decided to try out a common standard to continue process. No one could deviate from the decided standard before the manager group gave it's approval. *Treats:* Old well known solutions are presented. Loss of focus may occur. "The survival of the fittest" may be the result of choosing between old and new suggested solutions.

Conclusion: With this strategy of managing the implementing process, we have established a commitment to the solution.

B-912 10:57

The value of the radial head-capitellum view in the evaluation of patients with injury of the elbow

D. Koumarianos¹, E. Lavdas¹, N.I. Fezoulidis², I.V. Fezoulidis²; ¹Patras/GR, ²Larisa/GR

Although most radial head fractures are evident on AP and lateral views, additional projections are often necessary to demonstrate them. The radial head-capitellum view is a modified lateral view of the elbow joint accomplished by angling the tube 45° toward the shoulder.

Materials and Methods: A retrospective analysis of the radiographs of the elbow in 91 patients examined for acute trauma between January and August 2003 was undertaken. Each study included an AP, lateral and radial head-capitellum view and the data were analysed to determine the radiographic abnormalities detected by each view alone and if only AP and lateral views had been used.

Results: There were 31 abnormal studies; 11 studies with positive fat pad signs, but no evidence of bony injury and 20 studies with some radiographic evidence of bony injury. The radial head-capitellum view failed to demonstrate 8/20 (40%) of fractures and by omitting this view only one fracture would have been missed. The radial head-capitellum view proved to offer advantage over the diagnosis made by conventional views in 6 (30%) of all fractures.

Conclusion: The study suggests that the radial head-capitellum view should be considered a supplementary rather than a standard view in acute trauma of the elbow.

Follow-up of primary or secondary malignant liver tumors treated with radiofrequency ablation: Efficiency of PET/CT

H. Kuehl, G. Antoch, P. Veit, S. Rosenbaum, J. Barkhausen, A. Bockisch; Essen/DE

Purpose: Morphologic imaging can be seen as the standard for follow-up of patients with malignant liver tumors treated with radiofrequency ablation. The use of PET/CT in the surveillance of RF-ablation is evaluated in comparison to CT alone.

Methods and Materials: 26 patients with 37 liver tumors (HCC 14, metastases 23) were scanned with PET/CT (Siemens biograph) prior to RF ablation. FDG-PET/CT was only used for follow-up in patients with PET-positive tumors. Post-interventional PET/CT was performed within 48 h after ablation and repeated after 1, 3, 6 and 12 months. The accuracy of the different imaging modalities (CT, PET/CT) for detection of residual or recurrent tumor was assessed and compared with clinical follow-up.

Results: 13 of the 26 patients showed 17 liver tumors with elevated FDG uptake and were controlled with PET/CT. 34 PET/CT examinations were performed for follow-up. The mean time of follow-up was 10 months (min. 1, max. 24 months). 3 of 13 patients remained free of tumor during follow-up. 10 of 13 patients developed local, intrahepatic, or local and intrahepatic tumor recurrence. 5 recurrences were not detected with CT but with PET/CT. The sensitivity of CT alone for tumor detection was calculated to be 55%, the sensitivity of fused PET/CT data measured 89%. The accuracy of CT alone and PET/CT was 85%.

Conclusions: PET/CT proved to be superior to morphologic imaging with CT when assessing the liver after RF-ablation. Nevertheless very small areas of residual tumor may be missed on PET/CT.

B-914 11:15

Low-field open-MR imaging study of TMJ (temporomandibular joint)

L. Belli, M. Mentasti, R. Poletti Venegoni; Castellanza/IT

Purpose: Feasibility of the use of low-field open-MR imaging system to study temporomandibular joint (TMJ).

Materials and Methods: We studied TMJ in 55 patients (mean age 42 years) using an open-MR imaging system with a low field 0.3 T (AIRIS II, Esaote, Italy). We used brain-coil for comparative study; T1 and GET2 sagittal and coronal sequences have been performed at rest and during motion with progressive opening mouth. Condilar bone signal, presence of articular fluid and fibrocartilage were evaluated; motility was finally evaluated with dynamic images.

Results: Inflammatory distrophia was present in 22 cases, traumatic lesions of cartilage or ligaments in 12 cases, dynamic derangement or limitation in 10 cases.

Conclusions: Low-field rest and dynamic study of TMJ is useful to evaluate the status of the articulation especially in case of cartilage or adhesive pathology.

B-915 11:24

Comparative analysis of objective data and subjective impressions reported by patients related to iodinated oral contrast material administration

E. Fehér, A. Tökés, H. Tóth, Z. Mocsári, E. Turupoli, A. Bánkuti, A. Böröczki, A. Maléta; Budapest/HU

Aim: The study was the comparative evaluation of visual assessment of images and of patient's reports related to oral administration of two (partially) different iodinated oral contrast materials.

Materials and Methods: Two different contrast materials containing the same "Amidotrizoat" molecule in 60% Iodine concentration of 300 mg Iodine/ml were compared. The composition of additional vehicular materials were different: in one of them Sodium and Meglumin. In the other contrast material a physiological amino-acid, Lysin was the vehicular molecule. There are significant differences of water bounding, i.e. high osmotic effects of Sodium-Meglumin composition versus iso-osmotic behaviour of Lysin bound "Amidotrizoat" in the bowels. Other differences were related to added aromas (anis like versus fruit like). Statistical evaluation of questionnaires were done. Both undiluted (conventional G.I. studies) and diluted applications (for CT studies) were analysed in 200 patients.

Results: Contrast filling of bowel loops were equally intensive and homogenous in both materials. No physical reactions, like flocculation, crystallisation, sedimentation or inhomogeneous filling appeared. Significant differences in gastrointestinal reactions (nausea, retching, vomits, colic, diarrhoea) were observed, predominantly in diluted application (CT), and only smaller differences were if administered undiluted (conventional GI studies). Effects on bowel motility were significantly different, the Meglumin containing contrast material increased the bowel motility, but much less uncomfortable effects were reported by patients who got Lysin containing contrast material. Patients appreciated the offered choice of contrast materials with different tastes.

Conclusions: Image qualities didn't show significant differences. Different osmotic effects and different tastes can help the patient's comfort.

Can we trust each other?

L. Forsyth, E.M. Robertson; Aberdeen/UK

Purpose: To survey the perceptions of the Scottish Radiology community in relation to Radiographer role development.

Materials and Methods: A postal questionnaire was sent to all Consultant Radiologists recorded on the NHS Scotland database of Consultants.

Results: Response rate 61%. (i) Respondents considered increased professional standing of Radiographers, best use of manpower resources, reduced pressure on the service and improved recruitment and retention, as positive advantages of Radiographer development. (ii) The potential impact on SPR training, lack of clear medico legal responsibilities and Radiographers recognising the limitations of their abilities were identified as the main areas of Radiologist anxiety. (iii) 57% did not consider current post registration Radiography education and training adequate to underpin the clinical skills requirement of developed roles. (iv) Barriers to Radiographer development were identified as lack of Radiologists and Radiographer staff, suitable education, financial constraints, traditional views and resistance to change. (v) 81% reported support for Radiographer role development and willingness to participate actively in developments.

Conclusion: Despite reservations, Scottish Radiologists are supportive of the development of Radiography colleagues, however guidance is required on the medico legal and accountability aspects of Radiographers assuming new roles. Radiologist involvement in education and training for new roles may increase confidence and trust in Radiographers to work within the limitations of their competency and training.

Ultra-high-resolution whole-body MRA using parallel imaging on a 32-channel MR system and intravascular contrast agents: Protocol optimization for clinical applications

K. Nikolaou¹, S.O. Schoenberg¹, M. Hartmann², P. Chamberlin², M.F. Reiser¹;
¹Munich/DE, ²Cambridge, MA/US

Purpose: To optimize a whole-body MRA protocol with sub-millimeter spatial resolution and to assess its clinical utility for the evaluation of systemic atherosclerotic disease.

Methods and Materials: 10 healthy volunteers and 5 patients with proven atherosclerotic disease underwent whole-body MRA on a 32-channel 1.5 T MR imaging scanner with matrix coils and parallel imaging (Magnetom Avanto, Siemens Medical Solutions, Erlangen, Germany). For contrast-enhanced MRA, an albumin-binding Gadolinium chelate (MS 325, EPIX, Cambridge, MA and Schering AG, Berlin, Germany) was injected with a flow rate of 1 cc/s. In the dynamic phase, angiograms of the carotid arteries and calves were obtained during first pass of MS-325, with 1 mm³ isotropic spatial resolution. In the steady-state, a spatial resolution of up to 75 μm³ was realized. In patients, results were compared to state-of-the-art MRA protocols using conventional Gd-chelates.

Results: In the dynamic phase, MR angiograms with pure arterial contrast were consistently obtained without venous overlay. For the thorax and abdomen, MR angiograms were obtained with 1 mm³ isotropic spatial resolution within a single breath-hold during the steady-state phase of MS-325. In the thigh, knee and calf station of the lower extremity, the ultra-high resolution MRA datasets with voxel sizes between 75 and 130 μm³ revealed excellent vessel contrast and high signal-to-noise. In patients, MRA data obtained with this protocol showed excellent agreement with the conventional reference MR angiograms.

Conclusion: The combination of a whole-body MR imaging scanner and a blood pool imaging agent allows acquisition of a whole-body MR angiogram without compromises in spatial resolution or anatomic coverage.

B-918 10:39

Reduced angle double inversion recovery (RADIR): A flexible new pulse sequence for black-blood MR imaging

A.N. Priest, S. Hegerfeldt, G. Adam; Hamburg/DE

Purpose: To develop and demonstrate a new black-blood MR imaging preparation sequence with flexibility to choose the inflow time before signal nulling is achieved.

Methods and Materials: To achieve a net flip angle of zero within a slice-selective (imaging) region and α outside this volume (for $90^\circ < \alpha < 180^\circ$), a sequence of the following RF pulses was used: ($\alpha-180^\circ$), 180°, - α . Only the final - α pulse is slice-selective. The short interpulse delays were equal, so the central 180° pulse refocussed the transverse magnetisation. This prevented artefacts from phase dispersion off-resonance. To achieve nulling at delay TD, set $\alpha = \arccos((A-1)/(A-E))$ with $A = \exp(-TD/T1)$ and $E = \exp(-TR/T1)$. The abdominal aortas of four healthy volunteers were scanned using a 3 T clinical scanner (Philips) with an ECG-triggered turbo-spin echo sequence (TE/TR = 70 ms/3RR). The blood SNR from proposed sequence, with TD=100 ms, was compared with the standard black-blood methods 'double inversion-recovery' (DIR) and out-of-slice presaturation.

Results: The average blood SNR over 3 subjects, at trigger-delay 450-470, was 2.2 (RADIR), 2.6 (DIR) and 2.8 (presaturation). At trigger-delay 300 (where DIR was not applicable) SNR was 1.6 (RADIR) and 1.9 (presaturation). In another subject, RADIR at delay 200 ms and DIR at delay 1150 ms (= 200 ms+1RR) both achieved blood SNR 2.6.

Conclusions: The new preparation sequence achieves good blood suppression in these preliminary studies. RADIR will allow cardiac or vessel-wall imaging at shorter trigger-delays than standard DIR without limiting the suppression volume as with out-of-slice presaturation. This brings additional flexibility to black-blood imaging, for example triggering systolic acquisitions within the same heartbeat as the acquisition.

B-919 10:48

Outer volume saturation bands improve spatial signal homogeneity in MR 2D chemical shift imaging

R.H. Wu¹, D. Dureux², R. Lin¹, G. Guo¹, K. ter Brugge³, D.J. Mikulis³;

¹Shantou/CN, ²Le Kremlin-Bicêtre/FR, ³Toronto, ON/CA

Purpose: Many endeavors of improving chemical shift imaging (CSI) techniques have been made during last two decades. Good examples of two-dimensional CSI and three-dimensional CSI can be found in the literature. However, clinical CSI using available sequences is still not satisfactory. The purpose of this study was to assess the effect of outer volume saturation bands on signal homogeneity in MR 2D chemical shift imaging.

Methods and Materials: The 2D CSI scans were acquired using a point resolved spectroscopy (PRESS) CSI sequence on a phantom filled with brain metabolites. A single PRESS volume of interest was prescribed graphically. The acquisition matrix was 18x18 phase encodings over a 24 cm FOV. Identical acquisitions were obtained with and without outer-volume saturation bands. After initial acquisition was obtained, four more acquisitions were repeated for both studies with and without saturation bands. Identical five groups of voxels were compared for both studies. Standard deviations of ratios were calculated in each group for both studies.

Results: Spectra obtained without outer-volume saturation bands showed signal to noise gradient with higher concentration of signal within voxels at the center of the volume of interest. Outer volume saturation bands reduced this gradient. In general, standard deviations of metabolism ratios with saturation bands were smaller than those without saturation bands. Improved spatial homogeneity of spectra in voxels of CSI with saturation bands was obtained.

Conclusion: Outer-volume saturation bands improve spatial homogeneity of chemical shift imaging.

B-920 10:57

b-Matrix assessment in diffusion tensor imaging using a reference phantom

D. Güllmar, J. Haueisen, J.R. Reichenbach; Jena/DE

Purpose: In this study we try to establish a method to estimate the coefficients of the b-matrices in DTI experimentally. These coefficients are usually calculated by using a very simple equation which only takes into account the diffusion gradients. In this study we have determined the b-matrix analytically taking into account all gradients. The resulting system of equations with four unknown parameters can then be solved using a few measurements and an isotropic phantom with known diffusion coefficient.

Methods and Materials: All measurements were performed using a 1.5 T whole-body MR-Scanner. The diffusion coefficient of the phantom was determined by

Scientific Sessions

using a cross-term free diffusion acquisition method. To determine the full b-matrix we acquired a full diffusion tensor scan (six directions) and solved the corresponding system of equations.

Results: The individual elements of the experimentally determined b-matrix were different from the elements obtained by using the simplified b-value calculation. Depending on the actual b-value (100-1000 s/mm²) deviations of up to 30% (for low b-values) were observed for some of the elements. The experimentally determined b-matrix was in very good agreement with the fully analytically calculated b-matrix.

Conclusion: The presented experimental approach provides a simple way to assess the b-matrix in very good correlation to the analytically calculated b-matrix. For this approach only knowledge of the gradient scheme, the protocol parameter and the diffusion coefficient of the phantom is required. However, the accuracy of this method critically depends on the accuracy of the numerical value of the diffusion coefficient.

B-921 11:06 ♀

Caffeine-induced contrast enhancement in volunteers by using susceptibility-weighted imaging (SWI)

J. Sedlacik, A. Rauscher, A. Deistung, W.A. Kaiser, J.R. Reichenbach; Jena/DE

Purpose: Small susceptibility differences are only accumulated with phase with long echo times, which requires long measurement times. The aim of this work was to investigate the possibility of increasing SWI contrast with caffeine; thus reducing potentially measurement time.

Methods and Materials: High-resolution T2*-weighted images were acquired in four volunteers on a 1.5 T system using a velocity-compensated 3D-gradient-echo imaging sequence. Sequence parameters: TR/TE/FA = 67 ms/40 ms/15°, in-plane resolution = 0.5x0.75 mm², slice thickness = 1.75 mm, scan time 10 min. A native scan was performed first. Then the subjects drank a big cup of strong coffee (equivalent to 300 mg caffeine) directly in the scanner. The scan was repeated 5 times to cover a period of nearly one hour after drinking coffee. Complex images were reconstructed from the raw data and realigned. Maps of phase differences and relative signal changes were computed. SWIs were produced by combining phase and magnitude images.

Results: Maps of the relative signal change clearly visualized the caffeine-induced response of venous vessels. The signals in the veins decreased down to 50% compared to the native signal. Simultaneously, phase differences up to 90° were observed in the same vessels. The contrast could be increased impressively in the SWI, especially for the scans acquired up to one hour after coffee.

Conclusion: SWI contrast enhancement was demonstrated with caffeine. Maps of signal and phase changes showed most prominent effects in veins. It may therefore be possible to use the well-known vasoconstrictive effect of caffeine as a contrast-enhancer. Ultimately, acquisition time may be shortened while acquiring data after the intake of coffee.

B-922 11:15

Tmix imaging as alternative for femoro-tibial cartilage T2 mapping at 1.5 T

I. Van Breuseghem, I.M. Van Mieghem, R.R. Peeters, H.T.C. Bosmans, G.J. Marchal, S. Pans; Leuven/BE

Purpose: To evaluate the feasibility of T2 mapping of human femoro-tibial cartilage with tMIX imaging on a 1.5 T MR imaging system.

Methods and Materials: A turbo-mixed sequence was implemented on a 1.5 T MR imaging system. A standard knee coil was used. 25 healthy adult volunteers (male/female: 17/8; age range, 20.85-44.72 years; mean age 28.5 years) underwent MR imaging of either one or both knees after informed consent was obtained. The turbo mixed sequence was performed making 24 slices in a sagittal direction. T2 maps were calculated by using a built-in calculation tool. The images were transferred to a workstation for further post-processing to obtain colored quantitative T2 maps.

Results: A total of 46 knees were scanned. All areas demonstrate a similar pattern of spatial variation in cartilage T2 with longer values observed near the articular surface. 2 layers in T2 profile can be detected showing a first layer at the cartilage/bone interface (mean T2 relaxation value 36.8 msec - SD:1.4) and a second layer with T2 values progressively increasing towards the cartilage surface (mean T2 relaxation value 50.8 msec - SD:3.2).

Conclusion: To resolve technical challenges posed by the thin and curved femoro-tibial cartilage, we used a high resolution scan technique (in plane resolution of 270 µ) and post-processing (with color-encoding) for accurate T2 mapping of cartilage. As our results are in concordance with literature, the proposed tMIX technique can be used for T2 mapping of cartilage on a 1.5 T MR imaging scanner.

B-923 11:24 ♀

Complex data processing in dynamic MR-mammography

A. Rauscher, K.-H. Herrmann, J. Sedlacik, W.A. Kaiser, J.R. Reichenbach; Jena/DE

Purpose: Routine contrast-agent enhanced MR imaging uses a subtraction of the modulus of a native scan from one of several scans acquired after contrast agent administration. However, magnetic resonance images are complex (i.e. consisting of a real part and an imaginary part) by nature and processing of the modulus imposes limitations upon the information originally contained in the data sets. The purpose of this study was to evaluate the advantages of data processing in the complex domain.

Methods and Materials: For each of four patients (with invasive lobular carcinomas) four (1 pre-KM, 3 post-KM (0.1 mmol/kg bw Gd-DTPA)) T1 weighted 3D double-echo, gradient-echo scans (TR/TE1/TE2/FA = 7 ms/2.73/4.76 ms/15°) were acquired on a 1.5 T scanner using a double breast coil. Complex images were computed from the modulus images and the phase images and all operations such as subtraction or division of images were performed on the complex data and then the modulus of the resulting images was assessed.

Results: Contrast between the enhancing lesions and the healthy tissue is highly improved by complex processing. Complex division leads to a few pixels in noisy areas outside the breast where division by zero occurs. A simple thresholding of the resulting images eliminates the resulting spikes.

Conclusion: Complex processing preserves information and increases contrast-to-noise. Taking the modulus of the complex subtraction (instead of the subtraction of the modulus) may help to improve conspicuity of small lesions. More sophisticated calculations using combinations of in-phase and opposed-phase scans or the assessment of phase images are currently under evaluation.

B-924 11:33

Whole-body FDG-PET/CT with extended CT field-of-view for improved oncology imaging

T. Beyer¹, M.-J. Martinez², O. Sembritski³, F. Roberts⁴, S. Ziegler², H. Kuehl¹, A. Bockisch¹; ¹Essen/DE, ²Munich/DE, ³Forchheim/DE, ⁴London/UK

Purpose: We investigate the effect of CT-truncation in whole-body (WB) PET/CT-imaging of large patients and evaluate the efficacy of an extended field-of-view (e-fov) correction technique.

Methods and Materials: An 'arms-up'-phantom ('head': 20 cm-cylinder, 'arms': 1.5 l-plastic bottles) was filled with 10 kBq/mL FDG. A 'body'-phantom (40x30x20 cm³) was filled with 5 kBq/mL and contained 4 hot and 2 cold lesions. Both phantoms were positioned in the centre and with at least 10% of their volume beyond the transverse CT-fov. Phantoms were scanned on PET/CT tomographs with 2- and 16-row MD-CT (PET/CT-2.16). CT-based attenuation correction was performed using the CT-images reconstructed from truncated and extended projections to recover the truncated CT-information. The e-fov algorithm estimates full CT-projections from linear interpolation of the truncated projections. For clinical validation, we imaged 20 patients with significant truncation artefacts on PET/CT-2.16 with and without the extended CT-fov correction.

Results: PET tracer distribution was suppressed outside the transverse CT-fov in phantom and patient studies. Corrected PET activity concentration in the truncated regions of the 'arms-up' and 'body'-phantom was reduced to 40% and 10%, respectively but recovered within 7% of the true value through the use of the e-fov correction. With the e-fov correction visual distortion of lesions in the 'body'-phantom was reduced, and the body contour of patients was recovered to the anatomically-correct shape from the uncorrected emission images.

Conclusions: Truncation artefacts in WB-PET/CT imaging lead to a visual and quantitative distortion of the CT and corrected PET-images but can be corrected for through a simple algorithm for extended CT-fov reconstruction.

B-925 11:42

Does CT attenuation correction improve lesion conspicuity in nuclear medicine?

J.D. Birchall, R.H. Ganatra, R.M. Smith, K. Griffith, A.C. Perkins; Nottingham/UK

Purpose: Low dose CT for attenuation correction of SPECT studies improves the detection and localisation of activity deeper within the body and additionally the ability for the physiological NM image to be fused to an anatomical CT image. The CT dose is low being approximately 0.8 mSv.

Methods and Materials: We have used a dual headed gamma camera / CT system in our routine clinical practice over the last 12 months successfully on 44 of 45 occasions. In these studies, we have compared the effect of attenuation

Scientific Sessions

correction (AC) on count rate from the region of pathological interest. We have expressed this as a ratio of the AC counts to the non-AC counts (AC/NAC).

Results: Over all of the studies the effect of CT AC was to increase the AC/NAC ratio by a factor of 3.19 (Mann-Whitney U test $p < 0.0001$). For the 28 Tc^{99m} radionuclide studies the AC/NAC ratio increase was 3.64 ($p < 0.0001$). 36 SPECT studies were performed on the body trunk with an increase AC/NAC ratio 3.5 ($p < 0.0001$) and AC/NAC ratio increase of 2.19 (not significant) for 9 SPECT studies on the distal limbs. Not unsurprisingly, we found significant correlation between the AC/NAC ratio and depth of lesion from skin surface being for all radioisotopes ($r = 0.535$, $p < 0.0002$) and in particular for Tc^{99m} radionuclides ($r = 0.76$, $p < 0.0001$).

Conclusion: We conclude that SPECT with CT attenuation correction improves the NM image and will present clinical case vignettes highlighting the advantage of attenuation correction in SPECT/CT in the localisation of pathological lesions.

What is different in a radiologist's brain?

S. Haller, E.W. Radü; Basle/CH

Purpose: The neuronal correlate of expertise of experienced radiologists was investigated using event-related functional magnetic resonance imaging (fMRI).

Methods and Materials: Radiographic (RI) and control images (CI) were presented to twelve experienced radiologists and twelve naive subjects. Half of images were artificially manipulated, e.g. a local shadow was introduced. Subjects had to indicate whether a visually presented image was original or manipulated, while neuronal activity was assessed using event-related fMRI.

Results: RI compared to CI evoked stronger activations exclusively in the group of radiologists, notably in bilateral Middle and Inferior Temporal Gyrus, bilateral Medial and Middle Frontal Gyrus and left Superior and Inferior Frontal Gyrus. Additionally, the visual processing of CI (i.e. non-radiographic images) significantly differs between experienced radiologists and naive subjects. Radiologists show strongest activation in left-dominant more posterior Superior and Inferior Parietal Lobule, while naive subjects show strongest activation in right-dominant and more anterior Superior and Inferior Parietal Lobule and Postcentral Gyrus.

Conclusion: Radiological experience modifies neuronal representation twofold. First, there is a selective enhancement for radiographic images, which might reflect the behavioral relevance of these specific images. Second, the visual system is modified in general, which might reflect the extensive usage of the visual system by experienced radiologists.

Verbal communication: A fMRI imaging - DTI study

C.-V. Salvan, J.L. Ulmer, L. Hacein-Bey, W.M. Mueller, R.W. Prost; Milwaukee, WI/US

Purpose: Verbal communication is a characteristic and a unique feature of the human being. Its substrate is considered intriguing in many scientific fields. Our goal is to present the underlying anatomical and functional networks as identified by functional MR imaging and Diffusion Tensor Imaging (DTI)-fractional anisotropy (FA). Secondly, we present the influence of lesions on these networks, as well as the capacity of plasticity in the brain.

Materials and Methods: BOLD functional MR imaging and DTI-FA data were obtained in normal subjects and 13 patients with lesions involving speech and language areas. Gray matter organization was studied with fMRI imaging and a cross-correlation analysis ($p < 0.01$) and white matter with DTI- FA and direction-sensitive maps. We also superimposed fMRI imaging data onto FA images for a better understanding of functional networks. In patients, WADA-testing, intraoperative mapping and/or postoperative outcome was used for functional assessments.

Results: Expressive and receptive language was mapped, together with important components of executive function, memory, planning, attention. Correspondence to known anatomical and physiological knowledge was obtained. Lateralization of language functions was also investigated and confirmed. In pathological cases,

depending on lesion type, localization, size and handedness, different models of language networks were obtained, and case scenarios were exemplified. Plasticity of language areas was suggested in 9 cases. WADA-testing, intraoperative mapping and/or postoperative outcomes supported our data in 10 cases.

Conclusion: The complexity of verbal communication and brain plasticity is difficult to understand, but fMRI imaging and DTI can contribute to our knowledge and can be used to optimize patient outcomes.

B-928 10:48

Time-resolved analysis of event related fMRI imaging during language comprehension at word and sentence level

S. Haller¹, J. Schwarzbach², M. Klarhöfer¹, E.W. Radü¹; ¹Basle/CH, ²Nijmegen/NL

Introduction: Neuronal activation during language comprehension at word and sentence level was assessed using event-related fMRI imaging. The effect of increasing task difficulty on the BOLD response was investigated based on time-resolved analysis of fMRI imaging.

Methods and Materials: Sixteen healthy participants performed three reading tasks of increasing linguistic difficulty during fMRI imaging. In the latency analysis, delay and duration of the BOLD response were estimated by fitting gamma functions used as hemodynamic model function to event-related average BOLD response for each single voxel. In the correlation analysis, single trial BOLD delay estimates were correlated with response time.

Results: The latency analysis revealed shortest BOLD response delay in the visual area, consistent with the visual stimulus presentation. Activations in left Inferior Frontal Gyrus (IFG), i.e. Brocas language area, showed later activation. Increasing task difficulty was paralleled by increasing BOLD response latency in left IFG, but not in the visual area. The duration of the BOLD response increased uniformly in all areas with increasing task difficulty. Additionally, the correlation analysis of estimated BOLD delay and response time revealed strongest correlation in motor area. Correlation in left IFG was smaller despite comparable BOLD response delay, consistent with the direct link between motor area and response button press.

Conclusions: The presented time-resolved analysis of er-fMRI imaging data illustrates the cascade of cognitive processes at high temporal and spatial resolution. The temporal information of this time-resolved analysis complements statistical information of general linear model analysis.

B-929 10:57

Differences in regional BOLD responses in the primary and secondary auditory cortex induced by mixed noise and speech like stimuli

M. Golebiowski, P. Bogorodzki, W. Szczeszkowski, E. Piatkowska-Jankó, T. Wolak, M. Orzechowski, R. Kurjata, A. Cieszanowski; Warsaw/PL

Purpose: The aim of the study was to investigate the hierarchical organization within the auditory cortex of humans with mixed noise and speech like auditory excitation using functional magnetic resonance imaging (fMRI) technique.

Methods and Materials: For each of 20 healthy subjects (16 males and 4 females, 19 right-handed and 1 left-handed) at age 23.6 ± 0.7 four functional sessions with block type speech like stimuli (15 repetitions of the BA-LU) and variable amount of noise were acquired. Statistical parametric maps were generated under SPM99 software and additionally, the raw Blood Oxygenation Level Dependent (BOLD) signal intensities from left and right primary (A1) and secondary (A2) auditory cortex regions were averaged to form a time series spanning the entire length of the experiment. The variation of resulting curves was described with percent signal change (PSC) measure.

Results: The random effect analysis shows strong activations in both A1 ($T = 10.59$ in left hemisphere and $T = 9.94$ in right hemisphere) and A2 ($T = 11.73$ in left hemisphere and $T = 8.75$ in right hemisphere) regions. Additionally, we noted substantial correlation of PSC measure with noise level in A1 ($R = 0.95$, $T = 13.4$) and practically no correlation in A2 ($R = 0.05$, $T = 0.2306$).

Conclusion: The experiment revealed auditory hierarchical architecture with the special emphasis on primary and secondary cortex function fields. An attenuation of noise at secondary cortex with good response for BA-LU stimuli.

B-930 11:06

Functional CNR as a fMRI imaging specific quality parameter for presurgical mapping in tumor patients

A. Geissler, M. Barth, R. Lanzenberger, A. Gartus, A.R. Tahamtan, G. Meller, T. Foki, D. Milakara, R. Beisteiner; Vienna/AT

Purpose: fMRI imaging has high potential for delineating eloquent brain tissue at risk and could possibly substitute complex procedures such as awake craniotomy

Scientific Sessions

or WADA test. To obtain significant fMRI activation the functional CNR has to be as high as possible to reduce false positive activation as, in the worst case, even a difference in the resection margin of only 1 mm may lead to subsequent irreversible functional deficits. We tested the hypothesis that besides SNR, CNR is an important indicator for fMRI stability.

Methods and Materials: 7 healthy subjects and 6 tumor patients were measured using a multi-slice, single-shot gradient-echo EPI sequence using a 3 T scanner. One run consisted of 4 resting and 3 movement phases with 20 s duration each, six runs were performed. Opening and closing of the dominant hand was used as the stimulus paradigm. A correlation analysis was performed and the rank of each run (RR) when the most reliable pixel was estimated unambiguously for the first time was assessed. Image SNR was obtained as a measure for data quality. The functional CNR in the most reliable pixel was calculated.

Results: The run-averaged SNR values were 32 ± 8.2 , the RR values 3.5 ± 2.3 . CNR values were 2.8 ± 0.8 . Correlation between SNR and CNR was 0.8, and -0.4 between RR and CNR.

Conclusion: The results indicate that CNR reflects both data quality and, to a lesser degree, fMRI stability. CNR can thus be used as a fMRI specific quality parameter.

B-931 11:15

BOLD functional MR imaging in simple motor tasks and equivalent motor imagery

E.J.M. Vandervliet, Ö. Özsarlak, M. Maes, J. Van Goethem, P.M. Parizel; Antwerp/BE

Purpose: To compare the amplitude and spatial distribution of BOLD responses of brain areas involved in simple motor tasks and equivalent motor imagery (imaginary motor performance, IMP).

Materials and Method: We recorded the BOLD response of distinct brain areas in 9 healthy volunteers (mean age 31 years) who performed self-paced bilateral fingertapping and IMP. For each condition we used a comparable block design in which the task of interest was alternated by periods of rest. All experiments were performed on a 1.5 T scanner with high-performance 40 mT/m gradients (Siemens Sonata, Erlangen, Germany). We used gradient-recalled multi-shot EPI sequences (TE 50 ms, TR 3000 ms) with 30 slices covering the whole brain. Voxels measured 3x3x3 mm. Data analysis was performed in BrainVoyager (Brain Innovation, Maastricht, The Netherlands).

Results: In all subjects highly significant activation of the primary motor cortex (M1), supplementary motor area (SMA) and premotor cortex (PMC) was observed in both conditions. Thalamic activation was seen in all subjects during fingertapping. The spatial distribution of BOLD responses did not differ in M1, SMA and PMC but the amplitude of BOLD responses of M1 and PMC was larger during fingertapping. Centers of gravity remained the same.

Conclusions: 1) IMP offers a robust alternative for fingertapping in identifying the motor cortex; 2) the actual performance of motor tasks is dictated only by the level of activation and not by its spatial distribution; 3) thalamic activation can be seen with simple motor tasks, even at 1.5 T.

B-932 11:24

Comparison of T1-weighted inversion-recovery, gradient-echo and spin-echo sequences for imaging of the brain at 3.0 Tesla

C. Stehling, T.-U. Niederstadt, S. Krämer, H. Kugel, W. Schwindt, W. Heindel, R. Bachmann; Münster/DE

Purpose: The increased T1-relaxation times at 3.0 Tesla lead to a reduced T1-contrast; therefore imaging protocols for high field examinations need to be adapted. This prospective study assessed the performance of three techniques for T1-weighted imaging (T1w) at 3.0 T with regard to gray/white differentiation and CNR.

Methods and Materials: 32 patients were examined at a 3.0 T system (Gyroscan Intera, Philips) with axial T1w Inversion Recovery (IR:TR/TE/TI = 9900/15/400 ms; scan-time 4:07 min), T1w Spin Echo (SE:TR/TE = 570/8 ms; 3:09 min) and T1w Gradient Echo (GE:TR/TE/FA = 214/2.4 ms/80°; 2:59 min) sequences; after contrast enhancement (CE) CE-SE and CE-GE were acquired. For qualitative analysis images were ranked with regard to artifacts, gray/white differentiation, image-noise and overall diagnostic quality. For quantitative analysis CNRs of cortex and basal ganglia to white matter were calculated. Statistical significance was determined by Student's t and Wilcoxon tests.

Results: In the qualitative analysis IR was judged superior to SE and GE for gray/white differentiation, image noise and overall diagnostic quality, but was inferior to GE with regard to artifacts. CE-GE proved superior to CE-SE in all categories. In the quantitative analysis CNR of the basal ganglia was highest for IR (10.9), followed by GE (4.9) and SE (2.7) ($p < 0.003$). For CNR of the cortex

no significant difference was found between IR (16.9) and GE (15.4) but both were superior to SE (9.4). Cortex-CNR of CE-GE was significantly higher than compared to CE-SE (12.7 vs. 7.6, $p < 0.001$), but basal ganglia CNR did not differ significantly.

Conclusion: For unenhanced T1w-imaging at 3.0 T the IR technique is, despite increased artefacts, the method of choice, due to its superior gray/white differentiation and best overall image quality. For CE studies GE sequences are recommended. SE sequences give unsatisfactory results at 3.0 T.

B-933 11:33

Diagnostic value of T1-weighted fluid-attenuated inversion recovery sequence with 3.0 T MR in the central nervous system (CNS)

S. Chen, X. Feng; Shanghai/CN

Purpose: To determine the clinical use of T1-weighted fluid-attenuated inversion recovery (T1 FLAIR) sequence with 3.0 T MR in the CNS by comparing results with those at pre-and postcontrast T1 and T2 FLAIR MR imaging.

Materials and Methods: During a 11-month period, 385 cases including 200 normal cases and 185 cases with brain tumors, were examined with T1SE, T1FLAIR and T2FLAIR using 3.0 T MR (GE signa 3.0 T VH/i MR). T2FLAIR was only done on plain MR scan. 185 cases with brain tumors were performed with pre-and post-contrast T1FLAIR and T1SE MR imaging. Qualitative measures of overall image contrast, lesion detectability and lesion conspicuity in addition to quantitative measures of lesion-to-background, lesion-to-cerebrospinal fluid, gray-to-white matter signal contrast and contrast-to-noise ratio (CNR) were used for evaluation of whether T1FLAIR improves lesion conspicuity.

Results: Lesion-to-background, lesion-to-cerebrospinal fluid, gray-to-white matter contrast and CNR were statistically superior in pre-and post-contrast contrast T1FLAIR. Qualitatively, the T1FLAIR sequence provided comparable lesion detection, improved lesion conspicuity, and superior image contrast compared with T1SE and T2FLAIR on both pre-and post-contrast images, especially in detection of lesions at the gray/white matter junction.

Conclusion: T1FLAIR MR imaging on 3.0 T MR is a potentially useful tool for diagnosis in the CNS; pre-and postcontrast T1 FLAIR could replace pre-and post-contrast T1SE MR imaging.

B-934 11:42

New MR sequences to detect the neurovascular conflict in cranial nerves

B.P.J. Kress, S. Siebert, M. Krause, C. Schwark, D. Rasche, G. Kolling, V. Tronnier, K. Sartor; Heidelberg/DE

Purpose: To show the options in MR imaging of the neurovascular conflict by newly developed T1 and T2 weighted imaging sequences.

Materials and Method: 85 patients (19 patients: facial hemispasm, 63 patients: unilateral facial pain, 1 patient: glossopharyngeal neuralgia, 1 patient: recurrent trochlear paresis, 1 patient: recurrent restriction of visual field) were examined by MR imaging to rule out a neurovascular conflict between an artery and a cranial nerve. (T1 FLASH 3D vibe, 0.9 mm isovoxel, coronal [before and after intravenous application of GdDTPA], T2-True FISP, 0.3x0.4x0.4 mm, coronal. The result of the MR imaging was compared to a preliminary examination of the same patient.

Results: In all patients with typical neurological symptoms it was possible to show a neurovascular conflict (all patients with trigeminal neuralgia, facial hemispasm, glossopharyngeal neuralgia) Also in the patient with trochlear nerve dysfunction and recurrent visual deficits a vessel was detected which had close contact to the nerve. In 13 of 24 patients with non neurological facial pain a vessel was found to have contact with the trigeminal nerve.

Conclusion: High resolution MR imaging can detect the adjacencies between vessel and cranial nerves. T2 TRUE FISP with an isovoxel of 0.3 mm in combination with high signal to noise ratio makes it possible to detect even small vessels, which are not seen on T2CISS images. Contrast enhanced T1 FLASH 3D vibe sequence makes it possible to differentiate between nerve and vessel confidently.

B-935 11:51

The value of high-field MR imaging (3 Tesla) in the assessment of sellar lesions

K. Pinker, A. Ba-Ssalamah, S. Wolfsberger, V. Mlynarik, E. Knosp, S. Trattnig; Vienna/AT

Purpose: The aim of this study was the evaluation of the normal sellar anatomy in-vitro and in-vivo with high-field MR imaging and its application in the diagnosis of sellar pathologies in comparison to standard MR imaging.

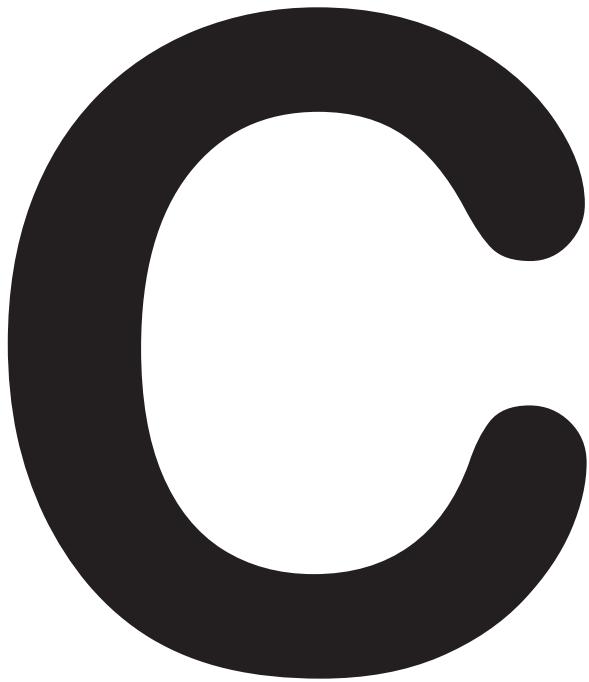

Methods and Materials: For high-field MR imaging we used a (3 T) Bruker Medspec 30/80 Scanner with a head birdcage transmit/receive coil and an actively

Scientific Sessions

shielded gradient system (maximum gradient strength 45 mT/m). We used a T2-weighted RARE sequence (TR/TE = 7790/19 ms; matrix size 512x512; FOV 200 mm) for coronal, axial and sagittal images and a T1-weighted-3D-MP-RAGE sequence (TR/TE/TI = 33.5/7.6/800 ms, matrix size 512x512; FOV 200 mm, SI 1.88 mm) for pre/post-contrast coronal images. 58 patients were enrolled in this study. Seven patients were examined for suspected microadenoma and in 51 patients 3 T MR imaging was used to obtain additional information about the sellar lesion already known to be present from standard MR imaging. In 21 cases the accuracy of the imaging findings was assessed by comparison with intraoperative findings.

Results: Infiltration of the medial cavernous sinus wall was suspected on standard MR imaging on 15 sides (47%), on high-field MR imaging on 9 sides (28%) and was verified by surgical findings on 6 sides (19%). Sensitivity of infiltration was 83% for 3 T MR imaging and 67% for standard MR imaging. Specificity was 84% for 3 T MR imaging and 58% for standard MR imaging. High-field MR imaging revealed microadenomas in 7 patients with a median diameter of 4 mm. The segments of the cranial nerves were seen as mean 4 hypointense spots on high-field MR imaging in contrast to 3 spots on standard MR imaging. This difference was statistically significant.

Conclusion: High-field MR imaging is superior to standard MR imaging for the prediction of invasion of adjacent structures in patients with pituitary adenomas and improves surgical planning.

MRCP findings of the choledochal cyst and anomalous pancreatico-biliary duct union: A comprehensive review with comparison to ERCP findings

M. Kim, J. Byun, H. Won, Y. Shin, A. Kim, P. Kim, H. Ha, M. Lee; Seoul/KR

Learning Objectives: To illustrate MR cholangiopancreatography (MRCP) and endoscopic retrograde cholangiopancreatography (ERCP) findings of various types of choledochal cysts and anomalous pancreatico-biliary duct union (APBDU). To assess diagnostic value with the benefits and pitfalls of MRCP compared with ERCP in evaluation of choledochal cysts and APBDU.

Background: The various types of choledochal cysts by Todani's classification are either associated with APBDU or not. The choledochal cyst is important to the patient because of the increased prevalence of malignancy or complications in the biliary tree. The presence of APBDU is helpful in diagnosis of choledochal cysts. We reviewed and classified MRCP images of 62 patients with choledochal cysts, with or without various APBDU. We also compared their MRCP findings with ERCP findings.

Imaging Findings: Of 62 patients with choledochal cysts the most common type was the type IVA ($n = 23$) and the second one was type IA ($n = 20$). Thirty-eight cases with choledochal cysts were associated with APBDU and the most common type was the type IIA ($n = 14$). Associated complications of choledochal cysts and APBDU were stone disease ($n = 14$), biliary malignancy proven pathologically ($n = 8$) and pancreatitis ($n = 52$).

Conclusion: MRCP provides equivalent information regarding choledochal cyst and APBDU to that provided with ERCP. MRCP should be considered as the first diagnostic modality for evaluation of the choledochal cyst and APBDU.

C-0002

Value of imaging findings in the detection of recurrent primary sclerosing cholangitis after orthotopic liver transplantation

M.-F. Bellin, J. Duclos Vallee, I. Ewenzyk, E. Bigot, D. Azoulay, D. Castaing, C. Guettier, D. Samuel; L. Gilbert; Villejuif/FR

Purpose: The aim of our study was to evaluate the role of imaging studies for the diagnosis of recurrent primary sclerosing cholangitis after liver transplantation.

Methods and Materials: 51 adult patients underwent liver orthoptic transplantation (LOT) between 1985 and 2004 for primary sclerosing cholangitis. Recurrent primary sclerosing cholangitis was histologically proven in 7 of these patients within 2-12 years following LOT. We reviewed the imaging studies [percutaneous cholangiography ($n = 6/7$), MR cholangiography ($n = 5/7$), Doppler ultrasonography ($n = 7/7$) and echoendoscopy ($n = 1/7$)] and compared the imaging findings with the biological and histologic results in these patients.

Results: The following aspects were observed on MR cholangiograms: non-anastomotic strictures ($n = 4$), segmental dilatation ($n = 3$) of intra or extrahepatic bile ducts, intrahepatic lithiasis ($n = 2$), irregular aspect of the bile ducts ($n = 3$), biliary abscess ($n = 1$) and normal aspect ($n = 1$). Percutaneous cholangiography confirmed the abnormalities observed with MR cholangiography in 4/7 patients and detected irregular walls of the intrahepatic bile ducts in one patient with normal MR cholangiography.

Conclusion: MR and cholangiographic abnormalities observed in patients with recurrent primary sclerosing cholangitis after LOT are identical to those observed in native livers. MR cholangiography may provide an excellent screening modality in patients with abnormal liver tests.

C-0003

Evaluation of biliary tract complications in hepatic transplantation with the use of magnetic resonance cholangiography

E. Maj, A. Cieszanowski, M. Golebiowski, K. Zieniewicz, E. Szwejda, B. Cieslak, M. Krawczyk; Warsaw/PL

Purpose: To assess the usefulness of magnetic resonance cholangiography (MRC) in the diagnosis of biliary complications after liver transplantation.

Methods and Materials: In 25 patients (17 women and 8 men) 29 MRC examinations were performed, from 1 to 56 months (mean=10) after liver transplantation. Indications for MR study were as follows: Suspected stenosis of biliary tree ($n = 16$), evaluation of intraductal stones ($n = 2$), abnormal biochemical tests ($n = 2$), recurrent biliary inflammations ($n = 1$) and other ($n = 8$). Studies were performed on a 1.5 T unit with the use of hydrographic TSE sequences: 2D, 3D and single-slice technique. The results were correlated with ERCP, percutaneous

cholangiography, ultrasound, clinical status and liver function tests. In 4 cases intraoperative confirmation was obtained during liver retransplantation.

Results: In 22 cases (76%) biliary strictures were diagnosed (10 at the anastomosis), in 18 (62%) marked dilatation of intrahepatic bile ducts was present and in 3 (10%) diffuse narrowing of biliary tree was identified suggestive of bile duct ischemia. In 4 patients (14%) stones or dense bile in the intrahepatic ducts were diagnosed and in 2 (7%) MRC revealed a bile leak at the anastomotic site. In 2 patients (7%) MRC was normal. In 27 cases (93%) there was concordance between MRC results and the standard of reference. Two remaining cases of bile duct ischemia and bile leak were not confirmed by other studies.

Conclusion: MRC is a noninvasive modality providing accurate assessment of biliary complications in patients after liver transplantation.

C-0004

Gall bladder wall thickening: An early sign of dengue fever

A.-L. Chang; Colombo/LK

Purpose of Study: To study whether the ultrasound findings of pseudo-thickening or oedema of gall bladder wall is a useful early sign of dengue fever in the recent epidemic in Sri Lanka.

Materials and Methods: A prospective study of 60 patients in the age group 10 to 65 years, with fever of 7 days or less with clinical suspicion of dengue fever, admitted to the medical ward or referred for assessment of fever and epigastric pain to our ultrasound practice were included in the study in the months of June and July 2004, during the peak of dengue fever epidemic in Colombo. Correlation with platelet count and serology for confirmation of presence of dengue antibodies was performed.

Results: Gall bladder wall thickening consisting of an echogenic inner wall and hypoechoic outer wall was demonstrated in the majority of patients with fever of 3-4 days. Only a small percentage of patients scanned on the 7th day of fever demonstrated gall bladder wall oedema. Majority of patients with marked gall bladder wall oedema scanned on day 3-4 of fever, demonstrated positive dengue IgM antibodies.

Conclusion: During an epidemic, sonographic finding of pseudo-thickening or oedema of the gall bladder in a febrile patient is an early sign of dengue fever. It suggests that the diagnosis of dengue fever can be strongly suggested by sonographic findings before antibody status is available. Other findings on ultrasound such as ascites and pleural effusion are helpful to the clinician in patient management.

C-0005

Usefulness of coronal multiple single slice mode balanced fast field echo MRCP with SENSE technique in the detection of choledocholithiasis

N.Y. Jung, S.K. Kim, H. Park, S.H. Hong, M.H. Lee, E.C. Chung; Seoul/KR

Purpose: The purpose of our study was to evaluate the usefulness of coronal multiple single slice mode (M2D) balanced FFE (fast field echo) MRCP with SENSE technique in the detection of choledocholithiasis by comparing observer performances with maximum-intensity-projection (MIP) of three-dimensional turbo spin echo (3D TSE) and single-shot turbo spin echo (TSE) MRCP.

Materials and Methods: MRCP was performed in 36 patients who were suspected having biliary calculi. Respiratory triggered MIP of 3D TSE, breath hold single shot TSE, and breath hold coronal M2D balanced FFE sequences with SENSE technique were compared. Image review was conducted for two anatomic compartments (upper biliary tract and common bile duct). Two independent radiologists reviewed a total of 72 compartments, including 13 bile duct calculi. The diagnostic accuracy of three sequences was assessed by means of receiver operating characteristic (ROC) analysis.

Results: Diagnostic accuracy of coronal M2D balanced FFE (96.5%) was higher than that of MIP of 3D TSE (89.6%, $p = 0.04$) and was similar to that of single shot TSE (95.1%, $p > 0.05$). Observer performance with coronal M2D balanced FFE ($Az = 0.956$) was higher than that with MIP of 3D TSE ($Az = 0.885$, $p = 0.12$) and was similar to that with single shot TSE ($Az = 0.970$, $p > 0.05$).

Conclusion: Coronal M2D balanced FFE MRCP is useful in the detection of choledocholithiasis as much as single shot TSE MR and MIP of 3D TSE MRCP.

C-0006

Acute cholecystitis: Helical CT findings

S. Quiroga, M. Sebastià, R. Boye, H. Cuellar, S. Roche, A. Alvarez; Barcelona/ES

Learning Objectives: To review and illustrate, as a pictorial essay, common and uncommon helical CT findings in acute cholecystitis, as well as a wide range of possible complications.

Scientific and Educational Exhibits

Background: Helical CT has become an important imaging technique for evaluating the acute abdomen. Although sonography is the method of choice to study the gallbladder when disease is suspected, the clinical signs and symptoms of acute cholecystitis are frequently nonspecific and helical CT is increasingly performed as the first-line technique in the evaluation of acute abdominal pain.

Imaging Findings: We review 79 cases of clinically unsuspected acute cholecystitis diagnosed with dual-slice or multidetector helical CT. The CT features of acute cholecystitis include gallstones, thickening of the gallbladder wall, pericholecystic inflammation or fluid, increased liver enhancement adjacent to inflamed gallbladder, hypertrophic cystic artery, air within the gallbladder lumen or wall, gallbladder rupture, hepatic or intraperitoneal abscess formation, extrahepatic bile duct obstruction (Mirizzi's syndrome), small bowel obstruction (due to abscess formation or gallstone ileus), portal vein thrombosis and gallbladder hemorrhage with or without haemoperitoneum.

Conclusion: Radiologists must be aware of the helical CT features of acute cholecystitis and its complications because of the widespread use of helical CT as the initial imaging technique for evaluating the acute abdomen.

C-0007

Primary sclerosing cholangitis: A spectrum of imaging findings with radiologic-histopathologic correlation

C. Belattar, A. Ayed, J. Duclos Vallee, I. Ewenzyk, C. Guettier, R. Adam, D. Samuel, D. Castaing, M. Bellin; Villejuif/FR

Learning Objectives: To become familiar with the broad spectrum of CT and MR characteristics of primary sclerosing cholangitis (PSC). To illustrate the typical and atypical aspects of CSP, as well as the complications after liver orthotopic transplantation (LOT). To correlate the pathological characteristics with the imaging findings and to discuss the key elements to be included in the differential diagnosis and to provide examples of them.

Background: PSC is an uncommon, chronic cholestatic disorder. Until recently diagnosis was based on percutaneous or retrograde cholangiography. Two experienced radiologists reviewed the ultrasound, CT, MR and cholangiographic studies in 50 patients with CSP who underwent LOT, and evaluated the presence of biliary strictures, segmental dilatations, biliary wall thickening, biliary stones, pseudodiverticula and associated parenchymal abnormalities.

Imaging Findings: The most common findings were diffuse and multifocal strictures. Long, confluent strictures were present in patients with long-standing disease. MR cholangiography proved useful as a suitable alternative method to radiological cholangiography. Extrahepatic involvement was observed in 15% of the cases. Diverticular protrusions were nicely depicted with MR and cholangiography. Recurrent PSC was observed after LOT in 7 patients.

Conclusion: The diagnosis of PSC may be difficult and is based on the association of clinical, biological and radiological abnormalities. MR imaging plays an increasing role for the diagnosis and follow-up of PSC. Early diagnosis of associated cholangiocarcinoma is essential and is based on subtle changes. MR and cholangiographic abnormalities observed in patients with recurrent PSC after LOT are identical to those observed in native livers.

C-0008

Radiologic findings of gallbladder adenomyomatosis: The importance of showing Rokitansky-Aschoff sinuses

J.-H. Yoon, S.-S. Cha, S.-S. Han, S.-J. Lee, M.-S. Kang; Busan/KR

Purpose: To demonstrate the radiologic characteristics of gallbladder adenomyomatosis (GADM) and emphasize the role of high-resolution ultrasound and MRCP.

Materials and Methods: We described 15 cases of GADM (eight males and seven females; 20-77 years old; mean age, 44.8) who underwent US (n = 11), helical CT (n = 8), PTC (n = 1) with MRCP and T2-weighted axial and coronal images (n = 8). All images were reviewed for the presence of GADM at three types (focal, segmental, diffuse), the involvement by compartment (fundus, body, neck), and radiological characteristics such as the presence of wall cystic spaces, intramural echogenic foci or hyperdense nodules and wall thickening.

Results: The types were as follows; focal (n = 9), combined focal and segmental (n = 4), segmental (n = 2). The compartments involved were as follows; fundus (n = 9), fundus and body (n = 4), body (n = 2). The sonographic appearances were as follows; intramural echogenic foci with or without associated acoustic shadows or reverberation artifacts (91%, 10/11), small anechoic cystic spaces, representing Rokitansky-Aschoff sinuses (73%, 8/11) and focal or diffuse thickening (73%, 8/11). The CT appearances were focal or diffuse wall thickening (50%, 4/8), hyperdense foci (50%, 4/8), focal cystic spaces (38%, 3/8), and the MRCP findings were as follows; focal or diffuse high-signal cystic structures, the so called pearl-necklace sign or diamond-ring sign (100%, 6/8).

Conclusion: GADM was commonly of focal type and usually involved the fundus with the most common radiological findings being intramural echogenic foci with acoustic shadows or reverberation artifacts and presence of wall cystic spaces. Sonography and MRCP has a higher sensitivity for visualization of Rokitansky-Aschoff sinuses in the differentiation of GADM from gallbladder carcinoma.

C-0009

MR cholangiography in the diagnosis and staging of extrahepatic cholangiocarcinoma

C. Juanco, F. González, R. Landeras, T. Piedra, P. Merino, M. Torres, M. Silván; Santander/ES

Purpose: To evaluate the role of MR and MR-cholangiography in the diagnosis and staging of extrahepatic cholangiocarcinoma.

Methods and Materials: We explored with a 1.5 MR unit (GE Genesis_Signa 1.5 T) 36 patients (22 women, mean age 23 y.o.) with a clinical onset and / or radiologic findings (CT or ultrasound) suggestive of a primary biliary tree neoplasm. All the examinations were performed with a phased array coil and T2-axial and coronal SSFSE sequences for the cholangiogram (thin and thick slab T2-SSFSE, radials) and in 17 cases (collaborative patients) we completed the examination with a dynamic 3D-FSPGR sequence before and after gadolinium injection and MR angiography using oblique and 3D-MIP vascular reformations to evaluate vascular involvement.

Results: MR examinations confirmed the presence of cholangiocarcinoma in 30 patients and assessed the exact location and tumoral extension. We classified the tumor pattern following the Bismuth scheme (7 cases Type I, 10 type II, 9 Type III and 4 Type IV). In 13 cases we diagnosed hilar vascular involvement with MR angiography (1 false negative and 2 false positive). Lymph node involvement was detected in 3 cases and satellite intrahepatic lesions were detected in 4 cases. We correlated MR findings with surgical excision or laparoscopic findings and also compared the MR with other diagnostic modalities (CT or ultrasound).

Conclusions: MR-cholangiography combined with a conventional and vascular MR examination is a complete, noninvasive diagnostic tool to confirm and stage biliary tree neoplasm. MR cholangiogram provides the surgeon with an exact biliary tree map that is necessary for surgical management.

C-0010

Preoperative surgical estimation of the portal venous based territories compared to the surgical planning landmark to the right of the middle hepatic vein

T. Abe¹, B.B. Frericks², B. Nashan³, Y. Ohgiya¹, T. Gokan¹; ¹Tokyo/JP,

²Berlin/DE, ³Halifax, NS/CA

Purpose: The purpose of our study was to evaluate the relationship between the surgical planning landmark of the middle hepatic vein (MHV) and the portal venous based avascular plane between the right and left liver lobe.

Methods and Materials: Contrast enhanced multi-detector row CT from 83 potential living donors were assessed. The patient group included 42 men and 41 women (mean age 39.4 ± 10.4 years). The data from the collimations of 2.5 mm and reconstructions at 2 mm were analyzed using the computer software "HepaVision 2" (MEVIS) for the portal venous based calculation.

Results: 76 adequate data were simulated. The anomalous portal venous branching were type I (with a short right common neck) in 57 cases, type II (trifurcation) in 10 (13%) cases, type III (right posterior portal branch division from the main portal branch) in 7 (9%) and type IV (the right anterior sectoral branches arose from left hepatic vein) in 2 (3%) cases. Based on portal venous territories, the avascular plane ran along the surgical plane, defined to the right of the MHV, in 23 donors. In 46 donors it ran to the left of the surgical plane (34 in type I, 8 in type II, 4 in type III) and it ran to the right of the surgical plane in 7 donors (4 in type I, 1 in type II, 2 in type IV).

Conclusion: When planning liver resection, knowledge of the shift of the portal venous based avascular plane is essential to estimate the ischemia of the portal venous territories.

C-0011

3D modelling of portal and hepatic venous analysis of the liver in living donor liver transplantation based on multi-detector row CT

T. Abe¹, B.B. Frericks², B. Nashan³, Y. Ohgiya¹, T. Gokan¹; ¹Tokyo/JP,

²Berlin/DE, ³Halifax, NS/CA

Purpose: The purpose of our study was to evaluate the portal and hepatic venous anatomy at the surgical plane to the right of middle hepatic vein, by using software in cases for living donor liver transplantation (LDLT).

Methods and Materials: Contrast enhanced multi-detector row CT (MDCT) from 83 potential LDLT were assessed. The patient group included 42 men and 41 women (mean age 39.4 ± 10.4 years). From the data from the collimations of 2.5 mm, reconstructions of 2 mm were analyzed using the computer software "HepaVision 2" (MEVIS, Bremen, Germany) for determining vascular anatomy. The prevalence of vascular variants for surgical planning was analyzed.

Results: A total of 76 venous data sets were considered technically adequate. A portal vein trifurcation was observed in 10 donors, an independent branch to the posterior sector from the main PV trunk in 7 donors and right anterior sectoral branches from the left portal vein in 2 donors. Segment VIII drained into MHV in 72 (95%) donors. In those cases, 44 MHV draining Segment VIII (diameter > 5 mm) occurred in 38 (50%) donors. Segment V draining into MHV occurred in 70 (92%) donors. In those cases, 43 MHV drained from Segment V (diameter > 5 mm) in 41 (54%) donors. 41 Small accessory right hepatic veins (ARHVs) (diameter ≤ 5 mm) were identified in 30 (39%) donors. 18 large ARHVs (diameter > 5 mm) were identified in 14 (18%) donors.

Conclusion: A wide range of anatomic variations is present which can be detected and visualized 3-dimensionally using the software and based on MDCT data.

C-0012

Comparison between highly fat selective MR imaging and volume localized 1H-spectroscopy of the liver for determination of intrahepatic fat accumulation

J. Machann, C. Thamer, B. Schnödt, H.-U. Häring, C.D. Claussen, A. Fritzsche, F. Schick; *Tübingen/DE*

Purpose: To test the feasibility of highly selective spectral-spatial fat selective MR imaging for determination of intrahepatic lipid content (IHL) and comparison with results from parallel proton MR spectroscopy (MRS) in healthy volunteers at an increased risk for type 2 diabetes.

Material and Methods: Fifty healthy volunteers were examined on a 1.5 T whole body unit (Magnetom Sonata, Siemens). MR imaging: single slice GE with spec-

tral spatial excitation, TR/TE 50 msec/16 msec, matrix 192x256 and an acquisition time of 16 sec in breathhold. Determination of hepatic lipids (HL) in ROI's of the posterior part (HL_P), anterior part (HL_A) and total cross-section of the liver (HL_T) referenced to subcutaneous fat. MRS: Single voxel STEAM, TE/TR 10 msec/4 sec, VOI 30x30x20 mm³ in the posterior part of segment 7 of the liver, 32 acquisitions. Determination of lipid/(lipid+water) ratio.

Results: MRS revealed reliable results in all volunteers with IHL in a range between 0.5 and 28.2% ($8.1 \pm 1.1\%$) using the water signal as internal reference. Fat selective MR imaging resulted in very similar data (HL_P: $1.52 \pm 0.18\%$, HL_A: $1.33 \pm 0.16\%$, HL_T: $1.36 \pm 0.16\%$) in different liver regions and correlated highly to spectroscopic results ($0.85 < r < 0.97$).

Discussion: Fat selective MR imaging of the liver within a single breathhold seems to be feasible even for determination of low amounts of hepatic lipids. However, the technique is more sensitive to breathing artifacts resulting in undesirable signal contaminations from subcutaneous fat. In healthy volunteers, lipids seem to be homogeneously distributed within the liver, but with a high interindividual variability in lipid content. Supported by a grant of the Deutsche Forschungsgemeinschaft (DFG, KFO 114/1).

C-0013

Double contrast MR imaging (DCMRI) of focal lesions in the cirrhotic and non cirrhotic liver: A problem solving technique

J.J. Sheehan, S.E. Harte, C.M. McKenna, D.E. Malone; *Dublin/IE*

Purpose: DCMRI synergistically combines unenhanced MRI with superparamagnetic iron oxide (SPIO), Gadolinium (Gd) enhancement and multiplanar, 3D imaging. We describe and illustrate our experience in cirrhotic and non-cirrhotic patients with focal liver lesions.

Methods and Materials: Consecutive patients presenting to a tertiary referral centre underwent DCMRI for characterisation of liver lesions first detected on US and/or CT. A GE 1.5 T magnet was used. Scan protocol included unenhanced sequences: (T1W GRE "in-phase/out of phase", T2W SSFSE, T2W FSE & Fat Saturation, T2*W GRE, T1W GRE 3D volumetric); SPIO-enhanced sequences: T2*W 10 minutes post SHU 555A (1.4 cc of 'Resovist'; 0.5 mmol of Fe/cc) followed immediately by the Gd-enhanced phase: (T1w GRE 3D volumetric: Gd-DOTA/Meg 20 cc @ 3 cc/sec by pump).

Results: 100 patients underwent DCMRI (M = 64, F = 36). 35 patients had cirrhosis. Diagnostic gold standards were applied. Illustrative US, CT and 3D DCMRI images will be shown from both groups. Cirrhotic Group: Solitary and multiple hepatocellular carcinomas, dysplastic nodules, siderotic nodules, transient hepatic attenuation defects, focal confluent fibrosis and portal vein thrombosis. Non-cirrhotic Group: Metastases, cavernous hemangioma, capillary hemangioma, cyst, focal nodular hyperplasia, adenoma, focal fatty infiltration and hamartomas. The added value of SPIO in terms of lesion conspicuity and characterisation will be illustrated. The benefit of 3D multi-planar imaging in terms of therapeutic planning will be shown.

Conclusion: DCMRI with 3D, volumetric acquisition is a valuable problem-solving and treatment planning technique. It is very useful for FLL characterisation and hepatic assessment in both cirrhotic and non-cirrhotic livers, especially when conventional imaging yielded indeterminate results.

C-0014

3D-CT angiography using 16-row multislice CT: Depiction of the feeding artery of hypervasculat HCCs

S. Kumano, H. Tanaka, H. Miki, T. Mochizuki; *Ehime/JP*

Purpose: Transcatheter arterial embolization (TAE) plays an important role in the treatment of hepatocellular carcinomas (HCCs). The purpose of this study was to evaluate the ability to depict the feeding artery of hypervasculat HCCs by 3D-CT angiography (3D-CTA) using 16-row multislice CT (MSCT) in the preoperative simulation of TAE for hypervasculat HCCs.

Method and Materials: Twenty patients with 35 hypervasculat HCCs underwent CT examination using 16-row MSCT (0.625-mm x 16) before TAE with digital subtraction angiography (DSA). In all patients 100 mL of contrast material was injected intravenously at a rate of 4 mL/sec. Timing for arterial phase scan was determined by a semiautomatic bolus tracking technique. Diagnostic scanning was started 10 seconds after the threshold was reached. 3D-CTA was produced using volume rendering and maximum intensity projection techniques.

Results: In all cases 3D-CTA demonstrated segmental branches of the hepatic artery, as well as hypervasculat HCCs. Feeding arteries of 18 HCCs were clearly identified. Fifteen of the 18 HCCs were fed by single segmental artery while the other three were fed by two different segmental arteries. Feeding arteries of the 13 HCCs were not clearly demonstrated but they could be predicted by the loca-

Scientific and Educational Exhibits

tion of tumors. Feeding arteries of the remaining four HCCs could not be identified or predicted because they were on the border between hepatic segments.
Conclusion: With 16-row MSCT 3D-CTA, segmental branches of the hepatic artery and feeding arteries of HCCs could be depicted. This technique is thought to be useful for the preoperative simulation of TAE.

C-0015

Differentiation of hemangiomas nonspecific at ultrasonography from malignant hepatic tumors: Comparison of the abilities of unenhanced and gadolinium-enhanced MR imaging and multiphase spiral CT
E. Szurowska, J. Pienkowska, E. Izycka-Swieszewska, R. Rzepko, M. Czarnowska, M. Studniarek; *Gdansk/PL*

Objective: To compare the abilities of unenhanced and gadolinium-enhanced MR imaging (MRI) and multiphase sCT in the differentiation of hepatic hemangiomas nonspecific at ultrasonography (US).

Materials and Methods: 183 patients with nonspecific, hypoechoic hepatic masses at US were examined with sCT and MRI. 77 hepatic hemangiomas in 38 patients and 416 malignant lesions in 145 persons were detected and confirmed pathologically or by clinical and imaging follow-up. Multiphase sCT included non-contrast scans, hepatic arterial-dominant, portal venous-dominant and equilibrium phase. Performed MR sequences included: SE, TSE, TFE-T1, double echo T2-weighted images, STIR and gadolinium dynamic study. The size of detectable lesions, their density, intensity, type of enhancement in CT and MRI (homogeneous, heterogeneous, nodular peripheral, ring, progressive fill-in) were prospectively analyzed by three radiologists.

Results: Moderately and heavily T2-weighted sequences correctly depicted 76 hemangiomas. Smaller hemangiomas (≤ 2 cm) more frequently (28/47) showed homogenous enhancement in three phases, but larger ones (22/30) showed nodular enhancement peripherally in HAP and progressive fill-in in PVP and EP. The sensitivity, specificity, PPV, NPV and accuracy of unenhanced versus gadolinium-enhanced MR and sCT imaging in the characterization of hemangioma were: 0.99 vs 0.84 vs 0.82; 1 vs 0.94 vs 0.93; 0.99 vs 0.70 vs 0.66; 1 vs 0.97 vs 0.97 and 0.99 vs 0.93 vs 0.91.

Conclusion: Unenhanced MRI is the most sensitive method for the characterization of hepatic hemangiomas which appear nonspecific in ultrasonography. There is no need for routine use of dynamic MR and CT exam in the differential diagnosis between hemangiomas and malignant tumors of the liver.

C-0016

Characterization of focal liver lesions appearing non-specific at ultrasonography: Comparison of usefulness of multiphase spiral CT and MR imaging
E. Szurowska, J. Pienkowska, E. Izycka-Swieszewska, B. Rutkowska, B. Balas, M. Studniarek; *Gdansk/PL*

Purpose: The purpose of the study was the evaluation of the utility of sCT and MR imaging in the characterization of HCC, metastases, hemangioma and FNH. **Materials and Methods:** Multiphase sCT and MR imaging was performed in 230 patients suspected (after ultrasonography) of having a hepatic tumor. 178 patients with an hepatic mass (confirmed pathologically or by clinical and radiological follow-up) were included in this study. Nonenhanced scans were performed in all cases along with HAP, PVP and EP. The following sequence MR imaging was obtained: SE, TSE, TFE T1- and T2-weighted images, STIR and dynamic study with administration Gd-DTPA. In statistical analysis, the sensitivity and accuracy of the methods were compared concerning the characterization of HCCs, metastases, hepatic hemangioma (HH) and FNH.

Results: 98 HCC foci, 316 liver metastases, 77 hemangiomas and 13 FNHs were detected in 178 patients. The lesions ranged in size from 5 to 140 mm (median value 20 mm). The sensitivity of MR imaging versus sCT for characterization HH was 0.99 vs 0.78 (significant difference). For HCC, the mean sensitivity of MR imaging (82%) was significantly higher than that of sCT study (66%). In characterization of FNH and metastases the sensitivity of both methods was as follows: 0.79 vs 0.82 and 0.92 vs 0.93.

Conclusion: The sensitivity of MR imaging seems similar to multiphase sCT study in the characterization of metastases and FNHs, but MR imaging is the most sensitive in characterization of hemangiomas and HCCs. MR imaging is superior to the routinely used methods (US and sCT) in the differentiation of focal liver lesions.

C-0017

Hepatic venous congestion in the anterior segment of the graft after living donor liver transplantation using right lobe: Characteristic findings at CT and Doppler ultrasound examination

S. Kim, K. Kim, T. Kim, S. Park, A. Kim, H. Won, J. Byun, Y. Shin, M.-G. Lee; *Seoul/KR*

Learning Objectives: To review the surgical techniques of middle hepatic vein reconstruction in living donor liver transplantation using a right lobe graft and to discuss the advantages and limitations of Doppler US and CT for the assessment of hepatic venous congestion of the graft.

Background: The recently increased incidence of living donor liver transplantation (LDLT) has led to increased demands on radiologists to educate themselves regarding the postoperative evaluation of these patients. Whereas LDLT using a donor's right lobe has been considered a safe and effective way in adult-to-adult LDLT to meet large metabolic demands of adult recipients, the graft usually does not contain the middle hepatic vein (MHV) because it is left in the donor for donor's safety. Therefore, the hepatic veins draining from the anterior segment of the graft are either ligated or anastomosed to the sidewall of the inferior vena cava using an interposition vein graft.

Imaging Findings: This operating method may result in variable degrees of hepatic venous congestion in the anterior segment of the graft, which produces several characteristic findings at CT and Doppler US examination.

Conclusion: In this exhibit, we illustrate a comprehensive pictorial review of the surgical techniques of middle hepatic vein reconstruction in LDLT using a right lobe graft, the CT and Doppler US demonstration of MHV tributaries and interposition vein graft, and various findings of hepatic venous congestion in the anterior segment of the right lobe graft at serial CT and Doppler US examination.

C-0018

Evaluating the relationship of the hepatic artery and portal vein using multi-detector row CT
H. Rikimaru, I. Kaneda, Y. Chiba, K. Igarashi; *Ishinomaki/JP*

Purpose: To investigate the relationship between the hepatic artery and portal vein near the pancreatic head using multi-detector row helical computed tomography (MDCT).

Materials and Methods: 1,160 patients underwent MDCT. Three-dimensional arteriograms and portograms were reconstructed to evaluate the relationship between the hepatic artery and portal vein, especially near the pancreatic head.

Results: In 984 (84.8%) patients, the common hepatic artery (CHA) arose from the celiac axis, crossed the portal vein immediately and then ran in front of the portal vein (type I). In 25 (2.2%), the CHA ran behind the portal vein before crossing it at the hepatic hilum (type II). The CHA arose from the celiac axis (IIa) in 6 (0.5%) and from the superior mesenteric artery (IIb) in the other 19 (1.6%). In 145 (12.5%) patients, the CHA ran in front of the portal vein and an aberrant right hepatic artery ran behind the portal vein (type III). The CHA arose from the celiac axis (IIIa) in 38 (3.3%) and from the superior mesenteric artery (IIIb) in the other 107 (9.2%). In 6 (0.5%) patients no CHA was found, and the hepatic inflow arose from the gastro-duodenal artery via the pancreatic arcade (type IV).

Conclusion: Six types of hepatic artery anatomy were seen in relation to the portal vein. Recognition of type IIa (0.5%) is clinically important for the preoperative evaluation of gastric malignancy, especially for video-assisted surgery.

C-0019

Hepatocellular carcinoma (HCC) suspected lesions: Detection and characterization at multislice-spiral computed tomography (MSCT) and Gd-BOPTA-enhanced magnetic resonance imaging (Gd-BOPTA-MRI)

I. Sansoni, A. Laghi, M. Celestre, C. Miglio, M. Di Martino, M. Rengo, L. Coletta, R. Passariello; *Rome/IT*

Purpose: To prospectively assess the diagnostic accuracy of MSCT versus Gd-BOPTA-MRI in the detection and characterization of HCC suspected lesions.

Methods and Materials: We studied forty-three patients with chronic hepatitis and HCC suspected lesions and they underwent CT and MRI liver evaluation. CT was performed using a 4-slice scanner with a tetraphasic acquisition protocol (unenhanced, contrasted arterial, portal venous and equilibrium phases). MR study was performed on 1.5 T-scanner using the following acquisition protocol: Pre-contrast T2-weighted HASTE and T1-weighted FLASH, dynamic Gd-BOPTA T1-weighted FLASH at arterial, portal venous and equilibrium phases and hepatobiliary (60 min) T1-weighted FLASH sequence. CT and MRI were blindly evaluated for presence, number and characterization of lesions. The number of lesions at final diagnosis was considered equal to CT plus MR detected lesions. Image

Scientific and Educational Exhibits

data were compared with histopathological studies of surgical specimens and/or follow-up imaging.

Results: Among the 43 patients, a total of 73 lesions (35 hepatocellular carcinoma, 17 dysplastic nodules, 3 focal nodular hyperplasia, 18 shunts) were detected in at least one technique. The detection rate of HCC suspected lesions was comparable for both MSCT and Gd-BOPTA-MRI (66/73; 90.41%). In particular 20 lesions were ≥ 2 cm and 46 were < 2 cm). MSCT offered a correct lesion characterization in 52/66 (78.79%) cases whereas Gd-BOPTA-MRI provided the correct diagnosis in 58/66 (87.88%) cases.

Conclusion: Concerning lesion identification, no statistically significant difference was observed between MSCT and Gd-BOPTA-MRI, independent of lesion size. They were also comparable for characterization. Both are valuable advanced techniques for hepatopathic liver screening and therefore they are interchangeable.

C-0020

Diagnosis of small hypervasculat hepatocellular carcinomas: Combined double phase CT during hepatic arteriography and CT during arterial portography versus dynamic CT with intravenous injection of contrast media, using multidetector-row CT scanner

T. Kamura, S. Yamamoto, T. Ozaki, T. Takano, K. Sasai; Niigata/JP

Purpose: Using a multidetector row CT scanner, we compared combined double phase CT during hepatic arteriography, CT during arterial portography (MD-DP-CTHA+MD-CTAP) and multiphase dynamic CT with intravenous injection of contrast media (IV-MDCT), for diagnosis of small hypervasculat hepatocellular carcinomas (HCC).

Materials and Methods: We reviewed 36 HCC nodules not more than 3 cm in diameter in 31 patients with chronic liver disease, who underwent both MD-DP-CTHA+CTAP and IV-MDCT. In all the nodules, increase of intranodular arterial blood flow was shown with at least one imaging modality. 29 nodules were diagnosed as HCC with surgical resection and 7 nodules were diagnosed with follow-up results. The findings of MD-DP-CTHA+CTAP were defined as confirmative of HCC when showing (a) Hyperdensity on 1st phase CTHA images, (b) Ringed enhancement on 2nd phase CTHA and (c) Hypodensity on CTAP. The findings of IV-MDCT were defined as confirmative of HCC when both (a) Hyperdensity on arterial dominant phase and (b) Visualization of the lesion besides arterial-dominant phase images were obtained.

Results: MD-DP-CTHA+MD-CTAP and IV-MDCT were confirmative in 32 nodules (89%) and in 27 nodules (75%), respectively. In all of 27 HCC nodules more than 1 cm in diameter, both MD-DP-CTHA+MD-CTAP and IV-MDCT were confirmative, without any false positive findings. In 9 HCC nodules less than 1 cm in diameter, MD-DP-CTHA+MD-CTAP confirmed 5 nodules and showed 1 false positive focus. IV-MDCT confirmed no nodules and showed no false positive findings.

Conclusion: MD-DP-CTHA+MD-CTAP may detect more hypervasculat HCC nodules less than 1 cm in diameter than IV-MDCT.

C-0021

Hepatic hemangiomas with arteriportal shunt in fatty liver: Atypical sonographic appearances by peritumoral sparing of fatty infiltration with CT and MR correlation

K. Kim, A. Kim, S. Kim, S. Park, H. Won, M.-G. Lee; Seoul/KR

Learning Objectives: To recognize spectrum of sonographic findings of hepatic hemangiomas with arteriportal shunt. To discuss the atypical sonographic appearance of hepatic hemangiomas with arteriportal shunt in fatty liver caused by peritumoral sparing of fatty infiltration, with CT and MR correlation.

Background: Hepatic hemangiomas are not uncommonly associated with arteriportal shunt. While several investigators focused on CT and MR findings of these tumors, relatively little attention has been paid to their sonographic appearances even though sonography has been considered the primary screening method for the evaluation of liver.

Imaging Findings: An associated arteriportal shunt may not influence sonographic appearances of hepatic hemangiomas in most cases. However, in the presence of fatty infiltration in liver, these tumors may occasionally exhibit atypical echo-poor appearance with peritumoral sparing of fatty infiltration, reflecting local hemodynamic alteration caused by associated arteriportal shunt. In this exhibit, we summarize and illustrate spectrum of sonographic appearances of hepatic hemangiomas with arteriportal shunt and correlate them with CT and MR findings.

Conclusion: Hepatic hemangioma with arteriportal shunt may show an atypical appearance in fatty liver by peritumoral sparing of fatty infiltration.

C-0022

Surgically important anatomical variations of the hepatic vasculature and intrahepatic bile duct in the evaluation of potential donor for living donor liver transplantation: A comprehensive pictorial review

S. Kim, K. Kim, A. Kim, S. Park, E. Chae, H. Won, J. Byun, Y. Shin, M.-G. Lee; Seoul/KR

Learning Objectives: To recognize the anatomical variations of the hepatic vasculature and intrahepatic bile duct that might influence surgical strategy of living donor liver transplantation (LDLT) and to determine their prevalence.

Background: Recently increasing performance of LDLT has led to increased demands on radiologists for an accurate assessment of the anatomy of the hepatic vasculature and intrahepatic bile duct in the evaluation of a potential donor for LDLT. A detailed understanding of their anatomy has become more important in living-donor evaluation, because the development of modified surgical techniques have allowed the use of grafts from donors with anatomical variation of these structures in some instances.

Procedure Details: Multi-detector row CT angiography, with three-dimensional volume rendering, maximal intensity projection and multiplanar reformation, is the most effective method for the evaluation of the hepatic vasculature. MR cholangiography or intraoperative direct cholangiography is used for the evaluation of intrahepatic bile duct anatomy. In this exhibit we illustrate a comprehensive pictorial review of the anatomical variations of the hepatic vasculature and intrahepatic bile duct that might influence surgical strategy of LDLT and discuss their prevalence.

Conclusion: Surgically important anatomical variations of the hepatic vasculature and intrahepatic bile duct are not infrequently seen in the evaluation of a potential donor for LDLT. A radiologic perspective in the evaluation of LDLT donors and an accurate assessment of these findings may help in establishing the surgical strategy.

C-0023

Computed tomography portography in the diagnosis of portal hypertension

S. Skrzewelski, J. Glowacki, R. Kachel, K. Gosek, W. Grzeszczak, S. Trzeszkowska-Rotkegel, H. Borowiak, Z. Jackowska; Zabrze/PL

Purpose: The aim of the study is an evaluation of computed tomography portography by spiral, multirow technique (MSCTP) in visualization of the anatomy of portal hypertension with special consideration to the portal vascular system and collateral circulations.

Methods and Materials: Biphasic MSCTP examination in 35 patients aged from 21 to 78 years with a clinical diagnosis of hepatic cirrhosis was performed. The received raw data underwent multiplanar reconstructions, maximum intensity reconstructions and three-dimensional volume reconstructions. The images of portal vessels, liver, spleen and other abdominal organs were assessed.

Results: Widening of portal and splenic veins and presence of a collateral circulation was found in 29 patients (82.9%). The observed anatomy included varicose coronary and short gastric veins, esophageal varices, retrogastric varices, perisplenic varices, retroperitoneal - paravertebral varices, collateral circulation through paraumbilical veins and abdominal wall varices and splenorenal shunts. There was no pathology within visible vessels in the remaining 6 patients (17.1%).

Conclusion: MSCTP in the diagnosis of portal hypertension allows fairly accurate, close to anatomical evaluation of the portal vascular system and collateral circulation vessels. The application of MSCTP can help the clinician to take a final decision about further clinical procedures. The use of a multirow spiral technique shortens the time of examination and decreases the dose of ionizing radiation. MSCTP, besides Doppler ultrasound examination, is in practice the only non-invasive method supporting the diagnosis of patients with portal hypertension. The limitation of MSCTP is a lack of the possibility to perform direct tension measurements and evaluate blood flow parameters in the portal system.

C-0024

Hemodynamic effects of a prostacyclin analog (Prostavasin) in systemic scleroderma patients

D. Salera, G. Argalia, G. Giuseppetti; Ancona/IT

Purpose: We examined the effects of a prostacyclin analog (Prostavasin) on the circulation of the upper extremities and visceral districts, portal vein, hepatic artery, superior mesenteric artery and interlobar renal artery in a group of scleroderma patients.

Methods and Materials: In an experimental group (EG) of 50 scleroderma patients without liver diseases or nephropathy, the peripheral vasculature was evaluated by brachial artery flow-mediated dilatation using high-resolution ultrasound

Scientific and Educational Exhibits

cross-sectional measurements. Splenic arterial pulsatility index (PI) and resistance index (RI) of the visceral arteries and portal vein flow were assessed by color Doppler sonography before and after 3 days of Prostavasin infusion. The control group (CG) consisted of 10 patients receiving no treatment.

Results: EG patients showed significantly ($p < 0.001$) increased brachial artery flow-mediated dilatation, portal vein velocity and splenic arterial PI after the infusion whereas the CG patients exhibited no significant changes. After treatment, interlobar renal artery, superior mesenteric artery and hepatic artery RI were reduced, though not significantly, in most EG patients.

Conclusions: The results indicate that Prostavasin has a powerful effect in improving the peripheral circulation of scleroderma patients. Prostavasin significantly increased portal vein flow but also splenic arterial PI, in contrast to the hypothesis of its direct and specific action on relaxation of hepatic micro-circulation.

C-0025

An algorithm-based approach to the sonographic diagnosis of focal liver lesions: A DVD-Rom teaching file with US image and video database

P.S. Zoumpoulis, I. Vafiadi, K. Pahou, E. Katsaounos, D. Dalakostas, I. Theotokas, S. Kyriazi; Athens/GR

Learning Objectives: 1. To teach the user to identify the principal sonographic features of a focal liver lesion. 2. To facilitate an accurate diagnosis by means of a simple algorithm employing sonographic characteristics. 3. To enable the comparison of the user's own US images to database images.

Background: This DVD-Rom is designed to aid the sonographic diagnostic approach of focal liver lesions by focusing on distinct ultrasonographic characteristics. The user provides US characteristics of a lesion by selecting key sonographic criteria. The system provides an algorithm leading to the differential diagnosis of all focal liver lesions pertaining to the criteria given. The user's US images can be compared to image galleries and videos of each diagnostic category. Interesting Cases with clinical, biochemical, imaging and histological findings highlight the overall profile of each diagnostic entity.

Procedure Details: The User can start using this teaching file by describing the US characteristics of a focal liver lesion that he has difficulty in characterizing (unilocular, hypoechoic, hypovascular). The system guides him through a specific algorithm of all possible liver lesions which fit the criteria. A large collection of US images and videos are available for comparison with the User's images. The User's image can also be linked to the contents of corresponding Interesting Cases, which are brief case reports with clinical, biochemical, imaging and pathological data.

Conclusion: This DVD-Rom establishes a diverse approach in the differential diagnosis of focal liver lesions.

C-0026

Digital subtraction MDCT (DS-MDCT): Impact in liver imaging

P. Tinazzi Martini¹, M. D'Onofrio², M. Pregraz¹, G. Zamboni², G. Mansueti²; ¹Peschiera/IT, ²Verona/IT

Purpose: To describe the digital subtraction, multidetector computed tomography (DS-MDCT) obtained with a double acquisition in a single breath-hold technique. This technique allows to subtract the pre-contrast from the contrast-enhanced acquisition obtaining a pure contrast-enhanced phase. The aim of this study is to discuss the possible applications of the DS-MDCT in liver imaging.

Methods and Materials: A 16 row CT (Sensation 16, Siemens, Erlangen) with standard software was used. The patients were asked to hold their breath for 22 seconds and, utilizing a 1.5 mm slice, this was enough to acquire two different phases in a single breath-hold. Later the pre-contrast enhanced acquisition, acting as a mask, was subtracted from the arterial phase thus obtaining images in the pure vascular phase in which the enhancing lesion were more clearly depicted (higher lesion conspicuity), since all the liver parenchyma having low or absent enhancement was erased.

Results: In our preliminary report we find this new technique useful and not time consuming, for example in HCC detection and follow-up after treatment with chemoembolization or radiofrequency ablation. In all cases the subtraction was possible thus obtaining the pure contrast-enhanced phase. The conspicuity of the studied lesions in the arterial and pure contrast phase was compared, being higher in the pure vascular phase than in the arterial phase due to a reduction of about 90% of the background liver parenchyma in terms of HU.

Conclusion: The DS-MDCT images in the pure contrast-enhanced phase obtained a better lesion conspicuity and improves the detection of HCC vascularization.

C-0027

Liver haemangiomas undetermined at grey-scale ultrasound: Contrast-enhancement patterns with SonoVue and pulse-inversion US

T.V. Bartolotta, M. Galia, G. Runza, G. Mamone, A. Comparetto, M. Midiri; Palermo/IT

Learning Objectives: To illustrate the spectrum of contrast-enhancement patterns of hepatic hemangiomas undetermined at grey-scale ultrasound (US) on SonoVue®-enhanced Pulse Inversion (PI) US.

Background: In about 20-40% of cases liver hemangiomas do not show typical features on B-mode US (homogeneous, hyperechoic mass with well-defined margins and posterior acoustic enhancement), thus making the correct diagnosis a difficult task. The introduction of contrast-specific US techniques, such as PI, has lead to a better depiction of both macro and microvascularization of liver tumors.

Procedure Details: Twenty patients with 35 hemangiomas (size range: 1-7 cm; mean: 3.1 cm) undetermined at baseline US underwent PI after i.v. injection of SonoVue®. All hemangiomas were confirmed by typical helical Computed Tomography and/or Magnetic Resonance Imaging findings. US examinations were videotaped and then reviewed by two experienced radiologists blinded to the final diagnosis. Readers evaluated by consensus the baseline echogenicity and the dynamic enhancement pattern of each lesion, in comparison with adjacent liver parenchyma.

Results: After administration of SonoVue®, 31/35 (88%) hemangiomas showed peripheral hyperechoic nodules in the arterial phase, followed by progressive centripetal fill-in, which was complete in 25/35 cases and incomplete in 6/35 cases. 3/35 (9%) hemangiomas showed rapid and complete fill-in in the arterial phase, which persisted in the portal and delayed phases. Finally 1/35 hemangiomas (3%) showed a rim of arterial contrast-enhancement with progressive and complete centripetal fill-in in portal-venous and delayed phases.

Conclusion: PI after the administration of SonoVue® enabled the depiction of typical contrast-enhancement patterns in haemangiomas undetermined at baseline US.

C-0028

Detection of hepatic metastases on ferucarbotran-enhanced MR imaging: Feasibility of 3D sensitivity-encoding water-excitation multi-shot echo-planar (3D-SWEEP) imaging

K. Mori, N. Takahashi, K. Matsueda, Y. Saida, M. Minami, T. Oda, N. Ohkohchi; Tsukuba/JP

Purpose: To evaluate the feasibility of ferucarbotran-enhanced 3D sensitivity-encoding water-excitation multi-shot echo-planar (3D-SWEEP) imaging for the detection of hepatic metastases compared with 2D gradient-recalled echo (GRE) sequence.

Materials and Methods: The study comprised 19 patients with surgically proven 65 hepatic metastases of which sizes ranged 3 to 90 mm (mean, 23.4 mm). The 3D-SWEEP sequence (TR/TE/Flip angle/EPI factor = 22/10/25/3) and 2D-GRE sequence (TR/TE/Flip angle = 148/9.2/30) were performed on a 1.5 T unit before and after administration of ferucarbotran. In the 3D-SWEEP sequence, 36 images of gapless 5-6.5 mm slice thickness covering the whole liver were acquired within a single breath hold of 23.4 seconds, whereas it took 27.2 seconds to acquire 18 images of 7-10 mm slice thickness with 0.7-3 mm inter-slice gaps in the 2D-GRE sequence. These two sequences were compared in terms of the percent signal intensity loss (PSIL), percent lesion-to-liver contrast (PLLC), lesion conspicuity and sensitivity. The lesion conspicuity was evaluated by consensus reading of two radiologists with the following 4 point scale.

Results: The mean values of PSIL, PLLC and lesion conspicuity were 66.7%, 46.6%, and 2.58 for the 3D-SWEEP and 64.3%, 41.6% and 2.42 for the 2D-GRE sequences, respectively. The sensitivity were 87.7% and 81.5% for the 3D-SWEEP and 2D-GRE sequences, respectively. Compared with the 2D-GRE, the 3D-SWEEP sequence showed significantly greater PSIL ($P = 0.036$) and depicted 4 more lesions.

Conclusion: The 3D-SWEEP sequence was clinically feasible and useful for the detection of hepatic metastases on ferucarbotran-enhanced MR imaging.

C-0029

MR imaging findings of focal eosinophilic infiltration of the liver

S. Kim, M.-J. Kim, J.-Y. Choi, J.-S. Lim, Y.-T. Oh, J.-H. Kim, K. Kim, J. Lee, H. Yoo; Seoul/KR

Purpose: To describe the MR imaging findings of focal eosinophilic infiltration (FEI) of the liver.

Scientific and Educational Exhibits

Methods and Materials: We retrospectively reviewed total of 70 FEIs of the liver in 15 patients (9 men and 6 women, mean age of 54 years), diagnosed by biopsy ($n = 6$) or clinically confirm ($n = 9$), and who had undergone MR imaging with unenhanced study, Gd-enhanced dynamic study, SPIO-T2WI and SPIO-T2'WI. The location, margin, shape, signal intensity (SI), enhancement pattern and size of FEI were evaluated. The margin and shape were evaluated on T2WI. Enhancement pattern was evaluated on delayed phase image. The size of FEI was measured three times on T2WI, SPIO-T2WI, SPIO-T2'WI, and the statistical significances of the size differences between T2WI and SPIO-T2WI, between T2WI and SPIO-T2'WI, and between SPIO-T2WI and SPIO-T2'WI were evaluated by the paired T-test.

Results: FEI of the liver more frequently showed a subcapsular location (61.4%), ill-defined margin (82.9%), non-spherical shape (81.4%) and homogeneous enhancement pattern (62.5%). FEI showed definite high SI on T2WI (50.0%), on SPIO-T2WI (58.6%), and on SPIO-T2'WI (82.9%). Therefore, FEI was the most conspicuous on SPIO-T2'WI. The average size of FEI was 13.3 ± 5.3 mm on T2WI, 10.5 ± 4.3 mm on SPIO-T2WI, and 10.8 ± 4.2 mm on SPIO-T2'WI. There were significant size differences ($p < 0.01$) between T2WI and SPIO-T2WI, and between T2WI and SPIO-T2'WI.

Conclusion: When a focal hepatic lesion with subcapsular location, an ill-defined margin, non-spherical shape, homogeneous enhancement pattern, and especially significant size decrease on SPIO-T2WI or SPIO-T2'WI in comparison with T2WI is found, the possibility of FEI of the liver should be considered.

C-0030

Thrombosis of the middle hepatic vein in living liver donors

A. García Criado¹, R. Gilabert¹, M. Vannoni², S. González¹, C. Brú¹; ¹Barcelona/ES, ²Porto Alegre/BR

Purpose: One of the most serious complications in liver donors after right hepatectomy for living donor liver transplantation (LDLT) is pulmonary embolism. Lower extremity venous thrombosis has been pointed out as the possible source of thrombi but sometimes the origin has remained unknown.

Methods and Materials: Thirty-two consecutive donors of right hepatic lobe for LDLT were included. The study protocol included abdominal Doppler sonography (DS) at 1, 2, 7 and 30 day after transplantation that assessed vessel patency (portal vein, hepatic artery, hepatic veins and cava vein). In the last 14 patients, the protocol included a DS of the lower extremities at 1 and 2 days after surgery looking for deep vein thrombosis.

Results: In three cases a partial thrombosis of the middle hepatic vein was detected by DS in the postoperative day 1 or 2. All thrombi began in a branch near of the edge of surgical resection and one of them extended to cava vein. These patients were treated immediately with heparin without serious hemorrhagic complications.

No cases of deep venous thrombosis were detected. There were no pulmonary emboli.

Conclusion: The middle hepatic vein must be carefully studied in living liver donors at the post-operative DS because partial thrombi after right hepatectomy is a possible complication that can be unseen in the imaging control. The cause of the thrombi could be related to surgical resection.

C-0031

The "C" sign: Sonographic assessment of hepatic hilar lymph node involvement

M.J. Sarrià Guzmán, X. Serres Créixams, S. Roche Vallés, M. Buti, A. Valdés, E. Castellà Fierro; Barcelona/ES

Learning Objectives: 1. To describe standard sonographic sections for the assessment of hepatic hilar lymph node (HLN) involvement. 2. To investigate the entities related with HLN. 3. To assess the degree of nodal involvement in these entities on the basis of the section area.

Background: HLN involvement has been described in CT, MR imaging and US studies. It is considered a non-specific manifestation, but has been related with the degree of liver inflammation activity. Nevertheless, evaluation of HLN involvement is not routinely performed.

Procedure Details: We studied 100 patients with chronic liver disease and HLN involvement (63 women and 37 men, mean age 57 years). The sonographic section we propose consists of a single oblique transversal plane through the left lobe that includes the HLN adjacent to the hepatic artery and those extending toward the portocaval region, forming a C-shaped configuration. Measurement of its section area gave the following values: 39 patients with hepatitis C virus (4.78 cm^2), 4 with hepatitis B (3.66 cm^2), 10 with enolic liver disease (2.05 cm^2), 6 with autoimmune liver disease (4.41 cm^2), 4 with primary liver disease (4.03 cm^2),

3 with pharmacological liver disease (2.65 cm^2), 2 with hemochromatosis (1.90 cm^2), 1 with non-enolic steatosis (1.50 cm^2), 16 associated with viral disease and other entities (4.45 cm^2) and 15 chronic liver disease of unknown origin (2.13 cm^2).

Conclusion: The "C-sign" is seen in various types of liver diseases and shows a higher area in processes of viral and immune origin and in primary biliary cirrhosis.

C-0032

Sonographic assessment of periportal hypoechoic halo

O. Persiva Morenza, X. Serres Créixams, S. Roche Vallés, H. Allende, C. Vilà Parera, R. Comet Segú; Barcelona/ES

Learning Objectives: 1. To describe the sonographic appearance of periportal hypoechoic halo. 2. To assess changes in this finding after i.v. contrast administration. 3. To investigate which entities are related with periportal hypoechoic halo.

Background: Periportal hypoechoic halo is a non-specific radiologic finding described in computed tomography and related with various hepatic alterations: trauma, transplant, biliary tract infections, tumoral process in the hepatic hilum and chronic liver disease. It has also been related with normal status.

Procedure Details: We studied 15 patients with generalized periportal hypoechoic halo, including ten women and five men with a mean age of 68 years. On ultrasound assessment, periportal hypoechoic was seen as a cuff around the portal vessels. On the transverse view, the portal vessels showed a target appearance and on the longitudinal view, the form of a rail. After contrast administration (4 patients), periportal hypoechoic halo demonstrated a slight delay in uptake as compared to hepatic parenchyma. At the onset of the portal phase the appearance became homogeneous and remained isoechoic also in the parenchymal phase. Among the 15 cases studied, eight had chronic hepatitis C infection, five primary biliary cirrhosis, one amyloidosis with pharmacological hepatotoxicity and in another case there was no apparent cause.

Conclusions: Periportal halo can be identified on ultrasound and shows characteristic features after administration of contrast material. This ultrasound finding may suggest a chronic underlying hepatic condition.

C-0033

Preoperative helical computerized tomography estimation of graft volumes: Experience in 150 living liver donors

S. Orguc, M. Zeytunlu, M. Kilic, U. Gurgan, Y. Yüzer, Y. Tokat; Izmir/TR

Purpose: The purpose of this study was to evaluate the accuracy of spiral computed tomography and 3D imaging models in measuring total and segmental liver volume in potential living donors.

Methods: A prospective study was undertaken to determine the correlation between the volumes of potential donor livers determined via helical CT and the actual volumes measured during operation. Left lateral segment (S2, 3) or left lobe (S2, 3, 4) transplantation was performed on 36 cases. In 96 recipients right lobe liver transplantation (S 5, 6, 7, 8) was done. Sixteen donor candidates were refused due to inadequate liver volumes.

Results: The regression analysis model showed a significant positive relation between the CT estimations of graft volumes and intraoperative weight measurements in living liver donors ($F:5525.37, p < 0.05$). 97.7% of changes in CT volume can be explained by the changes in the graft mass ($R^2:0.977$).

Conclusion: Preoperative estimation of segmental volumes of the donor livers is necessary to avoid donor-recipient size disparity and it has a major impact on the selection of the donor and type of surgical management. The accuracy of helical computerized tomography is very high in determining total and segmental liver volumes.

C-0034

Adding the hepato-biliary phase imaging to dynamic Gd-BOPTA magnetic resonance (Gd-BOPTA-MR): Its value in detection and characterization of hepatocellular carcinoma (HCC)

I. Sansoni, A. Laghi, M. Celestre, C. Miglio, M. Rengo, M. Di Martino, L. Coletta, R. Passariello; Rome/IT

Purpose: To assess if hepato-biliary phase imaging can supply triple-phase dynamic Gd-BOPTA-MR with adjunctive information for detection and characterization of HCC suspected lesions.

Methods and Materials: Eighty-one hepatopathics underwent MR-study on 1.5 T-scanner: Basal T2-weighted HASTE and T1-weighted FLASH; dynamic contrast-enhanced T1-weighted FLASH was acquired after i.v. administration of Gd-BOPTA (0.2 mM/kg) at 15-seconds, 55-seconds and 135-seconds; T1-weighted FLASH hepato-biliary phase was obtained 60 minutes after Gd-BOPTA administration.

Scientific and Educational Exhibits

Dynamic-MR and complete-MR study sets of images were reviewed for presence, number and characterization of lesions. Separate reading sessions were performed for dynamic-MR and complete-MR, calculating sensitivities and specificities. The value of delayed-phase images in characterization of HCC was finally assessed. The number of lesions at final diagnosis was considered equal to detected lesions at complete-MR study plus lesions detected by other imaging modalities (CT, US). Characterization of lesions was established by histopathologic examination after surgical resection or biopsy, or by follow-up imaging and treatment response.

Results: Diagnostic accuracy of MR study with the hepato-biliary phase was comparable to that of MR imaging without hepato-biliary phase, in particular, the percentage of identified HCC at complete Gd-BOPTA-MR imaging (92%) was slightly higher than that at dynamic-MR imaging (89.7%). Delayed phase images were not helpful in the characterization of suspected HCC lesions because the difference between the two set of images was not statistically significant.

Conclusion: Adding delayed phase imaging to dynamic Gd-BOPTA MR study does not provide significant additional benefit for the detection and characterization of hepatocellular carcinoma, probably in relation to reduced liver function and a subsequent inhomogeneous appearance.

C-0035

Benign liver tumors and metastases in normally functioning livers: The added value of the hepato-biliary phase imaging in Gd-BOPTA magnetic resonance imaging (Gd-BOPTA-MRI)

I. Sansoni, A. Laghi, C. Miglio, M. Celestre, M. Rengo, M. Di Martino, L. Coletta, R. Passariello; Rome/IT

Purpose: To verify if adding delayed hepato-biliary phase imaging to triple-phase dynamic Gd-BOPTA-MRI can provide further clues for detection and characterization of lesions in non-hepatopathic livers.

Methods and Materials: Fifty patients with liver lesions underwent Gd-BOPTA-MR study on 1.5 T-scanner: Basal T2-weighted HASTE and T1-weighted FLASH; dynamic contrast-enhanced T1-weighted FLASH acquired after i.v. administration of Gd-BOPTA (0.2 mM/kg) at arterial, portal venous and equilibrium phases; T1-weighted FLASH hepato-biliary phase obtained 60 minutes after Gd-BOPTA administration. Dynamic-MRI and complete-MR study were reviewed for the presence, number and characterization of lesions. Separate reading sessions were performed for images from both dynamic-MRI and complete-MR study, calculating sensitivities and specificities. The value of Delayed-phase images in the characterization of lesions was also assessed. The number of lesions at final diagnosis was considered equal to detected lesions at complete-MR study plus lesions detected by other imaging modalities (CT, US, MR with other specific c.m.). Characterization of lesions was established by histopathologic examination after surgical resection or biopsy, or by follow-up imaging and treatment response.

Results: Diagnostic accuracy of MR study with hepato-biliary phase was significantly higher than that of MRI without hepato-biliary phase in benign lesions and metastases. Hepato-biliary phase of Gd-BOPTA-MRI allowed us to detect 9% more lesions compared to dynamic MRI, whereas, considering lesions identified by both the set of images, delayed hepato-biliary phase images were helpful in the characterization of lesions in 5% of cases.

Conclusion: The addition of the delayed phase imaging to dynamic Gd-BOPTA MR study helps to detect and characterize focal lesions in normally functioning livers.

C-0036

Assessment of metastatic liver tumor burden on MR imaging: Validity of uni-dimensional and bi-dimensional measurements

M. Mazonakis¹, P. Prassopoulos², M. Mantatzis², J. Damilakis¹, N. Gourtsoyiannis¹; ¹Iraklion/GR, ²Alexandroupolis/GR

Purpose: Quantitative assessment of the extent of metastatic liver disease is an important parameter in the evaluation of anticancer treatment. The purpose of the study was to examine the validity of uni-dimensional and bi-dimensional measurements in the assessment of metastatic liver tumor burden on MR imaging.

Materials and Methods: Abdominal MR imaging examinations of 24 consecutive patients with liver metastases were analyzed. The size of each lesion was assessed using: (1) the maximum tumor diameter (d) according to RECIST guidelines, (2) the bidimensional tumor product, i.e. the product of maximum diameter and its longest perpendicular lesion dimension in accordance with WHO guidelines, and (3) the tumor volume planimetric measurement, based on manual tracing of lesion's boundaries, which was used as the gold standard. Lesions were categorized by maximum diameter as smaller than 1.5 cm (n = 41), between 1.5 and 3.0 cm (n = 26) and larger than 3.0 cm (n = 15).

Results: An excellent correlation was found between bi-dimensional tumor products and tumor volumes ($d < 1.5$ cm: $r = 0.90$, $p < 0.001$; $1.5 < d < 3$ cm: $r = 0.92$, $p < 0.001$; $d > 3$ cm: $r = 0.97$, $p < 0.0001$). Uni-dimensional measurements were strongly correlated with tumor volumes for lesions exceeding 1.5 cm in diameter ($1.5 < d < 3$ cm: $r = 0.89$, $p = 0.0034$; $d > 3$ cm: $r = 0.96$, $p < 0.001$). However, a weak correlation was observed between tumor diameters and planimetric measurements for lesions smaller than 1.5 cm ($r = 0.69$, $p = 0.0036$).

Conclusion: The validity of uni-dimensional measurements was dependent upon the size of the lesion. Bi-dimensional tumor product may be the preferred approach for assessing liver tumor burden on MR imaging due to its excellent correlation with tumor volume, irrespective of the size of the lesion.

C-0037

Role of contrast-enhanced sonography (CE-US) in percutaneous treatment for HCC

A. Nunziata, O. Catalano, F. Sandomenico, P. Vallone, A. Siani; Naples/IT

Learning Objective: To illustrate the CE-US findings during and after percutaneous ablation of HCC. To show the practical value of CE-US to help the ablation procedure and to assess results at early and late follow-up.

Background: Conventional US is the main tool in guiding percutaneous ablation therapies but fails to recognise residual viable tumour tissue during or after the ablation session. Contrast-enhanced, low-mechanical index US is being used with increasing frequency in the assessment of HCC during and after percutaneous ablation therapies.

Procedure Details: Cases are shown where CE-US is employed to guide percutaneous ablation of barely visible nodules, to demonstrate treatment complications, to depict incomplete treatment and need for retreatment, to assess tumour necrosis demonstrating viable tumour tissue persistence, to diagnose intra- and extrahepatic tumour seeding and to detect tumour recurrence after initially successful ablation therapy.

Conclusion: Real-time CE-US has several possible applications during percutaneous ablation therapies of HCC. It is also relevant after treatment, for short and long-term imaging follow-up.

C-0038

Detection of a hypervascular malignant focus in borderline lesions of hepatocellular carcinoma: Comparison of dynamic CT, dynamic MR imaging and SPIO-enhanced MR imaging

R. Shimura¹, O. Matsui¹, T. Gabata¹, K. Ueda²; ¹Kanazawa/JP, ²Shinshu/JP

Purpose: To assess the efficacy of dynamic CT, dynamic MR imaging, and superparamagnetic iron oxide (SPIO)-enhanced MR imaging in the detection of hypervascular foci in hypovascular borderline lesions of hepatocellular carcinoma (HCC).

Materials and Methods: 53 nodules in 33 patients showing hypodensity with internal hypervascular focus (or foci) on CT during hepatic arteriography (CTHA) and spotty hypodense area on CT during arterial portography (CTAP) were entered into the study (hepatitis B related 4, C 27, B and C 2). Dynamic CT was carried out using a helical CT system. Simultaneous multislice dynamic MR imaging was performed applying FMPSPGR technique after bolus intravenous administration of gadopentetate dimeglumine. SPIO-enhanced MR imaging was performed following intravenous injection of SPIO. Among these nodules, the detectability of hypervascular focus (sensitivity) and average size of the detected foci (AS) were analysed.

Results: Sensitivity and AS were 35.3% and 7.7 mm, respectively on dynamic CT, 25.5% and 8.2 mm on dynamic MR imaging, and 26.1% and 8.3 mm on SPIO-enhanced MR imaging. This difference between dynamic CT and MR imaging was not statistically significant. In 33 nodules (64.7%), malignant foci were not visualized on all three modalities, and the AS of them was 4.8 mm.

Conclusion: A hypervascular malignant focus in borderline hypovascular borderline nodules could be better visualized by dynamic CT than by MR imaging or SPIO-enhanced MR imaging without definite statistical significance, when it is larger than 7.8 mm. However, it was difficult to detect a malignant focus less than 5 mm by these non-invasive imaging modalities. Dynamic CT is recommended for the follow-up examination for hypovascular borderline lesions.

C-0039

Liver MR imaging with iron oxides: Is gradient-echo T2-weighted sequence always better?

L. Curvo-Semedo, F. Caseiro-Alves; Coimbra/PT

Objective: To compare the MR diagnostic performance of gradient-echo (GRE) T2-weighted to SE T2-weighted sequences (conventional and fast-spin-echo)

Scientific and Educational Exhibits

for liver lesion detection and/or characterization, after the administration of superparamagnetic iron oxide contrast agents (SPIO).

Material and Methods: From March 1996 to July 2004, 97 patients underwent MR imaging of the liver with administration of iron oxide particles (Endorem® or Resovist®) with pre- and post-contrast T2-weighted sequences, spin-echo (SE) or fast-spin-echo (FSE) and GRE sequences. Seventy-four patients had focal liver lesions that were retrospectively evaluated for signal intensity changes and conspicuity on SPIO-enhanced MR imaging for each T2-weighted sequence. Each sequence was evaluated regarding the ability to detect and characterize benign or malignant focal liver lesions, by consensus and by two observers.

Results: From the dataset there were three cases of patients with focal liver lesions, where detection or characterization of the nodules was better using the T2-weighted FSE sequence compared to the GRE T2-weighted sequence. There was a case of focal nodular hyperplasia in a male patient, a patient with liver metastases that underwent a previous surgical ligation of the right branch of the portal vein and a patient with simultaneous cysts and colorectal metastases that were not differentiated on the T2-weighted GRE sequence.

Conclusion: For SPIO-enhanced MR liver imaging the GRE T2-weighted sequence provides, in most instances, the best contrast for detection and characterization of focal lesions. However, to increase the overall MR accuracy, conventional SE T2-weighted sequences should also be routinely obtained.

C-0040

MR imaging assessment of radiofrequency liver tumor ablation

T.Y. Kudryavtseva, O.N. Sergeeva, A.V. Gavrilin, G.G. Karmazanovsky;
Moscow/RU

Purpose: Percutaneous US-guided radiofrequency ablation (RFA) of liver tumors is a widespread method nowadays, but US is unable to determine RFA margins. MR imaging was performed to assess the adequacy of tumor destruction.

Material and Methods: 18 patients (age range 32-66 years, 15 female, 3 male) have undergone percutaneous US-guided (Logiq-400, 3.5 MHz convex probe) RFA (Radionics Cool-Tip RF Ablation System, singe and cluster probes) of primary and metastatic liver tumors since January 2004. Pre- and post-procedural MR imaging was routinely performed in all patients (1 T Phillips Intera, using Synergy Body coil). The sequence protocol consisted of T1-weighted images (WI) and T2-WI in several planes, including fat-suppressed T2-WI STIR (TR = 1600 ms, TI = 155 ms, TE = 20 ms). Dynamic contrast enhanced (gadodiamide, dosage 0.2 mmol/kg, i.v. bolus, rate 2-3 ml/s) study (out-of-phase FFE (TR = 179 ms, TE = 3.5 ms, FA = 80°)) was performed. Arterial (25-30 sec), venous (60-70 sec) and late (3 min) phase images were analyzed.

Results: Real-time US assessed tumor destruction as complete in all patients, but post-procedural MR imaging revealed residual tumor at a periphery of the ablated regions in 6 (33.3%) patients. Non-damaged neoplastic tissue located at the posterior contour of the RFA-zone in 4 patients (66.6%), at the posterior superior contour in 1 patient (16.7%) and at the posterior lateral one in 1 patient (16.7%). Re-RFAs were required in all 6 cases and MR imaging verified their successes.

Conclusion: MR imaging accurately determines margins of the ablated areas. It allows to avoid incomplete tumor destruction in patients who have undergone RFA.

Assessment of liver iron: Normal values

V. Belan, M. Srbecký, L. Pruzincová, B. Wlachovská, J. Moczová, J. Andrísová;
Bratislava/SK

Purpose: MR imaging has been proven to be clinically useful in determining liver iron concentration. In order to differentiate between mild overload and normal iron content, the best achievable knowledge of the distribution of normal values is necessary. The aim of the study was to choose the best sequences for different clinical situations.

Methods and Materials: The simplest quantitative method of the liver iron concentration estimation by MR imaging is to measure liver to muscle signal intensity ratio (SIR). We examined 39 men and women without liver disease on 1.5 T Magnetom Symphony (Siemens), in a whole body coil. The following sequences were used: SE T1/685/25 and GRE (PD/120/4/20, T1/120/4/90, T2/120/9/20, T2/120/14/20, T2/120/21/20). SIR values were estimated and analyzed for all sequences.

Results: Distribution of SIR values did not significantly differ from normal, there-

fore assessment of the normal limits were estimated as average \pm 2 SD. Estimated averages and limits (average - 2 SD) of SIR were:

SE T1/685/25: 1.45 1.05, GRE PD/120/4/20: 1.50 1.10, T1/120/4/90: 1.15 0.96, T2/120/9/20: 1.06 0.90, T2/120/14/20: 1.07 0.84, T2/120/21/20: 1.12 0.64, resp.

Conclusions: Assessment of normal values allows us to find iron liver overload without necessity to correlate SIR and liver iron concentration, and also to eliminate the differences between different equipment.

C-0043

Acquisition and postprocessing procedures for 3D CT modeling of hepatic vessel architecture and volume calculation in major liver resection and living donated liver transplantation

O. Lucidarme, P. Malzy, J.-C. Vaillant, M. Cadi, J. Taboury, L. Hannoun, P. Grenier; Paris/FR

Learning Objectives: Our objective is to present, discuss and illustrate the multi-detector row CT (MDCT) imaging techniques (including iodinated contrast media injection protocol) and the currently available postprocessing procedures that can optimize the 3D non-invasive preoperative visualization of the portal and hepatic veins anatomy and the volumetric assessment of the hepatic lobes.

Background: Injection protocols used in our last 60 patients, acquisition settings, as well as threshold, propagation, separation and fusion postprocessing techniques and shaded-surface or volume rendering display will be detailed and illustrated.

Procedure Details: 80 sec after injection of 120 ml of a contrast agent (350 mg iodine/ml, 4 ml/s) followed by 100 ml of physiologic serum (2 ml/s), a strong enhancement of both portal and hepatic veins occurs in all patients. The shortest procedure (15 min) is obtained mixing the propagation and the threshold techniques for, respectively, parenchyma and vessel extraction. The shaded-surface display allows a better visualization of the superficial marks of the liver while the volume rendering display permits a better analysis of the vessels due to the control of the parenchyma transparency. The calculated volumes are well correlated ($r^2 = 0.86$) with the weight of the resected specimen when the virtual resection is performed jointly with a surgeon.

Conclusion: MDCT with 3D shaded-surface and volume rendering display of liver, hepatic and portal veins is a fast procedure that may help the surgeon in planning major resections. Virtual resections are improved when performed by a radiologist jointly with a surgeon.

C-0044

Ultrasonography of diffuse and focal liver disease: A multimedia DVD-Rom based educational tool and database

P.S. Zoumpoulis, I. Theotokas, I. Bechrakis, S. Kyriazi, D. Schizas, K. Pahou, I. Vafiadi, P. Karavitis; Athens/GR

Learning Objectives: 1. To review the role of ultrasound in the diagnosis of chronic liver disease, portal hypertension and focal liver lesions by using educational text, selected images, case studies and video cases. 2. To help derive a sonographic diagnosis through correct algorithms. 3. To provide comparison of an US image of diagnostic difficulty to the database.

Background: The user-friendly interface provides the possibility of free navigation throughout multimedia data and a comparative database including images, text, videos and relevant bibliography.

Procedure Details: The educational DVD-Rom contains: Instructions on ultrasonographic techniques (including video with voice instructions), analytical commentary of liver diseases, archived ultrasound images with captions, discussion pertaining to the case, its ultrasonographic findings, interpretation of the findings, many interesting cases and bibliography links. The aim of this project, to teach US technique, is achieved mainly by a twofold video presentation. More specifically, in your environment you will view both a presentation of a) the examiner and his manipulations with the transducer and b) a real-time ultrasound examination. Each chapter contains articles with key words that correspond to ultrasound images. The Image Galleries contain a broad selection of ultrasound images and comments on sonographic findings. A database is included to aid the user in reaching the correct diagnosis of a lesion detected in the liver by comparing it to the sonographic images available.

Conclusion: This multimedia DVD-Rom familiarizes the radiologist with CD-ROM multi-media presentations and covers all major fields of US evaluation of focal and diffuse liver diseases as well as presenting US-guided procedures of various focal lesions.

C-0045

Role of contrast-enhanced sonography (CE-US) in transarterial chemoembolization treatment for HCC

A. Nunziata, O. Catalano, F. Sandomenico, F. Fiore, E. Montemarano, A. Siani; Naples/IT

Learning Objective: To illustrate the real-time CE-US findings during and after transcatheter embolization of HCC. To show the practical value of CE-US to help the embolization procedure and to assess results at early and late follow-up.

Background: Contrast-enhanced, low-mechanical index US is a recently introduced technique in the assessment of HCC treated with transcatheter intrarterial chemoembolization therapy.

Procedure Details: Cases are shown where CE-US is employed to assess HCC vascularity immediately before and immediately after chemoembolization, to demonstrate treatment complications, to depict incomplete treatment and need for retreatment, to assess tumour necrosis demonstrating viable tumour tissue persistence and to detect tumour recurrence after successful initial chemoembolization.

Conclusion: Real-time CE-US has several possible applications during transcatheter embolization therapy for HCC (via selective hepatic arteriography). It is also relevant after treatment, for short and long-term imaging follow-up (via IV peripheral injection).

C-0046

Temporal and blood-flow phase subtraction technique of the liver for detection of subtle hepatocellular carcinoma on abdominal CT images

E. Okumura¹, S. Sanada¹, M. Suzuki¹, Y. Tsushima², O. Matsui¹; ¹Kanazawa/JP, ²Gunma/JP

Learning Objectives: 1. To demonstrate the advantages of an automated image-matching technique for abdominal CT images. 2. To demonstrate the advantages of the temporal and blood-flow phase subtraction technique for diagnosis of hepatocellular carcinoma.

Background: It is difficult for radiologists to identify subtle hepatocellular carcinoma (HCC) because it is often difficult to achieve sufficiently sensitive enhancement in contrast-enhanced images for detection of these tumours. Therefore, we developed a new temporal and blood-flow phase subtraction technique to enhance isolated structures such as subtle HCC.

Procedure Details: The present study was performed using CT images from 18 subjects. First, to register current and previous images, we used template matching based on similarities in liver shape, etc., between current and previous images (non-enhanced, contrast-enhanced images) at the same position. Second, temporal subtraction images were then obtained by subtraction of current images from previous images taken at the same position of the liver, and the blood-flow phase subtraction images were obtained by subtraction of plain images from contrast-enhanced images taken at the same position of the liver. Our results indicated that approximately 90% of current images from these 18 cases were correctly matched with previous images taken at the same position of the liver. Visualization of the enhanced lesions in temporal and blood-flow phase subtraction images was increased, especially for detection of HCC.

Conclusion: Our subtraction technique may be useful in assisting radiologists in diagnosis of liver CT images.

C-0047

Differential diagnosis of multiple hyperintense lesions of the liver on T1WI of MR imaging with pathologic correlation

K. Matsuzaki, M. Takeuchi, H. Uehara, H. Nishitani; Tokushima/JP

Learning Objectives: To demonstrate the differential diagnosis of multiple hyperintense lesions of the liver on T1WI of MR imaging including various benign and malignant tumors and tumor-like lesions with pathologic correlation.

Background: Multiple hyperintense lesions of the liver on T1WI are rare and include various benign and malignant pathologies. Some characteristic imaging findings and enhancement patterns with positive and negative contrast media may be diagnostic.

Imaging Findings: The causes of T1 shortening are fat, hemorrhage, hyperproteinous materials (mucin etc.), melanin and other miscellaneous factors. Multicentric well differentiated hepatocellular carcinomas (wHCCs), dysplastic nodules, angiomyolipomas and round fatty infiltrations may be observed as hyperintense lesions on T1WI due to their fatty components, which show signal reduction on fat-suppressed images. Dysplastic nodules and wHCCs are hypovascular on dynamic study with positive contrast media reflecting ischemic fatty metamorphosis and show superparamagnetic iron oxide (SPIO) uptake reflecting their

residual Kupffer function. Angiomyolipomas are hypervascular on dynamic study reflecting abundant hamartomatous vascular components and do not show SPIO uptake. Other benign hyperplastic nodules without adipose tissue may show hyperintensity on T1WI, but the cause is still unclear. SPIO uptake and patients' background conditions (portal hypertension, alcoholism etc.) may helpful for diagnosis. Metastatic melanomas and mucinous adenocarcinomas show contrast enhancement on dynamic study and do not show SPIO uptake. Hyperproteinous or hemorrhagic cysts do not show either contrast enhancement on dynamic study or SPIO uptake.

Conclusion: To diagnose multiple hyperintense lesions of the liver on T1WI of MR imaging the adequate use of positive and negative contrast media is helpful.

C-0048

Hepatic VX2 carcinomas in rabbits: Detection with ferucarbotran-enhanced MR imaging and comparison of optimized sequences

S. Kim¹, H.K. Lim², D. Choi², M. Kim², K. Jang³, W. Lee², J. Lim²; ¹Wonju/KR, ²Seoul/KR, ³Choncheon/KR

Purpose: To compare the accuracy of a variety of ferucarbotran-enhanced MR imaging sequences for detection of multiple hepatic VX2 carcinomas in rabbits.

Materials and Methods: Fifteen rabbits with VX2 carcinomas in the liver underwent ferucarbotran-enhanced MR imaging using the following sequences: a fat-suppressed proton density- and T2-weighted images, T2*-weighted fast multiplanar gradient-recalled echo acquisition in the steady state (FMPGR) with different TE or flip angle setting (TEs with 9, 12, and 15 msec, flip angle with 20° and 80°, respectively), T2*-weighted fast multiplanar spoiled gradient-recalled echo sequence (FMPSPGR), T1-weighted FMPSPGR and unenhanced and dynamic enhanced T1-weighted FMPSPGR obtained with delays of 20 seconds, 1 minute, 3 minutes, and 5 minutes. Contrast-to-noise ratios (CNRs) of the tumors were calculated quantitatively and image qualities were assessed qualitatively. The diagnostic performance was assessed by using receiver operating characteristic (ROC) analysis on a tumor-by-tumor basis, which was correlated with histopathologic examination.

Results: Quantitatively, the CNR of the proton density-weighted sequence was significantly higher than those of the other sequences ($p < 0.05$). Quantitatively, image qualities of proton density- and T2-weighted sequences were significantly more excellent than those of the other sequences ($p < 0.05$). In diagnostic performance, T2-weighted, proton density-weighted, and T2*-weighted FMPGR with a TE of 12 msec and a flip angle of 20° sequences were higher than those of the other sequences.

Conclusions: T2- and proton density-weighted, and T2*-weighted FMPGR with a TE of 12 msec and a flip angle of 20° sequences showed higher accuracy for detection of multiple hepatic VX2 carcinomas.

C-0049

Multidetector CT imaging of common and uncommon large cystic hepatic masses

E. Dominguez-Franjo, M. Diez Perez de las Vacas, P. Ramos Lopez, L. Garcia del Salto, I. Salmeron, E. Fraile Moreno; Madrid/ES

Learning Objectives: To identify the clinical and pathologic features of large cystic hepatic masses. To describe the MDCT imaging techniques and features of various cystic hepatic masses.

Background: Cystic lesions of the liver in the adult are frequently found in routine clinical practice. Large cystic masses (> 5 cm) often imply a diagnostic challenge. Multidetector CT, with the possibility of real multiplanar reconstruction, constitutes an important tool to define intrahepatic origin and relationships of lesions, and it provides images in a format more familiar to many surgeons. Cystic lesions can be classified as congenital, neoplastic, inflammatory and miscellaneous. In this exhibit we illustrate the CT findings of several large cystic masses including neoplastic cysts (like cystadenoma, metastases...), congenital cyst (simple-bile cyst, polycystic liver disease, Caroli disease...), infectious diseases (pyogenic, amebic abscess, hydatid cyst) or traumatic lesions such as intrahepatic hematoma, bilioma.

Imaging Findings: There are no specific signs for each tumor type, but several MDCT features are very useful to characterize the lesion. Important imaging findings include size of the lesion, presence and thickness of the wall, presence of septum, calcifications, solid poles, and the enhancement pattern.

Conclusion: Although there are not pathognomonic features, the better spatial resolution on thin sections MDCT data sets allows the identification of fine septum and calcifications as well as solid poles, necessary to approximate to the etiologic nature of the masses.

C-0050

Value of MR imaging in the diagnosis of hemochromatosis

M. Lirola Cruz, M. Muñoz Beltran, E. Garcia Casado, M. Tuñón Gómez, J.M. Blazquez Ortiz; Madrid/ES

Purpose: To assess the role of magnetic resonance (MR) imaging in the detection of liver iron overload.

Materials and Methods: MR imaging at 1.5 T was prospectively performed on 49 patients (20 with iron liver overload and 19 without). In all patients the sequences used were GRE T1W, TSE T2W and GRE T2W. Ratios of signal intensities between liver and paraspinal muscle were calculated from images obtained with spin-echo and gradient-echo sequences. Correlation between ferritin serum levels and ratios of signal intensities were obtained.

Results: MR measurements showed a highly significant ($p < 0.001$, Mann Whitney test) decrease in the signal-to-muscle ratio of the liver in patients with iron overload as compared to non-iron overloaded patients with GRE T2W sequence. Correlation between the liver-to-muscle ratio and serum ferritin levels with GRE T2W sequence was significant ($\rho = -0.708$, $p < 0.016$, Spearman test).

Conclusion: Mr imaging is a useful tool in the diagnosis and management of liver iron overload. Gradient-echo T2W sequence is the most sensitive for iron overload and there is a correlation between the magnitude of signal intensity decrease and the degree of iron overload. However it is still necessary to evaluate the usefulness of MR imaging for the quantification of hepatic iron concentration in order to avoid hepatic biopsy for the diagnosis of hemochromatosis.

C-0051

Imaging spectrum and minimally invasive therapy in neuroendocrine tumours

P. Rajiah, A. Khan; Manchester/UK

Learning Objectives: A. To understand the role of imaging in diagnosis of neuroendocrine tumours. B. To illustrate the appearances of neuroendocrine tumours in various imaging modalities such as ultrasound, CT, MR imaging, PET and octreotide scanning. C. To suggest a diagnostic approach and to learn the common differential diagnosis. D. To learn the role of minimally invasive therapy (embolisation) in management of metastatic neuroendocrine tumours.

Background: Neuroendocrine tumours are rare neoplasms that arise from the small, neuroendocrine cells and these are divided into carcinoid and pancreatic neuroendocrine tumours. They can arise anywhere in the body. The systemic and local symptoms are myriad. Tremendous advances have been made in the diagnosis, localisation and management of these tumours. This review illustrates the role of imaging, the imaging spectrum of the tumours in USG, CT, MR imaging, contrast ultrasound, angiography, endoscopic ultrasound, In 111 DTPA octreotide scintigraphy and management of neuroendocrine tumours.

Procedure: All patients with suspected neuroendocrine tumours had ultrasound, multislice CT and MR imaging scans. Angiography, octreotide scintigraphy, contrast ultrasound, Endoscopic ultrasound and intraoperative ultrasound were performed in tumours that were difficult to localise. Hepatic artery embolisation was performed in metastatic neuroendocrine tumours in those who were not candidates for hepatic resection.

Conclusion: Radiology plays a vital role not only in the diagnosis and localisation of neuroendocrine tumours but also in management in the form of minimally invasive therapy.

C-0052

CT imaging based scores as predictors of severity in acute pancreatitis:

A comparative study with statistical evaluation

C. Triantopoulou, P. Maniatis, D. Lytras, I. Siafas, K. Manes, J. Papailiou, C. Dervenis; D. Chryssovergis, Athens/GR

Purpose: The aim of the study was to analyze the course of the disease in patients suffering from acute pancreatitis in conjunction with computed tomography (CT) evaluation of severity, using Balthazar and computed tomography severity index (CTSI) scoring systems.

Methods-Materials: 148 patients with acute pancreatitis were treated in the surgery department of our hospital. All data concerning etiology, Atlanta classification, CT findings, Apache score, CRP levels, stay in the intensive care unit (ICU), length of stay, treatment, complications and deaths were analyzed with Mann Whitney, Wilcoxon, Pearson and Spearman statistical tests. CT was performed within 96 hours of admission on a spiral unit, using 3-5 mm collimation after i.v. administration of iodinated contrast material in a total volume of 100-120 ml. Images were graded according to the Balthazar scoring system while, after measurement of the non enhanced necrotic pancreatic lesions using the "area" tool provided by the software, the CTSI was also calculated.

Results: A very good correlation was noticed between Balthazar-CTSI scores and local complications, while a not statistical significant correlation was found between CT scores and stay in the ICU. Among survivors and non-survivors there were no statistical significant differences as far as CT scores were concerned.

Conclusions: Although the extent of necrosis as defined on contrast-enhanced CT examinations is considered as a risk factor for a negative prognosis, our findings suggest that initially documented disease severity according only to imaging parameters is not highly important for the final patient outcome.

C-0053

Imaging findings after pancreas transplantation with enteric exocrine drainage: Posttransplantation anatomy and pathology

M.C. Freund, K.M. Unsinn, M. Rieger, W. Mark, H. Bonatti, R. Margreiter, W.R. Jaschke; Innsbruck/AT

Learning Objectives: 1. To illustrate the spectrum of imaging findings after pancreas transplantation with enteric exocrine drainage, utilizing different imaging modalities with regard to anatomy and pathology. 2. To be familiar with the different surgical techniques of pancreas transplantation with enteric exocrine drainage.

Background: Pancreas transplantation has emerged as an effective treatment

Scientific and Educational Exhibits

for patients with long-standing type 1 diabetes mellitus resulting in an insulin-independent euglycemic state and normalization of glycosylated hemoglobin levels. Knowledge of the transplantation procedure and postoperative imaging anatomy of the pancreas allograft are basic requirements for radiologists. Graft survival, among other factors, corresponds to early diagnosis and therapy for specific graft-related complications.

Imaging Findings: Interpretation of imaging studies after transplantation depends on familiarity of the surgical anatomy. For these reasons this pictorial essay schematically illustrates the intraoperative appearance during the various procedures of pancreas transplantation. Each procedure is supplemented by various examples of typical anatomy as shown by several imaging modalities including sonography, CT, MR imaging, gastrointestinal contrast examination and angiography. Additionally, this pictorial essay displays the spectrum of imaged pathology including vascular graft complications such as rejection (venous and arterial graft thrombosis), pancreatic graft complications including infection (pancreatitis, pseudocyst formation including expansion, infection with abscess formation, pseudoaneurysm formation, leakage of the enteric anastomosis or duodenal stump and small bowel obstruction) and other transplantation-associated complications (pseudothrombosis of the iliac vein and posttransplant lymphoproliferative disorder).

Conclusions: This pictorial essay displays the spectrum of imaging findings after pancreas transplantation with enteric exocrine drainage utilizing different imaging modalities with regard to anatomy and pathology.

C-0054

Vascular thrombosis in pancreatic transplantation: Multidetector CT in the evaluation of pancreatic vessels and parenchyma

C. Cappelli, E. Neri, A. Pratali, R. Cioni, U. Boggi, C. Bartolozzi; Pisa/IT

Purpose: The role of multidetector CT in the evaluation of pancreatic vessels and parenchyma in patients submitted to pancreas transplantation with arterial and/or venous graft thrombosis.

Methods and Materials: 22 patients submitted to pancreas transplantation were evaluated with multidetector CT because of Doppler-US suspicion of vascular thrombosis. CT study included unenhanced, arterial and portal phases with 1.25 mm collimation and 0.6 mm reconstruction interval. For the evaluation of vascular structures MPR and MIP reformats were performed. The pancreatic parenchyma was assessed both in unenhanced and post-contrast phases by evaluating morphology and parenchymal enhancement.

Results: The CT study demonstrated 4 cases of arterial thrombosis involving both the splenic and mesenteric branches. In such cases the pancreas appeared small and inhomogeneous (3) or completely atrophic and calcified (1). In 3 cases an arterial thrombosis of the mesenteric (2) or splenic (1) branch was found. In isolated mesenteric artery thrombosis, the parenchyma was normal, while in splenic artery thrombosis the tail of the pancreas was small and inhomogeneous. When a partial venous thrombosis (portal vein-1 case, splenic vein-5 cases) was demonstrated, the pancreas appeared normal. In complete venous thrombosis, isolated (3 cases) or associated with arterial thrombosis (6 cases) the parenchyma appeared hypodense and enlarged, suggesting a parenchymal necrosis.

Conclusion: Multidetector CT can accurately identify vascular thrombosis in patients with pancreatic transplantation. By assessing the morphology and enhancement of the parenchyma, it can be useful in the follow-up and therapeutic planning of such patients, in association with clinical findings.

C-0055

Perfusion CT of the pancreas in acute pancreatitis

S.D. Rud, G.E. Trufanov, O.F. Pozdniakova, V.S. Dekan, I.V. Pyanov; St. Petersburg/RU

Purpose: To assess the clinical significance of perfusion CT in evaluation of the pancreatic parenchyma of healthy adults and in acute pancreatitis (AP).

Materials and Methods: 17 patients with clinical signs of AP (10 men and 7 women, mean age 48.6) and 10 asymptomatic patients underwent dynamic MDCT (Somatom Volume Zoom™, Siemens). Measurements of perfusion index was performed using a maximum slope method and special software BasamaPerfusion 3.0.3.6. In all patients with AP, contrast-enhanced MDCT and calculation of Balthazar severity index were used. Patients with AP were divided into two groups: severe AP ($n = 10$, Balthazar score 3-10) and mild AP ($n = 7$, Balthazar score 0-3).

Results: Normal perfusion index calculated in patients without clinical and laboratory signs of pancreatic disease was 0.7-1.5 ml/min/cm³ and did not depend on the age of patient. In patients with AP the perfusion index was 0.8-0.4 ml/min/cm³ in mild pancreatitis and < 0.5 ml/min/cm³ in severe AP. Perfusion abnormalities of pancreatic parenchyma had as local as diffuse character. All results correlated with Balthazar severity index and further development of clinical signs.

Conclusion: Perfusion CT of pancreas seems to be a strong diagnostic tool for early detection of perfusion abnormalities in AP and prognosis of AP severity.

C-0056

How to reach the sonographic diagnosis of pancreatic lesions using a simple algorithm: A DVD-Rom based teaching file with US image and video database

P.S. Zoumpoulis, I. Theotokas, A. Plagou, D. Schizas, E. Tako, D. Leli, C. Beligiannis, K. Pahou; Athens/GR

Learning Objectives: To teach how to describe US characteristics of a *focal pancreatic lesion*. To facilitate diagnosis imaging through correct algorithms. To help compare a US image of diagnostic difficulty to US images with a proven diagnosis.

Background: The user may simply view the images, video cases and interesting case studies or compare his images to those of the database.

Procedure Details: The user has the option of viewing and comparing B-mode or color Doppler images. The user may enlarge any image whether it is from the image gallery or the interesting case studies and adjust the brightness if necessary so as to view it better. The user starts using this teaching file by describing the US characteristics of a focal pancreatic lesion that he has difficulty in diagnosing. The system guides him through a specific algorithm of all possible pancreatic lesions which fit the given description. A large collection of classified US image galleries and videos in each diagnostic category are available for comparison with the User's images. The user's image can also be linked to the contents of corresponding interesting cases, which are brief case reports with clinical, biochemical, imaging and pathological data.

Conclusion: The user can be aided in deriving a diagnosis of a pancreatic lesion by comparing it to other "similar" sonographic images, available in galleries, videos and interesting cases.

C-0057

Macrocystic neoplasms of the pancreas: Differentiation of serous oligocystic adenoma from mucinous cystadenoma and intraductal papillary mucin-producing tumor with CT

S. Kim; Seoul/KR

Purpose: To describe typical CT findings of serous oligocystic adenoma (SOA) of the pancreas and to find differential points from other macrocystic neoplasms such as mucinous cystadenoma and intraductal papillary mucin-producing tumor of branch duct type (IPMT).

Materials and Methods: A total of 41 patients with histologically confirmed macrocystic neoplasms of the pancreas were enrolled into this study (SOA:10; mucinous cystadenoma:13; branch type IPMT:18). Two experienced radiologists reviewed the CT findings of these patients in consensus. The location, longest dimension, shape, presence of mural nodule, presence of wall calcification and extent and degree of main pancreatic duct (MPD) dilatation were analyzed. The shapes were categorized into 7 groups as below: multicystic; lobulated contour with/without internal septation; smooth contour with/without internal septation; pleomorphic cystic; clubbed finger-like cystic. Comparative studies of three types of lesions were performed using Fisher's exact test and Mann-Whitney U test.

Results: There was significant difference in shape of the lesion between SOA and the other macrocystic neoplasm such as mucinous cystadenoma ($P < 0.05$) IPMT ($P < 0.05$). SOA showed a shape of multicystic or lobulated contour while mucinous cystadenoma showed a shape of smooth contour and IPMT showed either a pleomorphic cystic or clubbed, finger-like cystic shape. Upstream MPD dilatation was predominantly observed in SOA compared to other two diseases while diffuse MPD dilation was noted in IPMT ($p = 0.025$).

Conclusion: SOA of the pancreas has typical CT findings differing from other cystic tumors. It appears as a multicystic or lobulated cystic lesion with septation and with upstream MPD dilatation from the lesion.

C-0058

MR pancreatography and secretin enhanced MR pancreatography for the study of anatomical variants and developmental abnormalities of the pancreas

C. De Juan, M. Sanchez, S. Navarro, M. Pages, J.R. Ayuso, C. Ayuso; Barcelona/ES

Learning Objective: To describe and illustrate the use of magnetic resonance pancreatography (MRP) in the evaluation of the normal anatomy, anatomical variants and developmental abnormalities of pancreatic ducts, specially focused on the role of secretin enhanced MRP (S-MRP). MRP is being used increasingly as

Scientific and Educational Exhibits

a non-invasive technique to study the pancreas. However, due to the small diameter of pancreatic ducts in physiological conditions, in approximately 20% of patients the entire ductal anatomy can not be completely identified. In these cases, the administration of secretin clearly improves the visualization of the ducts. Secretin acts as an endogenous contrast agent which stimulates the pancreatic exocrine secretion and transiently distends the ducts displaying their full length. By filling non-visualized ductal segments, S-MRP increases diagnostic accuracy. Normal anatomy of pancreatic ducts varies greatly. It is important to be familiar with the different configuration types because they may be mistaken for pathologic conditions. Because of its complex embryologic development, the pancreas demonstrates multiple variations in ductal drainage pattern (E.g. persistent duct of Santorini, ansa pancreatica, pancreas divisum...) and different developmental abnormalities (E.g. agenesis of dorsal pancreas, annular pancreas, partial duplication or ectopic pancreas). Our objective is to describe the technique and diagnostic key facts to evaluate these conditions, specially focused on S-MRP. Images are provided from our series of patients and technical considerations based on our clinical experience. In conclusion, MRP combined with S-MRP can provide high quality images to identify the course and drainage pattern of pancreatic ducts and to diagnose congenital anomalies.

C-0059

Cephalic duodenopancreatectomy (Whipple's procedure): Assessment of complications with helical CT

C. Juanco, F. González, R. Landeras, J. Jordá, E. Ruiz, T. Piedra, M. Lopez, M. Silván; Santander/ES

We evaluate the role of helical CT to assess normal anatomy and to depict complications after Whipple's procedure (WP) (cephalic duodenopancreatectomy). Accurate interpretation of these examinations requires knowledge of the type of surgery performed and the normal appearance of the abdomen on CT following this complex surgery. The purpose of this pictorial essay is to illustrate the normal appearance of the bowel following a Whipple's procedure as well as some of the complications. We retrospectively review the findings in helical CT examinations performed after pancreatic surgery in 70 patients that underwent WP emphasizing normal anatomy and common postoperative changes (unopacified anastomotic bowel loops in the porta hepatis, perivascular cuffing, pneumobilia, dilated intrahepatic bile ducts, reactive lymphadenopathy and transient fluid collections) and describing the most frequent complications (abdominal abscess, bilomas, biliary obstructions, pancreatitis, pseudocyst, haemorrhage, pancreatojejunum anastomotic leak, ascitis, delayed gastric emptying and vascular complications). We illustrate these findings with examples. We also compare the advantages of helical CT with other diagnostic methods (sonography, MR, barium...). Helical CT examination is an accurate method to depict immediate and subacute postoperative complications in patients that undergo cephalic duodenopancreatectomy giving the surgeon essential information for the adequate management of the patient.

C-0060

Detection and differential diagnosis of benign and malignant pancreatic lesions by unenhanced and contrast enhanced MR imaging

G.K. Schneider, P. Fries, K. Altmeyer, B. Kramann, R.M. Seidel; Homburg a.d. Saar/DE

Learning Objectives: To teach the principles of unenhanced and dynamic contrast enhanced MR imaging in the differential diagnosis of benign and malignant pancreatic disease.

Background: Pancreatic tumors represent an entity that is often asymptomatic and incidentally found by abdominal cross sectional imaging. For the adequate therapeutic approach an exact delineation and differentiation of detected pathologies is crucial.

Imaging Findings: This exhibit reviews the most frequent pathologies of the pancreas with a major impact on MR imaging. Cases will be presented with patient history and correlation to other imaging modalities such as CT, ultrasound or nuclear medicine is demonstrated when appropriate. The topics to be covered include benign lesions (e.g. adenoma, serous cystadenoma, microcystic adenoma, glucagonoma, islet cell tumor and lymphangioma), malignant lesions (e.g. (cyst-)adenocarcinoma, IPMT, insulinoma, multiple endocrine neoplasia and lymphoma) as well as pseudotumors (e.g. edematous or hemorrhagic pancreatitis, chronic pancreatic disease, pseudocyst and duct ectasia). A special regard will be taken to local staging of pancreatic adenocarcinoma based on MR findings. Cases with characteristic patterns and diagnostic pitfalls are demonstrated to elucidate both the potential and limitations of MR imaging in the work up of pancreatic pathologies.

Conclusion: Diseases of the pancreas include a large variety of differential diagnosis with a major clinical impact on therapeutic strategies. MR imaging represents an adequate imaging modality revealing the diagnosis and local staging for the appropriate therapy to be planned.

C-0061

Imaging findings of biliopancreatic involvement by lymphomas and leukemias

B.R. Arenas, L. Del Campo, A. Barbosa, M.A. Llosa, M. Caraballo; Madrid/ES

Purpose: To illustrate the imaging findings on computed tomography (CT) and magnetic resonance (MR) of biliopancreatic involvement by lymphomas and leukemias.

Methods and Materials: We have reviewed 424 cases of leukemias and 350 of lymphomas diagnosed in our hospital between January 1999 and December 2003. We have found ten patients with radiological involvement of the pancreatic gland and/or the extrahepatic biliary tree. Imaging findings on CT were evaluated in all the cases and on MR in two cases. Biliopancreatic involvement was verified by histological examination after imaging-guided biopsy in two patients and by clinico-radiological evaluation post-chemotherapy in eight patients.

Results: We have found pancreatic gland involvement by lymphoma in five patients and by leukemia in three. The radiological patterns were: a big mass in the pancreatic head in two cases, a diffuse enlargement of the pancreatic gland with alteration of the density on CT or the signal intensity on MR in two cases and peripancreatic adenopathies which secondary infiltrated the gland in four cases. One patient developed an isolated granulocytic sarcoma of the choledochal duct that caused a concentric stenosis in the middle third. Another patient presented with invasion of the distal choledochal duct by a primary lymphoma of the Ampulla of Vater.

Conclusion: In our series, in accordance with the current literature, pancreatic involvement by lymphoma and leukemia usually appeared on CT and MR as peripancreatic adenopathies that secondary involved the pancreas. The isolated involvement of the extrahepatic biliary tree by lymphoma and leukemia was extremely rare.

C-0062

Value of splenic artery resistive index in the differentiation between alcoholic and hepatitis B virus-related cirrhosis

J. Byun, J. Choi, D. Kim; Gwang-Ju/KR

Purpose: To assess the usefulness of splenic artery resistance index (RI) in the differentiation between alcoholic cirrhosis and hepatitis B virus-related cirrhosis.
Materials and Methods: Three groups with 109 subjects (28 controls, 38 hepatitis B virus-related cirrhosis patients, and 43 alcoholic cirrhosis patients) were included. Splenic artery RI and splenic size were compared in three groups. Splenic size, variceal bleeding episode and Child's score were compared in two cirrhotic groups. A cutoff value of splenic artery RI to differentiate two cirrhotic groups was defined as an RI of -2 SD. Sensitivity, specificity, accuracy, positive predictive value and negative predictive value for alcoholic cirrhosis were calculated.

Results: The mean splenic size (11.0 ± 1.6 cm) and mean splenic artery RI (0.58 ± 0.05) of controls were less than those of two cirrhotic groups ($p < 0.05$). Splenic size, variceal bleeding episode and Child's score were not different between two cirrhotic groups. In contrast, the mean splenic artery RI in patients with alcoholic cirrhosis was significantly higher than in patients with hepatitis B virus-related cirrhosis (0.72 ± 0.07 vs. 0.62 ± 0.06 , $p < 0.05$). The cut-off value of splenic artery RI for alcoholic cirrhosis was 0.7. If an RI was greater than 0.70 it suggested the possibility of alcoholic cirrhosis. Sensitivity, specificity, accuracy, positive predictive value and negative predictive value were 62.8%, 97.4%, 79.0%, 96.4% and 69.8% respectively.

Conclusion: A reasonable lower limit of alcoholic cirrhosis was an RI of 0.70, which appeared to be a specific parameter for differentiation between alcoholic and hepatitis B virus-related cirrhosis.

C-0063

Non-cutaneous peripheral T-cell lymphomas: Radiological-pathological correlation

X. Mallol, E. de Lama, E. Gonzalez, A. Fernández, E. Domingo, J. Narváez; Barcelona/ES

Learning Objectives: The aim of this exhibit is to illustrate the most common radiological patterns of peripheral T-cell lymphomas (PTCL), correlating them with clinical and histopathological manifestations. Differential diagnosis in each location is discussed.

Background: Most radiologists are unfamiliar with PTCL because it represents a relatively small proportion of lymphomas and has a low prevalence in Western countries. PTCL are an heterogeneous subgroup of lymphomas, being in their vast majority primarily cutaneous and which do not require imaging evaluation. The rest of them, represent specific clinicopathologic entities, with specific radiological imaging.

Procedure Details: Radiological images of patients with histologically proven non-cutaneous PTCL (classified according to the WHO classification) were retrospectively reviewed along with their clinical and pathological data. Our cases included: Precursor T lymphoblastic lymphoma/leukemia (n = 15), T-cell prolymphocytic leukemia (n = 4), T-cell granular lymphocytic leukemia (n = 29), Adult T-cell lymphoma leukemia (n = 2), Extranodal NK/T-cell lymphoma nasal type (n = 13), Enteropathy T-cell lymphoma (n = 4), Angioimmunoblastic T-cell lymphoma (n = 8) and peripheral T-cell lymphoma NOS (n = 35).

Conclusions: Non-cutaneous PTCL can present as a wide spectrum of disease involving different organs. There is a correlation between specific clinicopathological entities and the primary site of involvement, although findings in the disseminated stage of the disease do not allow differential diagnosis.

C-0064

Acute abdominal hemorrhage and its complications in hemophilic patients

K. Borbély, L. Nemes, A. Ceglédi, É. Cserepes, É. Bács, A. Laki, G. Székely, M. Barta, G. Forrai; Budapest/HU

Learning Objectives: To outline the forms of abdominal hemorrhage and its possible complications occurring in hemophilic patients with low coagulation factor levels.

Background: Spontaneous abdominal bleeding mostly occurs in severe hemophilia - patients with a plasma coagulation factor level as low as 1% of normal value. The frequently coexisting hepatic failure due to viral hepatitis acquired by transfusions worsens the coagulation disorder. Superinfection of hematoma is critical for immunocompromised patients just recovering from hypovolemic shock.

Imaging Findings: Characteristic types of abdominal hemorrhage occurring in hemophilic patients are demonstrated by CT and ultrasound images through the selected cases of the 128 severe hemophilic patients treated in the National Haemophilia Center between July 2003 and July 2004. Abdominal wall, intraperitoneal and retroperitoneal (iliopsoas muscle, pancreas) hematomas are presented giving rise to hypovolemic shock, abscess and fistula formation, sepsis, pancreatitis, peritonitis due to pseudocyst rupture, femoral nerve lesion, hip contracture and death. While ultrasound had a limited role, CT was required for the proper demonstration of abdominal status.

Conclusion: The knowledge of severe abdominal complications in hemophilic patients is essential. Cross sectional imaging (in emergencies, CT) is adequate for demonstrating abdominal status.

C-0065

The peripheral primitive neuroectodermal tumor in the abdomen and pelvis:

Imaging features of CT, MR, and ultrasound

M.-J. Kim¹, J. Byun², H. Won², Y. Shin², K. Kim², H.-S. Hong², A. Kim², P. Kim², H. Ha²; ¹Anyang, Kyungki-do/KR, ²Seoul/KR

Purpose: To evaluate the imaging features of the peripheral primitive neuroectodermal tumor (pPNET) in the abdomen and pelvis.

Method and Materials: Over a 9-year period, we found pPNET in 16 patients. There were 11 men and 5 women aged 5-80 years (mean age, 34.3 years). Histopathological proof was obtained by surgery in 10 patients and by percutaneous biopsy in six. Two abdominal radiologists reviewed the CT (n = 16), ultrasound (n = 8) and MR images (n = 4).

Results: The pPNET were located in the peritoneal cavity (n = 4), retroperitone-

Scientific and Educational Exhibits

um (n = 4), kidney (n = 3), abdominal wall (n = 1), liver (n = 1), GB (n = 1), CBD (n = 1) and jejunum (n = 1). Tumors appeared as solitary masses (n = 13, 81%) and multiple masses (n = 3). Tumors showed well-defined margin (n = 9, 56%) or clearly invasive margin (n = 7, 44%), internal necrosis (n = 14, 88%) and internal hemorrhage (n = 3, 19%). There was lymphadenopathy in six patients, ascites in another six, and omental and/or peritoneal nodules in five. The distant metastases were in the liver (n = 1) and the superior mediastinum (n = 1).

Conclusion: The pPNET should be included in the differential diagnosis of a large, solitary mass with internal necrosis and heterogeneous enhancement in the abdomen and pelvis.

C-0066

Melioidosis: A tropical disease with a spectrum of imaging features in different organ systems

S.-E. Lin¹, W.C.G. Peh¹, M. Muttarak², A.G.S. Tan¹, J. Euathrongchit², P. Lerittumongkun², S. Simarak², C. Sivasomboon², H.M.L. Oh¹; ¹Singapore/Singapore; ²Chiang Mai/Thailand

Learning Objectives: 1. To highlight the epidemiology, clinical patterns and management of patients with melioidosis. 2. To review the imaging features of melioidosis afflicting various organ systems, using multimodality illustrations.

Background: Melioidosis is an infectious diseases caused by Burkholderia pseudomallei, a bacterium endemic in South East Asia. We review the clinical and imaging features of 39 patients from 2 centers in Thailand and Singapore. Melioidosis was confirmed in all cases, mostly by culture. There were 19 Thais, 10 Chinese, 1 Indian and 9 Malays. All were adults (age range 20-77 years). 34/39 patient had fever, with other common symptoms being cough, dyspnoea, abdominal pain and pain/swelling due to local disease. 28/39 patients had co-morbid conditions, particularly diabetes mellitus (25) and renal failure (4).

Imaging Findings: Only 2 patients had localized infection (parotid and pseudoaneurysm) with the majority having pulmonary or systemic disease. Frequently-affected organs were the lung (18), spleen (18), liver (14), bone (9), superficial soft tissues (5), prostate (3) and kidney (2). 19/39 patients had multi-organ involvement.

Conclusion: Melioidosis infection can be localized or systemic. CT, ultrasound and MR imaging are useful for detecting deep lesions such as liver, splenic and prostatic abscesses and osteomyelitis. Melioidosis should be considered in patients with predisposing co-morbidities, whether the infection is localized or systemic, especially in an endemic area or with prior travel history to an endemic area.

C-0067

Posttransplant lymphoproliferative disease (PTLD): A pictorial review

L. Herraiz, A. Bermejo, M. Perez, S. Dieguez, S. Borruel, A. Arenas; Madrid/Spain

Learning Objectives: The purpose of this review is to summarize the clinical features of PTLD in liver, heart and kidney allograft recipients and the wide variety of imaging findings based on our experience in a tertiary hospital.

Background: PTLD occurs in patients who receive transplants in which chronic immunosuppression leads to an unregulated expansion of lymphoid cells. Risk factors affecting the incidence of PTLD include allograft type, Epstein-Barr virus infection and immunosuppression. Characteristics of PTLD include a proclivity toward extranodal involvement, affecting nearly any organ system including the allograft, and a variable response to treatment. We reviewed 2255 transplanted patients, finding 31 cases of PTLD.

Imaging Findings: Abdominal Imaging - The abdomen is the most common anatomic region involved. We report three patterns of hepatic PTLD: focal low-attenuation nodules, infiltrative hepatic lesions with hepatomegaly and porta hepatis involvement in liver transplant recipients. Gastrointestinal system (mostly the small bowel) is commonly involved. Splenic involvement by PTLD manifests as focal low-attenuation and/or splenomegaly.

We report also renal, adrenal, abdominal lymph nodes and mesenteric involvement. Thoracic Imaging - Pulmonary parenchymal disease presents as discrete nodules or masses with air-space pattern. We also report cardiac and pericardial involvement. Head and Neck - We present some cases of calvarian and brain parenchymal PTLD involvement. The neck involvement include cervical lymph nodes, sinonasal region and nasopharyngeal Waldeyer ring.

Conclusion: PTLD represents an increasing problem. Knowledge of the various appearances of PTLD is important because its clinical manifestations are non-specific and prompt diagnosis and appropriate treatment affects the outcome.

C-0068

Wisdom without answers: Patient care and medicolegal ramifications of incidental findings on thin-section body computed tomography

A. Kamaya, R.M. Hsu, R.B. Jeffrey; Palo Alto, CA/US

Learning Objectives: To illustrate the most common incidental findings in thin-section body computed tomography which are usually benign but have some finite probability to pose serious harm to the patient if not properly addressed. To enumerate the injurious potential of these findings. To review the evolving recommendations for clinical and radiological work-up and/or follow-up.

Background: As multidetector computed tomography allows the routine practical acquisition of thinner imaging sections with less partial-volume averaging, greater diagnostic accuracy can be achieved in many applications. However, with this power comes the burden to manage an increasing number of small incidental findings which hitherto may have been clinically and radiologically occult. From a patient care and medicolegal perspective, the proper analysis and workup of these findings is essential but in many cases still evolving.

Imaging Findings: Chest findings such as solid or ground-glass parenchymal nodules, apical pleuro-parenchymal changes and thyroid nodules. Abdominal parenchymal findings such as tiny hypodense foci in the liver, spleen, pancreas, or kidney, early enhancing foci in the liver or spleen, adrenal nodules and ovarian calcifications. Extrapancreatic findings such as small mesenteric nodes, misty mesentery, peritoneal calcifications, prominent bile ducts, subcutaneous nodules and lucent or sclerotic bone foci.

Conclusion: Increasing sensitivity for small incidental findings with small but finite probability for serious patient care and medicolegal ramifications requires the modern radiologist to stay abreast of evolving recommendations for clinical and radiological workup.

C-0069

Which assessment should be preferred for a polytrauma victim?

Y.K. Maratos, A. Kalai, O. Clément, T. Loeb, G. Frija; Paris/FR

Purpose: We compared the results of systematic use of whole-body-CT-scan in polytrauma exploration to the results of focused on-demand CT-scans performed after clinical evaluation of polytrauma and the resulting changes in patient assessment, care and survival.

Method and Material: 400 polytrauma victims (from January 2002 to September 2004) admitted at the level 1 Trauma Center European Hospital Georges Pompidou, Paris were reviewed retrospectively by experienced senior radiologists and clinicians. ISS (Index Severity Score), 24-hour mortality rate, number of surgical procedures and rate of delayed diagnosis were recorded. Our results were compared to those presented in the literature (multicentric studies) including 450 cases of polytrauma victims with comparable ISS assessed by focused, on-demand loco-regional scan after initial clinical evaluation.

Results: Patients assessed with whole-body-CT-scan had a better outcome: Percentage of delayed diagnosis was reduced from 24% to 7% by whole-body-CT (comparing patients with ISS > 20). Surgical procedures were reduced from 52 to 36%. 24-hour mortality is reduced from 16 to 9%.

Conclusion: Management of polytrauma victims by whole-body-CT-scan is highly recommended in order to enable prompt and early treatment of lesions and to ensure that the percentage of missed injuries is minimized, resulting in a better care of this patient group.

C-0070

US and CT in the detection and differentiation of peritoneal carcinomatosis and tuberculous peritonitis

F. Todua, L. Jvarsheishvili, G. Tsivtsivadze; Tbilisi/GE

Purpose: To determine the ability of US and CT in differential diagnosis of peritoneal carcinomatosis (PC) and tuberculous peritonitis (TP).

Methods and Materials: US and CT were performed in 36 patients with PC and TP. The cause of peritoneal damages was identified by radiological and histopathologic studies. We reviewed data about peritoneal, mesenteric and omental changes, the size and structure of lymph nodes and presence of calcifications.

Results: Mesenteric changes were more commonly seen in cases of TP (80.5%) than in PC (41.7%). The omentum appeared more irregularly infiltrated in PC. The "floating" omental cake on US was more frequently characterized for carcinomatosis. Various degrees of lymphadenopathy were observed in both pathologies but macronodules (> 5 mm) were much more frequently seen in cases of TP (63.9%) than in PC (22.2%). TP was characterized by "fatty" nodes on CT and had increased echogenicity relative to other enlarged nodes on US. The hypoechoic center within a node occurred in cases of caseation (38.9%) as well as in

Scientific and Educational Exhibits

necrosed metastatic nodes (16.7%). Simple ascites was more commonly associated with PC (83.3%) than TP (33.3%). In this group it contained fine, freely mobile septa and had latticelike pattern. In 52.7% of TP was revealed the "wet" type of ascites with high attenuation on CT. In 47.3% the "dry" type with caseous nodules and dense adhesions. In our series peritoneal calcification associated with calcified lymph nodes was more frequently seen in TP (41.5%) than in PC (13.8%).

Conclusion: Many of the patterns of peritoneal damage are nonspecific. The combination of US and CT findings in light of clinical findings increases the ability to diagnose and distinguish PC from TP.

Computed tomography patterns of mesenteric and omental disease

S. García-Asensio, H. Gómez, L. Sarría, R. Cozcolluela, A. Forradellas, M. Martínez-Berganza, F. Monzón; *Tudela/ES*

Objectives: To review the CT patterns of the broad spectrum of mesenteric and omental abnormalities.

Methods and Material: The scans of 438 patients (243 males and 195 females) with mesenteric-omental involvement were retrospectively reviewed. Spiral CT was performed after oral and i.v administration of contrast material on model ProSpeed SX GE scan.

Results: Diagnosis included: Infectious and inflammatory (33.56%): 1 tuberculous peritonitis, 108 inflammatory changes, 12 fluid collections, 8 abscesses, 2 increased attenuation after radiotherapy and 16 after surgery. Neoplasm (24.88%): 99 secondary neoplasm, 8 primary tumors, 2 pseudomyxoma peritonei. Tumoral mesenteric involvement was classified in four patterns: rounded masses, cake-like masses, ill-defined masses and stellate pattern. The type of primary tumors was determined at histopathologic examination of surgical specimen from 3 cases, and on the basis of follow-up CT and clinical data from 5 patients. Tumorlike lesions (2.73%): 4 mesenteric cysts, 2 echinococcosis, 3 pseudotumoral lipomatosis, 3 retroperitoneal fibrosis. Vascular disease (1.41%): 2 SMA thrombosis, 1 mesentery venous gas, 2 venous dilatation. In addition CT showed lymphadenopathy (27.62%), ascites (24.88%), mesenteric injuries (2.73%), pneumoperitoneum (3.65%), edema or congestion (1.41%), idiopathic retractile mesenteritis (0.68%) and mesenteric torsion (0.22%). Imaging features and histopathologic correlation of disease processes are demonstrated in this pictorial essay.

Conclusions: Spiral CT is a reliable imaging method for revealing evidence of mesenteric and omental disease and may suggest the diagnosis and biopsy site when necessary. Knowledge of the spectrum of these abnormalities and the characteristic CT appearances of them is essential for improving the diagnosis of these conditions.

C-0073

Abdominal tuberculosis presenting with acute abdomen: CT findings

H. Sun, R. Bai, E. Wu; *Tianjin City/CN*

Learning Objectives: To illustrate and characterize the spectrum of abdominal tuberculosis that can present as an acute abdomen.

Background: Abdominal tuberculosis can present with a variety of nonspecific radiological findings. Clinically, it often manifests with chronic abdominal pain associated with systemic symptoms, however unusual cases may occasionally present with severe abdominal pain. CT is especially useful in the diagnosis of acute abdomen, and can depict abdominal tuberculosis.

Imaging Findings: Acute abdomen derived from tuberculosis can be divided into four pathologies: intestinal, genitourinary, peritoneal and lymphatic. The ileocecal region is the most commonly involved segment. Transmural ulceration may result in a fistula, pericecal abscess or can perforate resulting in peritonitis. A hypertrophic lesion, in contrast, may lead to bowel obstruction. CT features include depiction of the ulcer or the asymmetric thickening of the ileocecal valve. Ureteral involvement is seen in 50% of patients with genitourinary tuberculosis. The pattern of hydronephrosis depends on the site of the stricture. A ruptured caseous ovarian abscess can often mimic malignancy. Tuberculous peritonitis may result from ruptured lymphatics, hematogenous spread, or GI tract perforation. Acute abdomen is more often caused by the wet type, with high-density ascites as a characteristic feature. Lymphadenopathy is the most common finding of abdominal tuberculosis. Large and clustered peripancreatic lymph nodes may cause arterial erosion, resulting in visceral ischemia and splenic infarction.

Conclusions: Complications of abdominal tuberculosis can result in an acute abdomen. Although the CT findings are nonspecific, abdominal tuberculosis should be considered in the differential diagnosis of an acute abdomen.

C-0074

Celiac plexus and splanchnic nerve neurolysis via a posterior or anterior approach

B.A.C. Kastler, E. Rodière, J. Litzler, P. Sarlieve, D. Michalachis, E. Delabrousse, B. Fergane; *Besançon/FR*

Management of pain in tumors located in the upper abdomen extending to the celiac region is difficult and because they do not respond properly to high doses of opiates. We have undertaken 126 procedures over the last year, combining a celiac and a splanchnic neurolysis which we believe to be more efficient. The intervention can be performed either by means of a classical posterior approach (usually using a Trans-aortic approach) or, as has not yet been described when aiming at both the celiac and splanchnic sites, via an anterior approach (possibly avoiding the aorta). We will demonstrate step-by-step our technique of percutaneous neurolysis under CT-guidance. CT-guidance allows safe needle progression and precise positioning at target which reduces complications and optimizes procedure results. Advantages, drawbacks and results of each approach will be outlined and illustrated with drawings and pertinent CT-images and protocols.

C-0075

Comparison of tissue harmonic imaging with standard ultrasound mode, in the evaluation of abdomen and pelvic organs

M. Chalkia, A. Spanos, I. Kirimlidis, A. Papageorgiou, E. Chartabillas, N. Vougiouklis; *Thessaloniki/GR*

Purpose: The purpose of this study is to compare tissue harmonic imaging (THI) with conventional ultrasonography, regarding image quality and organ visualization.

Methods and Materials: 358 different organs and lesions of the abdomen and pelvis, were evaluated with both conventional ultrasonography and tissue harmonic imaging. Ultrasound was performed with frequencies 2-4 MHz. Two experienced radiologists, blind to the mode used and blind to each other, rated each image pair for resolution, detail, and total image quality. The images were evaluated as: (1) Insufficient, (2) Good and (3) Very good. For analysis of the results we used the statistical program SPSS Version 11, Chi Square method.

Results: Both the examiners considered the THI images very good in 33.2% of the cases, good in 43.6% and insufficient in 23.2%, while they considered the conventional ultrasonography images, very good in 19.1%, good in 52.8% and insufficient in 28.1% of the cases. More specifically, the two methods exhibit a statistically important difference in imaging of the liver parenchyma, the gallbladder, the kidneys, the urinary bladder, and the ovaries, with THI being superior than conventional ultrasonography. THI did not show any distinct superiority in imaging of the pancreas and the prostate gland.

Conclusion: THI proved to be superior than conventional ultrasonography regarding image quality and organ visualization in the evaluation of abdominal and pelvic organs.

C-0076

MDCT of the acute abdomen: A pictorial essay

M. Tzaloniou, Z. Athanasopoulou, M. Chatzopoulou, M. Papoudos, V. Polimeropoulos, V. Papadopoulos, K. Stringaris; *Athens/GR*

Purpose: The term "acute abdomen" is used in cases of acute abdominal pain and which can prove to be a true emergency situation. Radiologists quite frequently are asked to give specific answers regarding the cause of an acute abdomen.

Materials and Methods: We prospectively studied all cases of patients who presented with acute abdominal pain and underwent CT examination in our department. All examinations were performed on a 16-row detector CT-scanner (Siemens, Germany). Axial images were obtained and coronal and/or sagittal reconstructions were performed in all cases. Oral and IV contrast medium was administered when indicated and possible. Normal examinations were excluded from our study. The CT studies were reviewed by two independent board certified radiologists. If there was any disagreement in the study interpretation, images were reviewed once more by the same radiologists in order to reach a consensus reading.

Results: Peptic ulcer, perforation of hollow viscera, cholangitis, cholecystitis and lithiasis of the common bile duct, acute pancreatitis, renal colic and pyelonephritis, mesenteric lymphadenopathy, small or large bowel obstruction, intussusception, appendicitis, diverticulitis, inflammatory bowel disease, ovarian cysts, hydrosalpinx, ruptured abdominal aortic aneurysm, mesenteric ischemia, thrombosis of IVC or other major veins, air in the portal vein, abscesses, strangulated hernias, volvulus, hematomas and abdominal trauma are the causes of acute abdomen that we have studied with the use of MDCT.

Conclusion: Treatment planning of the acute abdomen needs the underlying cause to be revealed and MDCT is both sensitive and accurate in most of these cases. Image reformation also proves to be a useful tool in some of the cases.

C-0077

Hydatid disease revisited

A. Oikonomou, S. Deftereos, M. Mantatzis, V. Fotiadou, P. Sourailidis, P. Prassopoulos; *Alexandroupolis/GR*

Learning Objectives: To discuss the prevalence and imaging findings of hydatid disease (HD) in unusual anatomic locations and describe the atypical manifestations of hepatic HD.

Background: HD is a worldwide parasitic disease produced by the larval stage of Echinococcus. The liver is the most frequently involved organ and the typical imaging findings are well known. However, unusual anatomic locations and findings related to rare manifestations of HD are less frequently described.

Imaging Findings: Radiological findings range from purely cystic to almost completely solid lesions. HD can become quite large and can be solitary or multiple. Calcification is more common in HD of the liver, spleen and kidney but it is not seen in the pulmonary location. Gallbladder, biliary, adrenal, peritoneal and brain locations are very rare and may not exhibit findings similar to liver HD. Growth rate in atypical cases may overcome duplication in volume annually. Exophytic growth and transdiaphragmatic migration of liver HD is a rare manifestation. The coexistence of hydatid cyst and malignant neoplasms should be included in the differential diagnosis when clinical findings cannot be interpreted by presence of HD alone. The imaging method indicated depends on the organ involved and evolution stage of the disease. US most clearly demonstrates hydatid in purely cystic lesions, with floating membranes and daughter cysts. CT is preferable for detecting calcification and revealing chest HD. MR imaging is indicated for central nervous system HD diagnosis.

Conclusion: Familiarity with unusual locations of HD or atypical radiological manifestations enables accurate diagnosis of the disease.

C-0078

"Misty Mesentery": Multidetector row CT (MDCT) features and differential diagnosis

F. Di Fabio, R. Cianci, E. Grassedonio, A. Filippone; *Chieti/IT*

Learning Objective: To describe and to review the most common MDCT features of "Misty Mesentery" in different pathologies, with a special focus on differential diagnosis.

Background and Imaging Findings: The term "Misty Mesentery" means a pathologic increase in mesenteric fat attenuation at MDCT. It may diffusely involve the mesentery or it may present as a segmental finding. The distribution patterns may be useful in the assessment of a primary cause. Diffuse mesenteric alteration may be often observed in patients with inflammatory bowel disease, mesenteric bowel injury, cirrhosis, hypoalbuminemia or heart failure. On the other hand, segmental "Misty Mesentery" may represent a characteristic feature of pathologies such as portal or mesenteric vein thrombosis, focal inflammatory conditions (appendicitis, diverticulitis, epiploic appendagitis) and localized neoplastic infiltration. The diagnosis of sclerosing mesenteritis should always be considered because this rare disorder of unknown origin may manifest as a diffuse, localized or multinodular mesenteric alteration.

Conclusions: "Misty Mesentery" can be seen in various pathological conditions, such as vascular disorders, inflammation, fibrosis and neoplastic infiltrations. MDCT plays an important role not only in the differential diagnosis, but also in the follow-up, especially for those patients without a demonstrable underlying cause.

Preoperative staging of rectal cancer using magnetic resonance imaging:

Comparison with endosonography and histopathologic findings

R. Ciosci, G. Pompili, P. Bianchi, M. Montorsi, G. Cornalba; *Milan/IT*

Purpose: The aim of our study was to examine the accuracy of preoperative MR imaging and endosonography in the staging of rectal cancer.

Methods and Materials: 43 patients with biopsy proven rectal adenocarcinoma underwent MR imaging and endosonography. A group of 28 patients underwent MR imaging with a body-coil. A second group of 15 patients underwent MR imaging with external phased array coil and 6 also with an endocoil. Endosonography was performed in 39/43 patients. The results of examinations were compared with final histology. 33 patients directly underwent surgery, and 10 received neoadjuvant therapy.

Results: In the T staging, the best results were obtained with a phased array coil (accuracy 80% in 12/15) especially when used alongside a rectal endocoil (correct T and N staging in 6/6). MR imaging with a simple body coil had an accuracy of 50% (14/28). Endosonography correctly staged rectal cancer in 74.3% of cases. In N-staging accuracy was 74% for MR imaging and 51% for endosonography. MR imaging with phased-array coil was as accurate as endosonography in the T-staging of rectal cancer and far superior in the N-staging.

Conclusions: MR imaging, especially with phased-array and endocoil, is an accurate method of staging rectal cancer and it allows both better selection and assessment of patients undergoing preoperative therapy.

C-0080

The efficacy of CT-colonography for diagnosis and staging of colon cancer in symptomatic patients

P. Zdunek¹, A. Gmur¹, M. Wykret¹, R. Pacho², P. Wandzel¹; ¹*Bielsko-Biala/PL*, ²*Warsaw/PL*

Purpose: To evaluate the clinical value of CT-colonography for the diagnosis and staging of colon cancer in symptomatic patients.

Methods and Materials: From the group of 232 patients who underwent operations because of colon cancer between June 2000 and December 2003, we chose 56 patients (24%) who had diagnostic CT-colonography either as the first examination or after incomplete colonoscopy. Patients with rectal cancers were excluded. We reviewed retrospectively the findings of preoperative colonoscopy, intraoperative organ palpation and histopathologic outcome in this group and compared them with results of CT-colonography. 61 cancers (32 sigmoid, 29 proximal colon) were removed. In 5 cases synchronous cancers were found. Metastases to the lymph nodes, liver and peritoneum were assessed. Other colon pathologies, namely polyps, diverticulosis, intussusception and inflammatory infiltration were also evaluated.

Results: 59 cancers were correctly diagnosed at CT-colonography (96%) and 56 at colonoscopy (92%). Due to obstructive carcinoma complete CT-colonography was possible in 52 (92%) and colonoscopy in 27 cases (48%). The correct diagnosis for more than 4 liver metastases was made in 7/8 (sensitivity 87.5%, specificity 97%) and for less than 4 in 6/9 cases (sensitivity 66%, specificity 89%). Lymph nodes metastases were found in 9/15 (sensitivity 60%, specificity 90%) and peritoneal dissemination in 1/2 patients. 6/15 (40%) polyps were detected. Diverticulosis was disclosed in 13, intussusception in 1 patient and inflammatory complications in 4 patients.

Conclusion: CT-colonography is an effective method for diagnosing colon cancer, evaluating the entire colon preoperatively and disclosing any distant metastases.

C-0081

Gastric MALT lymphoma: CT findings

A. Roque, M. Sarrias, S. Quiroga, C. Sebastià, H. Cuéllar, A. Álvarez-Castells; *Barcelona/ES*

Learning Objectives: To identify helical CT features that could be useful for the imaging diagnosis in gastric MALT lymphoma.

Background: Lymphoma of the gastric mucosa-associated lymphoid tissue (MALT) is a process with characteristic anatomical and pathological features. Its prognosis is favorable with prompt, appropriate treatment and thus early diagnosis is important. In this exhibit we will describe CT findings that could help in the diagnosis of this disease. CT scans were retrospectively reviewed in 14 patients (6 men, 8 women; mean age 62.9 years) with histologically proven gastric MALT

Scientific and Educational Exhibits

lymphoma. The following findings were assessed; gastric wall thickness, visualization of vessels within tumor tissue, presence and distribution of lymphadenopathy and involvement or not of other organs.

Imaging Findings: The imaging technique was contrast-enhanced helical CT scanning, using 800-1000 ml of water as negative oral contrast agent. Mean gastric wall thickness was 3.7 cm. Significant intra-abdominal lymphadenopathy was found in 11 patients (78.6%), mainly in a perigastric location. Involvement of other organs was found in 3 of our patients. Vessels were identified within the gastric tumor tissue in 10 patients (71.4%).

Conclusion: Helical CT visualization of vessels within a gastric mass was found to be highly suggestive of MALT lymphoma, a finding that has not been previously described in the literature.

C-0082

The correlation of endosonography versus peroperative and histopathological findings in a group of 350 patients with surgically treated anorectal tumor

Z. Chudáček¹, R. Sequens², M. Pechotová¹, J. Kuntscherová¹; ¹Plzen/CZ, ²Prague/CZ

Purpose: Endosonography (EUS) is a well established method in the staging of anorectal tumors, indispensable especially before the decision on radical surgery. Modern equipment for EUS providing a circular image with the possibility of an end-firing display, supplemented with a high resolution linear-array electronic transducer and doppler imaging and combined with the examiner's experience are the basic prerequisite of good results when using the method. In a retrospective study the accuracy of EUS was evaluated by comparison with peroperative and histopathological findings. The sources of errors and diagnostic constraints were reviewed.

Methods and Materials: In a group of 350 surgically treated patients the correlation between EUS, surgery and histopathology was evaluated. In cases with contemporary CT or MR finding the evaluation was extended to these methods.

Results: The overall accuracy in tumor staging was 89%. In regional lymph nodes involvement only 70% overall accuracy was achieved. EUS overall accuracy exceeded the same by CT and MR.

Conclusion: The study confirmed a high sensitivity and specificity of EUS in the staging of anorectal tumors and the acceptability for a decision before radical surgery, but not however in staging of regional lymph node involvement. The second weakest point of the method represented an occasional difficult distinction between T2 and T3 stage, probably due to peritumoral inflammation.

C-0083

Integrated sonography of Crohn's disease by combining high-resolution B-mode techniques and contrast enhanced ultrasound (CEUS) perfusion studies of the involved bowel segments

S.D. Yarmenitis, G. Kolios, N. Papanikolaou, T. Maris, E. Kouroumalis, N. Gourtsoyiannis; Iraklion/GR

Purpose: The aims of this paper are: To describe the significance of CEUS in improving the assessment of qualitative findings from B-mode studies. To present the possible application of CEUS in quantifying inflammation in the involved intestinal segments.

Methods and Materials: Thirty-five individuals with Crohn's disease (CD), (active:21, remission:9, fibrostenotic:5) were examined by a combined technique including standard B-mode scans and CEUS perfusion studies at the sites of the involved bowel loops. A control group comprised 20 healthy individuals who underwent CEUS at the terminal ileum loop. In addition to B-mode findings, contrast illustrated the presence of hyperemic, enlarged mesenteric lymph nodes and of abundant hyperemic vasa recta at the mesenteric border. Perfusion throughout the full mural thickness was further recorded. Time to contrast intensity transit curves were built. The maximum inclination of the wash-in component of the curves was calculated for each individual.

Results: The maximum inclination mean value was 16.34 sec⁻¹ for the patients with active CD. Patients with inactive CD showed a mean value of 4.7 sec⁻¹. In the control group, the mean value was 6.67 sec⁻¹. Statistically significant differences were found between the values from the active CD patients, the non-active CD patients and the control group. The non-active CD individuals, although very few at present, showed similar perfusion values with those of the control group. Only patients with active CD showed hyperemia and increased number of the vasa recta.

Conclusions: CEUS broadens sonography of the bowel CD. Initial results are promising in the quantification of Crohn's disease activity.

C-0084

MR imaging of the small intestine in paediatric patients: An overview of technical features and clinical results

P. Paolantonio, A. Laghi, M. Rengo, F. Iafrate, V. Martino, A. Guerrisi, R. Passariello; Rome/IT

Learning Objectives: To illustrate the major clinical indications for MR imaging study of the bowel in paediatric patients. To show an overview of some technical issues of MR imaging of the small bowel with emphasis on bowel distension. To outline the advantages and limitations of the technique and to illustrate clinical results based on a series of 215 paediatric patients.

Background: In this exhibit we will describe the MR imaging of the small bowel performed with a biphasic oral contrast agent with the most suitable indications, the results, the advantages and the limits of this technique in a paediatric population. 215 paediatric patients with clinical suspicion of small bowel disorders underwent MR study of the small bowel. The major clinical indication was in the work-up of children with suspected IBD. Other clinical indications are mainly the work-up of patients with Celiac disease or other causes of intestinal malabsorption. MR findings of several small bowel disorders with emphasis on Crohn's disease and Celiac disease will be presented.

Procedure Details: Small bowel distension was obtained by means of oral administration of 10 ml/kg/BW of PEG solution immediately before the examination. MR examinations were performed using T2W HASTE, True-FISP and T1W FLASH sequences acquired after iv injection of Gd-DTPA in both axial and coronal planes.

Conclusion: MR studies of the small bowel represent a feasible and valid diagnostic tool for small intestine evaluation in a paediatric population.

C-0085

Transmesenteric internal hernias: CT findings

C. Polidura Arruga, I. De la Pedraja Gomez-Ceballos, J.L. Abades Vazquez, E. Huelga Zapico, J. Jimenez del Rio; Madrid/ES

Purpose: To describe the radiological features of transmesenteric internal hernias on CT.

Patients and Methods: Retrospective review of CT scans of 8 patients with radiological diagnosis of internal hernia. The abdomino-pelvic images were obtained in a helical CT GE, collimation of 7 mm and with both oral and intravenous contrast medium. Only one of the patients had previous abdominal surgery (Billroth II).

Results: The CT criteria that are evaluated were based on prior publications. In 7 patients, CT showed a cluster of small bowel loops and central displacement of the colon. On 6 cases, the lack of omental fat between the clustered small bowel and the abdominal wall was seen. 4 CT scans showed features of bowel obstruction and 3 of them findings of bowel ischemia. Surgical confirmation was obtained in 6 patients: 3 of them had transomental internal hernia and the other 3 had pericecal transmesenteric hernia.

Conclusion: The internal hernia, and in particular the transomental subtype, is an unusual cause of small bowel obstruction. The radiological CT findings of abdominal internal hernia are: clustered small bowel loops, especially those adjacent to the abdominal wall without overlying omental fat, central displacement of the colon and bowel obstruction and/or bowel ischemia. CT scanning allows a confident preoperative diagnosis, especially in patients with suspicion of small bowel mechanical obstruction and no previous surgical procedures.

C-0086

Sonographic diagnosis of acute intestinal anisakiasis

A. Alonso, B. Viñuela, J. Simal, A. Releja, M. Nieto, M. G. Urbón, C. Niño, A. Louredo, E. Robles; Palencia/ES

Learning Objectives: To study the utility of sonography and to illustrate the spectrum of ultrasound (US) findings in the early diagnosis of intestinal anisakiasis.

Background: The imaging findings, clinical data and simplex-specific serum IgE of 28 patients with proven acute intestinal anisakiasis between January 1999 and January 2004 were retrospectively reviewed.

Imaging Findings: Anisakiosis is a parasitic infection that follows consumption of raw or insufficiently pickled, salted, smoked or cooked wild marine fish infected with Anisakis species larvae. In this exhibit, ultrasound (US) showed markedly thickened bowel loops associated with luminal narrowing, including long segment disease, swelling of Kerckring's folds and local infiltrated mesentery fat with increased Doppler signal. A small amount of ascitic fluid around the bowel loops was found. The most common site was the distal ileum and cecum. All patients underwent treatment of symptoms without laparotomy, and their symptoms disappeared by the tenth day after onset.

Conclusion: Patients with acute abdominal symptoms should be asked about

Scientific and Educational Exhibits

the intake of raw or undercooked fish. If the above US features are found, the diagnosis of intestinal anisakiasis must be seriously considered and should be treated conservatively avoiding unnecessary laparotomy.

C-0087

Intestinal transplantation: Imaging findings of posttransplantation anatomy and pathology

K.M. Unsinn, M.C. Freund, M. Rieger, B. Czermak, A. Koenigsrainer, R. Margreiter, W.R. Jaschke; Innsbruck/AT

Learning Objectives: 1. To be familiar with the different surgical techniques of intestinal transplantation in adults. 2. To illustrate the regular postoperative situs and the spectrum of expected pathology in different imaging modalities.

Background: Intestinal transplantation represents a potential alternative to long-standing parenteral nutrition in patients with irreversible, chronic intestinal failure. The following techniques of intestinal transplantation can be performed: isolated intestinal transplant, combined intestinal and liver transplantation or multivisceral transplantation.

Imaging Findings: Knowledge of the regular postoperative anatomy after intestinal transplantation is of great importance for the proper interpretation of imaging studies and early detection of postoperative pathologies. In the first part of this pictorial essay the various operation procedures of intestinal transplantation performed in adults are illustrated schematically. Examples of the regular postoperative anatomy in several imaging modalities including CT, MR imaging, gastrointestinal contrast examination and angiography will be demonstrated. Part two of this pictorial essay displays the spectrum of imaged pathology including abdominal infections (e.g. abscess, peritonitis, fistula), vascular graft complications (e.g. arterial pseudoaneurysm), intestinal graft complications (e.g. anastomotic dehiscence and strictures, intestinal motility disorder) and other transplant-associated complications (pancreatitis, hematoma, lymphocele).

Conclusions: This pictorial essay displays the spectrum of imaging findings after different techniques of intestinal transplantation utilizing different imaging modalities with regard to anatomy and pathology.

C-0088

How to perform CT colonography: A case-based tutorial

P. Lefere, S. Gryspeert; Roeselare/BE

Learning Objectives: To teach how to perform CT colonography (CTC) with a case-based tutorial allowing interactive participation of the reader.

Background: Adequate colonic preparation, distention and reading of the data sets is essential to obtain good results of lesion detection in CTC. Preparations with and without faecal tagging are demonstrated with emphasis on patient compliance and faecal residue hampering diagnosis of polyps. The importance of adequate colonic distension using dual positioning, a CO₂ injector and smooth muscle relaxants is discussed. In the reading section, the use of primary 2D or 3D reading and the importance of dual positioning are discussed. Different imaging findings of tumoral lesions and false positive findings are also demonstrated. The need for close collaboration with the gastroenterologist is stressed.

Procedure Details: The tutorial consists of 10 CTC data sets controlled with conventional colonoscopy. Each data set addresses particular issues in CTC with particular emphasis on preparation, colonic distention and reading of the data sets. The reader can actively participate by scrolling through the images. In this way he is invited to make his diagnosis of each case. Each case ends with a discussion of the technique and diagnosis and concludes with pearls summarizing the essentials to be remembered.

Conclusion: This case-based tutorial provides the reader with essential information on how to adequately perform CTC.

C-0089

Ileocecal valve appearance on CT colonography

M. Cadi, R. Chollet, O. Lucidarme, P.A. Grenier; Paris/FR

Learning Objectives: Our purpose was to describe different CT appearances of the normal and pathologic ileocecal valve on virtual colonoscopy.

Background: CT virtual colonoscopy is a promising tool to depict colonic polyps. However, pitfalls in 3D endoscopic views are numerous. Among them, prominent ileocecal valve can be misdiagnosed as tumor and its normal appearances (well known by endoscopists) must be recognized by radiologists. We will display virtual colonoscopy views, and corresponding 2D images and endoscopic findings of various normal ileocecal valves obtained in our last 60 patients, as well as examples of lymphoma and lipoma involving the valve.

Imaging Findings: At virtual colonoscopy, prominent valves are seen in most

patients. They bulge into the caecum lumen along its medial side. Three main appearances can be isolated: 1) labial, in which the mouth of the valve is set between an upper and lower fold; 2) papillary, in which the valve appears as a domelike protrusion and 3) mixed. Following terminal ileum into the caecum on 2D images is helpful to confirm the diagnosis of normal ileocecal valve. Lymphoma of the ileocecal valve may induce intussusception of the terminal ileon into caecum lumen easily recognized in virtual colonoscopy. Lipoma increases the usual bulging of the valve and is easily recognized on 2D images.

Conclusion: Being familiar with the 2D and 3D virtual colonoscopy appearances of the normal, prominent ileocecal valve may help radiologists to avoid unnecessary complementary endoscopy.

C-0090

Un-prepped MR colonography in paediatric patients with inflammatory bowel disease (IBD)

P. Paolantonio, A. Laghi, M. Celestre, F. De Angelis, A. Guerrisi, M. Rengo, R. Passariello; Rome/IT

Purpose: To assess the feasibility of MR colonography performed without colonic cleasing, by means of fecal tagging using oral administration of barium sulphate in a pediatric population with inflammatory bowel disease.

Subjects and Methods: 10 paediatric patients (mean age 13.8 yrs) with known IBD assessed at colonoscopy with biopsy were enrolled in the study. Fecal tagging was performed by the oral administration of a fixed amount of 150 ml of highly-concentrated barium sulphate at major meals starting three days before MR examination. The colon was distended by a water enema. MR imaging protocol included T2W HASTE (TR, inf; TE, 90 msec; FA, 180°) and contrast enhanced T1W 3D VIBE (TR, 5.2 msec; TE, 2.6 msec; FA, 20°) and T1W 2D turboFLASH (TR/TE/FA/TI: 8.5 msec, 4 msec, 10°, 10 msec) sequences. Contrast enhancement was obtained by i.v injection of 0.1 mmol/kg b.w. ml of Gd-chelate.

Results: Image quality was judged to be optimal in all patients. Fecal material was completely tagged in all the cases and residual luminal air did not cause any significant imaging artefact. Patient tolerance was high. All the patients showed signs of IBD, Crohn's disease in three cases and ulcerative colitis in the remaining seven cases. MR correctly defined thickening of the colon and localization and extension of the inflamed bowel wall by means of contrast enhancement following Gd-chelate injection.

Conclusions: Unprepped MR colonography by barium fecal tagging is a promising and well tolerated diagnostic method in the evaluation of colonic involvement in pediatric patients with IBD.

C-0091

The use of contrast-enhanced ultrasonography in the diagnosis and follow-up of Crohn's disease

G. Runza¹, F. Cademartiri², F. Barbiera³, G. Salvaggio¹, T.V. Bartolotta¹, S. Pardo¹, G. Caruso¹, R. Lagalla¹; ¹Palermo/IT, ²Rotterdam/NL, ³Sciaccia/IT

Learning Objectives: The aim of this exhibit is to assess the potential role of contrast-enhanced ultrasonography (CEUS) in the diagnosis and follow-up of local complications in patients with Crohn's disease.

Background: Accurate detection and assessment of intestinal complications and activity signs is important for the clinical management and treatment follow-up in Crohn's disease. Small bowel enteroclysis and multidetector CT enterography (MDCT-enterography) can be performed but they inflict a significant amount of radiation. Therefore, they cannot be repeated on a regular base. CEUS, because of its non-invasive approach, can be repeated during the treatment of patients with Crohn's disease.

Procedure Details: In this exhibit we describe the protocol that allows proper imaging of Crohn's disease with CEUS. This technique, small bowel enteroclysis, and MDCT-enterography were compared in their ability to detect various pathological findings related to Crohn's disease: Definite stenosis, wall thickening (> 5 mm) and enhancement, mesenteric proliferation, enlarged mesenteric lymph nodes, abscess, fistulae and colonic involvement. A 1500-2000 mL solution of contrast isosmolar electrolyte was obtained by dissolving 18.5 g of polyethylene glycol (Macro P, Promefarm) in each 250 mL of water. This solution was administered perorally just before CEUS and MDCT-enterography to allow the distention and the optimal visualization of the entire small bowel. CEUS was performed after intravenous administration of ultrasound contrast agent (SonoVue, Bracco).

Conclusion: The usefulness of CEUS can be considered as a valuable tool for detecting, monitoring and follow-up treatment of local complications in patients with Crohn's disease.

Scientific and Educational Exhibits

C-0092

A pictorial review of the various extracolonic findings and their clinical impact on CT colonography examination

F. Jafrate, A. Laghi, P. Paolantonio, M. Rengo, A. Guerrisi, V. Martino, V. Panebianco, R. Passariello; *Rome/IT*

Purpose: To present a pictorial review of the various extracolonic findings on CT colonography examination. To underline the prevalence and clinical impact of these findings in patients undergoing CT colonography.

Background: CT colonography (virtual colonoscopy) is a new technique being offered to patients as a non-invasive method of imaging the colon. Potentially important extracolonic findings were revealed in 24.8% of the patients, leading to additional diagnostic or therapeutic considerations. Some of these findings were clinically important, whereas others were previously known or led to unnecessary workup. This finding must be taken into account when CT colonography is considered for routine diagnostic workup or screening.

Imaging Findings: A total of 173 extracolonic findings were detected in 110 (60.1%) of 183 patients that underwent CT colonography. Of these, 43 (24.8%) were highly significant, 36 (20.8%) were moderately significant and 94 (54.33%) were of poor significance. In 72 (39.34) patients no extracolonic findings were observed. The most common highly significant lesions were mesenteric lymphadenopathy (n.18), aortic aneurism and liver metastases (n. 6), peritoneal carcinomatosis and pulmonary nodules (n. 4). 32 of these 43 (74.4%) highly significant findings were new, and in 15 (34.88%) these abnormalities resulted in further diagnostic examinations.

Conclusion: Additional work-up of extracolonic CT colonographic findings was relatively infrequent but was often worthwhile when performed for lesions classified as highly important. The evaluation of extracolonic structures at CT colonography has definite limitations with regard to solid organs but can help detect serious disease without substantially increasing the cost per patient.

C-0093

Evaluation of pararectal lymph nodes in rectal cancer with a submucous injection of SPIO at colonoscopy and imaging by MR imaging

M. Shimada, K. Yoshikawa, K. Funahashi, T. Teramoto, M. Watanabe, Y. Inoue, T. Ookubo, J. Kojima, S. Hayashi; *Tokyo/JP*

Purpose: SPIO was administered, at colonoscopy via a paracentesis needle, into the submucosa around the tumor. We compared images before contrast media with images after contrast media for signal loss in pararectal lymph nodes (LN). We examined whether it was possible to recognize micrometastases to pararectal LN.

Methods: Five patients with rectal cancer became subjects (45-78 yrs). CT was performed on these patients to diagnose the presence of pararectal LN greater than 10 mm, and it was done when there was no metastasis. In the five patients SPIO (40 micromol/ml) was injected into four submucous places (0.4 mlx4) in the neighbourhood of the tumor. MR imaging images were taken before injection and at 24 hours after injection. The imaging sequence was a Fast Field Echo sequence (TR:12 msec, TE:5.0, TI:650). Images before enhancement and images after SPIO were examined and loss of signal intensity of the pararectal LN was examined.

Results: In all five rectal cancer patients, pararectal LNs (45 lymph nodes) of 1 cm or less were able to be depicted. In 3 of 5 patients, pararectal LN without deposition of SPIO were recognized. These LNs were diagnosed as metastatic LNs in the pathology. In short, it was diagnosed with the metastatic LN in the pathology without the deposition in LN of 12 of 45 LNs. In SPIO MR imaging, we were able to detect 9 metastatic LNs without deposits of 12 metastatic LNs which were diagnosed as metastatic LNs in pathologic studies. In short, the proper diagnosis rate was 75%.

Conclusions: SPIO injection into the submucosa under colonoscopy improves the diagnosis of metastatic pararectal LN.

C-0094

Alternative diagnoses of acute appendicitis on helical CT with IV and rectal contrast

A.R. Karam, M.J. Mehanna, G.A. Birjawi, G.E. Ishak, C.A. Sidani, M.C. Haddad; *Beirut/LB*

Learning Objectives: To illustrate the wide spectrum of diseases presenting as acute right lower quadrant pain and simulating acute appendicitis.

Background: Acute appendicitis is a frequently encountered disease in the young population presenting to an emergency room. Many entities can also present as febrile right lower quadrant pain and hence mimick acute appendicitis. These

require different and usually conservative treatment, thus rendering their recognition mandatory. In this exhibit we illustrate and describe the imaging findings of those diseases. Between December 2000 and March 2003, 75 patients were imaged with contrast enhanced CT scan for subclinical acute appendicitis. 24 had a normal appendix and an alternative diagnosis. We are reviewing the imaging pattern of these appendiceal mimickers.

Procedure Details: From December 2000 to March 2003, 75 consecutive patients presenting to the Emergency Unit with suspected appendicitis. Helical CT (Philips AV, Netherlands) was performed using 5 mm collimation at the level of the pelvis starting just above the iliac bone and 10 mm collimation at the level of the abdomen following administration of rectal and IV contrast.

Conclusion: The aim of this exhibit is to display the imaging findings of the alternative diagnosis of acute appendicitis identified in approximately 32% of patients investigated by CECT for clinical suspicion of atypical appendicitis.

C-0095

Intraoperative tumor localization using laparoscopic ultrasound for laparoscopic assisted tumor resection

J. Lim, M.-J. Kim, W. Hyung, K. Kim; *Seoul/KR*

Purpose: During the laparoscopic resection of tumor arising from stomach or small bowel, exact tumor localization is critical in laparoscopic surgery, especially when it is small or growing intraluminally. It is impossible to identify early gastric cancer (EGC) and small intraluminal submucosal or mucosal tumors arising from stomach or small bowel by laparoscopy only. The purpose of this study was to report our experience in 20 patients with intraoperative LUS for tumor localization.

Materials and Methods: Indications included EGC (n = 17), benign gastric submucosal tumor (n = 2) and benign small bowel tumor (n = 1, proximal ileum). In cases of EGCS, three endoscopic clips were placed just proximal to the tumor for sonographic detection during preoperative endoscopy. Clipping was not done in cases of gastric submucosal tumor and small bowel tumor. A laparoscopic ultrasound probe was inserted into the abdominal cavity via 12 mm port. The LUS examinations were performed at the the presumed site by intra-operative imaging evaluation for tumor localization.

Results: In all EGC patients, endoscopic clips were successfully detected in all 17 patients by the LUS. In all cases of gastric submucosal tumor and small bowel tumor, the masses themselves were detected by the LUS and the locations of lesions were marked with dye at the serosal surface of the lesions. In the resected specimens, the serosal surfaces marked with dye were always just above the clips or masses themselves.

Conclusions: Intraoperative LUS was an effective method for tumor localization for laparoscopic assisted tumor resection.

C-0096

Utility of multi-detector row CT angiography in cases of gastrointestinal hemorrhage

P.S. Goh, S.K. Venkatesh, A. Shabbir, L.K.A. Tan, S.C. Wang; *Singapore/SG*

Purpose: To describe the utility of multi-detector row CT angiography (CTA) in patients with gastrointestinal hemorrhage and incomplete/failed or non-diagnostic endoscopy.

Materials and Methods: Twelve consecutive patients presenting with acute gastrointestinal bleeding with incomplete, failed or non-diagnostic endoscopy were referred for CTA. CTA was performed on a 4-channel multi-detector row CT with 120 kV, 120 mAs, 1 mm collimation, pitch 1.5, rotation time 0.5 s with intravenous administration of 100 mls Omnipaque 350 at 3 ml/s. Bolus tracking triggered the scans. Maximum intensity projection images were processed on the Siemens Wizard console. The patients subsequently had repeat endoscopy or surgery and the site of bleeding was confirmed.

Results: CTA demonstrated the site of bleeding in all patients and localized the bleeding to the colon in 9 patients and small bowel in 3 patients. CTA suggested a cause in 4 patients: 3 patients with bleeding colonic diverticula and in one patient with bleeding from recurrent small bowel lymphoma. Ten patients underwent surgery (hemicolectomy 8, resection of Dieulafoy's lesion 1 and 1 patient had underrunning of a duodenal ulcer). Two patients stopped bleeding spontaneously after repeat endoscopy. Final pathological diagnosis was diverticular disease (6), angiodysplasia (1) iatrogenic colonic perforation (1), tubular adenoma (1), rectal ulcer (1), Dieulafoy's lesion (1), duodenal ulcer (1) and recurrent small bowel lymphoma (1).

Conclusions: Multi-detector row CT angiography is a useful, sensitive and accurate technique for evaluating patients with acute gastrointestinal bleeding. Demonstration of bleeding is possible with a non-invasive technique and precise demonstration of bleeding point may spare patients from extensive exploratory laparotomy.

Scientific and Educational Exhibits

C-0097

Imaging of duodenal disorders in children and adulthood

A. Bravo, M. Lamas, T. Berrocal, M. Allona, J. Larrauri, N. Gómez León; Madrid/ES

Learning Objectives: To understand the embryology, pathology, and imaging features of a wide spectrum of congenital and acquired alterations involving the duodenum in children and adults. To evaluate the efficacy of plain radiographs, barium studies, ultrasound, CT and MR imaging in the diagnosis and management of these conditions.

Background: We reviewed the imaging findings of patients with disorders involving the duodenum from our database of gastrointestinal pathology. Plain radiographs and barium studies were performed in all patients while ultrasound, CT or MR were performed in all tumours and whenever barium studies were not conclusive. The key findings at each imaging modality are shown and compared with the underlying pathologic features when available. Pitfalls, diagnostic difficulties and differential diagnoses are emphasised.

Imaging Findings: Specific topics addressed include congenital anomalies (duodenal atresia and stenosis, duodenal diaphragm or web, annular pancreas, duodenal duplication and diverticula), inflammatory diseases (Crohn's disease, tuberculosis, actinomycosis, eosinophilic granuloma, AIDS, Whipple's disease, radiation duodenitis), non inflammatory diseases (sarcoidosis, systemic sclerosis, celiac disease, hemophilia, Henoch-Schönlein purpura), diffuse infiltrative diseases (amyloidosis, eosinophilic enteritis, intestinal lymphangiectasia, lymphoid hyperplasia), duodenal ulcers, benign tumors (adenomatous polyp, lipoma, leiomyoma, angioma, lymphangioma, neurogenic tumors, Peutz-Jeghers syndrome), malignant tumors (villous adenoma, adenocarcinoma, leiomyosarcoma, lymphoma, carcinoid tumor, Kaposi's sarcoma, metastasis), duodenal trauma and postsurgical complications.

Conclusion: Evaluation of patients with duodenal disorders frequently requires multiple imaging modalities for diagnosis and planning treatment. Because many of these disorders have characteristic imaging appearances, this exhibit will help the practising radiologist to better understand and recognise pathologic processes affecting the duodenum.

C-0098

Histopathologic concordance of MR imaging findings in the local staging of rectal cancer: Is IV contrast administration needed?

P. Ramos Lopez, L. García del Salto, E. Domínguez Franjo, B. Ramos Moreno, A. Santana Acosta, E. Fraile Moreno; Alcalá de Henares/ES

Purpose: The preoperative assessment of the local staging of colorectal cancer is essential for the planning of optimal therapy. MR imaging has proved to be a reliable method for local staging of rectal carcinoma. The purpose of this study is to describe the MR imaging technique and protocol used in our hospital, to compare the imaging findings with histopathological results and to evaluate the usefulness of gadolinium-enhanced scanning.

Methods and Materials: From May-2003 to September 2004, twenty-five patients with colonoscopic biopsy-proven rectal cancer were preoperatively evaluated using 1.5 T MR imaging scanner with a phased-array coil. The protocol consists of T1 and T2-weighted turbo spin-echo and gadolinium-enhanced T1-weighted images with oriented in the three tumoral axis. Three radiologists, blinded to surgical result, evaluated the four most accurate signs described of local spread: depth of tumor growth in the colonic wall (T stage), circumferential resection margin (CRM), surrounding pelvic structures invasion and the nodal metastasis stage. The MR imaging findings were correlated with histological findings.

Results: The kappa values for depth of tumor growth in the colonic wall, circumferential resection margin, surrounding pelvic structures invasion and nodal metastasis stage were over 0.4. Contrast did not increase the kappa value in any of the categories.

Conclusion: We found excellent concordance between the MR imaging and histological findings. MR imaging showed to be an excellent method for local staging of rectal carcinoma. MR imaging without contrast administration is a reliable method to evaluate the local stage of rectal cancer, with both cost and time saved when compared with contrast-enhanced studies.

C-0099

Helical CT in the evaluation of acute bowel ischemia: Common findings, uncommon findings and pitfalls

S. García-Asensio, R. Cozcolluela, H. Gómez, L. Sarría, M. Martínez-Berganza, A. Forradellas, I. Alberdi, F. Monzón; Tudela/ES

Purpose: To illustrate the spectrum of imaging findings of various types of acute bowel ischemia, and potential pitfalls in interpretation of helical CT images.

Methods and Material: The imaging finding of patients with acute bowel ischemia demonstrated at surgery were reviewed from our database (1996-2004). Cases that mimic this entity at CT were also reviewed. These patients underwent evaluation with contrast enhanced spiral CT. In some cases reformatting images were obtained.

Results: The most frequent signs on CT in this study were: Bowel wall thickening, dilatation of small bowel loops, free intraperitoneal fluid, mesenteric arterial occlusion/stenosis, mesenteric or portal vein thrombosis, mesenteric edema, intramural bowel gas, infarction of other abdominal organs, gas filled portal or mesenteric veins, inhomogeneous enhancement of bowel wall, target sign, lack of bowel lack enhancement, thin bowel wall and hazy mesentery. The most common pitfalls in interpretation of images were: Pneumatosis, small intramural gas bubbles and pseudothickening of bowel wall. Other entities that can mimic acute bowel ischemia at CT were: infections and inflammatory bowel disease, bowel obstruction and intrabdominal sepsis. Correlation between CT results and pathological findings was shown.

Conclusion: This exhibit provides an overview of the spectrum of findings on CT in acute bowel ischemia. This entity is a high mortality pathology but usually presents with clinically non-specific manifestations. The knowledge of different CT findings and the conditions that can be misinterpreted for it produce an improvement in diagnostic suspicion and may even be helpful in determining the primary cause.

C-0100

Preoperative spiral CT in staging of colonic cancer

L. Sarría, R. Cozcolluela, S. García, H. Gómez, T. Martínez-Berganza, A. Forradellas, I. Alberdi, F. Monzón; Tudela/ES

Purpose: To evaluate the accuracy of helical computed tomography for preoperative T and N staging of colonic cancer.

Materials and Methods: Fifty-five patients with colonic carcinoma previously diagnosed by colonoscopy underwent preoperative helical CT. CT was performed with oral and intravenous contrast. Images were obtained in the portal venous phase (start delay of 70 seconds). Tumor invasion of colonic wall and local spread (T), and regional lymph node involvement (N) on transverse CT were evaluated in this study. CT findings were compared with pathologic findings. Patients with rectal carcinoma were excluded from this study because preoperative adjuvant radiation therapy could modify the histopathological findings. Patients diagnosed in the emergency room were also excluded. Sensitivity, specificity, accuracy, PPV and NPV values were assessed.

Results: Colonic wall thickening was shown in 4 of 6 T2 patients (60%), 39 of 41 T3 patients (95%) and 3 of T4 patients; a patient with gross vegetant T1 tumor was also shown by CT. In 50 patients without local complications stranding of pericolic fat was shown by CT in 8 of 10 patients with local tumor extension and all of 17 patients with inflammatory spread (Sensitivity 80%, specificity 49%, PPV 26%, NPV 92% and accuracy 54.5%). CT detected lymphadenopathy in 7 of 18 patients with regional nodal metastasis and in 6 of 37 patients without evidence of invasion (Sensitivity 39%, specificity 84%, PPV 54%, NPV 74%, accuracy 69.1%).

Conclusion: Helical CT is not an effective method in determination of T and N staging of colonic cancer.

C-0101

Small bowel traumatic injuries: A pictorial essay

M. Osorio, A. Maroto, G. Laguillo, J.I. Rodríguez, P. Ortuño, J. Pont; Girona/ES

Learning Objectives: To illustrate the different CT radiological signs of small bowel traumatic injuries. To underline the need of a careful search for these subtle CT signs in order to influence their surgical or conservative management.

Background: Injuries of the gastrointestinal tract are prevalent lesions in patients with blunt abdominal trauma. They are present in 3-7% of patients in different series. Bowel injuries are challenging to diagnose on CT. The knowledge of the spectrum of radiological presentation may allow a rapid detection of these serious lesions.

Procedure Details: Clinical reports of 165 poly-trauma patients admitted to our hospital during 2003 were retrieved. 25 of the 165 patients (15%) were diagnosed with bowel injuries. Abdominal CT scans of these patients were retrospectively reviewed. The most relevant CT signs associated with bowel injury are shown: Extravasation of vascular contrast agent, presence of free air, clot sign with or without associated bowel wall thickening and streaky mesenteric infiltration. Absence of pneumoperitoneum, or clot sign as the only finding and a small amount of free fluid were the radiological findings which permitted conservative management in a clinical setting of hemodynamic stability.

Scientific and Educational Exhibits

Conclusion: Bowel injury is frequent in abdominal blunt trauma and radiologists must be aware of this potentially life-threatening condition. A combination of clinical parameters and CT radiological findings are the clue to conservative management of these lesions.

C-0102

Imaging small bowel ischaemia: The role of multidetector CT

K. Burney¹, S.P. Prabhu¹, I. Lyburn², R. Hopkins²; ¹Bristol/UK, ²Cheltenham/UK

Learning Objectives: 1. Review pathogenesis and causes of acute small bowel ischemia. 2. To demonstrate the often subtle radiological signs of acute small bowel ischaemia. 3. To demonstrate contribution of CT in the diagnosis of this complex disease.

Background: Acute mesenteric ischaemia is caused by arterial, venous occlusion or mesenteric hypoperfusion. The patient can present with various clinical and radiologic manifestations, and the causative pathology can range from localised transient ischaemia to necrosis of the intestine. The underlying causes include thromboembolism (50% of cases), bowel obstruction, neoplasms, vasculitis, inflammatory conditions, trauma, chemotherapy, radiation, and corrosive injury. It has a high mortality rate between 70-90% and clinical diagnosis can be difficult due to non-specific nature of signs and symptoms.

Procedure Details: We reviewed the imaging of patients with surgically proven small bowel ischaemia treated at our hospital over the last 5 years and present a review of pathologies seen on radiological investigations. Multi-detector CT is being increasingly used in the evaluation of such patients with equivocal clinical signs. Apart from enabling direct visualisation of cause of ischaemia such as arterial or venous obstruction, CT can demonstrate changes resulting from ischaemic bowel and demonstrate important coexistent findings or complications. Secondary signs like portal venous gas, bowel wall thickening, and pneumatosis can help confirm the diagnosis.

Conclusion: Diagnosis of acute small bowel ischaemia is facilitated by radiological examination like MDCT, but often a combination of clinical, laboratory and radiologic signs that may lead to a correct diagnosis.

C-0103

MR imaging of the effects of neo-adjuvant radiotherapy on rectal carcinoma

J.L. Hughes, M. Alijani, J. Chin-Aleong, S. Babar, A. Rockall, R. Reznek; London/UK

Purpose: Neo-adjuvant radiotherapy reduces local recurrence in rectal cancer patients. MR imaging has been used after neo-adjuvant therapy to stage the tumour and aid surgical planning. We aimed to document the effect of radiotherapy on rectal carcinoma using MR imaging.

Methods and Materials: MR imaging was performed before and after neo-adjuvant therapy in 13 patients. Nine patients had short course radiotherapy and 4 had long course chemoradiotherapy. Axial and sagittal T2W images were supplemented with high-resolution oblique T2W images axial to the tumour. We assessed radiological stage and maximum tumour thickness, before and after neo-adjuvant therapy. MR imaging of the rectal tumour specimen was used to help correlate the tumour appearance with histology, the reference standard.

Results: Eleven patients were radiological stage T3 and 2 were stage T4 prior to neo-adjuvant therapy. The T stage accuracy was 85%. Two patients were overstaged from T3 to T4 and none was understaged. Overall there was a 17% reduction in tumour thickness (cm) post neo-adjuvant therapy, which was statistically significant ($p < 0.01$). Following short course radiotherapy, 2 tumours were downstaged, one from stage T3 to T2 and the other from stage T3 to T1.

Conclusion: We have shown that both neo-adjuvant chemoradiotherapy and short course radiotherapy result in a significant reduction in the size of rectal tumours prior to surgery. Short course radiotherapy resulted in downstaging of tumour in two patients, one of whom would have benefited from local excision surgery alone.

C-0104

Virtual colonoscopy: The way our department is beginning the change from barium enemas to virtual colonoscopy

M.J.F. Tapp, J.R. Ferrando; Birmingham/UK

Learning Objectives: To start using new techniques in the radiology department there needs to be a reason to change, as well as the commitment of team members to maintain the momentum of change. Having advance knowledge of why and how the introduction of virtual colonoscopy should be undertaken can help make the process go more smoothly.

Background: Although barium enemas have been performed for many years to image the large bowel, virtual colonoscopy is now starting to replace it. Not only

can the large bowel be well demonstrated, but the CT scan also has the added benefit of allowing imaging of the rest of the abdomen. As with all new techniques, there is a gradual process that takes place during its introduction.

Procedure Findings: We explain how we have initiated virtual colonoscopy into the daily routine of our radiology department. Certain techniques, such as performing both prone and supine scans help improve the diagnostic quality of the scan, whereas proper patient selection helps to keep the number of scans down. Although there are many benefits from changing from barium enemas to virtual colonoscopy, it is likely that both will be performed for the foreseeable future.

Conclusion: A well planned introduction of virtual colonoscopy into the department will help maintain good working relations with the clinicians, whilst both improving the service to patients and keeping workloads within achievable levels.

C-0105

Appendiceal CT: A prospective randomized controlled study comparing three different protocols

D. Fischer, N. Awad, D. Hershko, L. Goralnik, M. Krausz, A. Angel; Haifa/IL

Purpose: The important role of CT in the diagnosis of suspected acute appendicitis has recently been validated. Numerous CT protocols using different combinations of oral, rectal and intravenous contrast agents and studies without contrast materials are all commonly used in the diagnostic workup for this clinical presentation, yet the protocol of choice has not yet been determined. Here, we prospectively compare the diagnostic accuracy of three different CT protocols for the diagnosis of suspected acute appendicitis.

Methods and Materials: 222 consecutive patients with suspected acute appendicitis were randomly assigned to one of three focused CT protocols. In group A, non-contrast CT was performed; in group B, contrast material was administered rectally (PR); in group C, contrast material was administered both orally and intravenously (PO/IV).

Results: 104 patients had acute appendicitis. High accuracy rates were observed for both the PR and the PO/IV studies (94%). The accuracy rate of the non-contrast studies group was 70%, significantly lower than the other groups ($p < 0.01$).

Conclusions: High and similar accuracy rates were observed by PR and PO/IV contrast protocols. PR contrast examinations are quicker to perform than PO/IV and can lead to a prompt diagnosis. Non-contrast studies require a high level of expertise to evaluate. Therefore, we suggest that the PR contrast protocol may be the preferred initial CT examination in the diagnostic work-up of suspected appendicitis.

C-0106

Acute colonic disorders: CT findings

A. Buzzi, M. Figueiroa, V. Alarcon, F. Arredondo, M. Hjelt, A. Mancini; Buenos Aires/AR

Learning Objectives: To illustrate the spectrum of CT findings in acute pathologies of the colon. To understand the radiological findings on the basis of pathologic correlation. To demonstrate the efficacy of CT in the management of these diseases.

Background: Acute colonic disorders are represented by a large variety of entities such as inflammatory disease, intestinal obstruction, colonic ischemia, perforation and colorectal carcinoma complications. CT has the ability to show accurately the bowel wall, the pericolic soft tissues and the neighboring structures, being a very sensitive method for detection of mural penetration and extraluminal extension of the colonic disease.

Imaging Findings: The cardinal findings are mural thickening, surrounding mesenteric densities and fluid collections. A dilated and thickened appendix is suggestive of appendicitis; a fatty pericolic lesion with surrounding mesenteric inflammation is diagnostic of epiploic appendagitis; the presence of diverticula suggest diverticulitis; cecal distention with circumferential wall thickening suggests typhlitis; circumferential, symmetric wall thickening with fold enlargement suggests ischemic colitis and the "bowel-within-bowel" appearance is pathognomonic of intussusception. In infectious colitis the site and thickness of colon affected may suggest a specific organism. Crohn's disease and ulcerative colitis may be distinguished by the location of the involved segment and the extent and appearance of the wall thickening. CT may predict mechanical obstruction, determine the etiology and location and detect signs of complications related to strangulation. In radiation colitis, the clinical history is the key to suggesting the diagnosis.

Conclusion: CT is valuable for detection and characterization of acute conditions of the colon.

Scientific and Educational Exhibits

C-0107

The role of virtual colonoscopy in the evaluation of inflammatory disease

P.M. Carrascosa, C. Capuñay, R. Castiglioni, M. Ulla, J. Carrascosa; Buenos Aires/AR

Learning Objectives: To be familiar with the virtual endoscopic technique. To identify the typical findings of these diseases by virtual colonoscopy. To outline the best indications and results of the method.

Background: Virtual colonoscopy is used worldwide for the evaluation of the colon in the detection of elevated lesions. There is no experience in the study of inflammatory diseases. The improvement of CT technology gives the opportunity to scan the colon using thin collimation, up to 0.8 mm, and fine changes of the colon wall in early stages of the diseases can be diagnosed. The technique, indications and contraindications of the method are described. From the patients evaluated, 12 had ulcerative colitis (UC) and 8 Crohn's disease (CD). In UC, the findings were: Ulceration, pseudopolyps, a coarse granular appearance of the wall with haustral blunting and increase of the presacral space. In CD, the findings were: Thickening of the mucosal wall greater than 5 mm, filiform polyps and marked mesenteric thickening.

Procedure Details: CT studies were performed with a 16 row scanner using slices of 0.8 mm thickness. Patients performed a standard colonic cleansing the day before the exam. Conventional colonoscopy was carried out during the same day, with an E-P Fujimon colonoscope and the images were saved in a digital format. Findings of the two modalities were compared.

Conclusion: with 16-row CT scanners, virtual colonoscopy can detect early as well as advanced changes in both diseases and it can be considered as a potential modality to evaluate these patients in a non-invasive way.

C-0108

MSCT imaging of patients treated with surgery and/or Imatinib Mesylate therapy for gastrointestinal stromal tumors (GIST)

M. Lusic, R. Stern Padovan, D. Vrbanec, M. Kralik, K. Potocki; Zagreb/HR

Learning Objectives: To evaluate changes in MSCT presentation of GIST after surgery and/or Imatinib Mesylate treatment and to recognise response to therapy in patients treated with imatinib mesylate.

Background: GISTS are non-epithelial tumors which mostly occur in the stomach and small intestine. Because of tyrosine-kinase expression they could be treated with a KIT tyrosine-kinase inhibitor drug (Imatinib). We evaluated the imaging findings on MSCT in twenty patients treated with surgery and/or Imatinib in a two-year period. Morphology, size, number and sites of primary lesions and metastases were assessed on subsequent MSCT examinations.

Imaging Findings: GIST was found in the stomach and small intestine with metastatic disease in liver, peritoneum, mesentery, retroperitoneum, kidney, subcutis and subpleural regions. Reduction of tumor mass and cystic and necrotic transformation of metastases indicate good response to therapy. In resistant disease there was increase in tumor mass; metastases tended to increase in size and density, and new secondary lesions were found, especially in regions which were under surgical treatment.

Conclusion: MSCT imaging is the major diagnostic tool for diagnosis and follow-up studies of surgically treated, and recurrent and metastatic GIST patients treated with Imatinib Mesylate. Imaging findings correlate with the course of the disease and are used for planning further therapy. It is important to know the expected morphological changes on MSCT images for evaluation of response to therapy in patients treated with Imatinib Mesylate.

C-0109

Magnetic resonance imaging assessing the three-dimensional biomechanical properties of the human rectum

J.B. Frøkjær, D. Liao, A. Bergmann, B.P. McMahon, E. Steffensen, A.M. Drewes, H. Gregersen; Aalborg/DK

Purpose: In many gastrointestinal disorders the mechanisms behind the symptoms are poorly understood. A method to evaluate the three-dimensional (3-D) geometry of the human gastrointestinal wall may be valuable for understanding tissue biomechanics, mechano-sensation and function.

Methods: A special-designed bag inserted into the rectum was stepwise distended while magnetic resonance images, bag pressure and the sensory perception were recorded. Images from three healthy volunteers were analysed. The inner and outer edges of the rectal wall were identified semi-automatically. 3-D models of curvatures, radii, tension and stress were generated and the circumferential and longitudinal strains were calculated.

Results: The calculated bag volume based on the 3-D model corresponded to

the infused volume. During bag filling, a bag elongation and decrease in wall thickness was observed. The spatial distributions of the biomechanical parameters were distinctly different in individuals and non-homogeneous throughout the rectal wall due to its complex geometry. The average 3-D tension and stress increased as function of infused volume and circumferential strain. The sensory perception increased as function of infused volume, pressure, tension, stress and strain. The average tension based on 3-D models corresponded to the estimated tension based on the assumption of a spherical bag configuration.

Conclusion: The present study provides a method for characterizing the complex in-vivo 3-D geometry of the human rectum obtained from a clinical imaging modality. The non-homogenous spatial curvature distribution suggests that simple estimates of tension based on pressure and volume do not reflect the true 3-D biomechanical and mechano-sensory properties of the rectum.

C-0110

Magnetic resonance imaging of the small bowel in inflammatory bowel disease

J.B. Frøkjær, E. Larsen, E. Steffensen, A.H. Nielsen, A.M. Drewes; Aalborg/DK

Purpose: Magnetic resonance imaging (MRI) of small bowel disease has several advantages. The aims were to optimise the MRI examination technique and to evaluate the capabilities of MRI compared to conventional enteroclysis (CE).

Methods: MRI and CE were performed in 36 patients with suspected Crohn's disease. Based on 26 pilot studies optimal oral administration of plum juice and bulk fibre laxative was found. T2-weighted and gadolinium enhanced T1-weighted images were obtained using breath-hold technique and butylscopolamine. Virtual endoscopy was performed. Duodenal intubation with administration of barium and air was used for CE. Two radiologists evaluated the examination pathology and quality independently. Finally, each patient scored the degree of discomfort and the preference to either MRI or CE was found.

Results: The MRI technique ensured sufficient distension of the small bowel. MRI revealed small bowel pathology in 12 patients. In three patients it was not seen on CE. The CE revealed no pathology which was not seen on MRI. Pathological abdominal changes were revealed in 70% more patients during MRI than CE ($P < 0.001$). Endoscopic examination corresponded to the MRI findings. The examination quality decreased with increasing age ($P = 0.002$). The inter-observer agreement of the pathological changes was high ($P < 0.001$). Virtual endoscopy resulted in excellent demonstration of the mucosal surface. The examination discomfort scores obtained during the MRI were lower than during CE ($P < 0.001$).

Conclusions: MRI with the current technique is preferable to CE because of excellent demonstration of the entire small bowel pathology, low patient discomfort and absence of radiation exposure.

C-0111

Imaging findings of small bowel tumors on MR imaging enteroctysis

A.A. Alhajeri, D.A. McKenna, J. Murphy, C. Roche; Galway/IE

Learning Objectives: The aim of the study is to present the findings of small bowel tumors in MR imaging enteroclysis.

Background: Primary tumors of the small bowel are rare, making up only 3% of all GI tumors, and often have a nonspecific clinical presentation. Consequently, preoperative diagnosis remains the exception rather than the rule. With the advent of rapid MR imaging sequences, there has been increasing interest in the use of MR imaging for small bowel evaluation. This has been attributed to its inherent advantages such as the lack of radiation exposure, excellent soft tissue contrast and direct multiplanar capabilities.

Procedure Details: Fifty five patients underwent MR imaging enteroclysis over the past 24 months for variable clinical inductions. Patients received a positive oral contrast (Klean prep, Norgine, Middlesex) and were then imaged by MR imaging using breath hold protocol (T1-weighted fast low-angle shot and T2-weighted turbo spin echo). Within this group, 6 patients had small bowel tumors identified which included lymphoma, plasmacytoma and carcinoid. Furthermore, MR imaging allowed the identification of extraluminal complications such as perforation.

Conclusion: In this poster we demonstrate the imaging findings of a range of tumors of the small bowel on MR imaging.

C-0112

Assessment of patients with acute mesenteric ischemia (AMI):

Multidetector CT (MDCT) signs and clinical performance in a group of patients with surgical correlation

F. Zandriño, E. La Paglia, L. Benzi, F. Musante; Alessandria/IT

Purpose: To describe signs and clinical performance of MDCT in patients with AMI.
Methods and Materials: MDCT examinations of 26 patients with surgically proved AMI were retrospectively evaluated. Moreover, MDCT studies of 34 patients with a preoperative clinical diagnosis of acute abdomen and a surgical diagnosis excluding AMI were assessed. All MDCT studies were performed with arterial and portal venous phase scans, 2.5 slice thickness and 1.25 image interval, maximum intensity projection and multiplanar reconstructions. All MDCT studies were reviewed by two abdominal radiologists by consensus. In all patients signs suggesting AMI were recorded. Patients with thrombosis of the mesenteric artery or vein or pneumatosis or venous gas or bowel wall thickening associated with lack of bowel wall enhancement or venous thrombosis or parenchymal ischemic lesions were considered to be affected by AMI.

Results: AMI was due to arterial thrombosis in 19 patients and venous in 7. In 65% of patients arterial thrombosis was visualized, in 19% venous thrombosis; vascular gas was seen in 27% and pneumatosis in 38%; bowel wall thickening associated with other signs was found in 45%. Sensitivity was 96% (1 false negative) while specificity was 100%.

Conclusion: Thanks to its high temporal and spatial resolution MDCT allows an accurate assessment of the mesenteric circulation and of the bowel wall. This makes possible optimal visualization of signs of AMI resulting in a very good clinical performance.

C-0113

Spectrum of findings of celiac disease at MR imaging of the small bowel

P. Paolantonio, A. Laghi, M. Rengo, V. Martino, M. Di Martino, E. Tomei, R. Passariello; Rome/IT

Purpose: The aim of our study was to asses the intestinal findings at MR imaging of the small bowel perfomed using polyethylenglycol solution as oral contrast agent (PEG-MRI) in a population of patients with known celiac disease.

Materials and Methods: Twenty nine patients, 19 adults and 10 children, with known celiac disease underwent MR study of the small bowel. After an overnight fast, immediately before MR examination a fixed amount of 10 ml/kg of body weight of PEG solution was orally administered. MR study protocol included HASTE (TR/TE/acq.t.: inf/90 ms/18 s) and True-FISP (TR = 4.8 ms; TE = 2.3 ms; Flip Angle 50°) sequences obtained sequentially on axial and coronal planes.

Results: Image analysis showed alterations of mucosal pattern of ileal loops with an increased number of folds (5 or more folds per inch) ("ileal jejunalization") in 18 patients; reversal jejunum-ileal fold pattern in 6 patients; intestinal intussusception was observed in two patients and hypersplenism in one patient. MR was also able to identify mesenteric lymphadenopathy. No alteration of the small bowel loops was observed in five patients.

Conclusions: PEG-MR imaging is a feasible and reproducible imaging technique in both adult and paediatric populations. It may suggest a diagnosis of celiac disease as well as being able to identify potential intestinal complications together with extra-intestinal findings.

C-0114

Spectrum of findings of intestinal non-neoplastic disorders at MR imaging of the small bowel

P. Paolantonio, A. Laghi, R. Passariello; Rome/IT

Learning Objectives: To describe the findings of several intestinal disorders at MR imaging of the small bowel.

Background: Moving from the conventional barium studies of the small bowel to MR of the small bowel, radiologists are called to shift their attention from the evaluation of mucosal abnormalities and indirect signs of visceral wall pathology to the direct visualization of the small bowel wall. Using MR of the small bowel the major findings are represented by changes of small bowel thickness or in the enhancement pattern of the intestinal wall. Nevertheless, some evaluation of the intestinal mucosal layer is also possible using MR imaging. We show the typical MR findings of Crohn's disease and Coeliac disease and also several findings of intestinal infections like giardia intestinalis, taenia solium and tuberculosis. Some cases of congenital abnormalities like intestinal malrotation and small bowel involvement during vasculitis are also described.

Procedure Details: In the past 4 years we analized over 200 patients, from both the pediatric and adult populations, referred for intestinal disorders. All the MR

examination were performed acquiring HASTE and True-FISP sequence and Gd-DTPA-enhanced-FLASH T1W sequence after intestinal distension was obtained by means of oral administration of a fixed amount of 10 ml/kg of body weight of PEG solution 20 minutes before the MR examination.

Conclusions: PEG-MR imaging is a valid diagnostic tool in the identification of several intestinal findings and may help in the diagnostic process of several intestinal disorders.

C-0115

Advanced gastrointestinal stromal tumors (GIST) treated with Imatinib Mesilate: CT and MR tumor response assessment

A. Messina, C. Spreafico, P. Casali, D. Vergnaghi, F. Bianchi, A. Gronchi, R. Musumeci; Milan/IT

Purpose: To evaluate CT and MR patterns of tumor response to Imatinib Mesilate in advanced GIST.

Methods and Materials: 84 patients with abdominal advanced GIST, undergoing therapy with Imatinib Mesylate, were retrospectively reviewed. Liver lesions were detected in 69% of cases and peritoneal involvement in 59% of cases. CT (54 pts) and MR (30 pts) examinations were performed at baseline and than at 2, 4, 6, 8, 10 and 12 months during treatment.

Results: 84% of patients were judged to be responsive to therapy after 12 months. CT and MR patterns in responsive patients were: A) Tumor decrease in size (with an increase in tumor volume in 8% of cases at the first 2 months due to necrosis or bleeding), B) Hypovascularization of the lesions (due to the presence of degenerative tissue or necrosis), C) Presence of peritoneal fluid at the first month, reabsorbed in the following months and D) Hypointensity of the lesions on MR T1W images, hyperintensity of the lesions on MR T2W images and hypodensity on CE-CT images (correlating with presence of degenerative tissue or necrosis).

Conclusion: CT and MR are adequate to identify tumor response to Imatinib Mesylate in advanced GIST from the early months of therapy. Decrease in tumor size and increase in necrosis are held as early indicators of response. Nevertheless tumor volume should not be held as the only indicator of activity and in particular, volume increase should not be held as evidence of progression when associated with an increase in necrosis.

C-0116

Multiphase fusion technique of three-dimensional images using 16 MDCT for the preoperative simulation and intraoperative navigation of laparoscopic gastrectomy and colectomy

M. Matsuki, M. Tanikake, H. Kani, I. Narabayashi; Takatsuki/JP

Purpose: Recently, laparoscopic surgery has been attracting attention for its capability of improving the patient's QOL. However, this technique has the disadvantage that much time is required to deal with the arteries and veins, the pattern of which varies between patients, and the vessels are sometimes injured during dissection of lymph nodes along the arteries. We considered that the simultaneous assessment of arteries and veins by 3D CT angiography is helpful for the safe ligation of the vessels and dissection of lymph nodes. In this study, we evaluated the usefulness of the multiphase fusion technique for 3D images obtained using 16 MDCT for preoperative simulation and intraoperative navigation of laparoscopic surgery.

Methods and Materials: We performed contrast-enhanced examination at arterial and venous phase using 16 MDCT in twenty-five patients with gastric cancer and fifty patients with colorectal cancer. The slice data obtained from each phase were transferred to a work station, in which the data were individually converted into a 3D imaging format using the volume-rendering technique. Thereafter, the 3D arteriography and venography were fused together by multiphase fusion technique.

Results: In all the 75 patients, multiphase fusion images demonstrated clearly and simultaneously the arteries and veins around the stomach and the colon, which were correctly identified during surgery. We could utilize the multiphase fusion image for preoperative simulation and intraoperative navigation of laparoscopic gastrectomy and colectomy.

Conclusion: The utilization of multiphase fusion images contributed to the safe and prompt performance of laparoscopy.

C-0117

The evaluation of strangulation ileus using contrast enhanced ultrasonography

J. Koizumi; Isehara-city/JP

Purpose: To evaluate blood flow in strangulation ileus using contrast enhanced ultrasonography.

Scientific and Educational Exhibits

Materials and Methods : New Zealand white rabbits (approximately 3 kg) were incised under pentobarbital and medetomidine anesthesia. A small intestinal loop was extracted into the normal saline pool and observed using Coded Harmonic Angio by Logiq 700 (General Electric) under Levovist enhancement. A strangulation ileus was made by advancing a loop through a plastic syringe and compressing the bowel neck by the same diameter angioplasty balloon catheter inside in the syringe. For quantitative analysis the left carotid artery was cut down and the arterial pressure was monitored. The 'arterial' strangulation was made at higher balloon pressure than the systolic pressure, and the venous strangulation at lower one than the diastolic pressure. Enhancement was repeated approximately every thirty minutes after the previous injection.

Results: In the control, contrast enhancement distributes from the mesenteric artery to the bowel wall. In the arterial strangulation, contrast enhancement disappeared immediately after the compression. In the venous strangulation, contrast enhancement was delayed and diminished after the compression, and gradually disappeared in two hours.

Conclusions: Contrast enhanced ultrasonography can demonstrate vascular flow in the bowel and has efficacy in detecting strangulation.

C-0118

MR imaging of stomach cancer and ex vivo ^1H MR spectroscopy of the resected stomach

J.-H. Yoon, S.-S. Cha, S.-S. Han, S.-J. Lee, M.-S. Kang; Busan/KR

Purpose: To evaluate the usefulness of MR imaging and ex-vivo ^1H MRS to distinguish normal from tumor invasion of gastric wall.

Materials and Methods: Two specimens were examined with single-voxel ^1H MRS with 9.4 T equipped with custom-made surface coil. Fifty six surgical specimens were examined at 1.5 T MR imaging and ^1H MRS. Spectral measurements were done in the proper muscle layer and composite mucosa-submucosa layer. For all spectra, a PRESS technique with parameters of TR/TE = 2000/30 msec and 256 averages was used. Twenty one patients underwent preoperative MR imaging, and comparison to diagnostic T- and N-staging. High-resolution MR imaging was performed on resected specimens.

Results: The results at 9.4 T ^1H MRS showed metabolite peaks at 0.9 (lipid), 1.3 (lipid), 1.58 (Alanine), 2.03 (Sialic acid) and 2.25 ppm (glutathione) and with 1.5 T MRS, peaks are present at 0.9, 1.3, 2.0 and 2.2 ppm in normal gastric tissue. The peak levels of choline at 3.22 ppm were increased and peaks of lipid were decreased and split into 1.26 ppm and 1.36 ppm in gastric cancer tissues. Patients with gastric cancer showed various SI in MR imaging preoperatively, and overall accuracy was 80% (12/15) in T-staging and 86.7% (13/15) in N-staging. MR imaging of resected specimens clearly showed three different layers of normal gastric walls.

Conclusion: In evaluating the extent of gastric carcinoma, differentiation of up to three layers of the gastric wall was possible on ex vivo high resolution MR imaging. In the area of focal tumor invasion, the spectra obtained during ^1H MRS were useful, with the lipid peak decreasing and the choline splitting into two resonance peaks.

C-0119

Blood-borne metastatic tumors to the gastrointestinal tract: CT findings with clinicopathologic correlation

S. Kim, K. Kim, A. Kim, J.-S. Kim, H. Ha; Seoul/KR

Learning Objectives: To recognize the spectrum of CT findings of blood-borne metastases to the gastrointestinal tract from various malignancies and to discuss the characteristic CT findings of gastrointestinal metastases from each underlying primary malignancy, with clinicopathologic correlation.

Background: Although rare, blood-borne metastases to the gastrointestinal tract have been observed in patients with various malignancies. Most lesions are from malignant melanoma, carcinoma of the breast or lung, and hepatocellular carcinoma, and they most commonly involve the stomach and small bowel because of their rich blood supply. While most gastrointestinal metastases are encountered in patients with a known underlying malignancy and a widespread metastatic disease, they may occasionally occur as the initial manifestation of an occult primary lesion.

Imaging Findings: Although CT has played a key role in the evaluation of patients with a known or suspected malignancy, relatively little attention has been paid to the CT findings of gastrointestinal metastases. In this exhibit, we illustrate the spectrum of CT findings of gastrointestinal metastases, with clinicopathologic correlation.

Conclusion: A familiarity with this condition may ensure an accurate diagnosis and proper management in these patients.

C-0120

Branching patterns of the first jejunal vein: Evaluation using multi-detector row CT angiography

H. Kim, J. Lim, D. Lee, Y. Ko; Seoul/KR

Purpose: To evaluate branching patterns of the first jejunal vein using MDCT angiography in adults.

Materials and Methods: Two hundred twenty consecutive patients were enrolled in this study. Among 220 patients, 152 patients had no history of abdominal surgery. Branching patterns of the first jejunal vein were classified as follows: Type I, first jejunal vein crossed dorsal to the superior mesenteric artery (SMA) towards the left abdomen; Type II, First jejunal vein crossed dorsal to the SMA and abruptly turned towards the right abdomen; Type III, First jejunal vein crossed ventral to the SMA. Two radiologists classified branching patterns on PACS monitor using serial 5-mm thickness axial images of portal and delayed phase and MDCT angiography (volume rendering and maximum intensity projection technique).

Results: Of 220 patients, type I, II, and III branching patterns were identified respectively in 146 (66%), 38 (17%), and 36 (16%) patients. In the type II branching pattern, previous surgery or pathologic process that caused abrupt turning of first jejunal vein towards the right abdomen were as follows; biliary-enteric bypass surgery ($n = 7$), large hematoma in left abdomen ($n = 1$) and atrophy of the right kidney ($n = 1$). Of 152 patients who had no history of previous surgery, type I, II, and III branching patterns were identified respectively in 106 (70%), 22 (14%) and 24 (16%) patients.

Conclusions: We present the branching patterns of the first jejunal vein using MDCT angiography. The first jejunal vein, abruptly turning toward the right abdomen may be an anatomic variant or indirect finding of previous surgery such as biliary-enteric bypass.

C-0121

Imaging of non-tumoral disorders involving the small bowel in infancy and adulthood

M. Parrón, M. Lamas, T. Berrocal, E. Fernández, J. Gutiérrez, J. Fernández; Madrid/ES

Learning Objectives: To understand the embryology, pathology, and radiological features of disorders involving the jejunum and ileum. To know the utility of each imaging modality that can be applied to the management of these conditions. To show pitfalls, diagnostic difficulties and differential diagnoses.

Background: Non-tumoral disorders affecting the small bowel are a significant cause of morbidity in infants, children and adults, frequently requiring multiple imaging modalities to diagnose and plan treatment. This teaching exhibit analyses and illustrates practical aspects of a wide spectrum of usual, unusual and exceptional non-tumoral disorders affecting the jejunum and ileum, with particular emphasis on radiologic manifestations. The efficacy of the different imaging modalities in the diagnosis and management of these conditions will be evaluated.

Imaging Findings: Specific topics addressed include congenital anomalies (jejuno-ileal atresia and stenosis, Meckel's diverticulum, meconium ileus, anomalies of rotation and fixation, short bowel syndrome, duplication cysts), inflammatory diseases (Crohn's disease, therapy-induced enteritis, graft-versus-host disease, radiation enteritis), infective diseases (yersinia, salmonella, tuberculosi, actinomycosis, parasites, Whipple's disease), diffuse infiltrative diseases (amyloidosis, eosinophilic enteritis, intestinal lymphangiectasis, lymphoid hyperplasia), vascular disorders (acute and chronic ischaemia, vasculitis, necrotizing enterocolitis of newborn), intestinal obstruction (hernia, volvulus, intussusception, gallstone ileus), scleroderma, coeliac disease, diverticula, trauma and post-surgery complications.

Conclusions: This exhibit provides an overview of the small bowel disorders as well as the utility of the various imaging techniques available. Because many of these disorders have characteristic imaging appearances, this exhibit will help the practising radiologist to better understand and recognise pathologic processes affecting the small bowel.

C-0122

Ischemic colitis: Sonographic findings and differential diagnosis

M.R. Pastor-Juan, T. Ripollés, M.J. Martínez, J.R. Olalla-Muñoz, M.D. Monedero, A. Ruiz; Valencia/ES

Purpose: To describe the sonographic findings of ischemic colitis, and to differentiate this entity from other conditions that produce wall thickening of the colon.

Materials and Methods: A review was made of the histories of patients diagnosed with ischemic colitis over a period of 6 years and 4 months. Eighty patients had undergone sonographic examinations. The spectrum of sonographic find-

Scientific and Educational Exhibits

ings in ischemic colitis was based on the original imaging report, with an analysis of the presence of colonic abnormalities and their associated alterations.

Results: The prospective sensitivity of sonography for the characterization of colonic abnormalities was 95% (76 from 80 patients). Segmental involvement was detected in 75 of the 76 patients, with left-sided colitis in 61 (80%). The mean length of bowel involved was 20 cm with a mean wall thickness of 7.7 mm. Colon wall stratification was preserved in 50 patients (66%). Altered pericolic fat was observed in 24 patients (32%). Absent or barely visible color Doppler flow in the thickened bowel wall was recorded in 82% of cases.

Conclusions: Sonography is a valuable technique for the detection of colonic abnormalities secondary to ischemic colitis. However, there are other causes of colonic wall thickening, such as pseudomembranous colitis, Crohn's disease, ulcerative colitis, diverticulitis or malignancy. Knowledge of sonographic appearances of diseases that involve the colon may suggest a specific diagnosis based on the changes in the colonic wall and peri-enteric tissues.

C-0123

Intestinal perforation by fish bone: A radiologic diagnosis when not clinically suspected

F. Romero Cique, C. Martínez, E. Santos-Armentia, M. Fernández-Carrera, E. Chávarri, J. Táboas; Vigo/ES

Purpose: To describe CT findings in patients with intestinal perforation caused by fish bone (IPFB).

Patient and Methods: 14 patients with a surgically proven diagnosis of IPFB were retrospectively analyzed. Clinical symptoms, radiologic findings and presumption diagnosis with CT were variables recorded.

Results: 14 patients presented acute abdomen by IPFB. None was clinically suspected. CT showed subtle linear lesion with high density in 7 (50%) patients in whom a correct radiologic diagnosis was established. Other findings were; thickening of the bowel wall with stranding of mesenteric fat (3), extraintestinal bubble of gas (1), abscess (4), thumbprinting (1), mass in the middle line (1), focal thickened of bladder wall (1) and gas in the bladder(1).

Conclusion: The radiologist plays an important role in the diagnosis of IFPB because this entity is usually mistaken clinically in patients with acute abdomen. The presence of a linear and high-density lesion must suggest this diagnosis.

C-0124

Computerized analysis of abnormal areae gastricae on barium examination

S.M. Zangan, A.E. Gasparaitis, M.L. Giger; Chicago, IL/US

Purpose: Visualization of areae gastricae on double-contrast upper gastrointestinal tract examinations is related to technical, physiological and pathophysiological factors. Enlarged, irregularly shaped areae gastricae can be seen in patients with gastritis. A method utilizing computerized radiographic texture analysis to recognize abnormal areae gastrica is introduced.

Methods and Materials: Supine double contrast digital images of the stomach were acquired from 26 patients and regions of interest (ROI) 128 by 128 pixels in size were extracted. Computerized texture analysis was performed to assess the variation in the anatomic pattern. Individual texture features that describe the magnitude and spatial frequency content of the patterns were calculated. The area under the receiver operating characteristic (ROC) curve (Az) was used to assess the performance of the texture analysis in the task of distinguishing between patients with gastritis and normals.

Results: Computerized texture analysis performed favorably. ROC analysis yielded an Az value of 0.90 in accurately diagnosing gastritis based on the surface pattern of the areae gastricae.

Conclusion: Computerized radiographic texture analysis is capable of determining whether the areae gastricae is abnormal on double-contrast upper gastrointestinal barium examination. This technology has the potential not only to aid radiologists in assessing the gastric mucosa but also to objectively characterize the radiographic features of the areae gastricae in pathologic states.

C-0125

Radiographic imaging of normal anatomy and complications after gastric banding and gastric bypass surgery

H. Prosch, R. Tscherney, S. Kriwanek, D. Tscholakoff; Vienna/AT

Learning Objectives: To understand the normal radiographic findings after gastric banding and gastric bypass surgery and to recognize its most frequent complications.

Background: As the incidence of morbid obesity increases, bariatric operations to reduce body weight become more frequently performed. Among the wide vari-

ety of bariatric procedures, gastric banding and gastric bypass are the most common. Understanding the principles of these interventions is essential for the interpretation of resulting radiographic findings.

Procedure Details: Between 1.1.1998 and 1.9.2004 157 gastric banding and 107 gastric bypass operations were performed at our hospital. We report on the normal postoperative findings and observed complications in this patient population. Gastric banding aims to achieve an early sensation of satiety by dividing the stomach into two pouches with an adjustable silicone band. Fluoroscopy after gastric banding should reveal a small proximal pouch and a stoma with a diameter of approximately 3-4 mm. The most common complications after gastric banding are a slippage of the band, pouch enlargement and esophageal dilatation. Gastric bypass surgery is performed by creating a small gastric pouch that is anastomosed end-to-side to a Roux-en-Y limb. The most frequent complications are leaks at anastomoses, anastomotic strictures and small bowel obstruction. Fluoroscopy is performed as a routine radiological evaluation after both procedures. CT scans are performed to evaluate possible complications.

Conclusion: Radiologists play an important role in the evaluation of potential complications after bariatric surgery. The knowledge of surgical procedures and potential complications is essential for the correct interpretation of the findings.

C-0126

An illustrated history of gastrointestinal and abdominal medical imaging

D. Novak; Osijek/HR

Purpose: The aim is to show the early development of gastrointestinal radiology as the first step in the history of gastrointestinal and abdominal medical imaging.

Materials and Methods: In order to achieve an overview of the historical development of gastrointestinal radiology, the original publications were studied and systemized in chronological order. The biographies of pioneers of gastrointestinal radiology are illustrated with portrait photographs.

Results: The following historical landmarks are described and documented with corresponding illustrations: **1.** Upper gastrointestinal studies: W.BECHER (1896), W.B.CANNON (1896), J.-CH.ROUX and V.BALTHAZARD (1897), F.WILLIAMS (1901), G.HOLZKNECHT (1903), H.RIEDER(1904), H.HULST(1905), L.G.COLE(1905), M.KASSABIAN(1906), C.BACHEM and H.GUNTHER(1910), M.HAUDEK(1910), R.D.CARMAN(1917), G.FORSELL(1923); **2.** Examination of the colon: A.SCHUELE(1904), G.F.HAENISCH(1910), L.G.COLE(1910), M.EINHORN and H.LAUREL(1921), A.W.FISCHER(1923); **3.** Examination of the small bowel: H.RIEDER(1904), H.HULST(1905), L.G.COLE(1911), G.SCHWARZ(1924), G.S.PESQUERA(1929), E.P.PENDERGRASS(1935), J.GERSHON-COHEN(1939).

C-0127

CT in acute perforated sigmoid diverticulitis

C. Lohrmann, N. Ghanem, G. Pache, F. Makowiec, E. Kotter, M. Langer; Freiburg/DE

Purpose: To assess the value of computed in patients with acute perforated sigmoid diverticulitis.

Methods and Materials: 30 patients with acute perforated sigmoid diverticulitis underwent computed tomography prior to surgery (mean: approximately 4 days). Computed tomography scans were reviewed and subsequently compared with the surgical and histopathological reports in accordance with the Hinchen classification of perforated diverticular disease.

Results: Computed tomography correctly determined the Hinchen stage in 28 of the 30 (93%) patients examined. Computed tomography revealed 12 out of 14 (86%) patients with perforation sites and 3 out of 3 (100%) patients with contained perforation. In one (6%) patient a bowel wall discontinuity could be revealed on Computed tomography scans in 17 patients with surgically or histopathologically proven perforation or contained perforation. In 6 of the 17 (35%) patients with surgical or histopathological perforation or contained perforation, extraluminal contrast material was detected on Computed tomography. Computed tomography identified 23 out of 25 (92%) patients with pericolonic inflammation and 26 out of 28 (93%) patients with pericolonic oedema. Computed tomography detected 21 out of 23 (91%) patients with abscess formations and all 11 (100%) patients with free fluid collections in the mesentery root. 3 of the 30 (10%) patients successfully underwent Computed tomography-guided percutaneous abscess drainage before undergoing surgery.

Conclusion: Computed tomography is a valuable imaging tool for determining the degree of acute perforated sigmoid diverticulitis, by which means patients can be stratified according to the severity of their disease, and is therefore of assistance in surgical planning.

Scientific and Educational Exhibits

C-0128

Spectrum of CT colonography findings in colonic tuberculosis: A pictorial essay

V. Jain, S. Bandhu, S. Vashisht, M.S. Gulati, P.K. Garg; *Delhi/IN*

Learning Objective: To display and discuss the spectrum of findings in patients with colonic tuberculosis (TB) on CT colonography (CTC).

Background: Conventional barium studies are the most widely used modalities in patients with suspected colonic/abdominal TB. CT is frequently performed to investigate such patients when barium findings are equivocal. In addition to the mural aspect of the disease, CT helps in demonstrating the extracolonic findings of TB, thus adding specificity to the diagnosis. Although CTC has been extensively evaluated as screening modality for colorectal cancer, its role in patients with inflammatory bowel disease and particularly tuberculosis has not been examined.

Procedure Details: CT colonography (CTC) was performed in 12 patients with colonic TB, using a 4-slice CT scanner with a 3 mm slice width, 2.5 mm effective collimation, table feed 15 mm (pitch-6.0), 120 kVp, overlapping reconstruction at 2 mm intervals and 0.5 s rotation time, following intravenous contrast, in supine and prone positions. CT data were transferred to a remote 3D workstation where 2- and 3-D CTC were performed and findings compared with those of CC. A final diagnosis of colonic TB was based on positive histopathological report and/or a definite positive response to anti-tuberculosis treatment in all patients. We will display the comparable endoluminal images of CTC and CC in this patient group. Additional mural and extraluminal findings related to TB seen in these patients will also be demonstrated.

Conclusion: CTC gives comprehensive information regarding luminal, mural and extraluminal involvement in patients with colonic tuberculosis. Appearances at CTC are comparable to those seen at CC.

C-0129

Digital radiographs (DR) versus conventional screen films (SF) in small bowel follow-through: A prospective study

O.R. Brook, D. Fischer, A. Hirshenbaum, A. Engel; *Haifa/IL*

Purpose: We propose to perform in-between radiographs of SBFT with digital equipment. We prospectively compared subjective radiological quality and radiation dose of digital (DR) versus conventional screen film (SF) radiographs SBFT. Effect on workflow was also evaluated.

Methods: Five senior and four resident radiologists compared printed images from 11 SBFT examinations, when every patient has SF and DR images (Smart Rad®, CMT Medical Technologies, Ltd.). SF and DR images were done with same exposure data (102 kV and automated phototimer). Overall satisfaction, demonstration of mucosa and bone were graded 1-5, 5 being the best. The radiation doses and effect on workflow were compared between DR and SF.

Results: A total of 546 observations of image quality were made. DR produced images with significantly higher overall satisfaction (4.4 vs. 3.1, p < 0.001), better definition of mucosa (4.2 vs. 3.3, p < 0.001), and demonstration of bones (4.5 vs. 2.3, p < 0.001) compared to SF. The radiation dose with DR was 0.57 mGy, with SF - 0.86 mGy (p = 0.023). Production of DR image took 3.5 minutes; 5.5 minutes with SF.

Conclusion: Substituting conventional radiographs with DR combined with a PACS reading station in the SBFT examination results in significantly better image quality, lower radiation doses and speeds up the workflow.

C-0130

MR findings that may aid in the evaluation of Crohn's disease activity

S. Giusti, P. Giusti, L. Marchetti, C. Bartolozzi; *Pisa/IT*

Learning Objective: 1.To evaluate MR feasibility in the assessment of morphological bowel wall changes and mesenteric disease extension after the administration of a biphasic contrast agent. 2.To show the great variety of imaging findings detected with MR at early, advanced, and complicated stages.

Background: Thanks to higher performance gradient systems which allow ultra-fast sequences, MR examination has become a valid alternative to CT in the evaluation of Crohn's disease. Patients included in our series had advanced disease which had been diagnosed on small bowel follow-through studies. They underwent MR study to follow-up the disease and to detect eventual complications.

Procedure Details: MR was performed after the manual administration of 2 L of a biphasic contrast agent through a pediatric nasojejunal catheter, at a flow rate of 60 mL/min. Each patient was investigated in a prone position with a phased-array coil. Our protocol employed true FISP, HASTE and Gd-enhanced 3D FLASH fat sat sequences to evaluate each patient. In our experience, with true FISP we

were able to demonstrate all the different morphological changes found in Crohn's disease, with 3D FLASH sequences we succeeded in evaluating the severity of disease activity, mesenteric vascularity and lymph node enhancement. The use of HASTE sequences could be limited to the cases in which susceptibility artifacts, due to the presence of air, hamper true FAST images or when it is necessary to provide a more accurate quantification of the intestinal wall thickening.

Conclusions: MR examination is a promising technique and a valid alternative to CT in the evaluation of Crohn's disease, especially during the follow-up period.

C-0131

Appendiceal mucocele: Imaging with US and CT

F. Sandomenico, O. Catalano, A. Nunziata, M. Mattace Raso, A. Siani; *Naples/IT*

Learning Objectives: To illustrate the sonographic and CT findings in appendiceal mucocele with clues to differential diagnosis. To make the radiologist aware of the typical and atypical appearances of appendiceal mucocele as shown with US and CT. Knowledge of all possible appearances is necessary for adequate preoperative diagnosis.

Background: Appendiceal mucocele is an uncommon disorder of the ileocecal area. Sometimes it can create interpretation difficulties, especially in atypical or large-sized cases.

Procedure Details: Eight patients (5 M and 3 F, 51-78 years, mean 55) with surgically confirmed appendiceal mucocele (larger diameter 4-28 cm, mean 6 cm - volume 100-6000 mL) were evaluated with US, contrast-enhanced US, and CT. US and CT findings depend mainly on mucocele size. Smaller lesions appeared as thin-walled, cystic images close to the ileocecal area, sometimes showing mural calcification. Larger mucoceles were recognisable as large-volume masses filling the pelvis or even the abdomen and pelvis in a peritoneal or retroperitoneal location. Bowel loops were dislocated and, in the eventual absence of parietal calcification, the diagnosis of origin and nature was difficult.

Conclusion: Appendiceal mucocele may show various typical and atypical findings at sonographic and CT imaging.

C-0132

Histologic, surgical, endoscopic and imaging findings in gastrointestinal stromal tumors (GIST)

A. Nunziata¹, O. Catalano¹, E. De Lutio di Catelguidone¹, V. De Rosa¹, A. Prisco², L. Cipolletta², A. Siani¹; ¹Naples/IT, ²Torre del Greco/IT

Learning Objective: To illustrate all histologic, endoscopic, and radiological findings in GIST of stomach, small bowel and large bowel. To make the radiologist aware of clues to diagnosis because this outgrowing gastrointestinal tumour frequently mimics abnormalities arising in contiguous organs.

Background: GIST is the most common mesenchymal lesion of the alimentary tract, identified for expressing KIT-protein. This exhibit is a fulfilled essay of all typical and atypical histologic, endoscopic, and radiological aspects of GIST.

Procedure Details: Histological images are presented. Findings typical and atypical of GIST, with special references to clues to diagnosis and to suggest malignancy are provided. A review of GIST appearance with different tools is provided: transluminal conventional endoscopy (gastroscopy, enteroscopy, colonoscopy), capsule endoscopy, endoscopic sonography (US), transabdominal US, contrast-enhanced US (liver metastases), conventional gastrointestinal X-ray imaging, CT, virtual colonoscopy and MR imaging. Appearance of primary GIST, recurrence and metastasis is illustrated. Cases arising from stomach, small bowel, and colon are presented.

Conclusion: Current endoscopic and radiological techniques allow demonstration of all typical and atypical aspects of GIST.

C-0133

The role of spiral CT colonography in the pre-treatment staging of colorectal cancer

J.M. Pienkowska, E. Szurowska, J.M. Wierzbowski, I. Marek, B. Rutkowska, M. Studniarek; *Gdansk/PL*

Purpose: The aim of this study was the estimation of the role of spiral CT colonography (STC) in the pre-treatment staging of colorectal cancer.

Material and Methods: A total of 58 patients with a clinical suspicion of colorectal cancer underwent conventional colonoscopy and on the same day spiral CT colonography with a standard protocol. All results were compared with histopathologic examination. Pre-operative TNM staging was correlated with surgical/histologic staging.

Results: There were 32 colorectal cancers and 23 polyps identified in conven-

Scientific and Educational Exhibits

tional colonoscopy. SCTC detected all cancers (sensitivity 100%), as well as 16 of 23 polyps. In 7 patients liver metastases, in 21 patients local, pericolic fat extension and in 11 lymphadenopathy were detected. Additionally two synchronous tumours and five polyps located in the colon proximal to the stenosing lesion which could not be tranversed endoscopically were identified. Surgical excision was possible in 24/32 cases of colorectal cancer. SCTC correctly staged T in 19 (79.2%) cases, N in 13 (54.2%). T was overstaged in 3 (12.5%) cases and understaged in 2 (8.3%). SCTC overstaged N in 4 (16.7%) and understaged in 7 (29.2%).

Conclusion: SCTC is an accurate procedure for pre-operative staging assessment of colorectal cancer and can be used for treatment planning.

C-0134

Color Doppler of superior mesenteric artery in the semi severe form of Crohn's disease of the terminal ileum

L.V. Lukic-Kostic, S.Z. Sekulovic; Belgrade/YU

Purpose: To assess the value of color Doppler (CD) flow parameters in the superior mesenteric artery (SMA) in the semi severe form of Crohn's disease with disease activity index (CDAI) in the range 250-400.

Methods and Materials: 30 patients with CDAI in the range 250-400 and 10 healthy volunteers were examined with 3.5 MHz CD probe. We measured resistive index (RI) and maximum flow volume (MFV) in the SMA after overnight fasting and 15 minutes after a liquid meal in both groups.

Results: In the group with active Crohn's disease the value of RI after overnight fasting was 0.78 ± 0.02 and after the meal 0.70 ± 0.02 . In the group of volunteers it was 0.81 ± 0.04 on fasting and 0.67 ± 0.04 after the meal. We also measured MFV in both groups after fasting period and after the meal. In the group with active Crohn's disease, a marked increase in MFV was noted on fasting instead the healthy group: $1.549 \text{ ml/min} \pm 512$ versus $437 \text{ ml/min} \pm 152$. After the meal, MFV in the first group was $1.792 \text{ ml/min} \pm 576$ versus $672 \text{ ml/min} \pm 169$ for volunteers.

Conclusion: Results in this work support the fact that active Crohn's disease causes enormous increase of MFV in the SMA. Analyzing postprandial changes in RI and MFV in the SMA shows that these parameters are of more than physiological interest because they can focus attention on possible inflammatory disease which becomes apparent only during functional stress. We strongly suggest CD as a follow-up method in assessing the acute phase or regression of the semi severe form of Crohn's disease.

C-0135

Laparoscopic gastric bypass surgery in morbid obesity: Radiologic features and complications

J. Catala, D. Hernandez, M. Escobar, P. Veciana, S. Gispert, L. San Roman, J.I. Poves; Barcelona/ES

Purpose: To show the radiological anatomy and present our experience in post-operative complications after laparoscopic gastric bypass surgery in morbid obesity.

Methods and Materials: During a two-year period (January 2002 to January 2004) laparoscopic gastric bypass surgery was performed in 448 morbidly obese patients or as substitutive technique of previous bariatric surgery. In all patients, upper gastrointestinal radiography was performed within 48 h after surgery as part of a routine follow-up. CT was performed when an anastomotic leak was diagnosed on radiography or when the clinical outcome was not satisfactory and complications were suspected.

Results: We detected 43 complications (9.5%). They were classified as suture dehiscence (19 patients), gastrointestinal obstruction (8 patients): edema (2), torsion (2), clots (3), inappropriate anastomosis (1), miscellaneous (15 patients): abscess (5), paralytic ileus (3), other (7).

Conclusions: The particular characteristics of laparoscopic bypass surgery in morbid obesity makes necessary a proper knowledge of the radiologic anatomy as well as the imaging findings of the most common complications.

C-0136

Rectal carcinoma staging with MR imaging: The accuracy in the prediction of free tumour resection margins

C. Gonzalez¹, C. Garcia de Iturraspe², E. Fernandez¹, J. Alustiza¹, J. Ontañon¹, A. Arriillaga¹, M. Barrera¹, C. Gervás¹; ¹San Sebastian/ES, ²Bilbao/ES

Purpose: To identify patients with high risk for local recurrence after total mesorectal excision (TME) by predicting tumour involvement of circumferential resection margins.

Methods and Materials: In a prospective study of 42 patients with rectal aden-

carcina after colonoscopy and biopsy, preoperative MR imaging was performed with a phased-array coil and high resolution T2 weighted sequence. As we know from the literature a distance ≥ 5 mm from the mesorectal fascia in MR imaging, predicts at least 1 mm tumour-free resection margin at histology. We therefore separated tumours in two groups at staging. In one group tumours that affected only the rectal wall (T1 and T2), and tumours that extended to the perirectal fat but with a distance ≥ 5 mm to the fascia (T3 incipient). The second group included tumours with fat involvement with a distance < 5 mm to the mesorectal fascia (T3 advanced) and tumours that involved and crossed the fascia (T4). We compared our results with histology after EMT.

Results: MR imaging classified 32 tumours in the first group (T1, T2 and T3 incipient) and 10 in the second (T3 advanced and T4), with one false positive and 1 false negative. We found a sensibility = 88'8%, specificity = 96'9%, positive predictive value = 88'8% and negative predictive value = 96'9% of MR imaging to predict tumour-free circumferential resection margins.

Conclusion: MR imaging offers an excellent anatomic map of the rectum and tumor and its relation with mesorectal fascia, allowing the identification of patients at risk of local recurrence after surgery and to asses preoperative therapy.

C-0137

MDCT gastroscopy

A.M. Miranda, H. Cuellar, S. Quiroga, C. Sebastia, R. Boye, A. Alvarez; Barcelona/ES

Learning Objectives: To show the virtual gastroscopic evaluation of gastric tumoral pathology and to describe the advantages of gaseous gastric distension in MDCT gastroscopy in comparison to hidric distension.

Background: Virtual MDCT colonoscopy is an expanding technique that has established its sensitivity in the detection of colonic wall thickening. MDCT with gaseous gastric distension achieves a complete visualization of gastric and extragastric pathology, in contrast to gastroscopy and double-contrast studies of the stomach. Virtual navigation allows for mucosal mapping, clearly superior to double-contrast study. Multiplanar reformatted images depict local extension as well as regional lymphatic involvement. Preliminary results of virtual endoscopy after intravenous contrast injection show promise in identification of tumoral tissue through increased enhancement.

Procedure Details: 40 patients with gastric carcinoma underwent MDCT for staging of the disease. All the patients had fasted for a minimum of 6 hours. Scans were performed after oral administration of effervescent granules and intravenous injection of 20 mg of scopolamine. MDCT was performed before and after intravenous contrast injection using a 16 detector MDCT. Scan data were reconstructed using specially dedicated software for virtual colonoscopy.

Conclusion: MDCT with gaseous gastric distension is useful in the staging of gastric tumoral lesions, allowing for excellent mucosal mapping with virtual gastroscopy as well as tumoral delineation and extra-gastric extent of disease. Virtual gastroscopic study of tumoral enhancement after intravenous contrast injection might show advantages in tumoral characterization. MDCT with gaseous gastric distension might alter current diagnostic approaches to gastric tumor detection and staging.

C-0138

MR colonography versus conventional colonoscopy for the detection of colonic lesions

R. Haykır, S. Karaköse, A. Karabacakoglu, M. Sahin, E. Kayaçetin; Konya/TR

Purpose: MR colonography (MRC) based on MR imaging is a relatively new diagnostic modality for diagnosing colon pathology. The aim of this study was to evaluate its performance in detecting colonic lesions.

Material and Methods: 35 patients (22 men, 13 women; age range 2-85 years; mean age: 59.7) suspected of having colonic lesions because of rectal bleeding, positive fecal occult blood test results or altered bowel habit underwent MRC and subsequent conventional colonoscopy (CC). All patients underwent standard bowel preparation 24 hr before MRC. After placement of a rectal tube, the colon was filled with 1500-2000 ml of mixture 0.9% NaCl solution and 15-20 ml of 0.5 mmol/L gadopentetate dimeglumine solution. Once colonic distension was achieved 3D GRE MR colonography and complementary MR images were taken in all cases.

Results: Sensitivity of MRC for colon pathologies was 95.2% and specificity was 100%. The percentage of correct diagnosis of MRC was 97.1%. MRC was well tolerated without sedation or analgesia.

Conclusion: In detecting colonic lesions MRC achieved a diagnostic accuracy similar to CC. MRC is minimally invasive, has no need for sedation or analgesics during the investigation and has a lower percentage of perforation complications.

Scientific and Educational Exhibits

It can also demonstrate all colon segments due to multisectional imaging and intramural and extra-intestinal components of colonic lesions, metastasis and additional lesions can easily be seen. MRC is a new radiologic techniques that promises to be highly sensitive for colorectal screening.

C-0139

Look at what can be inserted into orifices

P. Rajiah, A. Khan; Manchester/UK

Learning Objectives: A. To illustrate the bewildering array of foreign bodies are inserted into different body orifices. B. To understand the role of imaging. C. To wonder why people have to insert these objects into their orifices.

Background: Some people insert foreign objects of all sizes and shapes into their orifices. This can be done for recreational or malvolent purposes such as smuggling contraband substances. It is more common in children and in psychiatric patients. Curiosity, sexual activities, non traditional medical treatments and instrumentation are other recognised causes. Rectum, vagina, urethra, nose, ear and mouth are the common sites of foreign body insertion.

Procedure: Plain X-rays are done in all cases of suspected foreign body insertion for confirmation and anatomical localisation. CT scans with oral or rectal and intravenous contrast may be required for accurate localisation and demarcation of the anatomical planes traversed by the foreign body. Most of the foreign bodies cause only minor injuries, but they can cause perforation, haemorrhage, sepsis or can migrate to distal places. The foreign bodies in our exhibit include nails, pins, needles, cups, cans, bottles, drug packets and wood.

Conclusion: Recognition of foreign bodies is important for prompt management and to prevent development of complications.

C-0140

16-Row CT colonography (MDCTC): Technique and pitfalls of 3D primary approach

D. Salovic; Tournai/BE

Learning Objectives: To understand the technique and pitfalls of 3D primary approach as an interpretation technique for the MDCTC with a 2D imaging reserved for problem solving.

Background: The 3D primary approach (endoluminal fly through) shows a greater ease of polyp detection owing to increased polyp conspicuity and better fold depiction. Inconveniently there is an elevated risk of false positive findings for the non experienced reader. The examples show the semiology of true (+) and true (-) lesions compared to the false (+) and a false (-) lesions. The importance of 3D global view (virtual double contrast) is also stressed.

Procedure Details: MDCTC was performed in 400 patients using the standardized technique: Bowel cleansing with phospho soda as a laxative (dry prep). Faecal tagging with 3% barium suspension. Electronically controlled CO₂ insufflations (PROTOCOL, E-Z-EM, Westbury, USA). Bowel hypotonia with 20 mg i.v. Buscopan (Hyoscine butylbromide). 16 row helical scanning in the prone and a supine position (Siemens Sensation 16, Forchheim, Germany) with 1.5 mm collimation, 1 mm increment, 120 kV and 50 mAs (effective). Interpretation on 3D endoluminal display for polyp detection (Leonardo work station, Siemens, Forchheim, Germany).

Conclusion: MDCTC is simply to perform. The primary 3D interpretation approach needs standardised technique and knowledge of the pitfalls for the detection of true(+) findings.

C-0141

Small and large bowel virtual colonoscopy in patients with Crohn's disease

G. Tóth, L. Tóth, B. Forgács, Z. Tarján, E.K. Makó; Budapest/HU

Purpose: Virtual enteroscopy is a new method for the assessment of inflammatory small bowel disease. Our goal was to assess the visualisation the small bowel and colon simultaneously by virtual colonoscopy.

Materials and Methods: In 42 patients with known Crohn's disease CT virtual colonoscopy was performed. We were searching for the typical CT features of inflammation by two radiologists by consensus.

After 2-5 days colonoscopy was performed. Results of CT colonoscopy were compared with colonoscopy and surgery. Colonoscopy and surgery were considered gold standard.

Results: Good small bowel distension was obtained in 35 cases, sufficient in 4 and insufficient in 3 cases. Large bowel distension was good in 39 cases, sufficient in 2 and insufficient in 1 cases. In 37 cases the thickness of the wall in all segments of the small and large bowel were correctly evaluated. In 8 cases we found a minimal, in 19 cases a medium and in 7 cases a strong small bowel wall

thickening. In 5 cases virtual enteroscopy did not show a small bowel wall thickening but colonoscopy showed aphthoid ulcerations in the terminal ileum. Virtual enteroscopy showed skip lesions in the small bowel in 9 cases.

Virtual colonoscopy detected 94% of mucosal abnormalities and all strictures in comparison with colonoscopy. Virtual colonoscopy showed 8 abscesses and 10 extraintestinal fistulas all confirmed at surgery.

Conclusion: Virtual colonoscopy can be a good tool in detecting intramural and complicated Crohn's disease in the small and large bowel, but we don't advise this in early Crohn's disease

C-0142

Use of Calogen® as an oral contrast medium in the evaluation of the gastric wall at MR imaging

D.G. Lohan, S.M. Walsh, P. McCarthy; Galway/IE

Purpose: Evaluation of gastric wall pathology using cross-sectional imaging has proved difficult, particularly in the imaging of early, localized disease. The properties of Calogen as a negative oral contrast agent for the evaluation of the upper gastro-intestinal tract and retroperitoneum in CT has been well described. We assess the suitability of this agent as an oral contrast medium for use in MR imaging examination of the gastric wall.

Materials and Methods: Multisequence, multiplanar acquisitions using a Siemens Symphony 1.5 T scanner were acquired following ingestion of 500 mL of either Calogen or a similar volume of water by 15 subjects, including healthy volunteers and patients with suspected mural abnormalities. Images were acquired in both supine and prone positions. These images were then blindly evaluated by 3 Consultant Radiologists and scored according to gastric distension, elimination of peristaltic artefact and homogenous distribution.

Results: The mean scores for Calogen and water with regard to gastric distension are 8.46 and 5.49, respectively ($p < 0.01$). Concerning obliteration of mucosal detail, the respective scores are 8.48 and 3.84 ($p < 0.01$). Calogen is also statistically superior to water with regard to prevention of peristalsis and homogeneity (mean scores 8.15 vs 5.74 and 8.69 vs 6.30 respectively). Oral Calogen, therefore, is superior to water as an oral contrast agent for MR imaging examination of the gastric wall.

Conclusions: Calogen preparation is a suitable oral contrast medium for assessment of gastric wall anomalies at MR imaging. While often poorly tolerated by patients, it is superior to water in the non-invasive assessment of potential mural lesions.

C-0143

A pictorial review of extra luminal findings on MR imaging of the small bowel

D.A. Mc Kenna, A. Alhajeri, C.J. Roche, J.M. Murphy, P.A. McCarthy; Galway/IE

Learning Objectives: MR imaging is a useful imaging modality in the investigation of small bowel pathology. MR imaging has been shown to be comparable to conventional enteroclysis in the detection of luminal involvement and superior in the detection of extramucosal extent. The aim of this paper is to present an atlas of extraluminal pathology found at MR imaging of the small bowel.

Abstract: Images were reviewed from 31 patients over a 2-year period to identify extra luminal pathology. The oral contrast used was Norgine (Klean-pep, Middlesex, UK) which is a balanced mixture of polyethylene glycol and electrolytes. MR imaging sequences were a T2* localiser and a true FISP sequence.

Results: In 68.5% of patients supplementary imaging was available, showing positive correlation with conventional imaging in 92.1%. Pathologies included Crohns, celiac disease, lymphoma, plasmacytoma and carcinoid. MR imaging allowed further characterisation of the extra luminal extent of the above pathologies and in 26.3% of patients showed additional unsuspected pathology such as hepatoma, colitis of the transverse colon, gallstones and primary biliary sclerosis.

Conclusions: Not only does MR imaging of the small bowel permit accurate assessment of the bowel but it also allows identification of extraluminal pathology in a quarter of patients, with no radiation.

C-0144

Contrast-enhanced transabdominal US with 2nd generation contrast medium and multislice CT in Crohn's disease: A preliminary report

M. Alabiso, I. Marano, F. Morace, N. Bonavolonta', G. Penza; Naples/IT

Learning Objective: The aim of the present study was to evaluate the diagnostic efficacy of Sonovue in differentiating active wall inflammation from fibrotic wall thickening in comparison to multislice CT with intravenous contrast medium.

Background: We enrolled 36 patients (20 M and 16 F, mean ages 34 and 7 y) with

Scientific and Educational Exhibits

Crohn's disease (CD) having a CDAI ranging between 80-470 (22 pts CDAI > 150). The location of CD was colonic in 20 patients, ileocolonic in 13, ileo-jejunal in 2 and colonic-jejunal in 1. All patients underwent colonoscopy and CT scan to evaluate extention and endoscopic score of the disease. These data were compared to US appearance of intestinal wall obtained after iv injection of 25 mg of Sonovue diluted in 5 ml of 0.9%NaCl and studied with a multifrequency convex-probe.

Procedure Detail: In all patients US showed an increased wall thickness (6.3 mm-range:2.8 mm). After injection of Sonovue all the patients with CDAI > 150 and 2 patients with CDAI < 150 had marked enhancement involving all wall layers, probably due to inflammatory hypervascularisation, similar to CT that, however, have a better visualisation of perivisceral inflammation. Furthermore, in 3 pts CT correctly detected a jejunal involvement which was undiagnosed by US. In the 14 pts with CDAI< 150 we found a mild increase of wall thickness (4.2 mm-range2.2 mm) but in 12 we did not record any enhancement after Sonovue.

Conclusions: The present study suggest that contrast enhanced US can improve the sonographic study of the intestinal wall and helps in detecting active wall inflammation in CD.

C-0145

Advanced abdominal gastrointestinal stromal tumors (GIST) treated with Imatinib Mesilate: MR tumor response assessment after 24 months follow-up

A. Messina, P. Casali, D. Vergnaghi, F. Bianchi, A. Gronchi, R. Musumeci; Milan/IT

Purpose: To evaluate MR imaging patterns of tumor response of advanced GIST treated with Imatinib Mesylate after a mid-term follow-up (24 months).

Methods and Materials: 26 patients with advanced GIST (83% with liver lesions and 75% with peritoneal involvement) underwent therapy with Imatinib Mesylate. All underwent a baseline MR imaging and then MR imaging every 2 months until 24 months after the treatment had started. MR imaging was performed with a 1.5 T system using morphologic GRE T1W, TSE T2W and CE dynamic GRE T1W sequences.

Results: 66% pts were judged to be responsive to therapy after 2 months and 84% after 12 months. Patients responsive to therapy showed: A) Tumor decrease in size (with an increase in tumor volume in 8% of cases due to necrosis or bleeding after 2 months of therapy). B) Hypointensity of the lesions on T1W images in 83% cases (hyperintensity in 17% cases for bleeding) and hyperintensity of the lesions on T2W images (correlating with degenerative tissue or necrosis), C) Hypovascularization of the lesions on CE-T1W images due to degenerative tissue or necrosis and D) Presence of peritoneal fluid in 30% cases at the first month, reabsorbed in the following months.

Conclusion: MR imaging is adequate to identify tumor response to Imatinib Mesylate in advanced GIST from the early months of therapy. Decrease in tumor size and increase in necrosis are effective indicators of response. Nevertheless, in the first months an increase in tumor volume should not be held as evidence of progression when associated with an increase in necrosis.

C-0146

CT Evaluation of the acute abdomen caused by colorectal carcinomas

K. Furuya¹, I. Sakino², N. Harada², K. Yasumori¹, T. Muranaka¹; ¹Fukuoka/JP, ²Kitakyushu-City/JP

Learning Objectives: To describe a wide variety of helical CT and multidetector-row CT images of acute abdomen in patients with colorectal carcinomas and to assess the diagnostic value of CT for such patients.

Background: Colorectal carcinomas cause a variety of acute abdominal conditions and sometimes an acute abdomen itself can be the first symptom for a patient with colorectal carcinoma. Thus, to detect hidden malignancies radiologists need to be familiar with various images of acute abdominal conditions.

Procedure Details: We reviewed the helical CT findings and medical records of 64 patients with colorectal carcinoma whose initial symptom was acute abdomen: large bowel obstruction in 30, perforation of the oral-sided intestine 7, acute appendicitis 6, abscess 3, intussusception 3, fistula formation and invasion to an adjacent organ 2, peritonitis 2, volvulus 1, obstructive colitis 1 and others 9. Pathological correlations were done with actual cases. CT with intravenous contrast media could well show these acute abdominal conditions and in many cases showed the tumors present. The modality presented hemodynamic conditions of affected bowel well. Multidetector-row CT provided additional precise information., although tumors were detectable by CT in many cases, some appendiceal and cecal carcinomas could not be shown because of accompanying acute appendicitis and/or abnormal cecal position.

Conclusion: Helical CT with intravenous contrast media provides detailed information for cancer diagnosis and management of patients suffering acute abdominal pains caused by colorectal carcinomas. Familiarity with the variety of acute abdominal conditions caused by colorectal carcinomas should improve diagnostic accuracy.

C-0147

Distributions of periods, sites and appearances of metastases from early and advanced gastric carcinomas

Y. Kobashi, Y. Imanishi, N. Tachizawa, M. Yanagihara, S. Sakaino, M. Yoshimatsu, N. Bhattacharai, K. Ishizuka, Y. Nakajima; Kawasaki/JP

Learning Objectives: To learn the appearances of metastatic lesions in various organs in conventional imaging modalities and distributions of metastatic periods and sites from early and advanced gastric cancers.

Background: It is very important in a long-range plan of follow-up examinations in a patient with gastric cancer for radiologists to know about distributions of metastatic periods of gastric cancers from first detection, metastatic sites and their frequencies. However, they have not been reported in detail.

Procedure: In 401 patients with gastric cancer, we investigated the distribution of periods from first detection, the sites and appearances of 494 metastatic lesions. Ninety-five percent of first metastases from advanced gastric cancers were seen within 4 years after primary tumor detection. However, early gastric cancers had three peaks of within a year, 3 and 7 years. The metastatic lesions were in 12 sites including liver, ovary, lung, bones, brain, adrenal glands and spleen. At primary tumor detection, both early and advanced gastric cancers showed the same distribution of metastatic sites, except for peritoneal and ovarian metastases in advanced gastric cancers. Adrenal metastases were prominent on the left side. Sixty-one percent of metastatic bone lesions were osteosclerotic and 11% of them showed beautiful bone scan.

Conclusion: Early and advanced gastric cancers were different in site and period of metastasis. Eight-year observation was necessary for an early gastric cancer although 4-year observation was enough for an advanced gastric cancer. In an early gastric cancer, follow-up examinations were necessary within a year, at 3-4 years and at 6-7 years from the detection.

C-0148

The imaging findings of primary gastric lymphoma in children

U. Zaleska-Dorobisz, J. Weclawek-Tompol, B. Kazanowska; Wroclaw/PL

Purpose: Primary gastric Non-Hodgkin Lymphoma (NHL) in childhood is rare. It was found in less than 2% of NHL pediatric patients. The aim was to illustrate the imaging findings of primary gastric lymphomas in children.

Material and Method: We reported four children with primary gastric lymphoma detected by ultrasound imaging. The imaging findings (US, Contrast-enhanced US, CT, MR) revealed large tumors of the stomach wall with markedly thickened gastric wall.

Results: Histologically three tumors were evaluated as Burkitt's lymphoma. One tumor was with histopathological diagnosis as lymphoblastic T-cell lymphoma. Clinical symptoms were nonspecific. Abdominal pain, anemia, vomiting, constipation and rapidly growing abdominal tumor were observed before admission. In 2 cases we had trouble obtaining remission after first cycle of chemotherapy. We decided to qualify these children to more intensive chemotherapy with second-look surgery. Two patients were qualified to autologous bone marrow transplantation. All patients are in complete remission.

Conclusion: Primary gastric lymphomas are a very rare tumor in children. This may cause diagnostic difficulties. US and CT is very important in the diagnosis and monitoring of treatment of gastric lymphomas. Contrast US and MR are useful to assess the tumor staging regarding invasion to the gastric wall, perigastric tumor involvement and neovascularisation.

C-0149

The role of spiral CT colonography as a routine method in patients after incomplete conventional colonoscopy

J.M. Pienkowska, E. Szurowska, J.M. Wierzbowski, M. Czarnowska, G. Rompa, M. Studniarek; Gdansk/PL

Purpose: The aim of this study was the estimation of the role of spiral CT colonography (SCTC) as a routine method in patients with incomplete conventional colonoscopy.

Material and Methods: A total of 28 patients with strong clinical suspicion of colorectal cancer underwent SCTC with the use of a standard protocol. Conventional colonoscopy was incomplete due to stenosing lesions in all cases in this study. All results were correlated with histopathologic findings.

Scientific and Educational Exhibits

Results: In all cases conventional colonoscopy was incomplete because of occlusive lesions which could not be transversed endoscopically. SCTC reached the cecum in all cases and correctly detected 19 cancers (sensitivity 100%), seen at conventional colonoscopy. Additionally, two synchronous tumours and five polyps located in the colon proximal to the stenosing lesion were identified. In 4 patients liver metastases and in 9 patients local, pericolic fat extension and in 7 lymphadenopathy were detected.

Conclusion: SCTC reaches the entire colon even in cases of occlusive colorectal carcinoma. Additionally the method is able to simultaneously assess other abdominal organs. It can be used as a routine method in patients with incomplete conventional colonoscopy for detection of colorectal cancer and for treatment planning.

C-0150

Barium contrast studies in Crohn's disease: Still fundamental?

M. Certo, R. Themudo, R. Santos, P. Varzim, A. Ferreira, A. Ribeiro; Porto/PT

Learning Objectives: To illustrate the importance of contrast study findings in classical and rare presentations of Crohn's disease.

Background: Crohn's disease is a condition of chronic inflammation potentially involving any location in the alimentary tract, but with a propensity for the distal small bowel and proximal large bowel. Nearly one half of all patients have disease affecting both ileum and colon. Another one third have disease confined to the small bowel, primarily the terminal ileum and in very rare cases the jejunum too. Gross involvement of the oesophagus, stomach and duodenum are rare. Clinical behaviour can be roughly divided in the two categories of penetrating and fibrostenotic. The diagnosis is established through a total assessment of the clinical presentation with confirmatory evidence from radiographic, endoscopic and, in most cases, pathologic findings. Barium studies accurately define the anatomic location of disease and can discern evidence of active inflammation.

Procedure Details: We reviewed the contrast barium studies (barium enemas, small bowel follow-through studies and enteroclysis) in 245 patients with Crohn's disease from our inflammatory bowel disease unit. In our series, most of the patients have disease affecting the terminal ileum and the ileocolon as is reported in the literature. The colon is affected in about 19% of our cases and upper gastrointestinal involvement affects about 3% of our patients. We present the classic radiographical features, such as cobblestoning, ulceration, fistulae, sinus tracks, different strictures, etc.

Conclusions: Barium contrast studies are still important in the diagnosis, location, behaviour and extension of Crohn's disease.

C-0151

Contribution of conventional radiology in adjustable gastric procedures for morbid obesity

N. Costa, H. Marques, P. Alves, R. Marques, J. Barros, J. Mauricio; Lisbon/PT

Learning Objective: To illustrate the conventional radiological findings in patients who underwent laparoscopic adjustable gastric banding procedure (LAGBP): - post surgical evaluation; - detection of early and late complications.

Background: Morbid obesity is associated with secondary health problems, having an important downsizing effect on life expectancy. LAGBP has gained importance due to low invasiveness and adjustability. Since 2001, LAGBP has been performed in the treatment of morbid obesity in our hospital in a total of 63 surgeries. The early and late post-surgical radiological evaluation was performed in our department. The main radiological evaluation items and the complications are reported and illustrated.

Procedure Details: In the early follow-up (first 48 h), we used water-soluble contrast agent to access the band position, size and morphology of gastric pouch, stomal width and presence of complications. Whenever complications were suspected we used the same contrast. In the late follow-up (6 to 8 weeks, 12 months) we used barium sulfate contrast agents, to access the stomal width and direct its adjustability. All of the parameters reported in the early follow-up were again investigated, paying particular attention to complications (pouch dilatation, slippage, system disconnection and transmural band penetration).

Conclusion: Single contrast conventional radiology is the method of choice for detecting the main complications as well as directing and monitoring band adjustment.

C-0152

Recurrence patterns after curative resection of colorectal cancer: Emphasis on comparison between colon cancer and rectal cancer

S. Shin, Y. Jeong, H. Kang, H. Lim, Y. Kim, J. Park, J. Oh; Gwang-Ju/KR

Background: Postoperative surveillance for colorectal cancer is focused on the early detection of potentially curable recurrent disease. Recurrence pattern of colorectal cancer can be reliably predicted based on the site of the primary tumor. In this exhibit, we will illustrate the recurrence patterns after curative resection of colorectal cancer with emphasis on distinguishing patients with colon cancer from those with rectal cancer.

Materials and Methods: Pathology records and 1127 CT studies of 437 patients with colorectal cancer were retrospectively reviewed. Overall median follow-up duration was 17.6 (range, 3-49) months. The recurrence pattern was determined based on the first site of recurrent disease after the initial operation.

Results: The most common site of recurrence was the liver in colon cancer. Recurrent disease was seen in the retroperitoneal lymph nodes, lung, and pelvic mass in decreasing order of frequency, whereas the pelvic mass or locoregional recurrence was the most frequent pattern in rectal cancer. Recurrent disease was seen in the lung, liver, and retroperitoneal lymph nodes in decreasing order of frequency.

Conclusion: It should be recognized that the common sites of recurrence are different in frequency according to the site of the primary tumor and postoperative surveillance must be focused on the most frequent site of recurrence.

C-0153

Immunoscintigraphy in the management of colorectal carcinomas

V. Artiko, V. Obradovic, N. Petrovic, M. Petrovic, Z. Krivokapic; Belgrade/YU

Purpose: The aim of the study is detection of the recurrences and metastases of colorectal carcinomas by immunoscintigraphy.

Materials and Methods: Fourteen patients were examined (13 with adenocarcinomas of caecum, colon and rectum and one with squamocellular colonic carcinoma) from 4 months till two years after surgery, two of them after two months after the end of radiotherapy. Planar scintigrams (tomography when necessary) of thorax, abdomen and pelvis were done after from 10 min till 96 h after i.v. injection of Oncoscint CR-103, containing monoclonal antibodies B72.3 labelled with 150 MBq 111-In.

Results: In 12 patients recurrences of carcinomas (5-12 cm), in 6 recurrences with liver metastasis, and in two only liver metastases were detected by immunoscintigraphy and confirmed by surgery. Planar immunoscintigraphy was positive in 8/8 patients with liver metastases and 9/14 patients with recurrences while in 5/14 recurrences were detected only by tomography. US was positive in all patients with liver metastases, CT finding was falsely negative in two patients with recurrence, while MR imaging in one. In three patients with recurrences, CEA blood level was not increased. In 4 patients intensive accumulation of labelled antibodies was observed in colostomas, in one with granuloma, as well as in one with recurrence of squamocellular carcinoma.

Conclusion: Oncoscint CR-103 can be useful in diagnosis of recurrences and metastases of colorectal carcinoma, viability assessment after radiotherapy and in the choice of adequate surgical treatment depending on the spread of the disease.

Sonography and CT in duodenal pathology

E. Blanc, J. Cogollos, T. Ripollés, M. Martínez, M. Monedero, R. Pastor-Juan; Valencia/ES

Purpose: The duodenum is a segment of the gastrointestinal tract that due its intraperitoneal and retroperitoneal location and the proximity to other organs and structures, can be involved by a multitude of primary and secondary processes. The purpose of the study was to describe sonographic and CT findings of duodenal pathological conditions: congenital, traumatic, inflammatory, postsurgical and neoplastic disorders.

Methods and Materials: 58 patients with duodenal pathology diagnosed with sonography and CT were retrospectively reviewed from 1996 to 2003.

Results: We found the following pathologies: - *Developmental anomalies:* Congenital diverticula (some of them complicated with diverticulitis), intestinal malrotation and annular pancreas. - *Inflammatory conditions:* Duodenal ulcers (complicated with perforation or penetrating to the pancreas), secondary involve-

Scientific and Educational Exhibits

ment from pancreatitis (pancreatic pseudocyst in duodenal wall and intramural hematoma), groove pancreatitis, secondary inflammation of duodenum from cholecystitis, gallstone ileus with cholecystoduodenal fistula, Crohn disease and eosinophilic enteritis. - **Tumoral:** Benign primary neoplasms: lipoma, villous adenoma, leiomyoma and neurofibroma. Malignant primary neoplasms: adenocarcinoma, lymphoma and neuroendocrine tumor. Secondary duodenal involvement from other primary malignancies from stomach, pancreas, biliary tract and kidney. - Other more unusual pathologies found were: Traumatic duodenal perforation, intramural duodenal hematoma after surgery, foreign body (duodenitis from fish body ingestion), duodenal bezoar and aortoenteric fistula.

Conclusion: In this review of duodenal pathology we show how sonography and CT are reliable techniques in the study of this segment of gastrointestinal tract which can be involved in a multitude of primary and secondary diseases.

C-0156

Ultrasound of acute appendicitis: Spectrum of findings and role in the treatment planning

E. De Lama Salvador, C. Canas, M. de Albert, A. Guma, F.J. Garcia-Barriga, H. Aranda; Barcelona/ES

Learning Objectives: To describe the typical US findings of appendicitis, and to discuss the role of US in the clinical management. To describe the US findings of other entities that can mimic acute appendicitis

Background: Acute appendicitis is a common clinical problem. Accurate and prompt diagnosis is essential to minimize morbidity. The atypical presentations may result in diagnostic confusion and delay in treatment. US is a highly accurate means of establishing the diagnosis and it has now assumed a critical role in the treatment planning of patients suspected to have appendicitis. In addition, US can be used to guide abscess drainage treatment in patients with perforation.

Procedure Details: A retrospective review of medical charts and US of all cases of surgically proved appendicitis seen in our hospital in the last 2 years. US examinations were initially done using a broadband 4-7-MHz convex-array transducer, a broadband 5-10-MHz linear-array transducer and the graded-compression technique described by Puylaert. We illustrate the diagnostic findings of appendicitis, which were based on a set of eight criteria derived from reports in the literature and can be grouped into the two categories of appendiceal and periappendiceal findings. US findings of other entities mimicking appendicitis are also reviewed.

Conclusion: The effect of US on the management of acute appendicitis is considerable because it has decreased the rate of negative appendectomies and the number of appendiceal perforations. Moreover, the less severe disease observed indicated the earlier detection of appendicitis and the earlier initiation of treatment, which may explain the significant decrease in complications.

C-0157

Contrast-enhanced abdominal CT scan without bowel preparation for detection of colorectal polyps: A prospective comparative study

S.T. Bodewitz, M.H.J. Voormolen, J.M. Jansen, K.H. Schuur, W.N.H. Stuifbergen, A.W.M. van Milligen-de Wit, L.H. Visser; Tilburg/NL

Purpose: Virtual colonoscopy (VC) is as effective as conventional colonoscopy for detection of adenomatous polyps larger than 1 cm. However VC is time consuming, involves high radiation dose, requires bowel preparation and workstation processing. In order to develop a relatively simple screening method for colorectal polyps for both the radiologist and patient, the value of contrast-enhanced abdominal CT scan without prior bowel preparation was evaluated.

Methods: Prospective double-blind follow-up study in 53 patients with high risk for developing colorectal malignancy. Contrast-enhanced abdominal CT scan with air insufflation in prone position without prior bowel preparation. Independent interpretation of 2D images by three radiologists. Size and location of polyps were noted. Contrast-enhanced lesions were looked for. Final findings were scored upon corresponding interpretations by two or three radiologists. Colonoscopy ('gold standard') was used for reference without knowledge of CT findings.

Results: Thirteen patients were excluded because of incomplete colonoscopy or uncertain histology. In 40 included patients (mean age 60 (34-75 y), M:F = 28:12) colonoscopy showed adenomatous polyps in 16 patients (40%), CT in 10 patients (25%). CT showed 2 false positive findings (5%). Suboptimal interpretation due to faeces and/or bowel spasm in the entire or part of the colon in 1 (3%) and 10 patients (25%) respectively. Sensitivity, specificity, positive and negative predictive value of CT screening were 63%, 92%, 83% and 79% respectively. Interobserver variability was large ($\kappa < 0.5$).

Conclusions: We do not recommend contrast-enhanced abdominal CT scan without prior bowel preparation as screening method for colorectal polyps in high risk patients.

C-0158

Computed tomographic evaluation of serosal invasion and regional lymph node metastasis in colorectal adenocarcinomas

N. Tuncbilek, O. Okten, H. Sezer, F. Tokatli, M. Kaldir; Edirne/TR

Purpose: Tumor prognosis in colorectal carcinomas is determined by many factors. These prognostic factors may be used to choose suitable treatment and to develop new treatment strategies. We assessed the role of computed tomography (CT) in the presence of serosal invasion and regional lymph node metastasis of colorectal carcinomas.

Materials and Methods: The study group consisted of 39 patients (27 men, 12 female) aged between 29 and 82 (mean 59.9). Colorectal adenocarcinoma was diagnosed in all cases histopathologically. The cases were evaluated preoperatively with CT using oral and intravenous contrast material. The findings were correlated with CT features and histopathological data by using Kappa analysis.

Results: Serosal invasion and regional lymph node metastasis of tumor correlate well with CT scan and histopathologic findings and accuracy rates of 74% and 69% (sensitivity ratio: 96.2%, 94.4% and specificity ratio: 31%, 47.6%) (Cohen's kappa = 0.318; $p < 0.05$; 0.405; $p < 0.05$) were found respectively. The accuracy ratio of CT in TNM classification was found as 67% (26/39) (Cohen's kappa = 0.327; $p < 0.05$). The mean survival rate was 48.3 months. Survival rate for four years was 40.7% with regional lymph node metastasis and 62.5% without lymph node metastasis.

Conclusion: CT is reliable for confirming spread of advanced cancers through the bowel wall but is less useful in excluding such spread. A preoperatively performed CT enables the determination of the accurate treatment process by identifying serosal and regional lymph node metastasis and an indirect method of prognostic estimation in colorectal carcinomas.

C-0159

Staging of gastric cancers by computed tomography

N. Tuncbilek, O. Okten, H. Sezer, F. Tokatli; Edirne/TR

Purpose: Ultrasonography, CT and MR imaging can be used in preoperative staging of gastric cancers. The depth of the gastric wall invasion is one of the most important factors determining the prognosis in patients with gastric cancer. We evaluated the role of CT in determination of extraserosal invasion and staging in the preoperative assessment of gastric cancers.

Materials and Methods: We evaluated 21 patients (age range; 30-76; mean: 64.05) with gastric cancer using CT imaging in the preoperative period. The findings were correlated with CT features and histopathological data by using Kappa analysis.

Results: CT findings of extraserosal invasion of tumor correlate well with CT scan and histopathologic findings and accuracy rates of 85% (sensitivity ratio: 86.7% and specificity ratio: 83.3%) were found (Cohen's kappa = 0.667; $p < 0.05$). The accuracy ratio of CT in TNM classification was 66% (14/21) (Cohen's kappa = 0.491; $p < 0.001$). On the other hand, in classification of low and advanced stages, this ratio was 76% (Cohen's kappa = 0.483; $p < 0.05$).

Conclusion: Accurate diagnosis is now a highly specialized, intensive, multidisciplinary undertaking applicable both to early cancer and to less advanced stages of invasive cancer. CT imaging, performed preoperatively, is useful to evaluate the extraserosal invasion of gastric cancers with high accuracy rate so it can be used as a guiding method in treatment management and in estimation of prognosis. CT becomes useful to evaluate distant metastasis or regional spread when there is reason to consider avoiding or modifying plans for surgery. CT is clearly useful as both a baseline and assessment test when the physician contemplates chemotherapy.

C-0160

Reducing non-attendance rates for barium enemas through enhanced booking procedures

C.J. Garvey, L. Abraham, I. Furmidge, E. Holme; Liverpool/UK

Learning Objectives: To illustrate how enhanced booking procedures can reduce non-attendance rates for radiological investigations e.g. barium enemas, and to assess the impact on departmental efficiency.

Background: 10-15% is a typical non-attendance rate for barium enemas in the UK. Studies indicate poor patient satisfaction with current systems, largely due to lack of choice when scheduling appointments. Furthermore, many non-attenders will be referred again for investigation increasing demand. This has a detrimental effect on departmental efficiency.

Procedure Details: Following pilot work by the NHS Modernisation Agency, a new booking system was set up. A new referral form was designed in consultation with interested parties. Patients come directly from clinic with the form and

Scientific and Educational Exhibits

are greeted by a trained clerk. The test is explained and queries answered, preparation and instructions are supplied and a choice of appointments offered. Follow-up clinic appointments can be scheduled. Following these changes, non-attendance rates have dropped to 2-3% and this has been sustained over a 2 year period. Follow-up studies confirm improved patient satisfaction and further modifications have been introduced. Abolition of re-referral for non-attenders has reduced variation in demand and allowed better capacity/demand matching.

Conclusion: Improved booking procedures offering choice reduce non-attendance rates to an acceptable level, increase patient satisfaction and improve departmental efficiency. This model can be extended to many areas within a radiology department.

C-0161

Radiological review of lymphoma involving the gastrointestinal tract

P. Litter, C.J. Garvey; Liverpool/UK

Learning Objectives: Understand the radiological appearances and the complications of primary and secondary lymphoma involving the gastro-intestinal tract (GI tract). An educational text will accompany the images.

Background: Lymphomas involving the GI tract are predominantly of the non-Hodgkin's type (NHL) and are frequently on a background of immunosuppression. They may be primary, developing from lymphoid elements in the bowel wall or secondary, due to direct invasion of the bowel by locally involved lymph nodes. The commonest site of involvement is the stomach, followed by the small bowel and the colon (caecum and rectum). The oesophagus is rarely involved. Multi-site involvement in the GI tract is common. NHL usually presents with peripheral lymph node enlargement. Patients with low grade lymphoma may present with symptoms of marrow suppression such as anaemia or bleeding. Lymphoma affecting the GI tract may present with symptoms of obstruction, abdominal pain from intussusception or malabsorption due to small bowel involvement. If lymphoma affects the GI tract alone, it may mimic other pathology. Computerised tomography (CT) is very useful in the initial diagnosis, staging and follow-up of patients with lymphoma involving the GI tract.

Procedure Details: Multiplanar CT and barium studies will be used to illustrate the key radiological findings.

Conclusion: Lymphoma is an increasingly common malignancy and accurate diagnosis and treatment are crucial. This pictorial review will familiarise radiologists with the imaging appearances and complications of GI lymphoma.

C-0162

MR imaging staging of rectal carcinoma, pre and post chemoradiation, with histological correlation

S.D. Allen, A. Padhani, A.S. Dzik-Jurasz, R. Glynne-Jones; Northwood/UK

Purpose: To evaluate the accuracy of MR imaging staging of rectal carcinoma in patients undergoing chemoradiotherapy.

Methods: 24 patients with locally advanced rectal carcinoma were treated with chemoradiation and subsequently either had total mesorectal excision or abdominal-perineal resection. MR imaging was performed pre and 6 weeks post chemoradiation. Tumour morphology, extramural spread (including distance to mesorectal fascia, which forms the surgical circumferential resection margin, CRM), nodal presence and characteristics, overall TNM staging and post radiotherapy changes were recorded. Histopathology was subsequently examined for comparison.

Results: The majority of the patients in the study had extensive local disease. Prior to chemoradiation, MR staged 4.2% T2N0, 4.2% T2N1, 33.3% T3N0 and 58.3% T3N1+/T4. Different morphological subtypes were identified with annular and polypoid being the most common. Each subtype demonstrated different signal characteristics pre and post chemoradiation. Mucinous tumours were often difficult to stage as residual mucin pools were often indistinguishable from viable tumour or nodes. Post chemoradiation down staging was well demonstrated on MR in 12/14 cases (85.7%), with exact nodal staging shown in 16/24 cases (66.7%). 9/10 N0 patients remained N0 post chemoradiation, and 10/14 (71.4%) nodal positive patients became Nodal negative following treatment, indicating significant regression. CRM and post radiotherapy changes were also well predicted.

Conclusion: Preoperative chemoradiotherapy is standard treatment for locally advanced adenocarcinoma of the rectum. MR imaging can assess response to treatment and can often accurately predict histology. Mucinous tumours were less well assessed though, and certain types of post treatment fibrosis were indistinguishable from viable tumour.

GI Tract

Esophagus

C-0163

New method of evaluating pericardial invasion of esophageal cancer in 22 subjects using electrocardiogram-gated multislice computed tomography and compared with histological findings

K. Shuto, S. Okazumi, N. Yanagawa, T. Ochiai; Chiba/JP

Purpose: Evaluation of whether invasion of esophageal cancer (EC) stops at the adventitia or invades other organs is important because invasive EC is not amenable to surgery. Pericardial invasion, especially of the left atrium (LA), can be difficult to evaluate because of its pulsation. We tried to evaluate EC invasion to LA using ECG-gated enhanced multislice CT to eliminate the influence of pericardial pulsation.

Materials and Methods: Retrospective ECG-gated MSCT (Light Speed Ultra 16, General Electric) was performed in 22 subjects (17 male) with EC. Thirty seconds after intravenous injection of contrast, CT scanning was performed and images were reconstructed every 10% of the R-to-R interval (0-90%).

Results: In 21 subjects, in the 70% interval when the LA contracts, we could observe a low attenuation CT area between the LA and EC. But in the 40% interval, we could not observe a lower attenuation CT area between them. 4D movies using 10 phase data revealed the LA contracts separately from the EC, and we determined that the EC did not invade to the LA. All 21 subjects underwent surgery and none had EC invasion to the LA at histology.

Conclusions: ECG-gated MSCT can eliminate the influence of pericardial pulsation, and if there is no EC invasion of the LA, there is a low attenuation CT area between them during atrial contraction and in 4D images there is separate movement between them. This modality may become a useful tool to evaluate EC invasion of the pericardium.

C-0164

High resolution MR imaging of the anatomy of the oesophagus and surrounding posterior mediastinal structures

A.M. Riddell, C. Davies, A. Wotherspoon, G. Brown; London/UK

Purpose: Surgical resection for early stage oesophageal adenocarcinoma offers the longest disease free survival. Locoregional recurrence however remains the main cause of recurrent disease and tumour close to the circumferential resection margin (< 1 mm) has been shown to reduce survival. The aim of our study was to use high resolution MR imaging to: (1) Depict the oesophagus and its relationship to surrounding anatomical structures; (2) Identify fascial planes which could represent potential surgical resection margins and (3) Determine the importance of these structures in defining resectability.

Materials and Methods: High resolution T2W images of the thorax were performed on two cadaver specimens and patients prior to oesophageal resection. Comparison was made between structures identified on axial MR images of cadaveric and *in vivo* sections at corresponding anatomical levels with wholemount histological sections.

Results: High resolution MR imaging defined the layers of the oesophageal wall and clearly depicted surrounding structures such as the azygos vein and its tributaries, the prevertebral fascia and its attachments to the right oesophageal wall. Inferior to the level of the pulmonary trunk a band of connective tissue was identified arising from the aorta which encircled the lower oesophagus. Perioesophageal fat was situated beyond these fascial planes and extended to the parietal pleura laterally and the pericardium anteriorly. These structures were confirmed histologically.

Conclusion: High resolution MR imaging demonstrates detailed anatomy of the posterior mediastinum. Fascial planes described by the study will potentially be of importance for local staging of oesophageal cancer and surgical planning where indicated.

C-0165

Comparative observation on different interventional procedures in benign esophageal strictures

Y.S. Cheng, M.H. Li, K.Z. Shang; Shanghai/CN

Purpose: To determine the most effective interventional procedure in benign esophageal strictures.

Material and Methods: Different interventional procedures were used to treat benign esophageal strictures in 180 cases including pneumatic dilations (group A, n = 80), permanent (group B, n = 20) and temporary (group C, n = 80) placement of expandable metal stents.

Scientific and Educational Exhibits

Results: In group A, 160 dilations were performed (mean, 2.0 times per case). Complications in group A included chest pain (n = 20), reflux (n = 16) and bleeding (n = 6). Dysphagia relapse (DR) occurred in 24 (30.0%) and 48 (60.0%) cases respectively during 6-and-12 month follow-up periods in group A. In group B, 20 uncovered or partially covered or antireflux covered expandable metal stents were placed permanently, complications included chest pain (n = 9), reflux (n = 13), bleeding (n = 3), stent migration (n = 3) and DR occurred in 3 (15.0%) of 20 cases and 5 (31.3%) of 16 cases during the 6-and 12 month follow-up periods respectively. In group C, 80 partially covered expandable metal stents were temporarily placed in 80 cases and removed after 3-7 days via gastroscopy, complications including chest pain (n = 32), reflux (n = 10), bleeding (n = 13) and DR occurred in 8 (10.0%) of 80 cases and 12 (16.0%) of 75 cases during the 6-and-12 month follow-up periods respectively. The placement and withdrawal of stents were all successfully performed. The follow-up of all cases lasted for 6 to 103 months.

Conclusion: The effective procedures for benign esophageal strictures are pneumatic dilation and temporary stent. Temporary stent is one of the best methods for benign esophageal strictures.

C-0166

Barium esophagogram versus upper endoscopy for the screening of esophageal varices in patients with compensated cirrhosis: A blinded prospective study

D. Fischer, E. Farber, R. Eliakim, N. Beck-Razi, A. Angel, D. Gaitini, S. Linn, Y. Baruch; Haifa/IL

Purpose: To evaluate and compare the accuracy of barium esophagogram (BE) versus endoscopic gastroduodenoscopy (EGD) in diagnosing esophageal varices in patients with compensated cirrhosis and portal hypertension at an early stage. **Methods and Materials:** Sixty-one patients with liver cirrhosis were diagnosed by liver biopsy (62% postnecrotic, 14.5% NASH, 14.5% alcohol, 5% autoimmune hepatitis and 4% PBC. 87% were Child-Pugh's score A and 13% were Child-Pugh's B). They were subsequently evaluated by EGD using Japanese General Criteria as the gold standard, and BE for the presence and size (small, large) of varices. BE was performed within three weeks of endoscopy, with 98% barium sulfate (E-Z-HD), as suspension adjusted for double contrast studies and barium paste (E-Z, 60%, esophageal cream) for mucous coating.

Results: All large varices (F2-F3) were diagnosed by BE. Sensitivity declined with small varices (F1) to 71.5%. The overall sensitivity of BE was 89%, the overall positive predictive value was 89.2%. The correlation between EGD and BE was high, $r = 0.75$; $p < 0.0001$.

Conclusions: BE can be used as a non-invasive procedure for the screening of patients with varices and compensated liver disease at a minimal cost. Furthermore, using BE will preclude universal prophylaxis with beta-blockers.

C-0167

Digital cineradiographic study of swallowing in infants with neurologic disease: Our experience

G. Runza¹, F. Barbiera², F. Cademartiri³, M. Bellia¹, M. Galia¹, F. La Seta¹, M. Midiri¹; ¹Palermo/IT, ²Sciaccia/IT, ³Rotterdam/NL

Learning Objectives: To display the findings and clinical role of digital cineradiography in the evaluation of swallowing disorders in children with neurological or severe developmental disability. To determine the best feeding protocol and improve the nutritional status based on administration of oral contrast material with different consistency.

Background: Severe neurological and developmental disorders in children can determine recurrent respiratory infections, asthma and hospitalization in intensive care units for acute respiratory failure. The diagnosis of these disorders enables proper therapeutic solutions which will significantly improve the nutritional status of the patient while reducing the risk of lung infections. From March 2001 to July 2003 12 children (8 males, mean age 6.2 years) affected by severe neurological or psychomotor disorders were evaluated.

Procedure Details: The dynamic study of the swallowing was performed for recurrent pulmonary infections and/or dysphagia with weight loss. All the examinations were performed with radio-controlled equipment provided with a digital C arm. Using this technique, in all 12 patients it was possible to differentiate those with disorders of the oral and/or pharyngeal swallowing phase (9/12) from those without swallowing dysfunction (3/12). We will show the findings of digital cineradiography, the role of the radiological information relevant for clinical and therapeutic management and the different protocols that we use to address the problem of the type of food more suitable for optimal feeding.

Conclusion: The dynamic swallowing study with digital technique allows a clear-cut evaluation of the swallowing process with minimum discomfort for the patient.

GI Tract

Peritoneum

C-0168

The place of peritoneography in the evaluation of chronic groin pain compared with ultrasound and CT: A forgotten technique gets its due.

A retrospective study of 112 patients

R.A. Salgado¹, M. Maes¹, P. Bellinck², B. Op de Beeck¹, J.-L. Termote², P.M. Parizel¹; ¹Edegem/BE, ²Lier/BE

Purpose: To assess the usefulness of peritoneography in the evaluation of patients with chronic, indeterminate groin pain.

Materials and Method: 112 consecutive patients with groin pain who underwent a peritoneography during a four year period were retrospectively reviewed. The results were compared, when available, with the findings on CT, ultrasound and surgical exploration.

Results: Peritoneography showed an occult hernia in 40/106 (38%) patients with a negative or inconclusive clinical examination. 24/40 (60%) of these patients underwent laparoscopic exploration, which confirmed the hernia on all occasions (100% positive predictive value). In 9 patients peritoneography also revealed an asymptomatic hernia on the contralateral side. Of the 58/106 (54%) patients who showed no abnormality on peritoneography, 41/58 (70%) showed clinical improvement with time without surgical intervention. Eventually, no specific diagnosis could be found in 45/106 cases (42%). Three patients had a positive clinical examination for an inguinal hernia which was, on all cases, confirmed with peritoneography. Intraperitoneal injection could not be accomplished in two patients. One patient had injection of contrast into the colon, which required no significant intervention. An abdominal CT examination was performed in 22/112 (19.6%) patients, revealing an inguinal hernia on only one occasion. Thirty patients (26.7%) also underwent an ultrasound examination, clearly demonstrating an inguinal hernia in only three occasions.

Conclusion: Peritoneography is a safe and reliable technique in ruling out or demonstrating an occult hernia in patients with chronic unexplained groin pain. It is clearly superior in this respect to CT and ultrasound.

C-0169

Pictorial review of pneumoperitoneum: X-rays with CT correlation

P. Rajiah, A. Khan; Manchester/UK

Learning Objectives: A. To recognise the signs of pneumoperitoneum in a supine film. B. To correlate plain film findings of pneumoperitoneum with CT scan findings. C. To understand the role and limitation of CT in the diagnosis of hollow viscus perforations.

Background: Pneumoperitoneum is an important radiological sign which indicates perforation of a hollow viscus. Prompt recognition is vital for early surgical management. The findings in a supine film are often subtle and a beginner can be easily misled thus resulting in errors. The aim of this exhibit is to demonstrate the subtle findings of pneumoperitoneum in a supine film and to correlate this with appearances on the CT scan.

Procedure: Abdominal X-rays were obtained in both in erect and supine positions. CT scan was performed in subtle cases to confirm the presence of gas in the peritoneum or retroperitoneum. Multiplanar reconstruction and lung window settings were used for demonstrating small amounts of intra/retroperitoneal air. The signs described include the football sign, Rigler sign, urachus sign, cupola sign, tell tale triangle sign, visualisation of umbilical ligaments/falciform ligament/ligamentum teres, scrotal air, visualisation of diaphragmatic slips, air around the spleen, subhepatic gas, triangular collection in Morrison's pouch and gas in lesser sac/paraduodenal region/gall bladder.

Conclusion: Diagnosis of pneumoperitoneum in an erect X-ray of the abdomen is straightforward. The signs are more subtle in a supine film. Recognition of these subtle signs is essential for prompt diagnosis of perforations. CT scans are helpful in doubtful cases and can demonstrate the exact site of perforation.

C-0170

Diseases of peritoneum, mesentery, and omentum: Spectrum of helical and multidetector-row CT findings

K. Furuya¹, I. Sakino², K. Yasumori¹, T. Muranaka¹; ¹Fukuoka/JP, ²Kitakyushu-City/JP

Learning Objectives: To demonstrate miscellaneous CT findings of the diseases of peritoneum, mesentery, and omentum. To assess the role of CT for differentiating the nature of them.

Scientific and Educational Exhibits

Background: Peritoneum, mesentery, and omentum play important roles as pathways for the spreads of various inflammatory process and malignancies. Great improvements in CT have made it possible to determine these precisely. The purpose of this exhibit is to present their numerous features and to assess the diagnostic value of CT in these disease. Multidetector-row CT images will be also demonstrated.

Procedure Details: We reviewed the Helical CT findings of 105 patients who showed peritoneal, omental and mesenteric abnormalities on CT and had confirmed diagnosis. They included peritoneal dissemination 61, pseudomyxoma peritonei 3, malignant mesothelioma 3, malignant lymphoma 1, polycythemia vera 1, primary serous papillary tumor of peritoneum 1, desmoid tumor 1, abscess 19, peritonitis 10, mesenteric hematoma 2, tuberculous peritonitis 1 and mesenteric ischemia 2. The review was focused on 1) Smooth thickening of parietal peritoneum, 2) Nodules or masses, 3) Increased fat attenuation 4) Ascites, 5) Fixation or dislocation of intestinal loop, 6) Wall thickening of intestine and 7) Involvement of the abdominal wall. The relationship of these findings and the nature of the lesion were assessed.

Conclusion: Although some abnormalities, especially peritoneal tuberculosis, hematologic malignancy, malignant mesothelioma, and peritoneal dissemination, are difficult to differentiate the nature of by CT, CT provides precise information regarding peritoneal, omental, and mesenteric abnormalities and is useful for the differentiation their nature. Multidetector-row CT gives us additional information.

Miscellaneous

C-0171

Focal fat stranding in computed tomography as a diagnostic tool in the acute abdomen

E.M. Dieguez-Costa, J. Borrego-Gomez, P. Fernandez, B. Gonzalez, S. Novo; Madrid/ES

Purpose: CT has been proven a useful method to evaluate those patients with acute abdomen because of its ability to display both mural and extraluminal abnormalities. The purpose of this study was to assess the diagnostic value of computed tomography in those diseases with focal pericolonic fat stranding as a dominant sign (exceeding other findings).

Material and Methods: The CT scans of 260 patients who were admitted to our institution because of acute abdominal pain were retrospectively reviewed.

Results: We found 214 cases with focal fat stranding in CT. Among them, the following diagnosis were obtained by CT: Diverticulitis (97), appendicitis (39), ischemic bowel disease (14), epiploic appendagitis (4), bowel infection (17), trauma (5), recent surgery (7), omental infarction (2), pancreatitis (20) and cholecystitis (9). The CT findings were; focal fat stranding, segmental bowel wall thickening, pneumatosis intestinalis, pneumoperitoneum, fluid collections and abscesses, ascitis, diverticula and bowel obstruction. We found that in diverticulitis, appendicitis, epiploic appendagitis and omental infarction, focal fat stranding was greater than the degree of bowel wall thickening, being more obvious (although less specific) than other abnormalities.

Conclusion: Focal fat stranding as a prime finding is a valuable CT sign in patients with acute abdominal pain. It helps to narrow the broad differential diagnosis to four main entities; diverticulitis, appendicitis, epiploic appendagitis and omental infarction. The characteristic CT findings of each of these entities often leads to a final diagnosis.

C-0172

Normal anatomy and non-hernia pathology of the abdominal wall on cross-sectional imaging

J. Quintero¹, C. Pozuelo¹, C. Medrano¹, D. Mulattieri¹, S. Capurro², F. Tous³; ¹Badalona/ES, ²Barcelona/ES, ³Santa Coloma de Gramenet/ES

Learning Objectives: The purpose of this exhibit is to review normal anatomy of the abdominal wall by CT and to present the more usual non-hernia pathologies of the abdominal wall diagnosed in our institution.

Background: We revised all the reports for three years of abdominal CTs performed in our institution. We selected the cases where non-hernia pathology of the abdominal wall was present and they were read, retrospectively, by two radiologists who were unaware of CT findings. Usually the studies consisted of oral contrast, a 5-mm collimation, pitch: 1.5, 100 mL of contrast medium, rate: 2.5 mL/sec and with a delay of 70 sec. Since July 2001 from to July 2004 we found 6978 consecutive abdominal CTs. We encountered 87 cases (1.24% of the studies) of non-hernia pathology of the abdominal wall.

Procedure Details: To exhibit any cases of normal anatomy of the abdominal wall with their components: muscles, fascias layers, aponeurosis, ligaments, skeletal, vessels and nerves. The cases revisited were classified as: Congenital lesions: Urachal abnormalities (3) and omphalomesenteric duct abnormalities (1). Fluid collections: Hematoma (22), abscess and cellulites (10) and urinoma (3). Neoplasm: Primary malignancies (7), metastatic disease (10) and benign lesions (12). Miscellaneous: Vascular lesions (4), vascular grafts (7), calcifications (3) and subcutaneous gas (5).

Conclusion: Cross-sectional imaging provides an excellent, non-invasive means of evaluating pathologic processes of the abdominal wall. Specific observations on the nature, location, extent, and underlying causes of these lesions can be made, therapy planned and instituted, and follow-up accomplished.

C-0173

Multi detector CT in internal and external abdominal hernias:

A pictorial review

P. Rajiah, R. Sinha, J. Kirk, K. Irion, A. Khan; Manchester/UK

Learning Objectives: A. To illustrate the anatomy of normal peritoneal spaces and common sites of external and internal herniation, their pathogenic and demographic features. B. To learn the role and limitations of multi detector CT in diagnosis of abdominal hernias. C. To illustrate the imaging appearances of abdominal herniations, including Spigelian hernia. D. To recognise the CT features of complications of herniations.

Scientific and Educational Exhibits

Background: Abdominal hernia is a very common surgical problem. It can be external, internal or diaphragmatic. External hernia is herniation through a defect in abdominal wall. Internal hernias occur through peritoneal spaces. Diaphragmatic hernias occur through defects in the diaphragm, which can be congenital or traumatic.

Procedure: Abdominal X-ray is often the initial investigation in most patients who present with hernias and pain. CT scans were performed using a 4 slice GE scanner, after 1 L of oral contrast and 100 ml of i.v. contrast. Images were acquired from the dome of the diaphragm to just below pubic symphysis and were reconstructed in multiple planes. The hernias illustrated include midline defects (epigastric, hypogastric, umbilical), Spigelian, incisional hernias, inguinal, femoral, Littres, Richters, obturator, sciatic, perineal, lumbar and internal hernias.

Conclusion: Imaging plays an important role in diagnosing hernia, identifying the contents, demonstrating the anatomy, recognising complications such as incarceration, obstruction, strangulation, volvulus or underlying neoplasms and differentiating it from other similar conditions. Multi detector CT is the ideal method for elegant demonstration of the anatomy, especially with the multiplanar reconstructions. Early recognition of complications is an added advantage.

C-0174

Ultrasonographic visualisation of abdominal wall hernias

A. Djuric-Stefanovic, A. Ivanovic, D. Saranovic, D. Masulovic, B. Dobriserevic; Belgrade/YU

Learning Objectives: To exhibit the ultrasonographic appearance of different types of abdominal wall hernias. To show the possibilities of ultrasound in visualisation of hernial site, size, and contents of hernia sac. To correlate the ultrasonographic and surgical findings in 117 adult patients with different types of external abdominal hernias.

Background: Types of abdominal wall hernias are: ventral, umbilical, incisional, Spigelian hernia, lumbar, inguinal and femoral. Herniography, CT, barium studies and ultrasonography are the methods of possible diagnosis of hernia type, size and contents of hernia sac. Ultrasonographic examination of the abdominal wall enables visualisation of muscles and fascias of abdominal wall and consequently, the site, size and contents of hernia sac could be visualised. 117 adult patients with palpable suspected hernias underwent ultrasonographic examination between January 2003 and September 2004, and then they were operated upon. We will exhibit ultrasonographic appearance of different types of external abdominal hernias and correlate them with intraoperative findings.

Imaging Findings: Sonography was performed with a 7,5 MHz linear transducer, with the patient lying and with both relaxed and contracted abdominal muscles. The indication for ultrasonographic exam was a palpable mass of the abdominal wall which was clinically diagnosed as hernia. We will present the ultrasonographic appearance of two types of inguinal hernias: direct and indirect and criterions for their differentiation. Incisional, ventral and umbilical hernias of different sizes and contents will also be presented.

Conclusion: Ultrasonography of the abdominal wall is a convenient method for precise diagnosis of localisation, type, size and contents of abdominal wall hernias.

C-0175

High resolution ultrasound (HRUS) in small lesions of the abdominal wall

C.M.I. Brancaleone, C. Candia, C. Ambrogi, M. Blasetti, L. Tipaldi; Rome/IT

Pathology of the anterior abdominal wall is often overlooked in subacute/chronic abdominal pain. The purpose of this exhibit is to discuss the imaging findings of small abdominal wall lesions and present a pictorial comparative US and CT review of our findings. Twenty-six patients with subacute/chronic abdominal pain previously investigated by US and CT were evaluated by high resolution ultrasound (HRUS) of the anterior abdominal wall. Pathological lesions were revealed in 18 patients and included non iatrogenic (inflammatory, hernia, metastatic and neoplastic disease) and iatrogenic lesions (recent surgery, hematoma, incisional hernia, biopsic procedures). Good image quality was obtained with delineation of the rectus muscle, the three lateral abdominal muscles, the transverse fascia and the peritoneal line. Site of the lesions and extent of involvement was retrospectively compared to CT images. Dynamic scanning and repositioning were used in all cases. Contrast (Sonovue) harmonic imaging was used in 10 selected cases and compared to 10 normal subjects and this will also be depicted and discussed. HRUS appears to be a cost effective first line diagnostic tool for small unsuspected lesions of the abdominal wall. It requires meticulous technique and sound knowledge of HRUS anatomic-radiologic correlations and appears superior to CT in structure information.

C-0176

MDCT and MR imaging of abdominal inflammation: Beyond abdominal abscesses

J.L. Sancho¹, J.M. Vida², A. Luna³, R. Ribes², P. Ros⁴; ¹Andujar (Jaén)/ES, ²Cordoba/ES, ³Jaen/ES, ⁴Boston, MA/US

Learning Objectives: To describe the most important clinical and imaging findings of the different inflammatory conditions that may affect the abdominal cavity. To recognize and differentiate them from other entities by imaging. To evaluate the usefulness of the MR and MDCT in the diagnosis of abdominal inflammation.

Background: The spectrum of abdominal inflammatory conditions is extraordinarily ample. Although intraperitoneal abscesses represent a common cause of abdominal inflammation, especially in immunocompromised and postsurgical patients, many other entities such as pancreatitis, cholecystitis, appendicitis, epiploic appendagitis, inflammatory bowel disease, diverticulitis, radiation colitis, pelvic inflammatory disease, pyelonephritis, etc. must be taken into consideration.

Imaging Findings: We retrospectively review a group of patients with different abdominal inflammatory processes by MDCT and MR. This exhibition presents a comprehensive review of the distinctive features by MDCT and MR of the most clinically relevant abdominal inflammatory conditions, describing the key epidemiological, clinical and radiological features that may allow their diagnosis and differentiation from possible mimickers, especially neoplasms. A common imaging finding, although non-specific, is the presence of fat stranding that may help sometimes to differentiate them from other entities such as neoplastic processes.

Conclusion: MR and MDCT are valuable tools in the evaluation and characterization of the different inflammatory conditions that may affect the abdominal cavity.

C-0177

Anatomical considerations and imaging features of abdominal wall hernias: A pictorial review

R.R. Misra¹, P.J. Shorvon²; ¹High Wycombe/UK, ²London/UK

Learning Objectives: The aims of this poster are to review the indications for investigating potential hernias, to outline the important anatomical considerations for accurate diagnosis of hernias, to discuss the modalities available and their strengths in application, to illustrate the findings within the different modalities and to develop a suggested protocol for investigation.

Background: Radiology departments are increasingly being asked to diagnose potential abdominal wall hernias. A number of imaging modalities are available, all with their own strengths and weaknesses. High resolution near field ultrasound has taken a pre-eminent place in the detection of abdominal wall hernias. It can be performed in a dynamic manner asking the patient to cough or strain. Herniography is often considered the gold standard but requires injection of contrast into the peritoneal cavity. CT is good at identifying non-reducible hernias. MR imaging has the potential to replace CT and be used dynamically to identify hernias, which only occur during raised intra-abdominal pressure.

Imaging Findings: Ultrasound is the first line investigation but requires meticulous technique. Herniography may be negative in incarcerated hernias or those in concealed positions such as midline anterior hernias. To date, CT has not been able to demonstrate transient hernias which are only present during episodes of raised intra-abdominal pressure. Fast MR imaging techniques show promise in this latter regard, but the speed of herniation may still be too fast.

Conclusion: Radiologists and radiographers need to be familiar with both the anatomy of the abdominal wall and the appearances of hernias to allow accurate diagnosis.

C-0178

Detection and occurrence of retained surgical textilomas

R. Klaric-Custovic, N. Gotovac, I. Krolo, M. Marotti, N. Babic; Zagreb/HR

Learning Objectives: Retained surgical textile bodies are rare problem, but they occur at increased rate during stressful events. CT is the method of choice in diagnosing them. They are similar to several structures and processes, yet they have characteristics of their own.

Background: In our experience, textilomas are exceedingly rare. Several situations, such as war, natural catastrophes or terrorist attack can make the occurrence of textilomas more likely. Such situations happened in several hospitals during the war in Croatia, since they were in proximity to frontlines with large number of causalites. In all cases, acute textilomas resulted in a spongiform appearance, with a considerable amount of air trapped between textile fibres. Such air was the strongest diagnostic sign, together with a peripheral capsule and blood soaked rim. In most chronic cases calcifications were found and lesions did not enhance after administration of contrast media. We recorded 13 patients

Scientific and Educational Exhibits

that were admitted to CT for non-specific abdominal pain during period of 12 years. During one year of war, 9 cases of acute textiloma were found. Peroral contrast was given in six patients, while others were too weak or vomiting.

Conclusion: The procedure of choice is CT, where retained surgical material will be shown best due to entrapment of air inside textile material, while radio-opaque markers did not solve diagnostic problem completely. Calcifications are more common in chronic forms. There is no post-contrast enhancement. Despite precautions and care by surgical staff, textilomas are more likely to happen during war and similar events.

C-0179

Value of computed tomography in the follow-up of patients after laparoscopic repair of abdominal wall hernias

M. Moreno-Ramos, B. Vargas Serrano, E. Domínguez Ferreras, F. Castell Monsalve, M. Bustos Jiménez; Sevilla/ES

Learning Objectives: To illustrate the usefulness of CT in the follow-up of patients after laparoscopic repair of abdominal wall hernias in depicting normal findings as well as complications.

Background: Laparoscopic repair of abdominal wall hernias is a procedure that is replacing the open repair method because it is less invasive and has a lower rate of complications and recurrence. After surgery, CT is the procedure of choice to rule out complications or recurrence of hernias and to verify the normal appearance of the mesh. Within a 2 year period, 46 patients, 27 female (average age 57.25 years) and 19 males (average age 53.57 years) underwent laparoscopic repair of abdominal wall hernia in our hospital (43 ventral and 3 inguinal) and 28 abdominal CT were performed 10 to 304 days after surgery in the follow-up of 22 patients.

Procedure Details or Image Findings: 4 studies were not available. The other 24 CT examinations were reviewed with adequate visualization of the mesh in all cases. 8 cases were normal. CT detected recurrence of the hernia in 7 cases, fluid collections in 5 cases, fibrosis in 3 cases, wrinkling of the mesh in 3 cases and 1 abscess.

Conclusions: The laparoscopic approach is replacing conventional surgical repair for abdominal wall hernias. CT is a useful technique in the post-surgical follow-up of these patients, being able to detect recurrence of hernia as well as complications.

Radiological and histological features of mammography screen detected lesions undergone benign surgical excision

D.D. Manuel, S. Bose, D.D. Evans, R. Wasan, G. Ralleigh, M. Michell; London/UK

Purpose: The development of modern image breast guided biopsy techniques including core biopsy and vacuum assisted core biopsy has improved the non-operative diagnosis for most screening mammography detected lesions, leading to a decrease in benign surgery. The aim is to describe the radiology and histology of benign screen detected lesions requiring surgical excision in our practice.

Methods and Materials: From April 1998 to March 2003, 155621 women were screened in the South East London Breast Screening Programme, 8836 women were assessed (5.7%), 182 benign lesions were surgically removed (0.1% of women screened). Radiological and histological features were recorded on a database.

Results: The primary histological diagnosis was: Fibrocystic change (FCC) (26%), radial scar/complex sclerosing lesion (CSL) (24%), fibroadenoma (FA) (14%), papilloma (11%), atypical ductal hyperplasia (ADH) (7%) and miscellaneous other (15%). The mammography features of benign lesions excised were well-defined mass (38%), microcalcifications (28%), stellate distortion (28%), asymmetry density (3%), other signs (4%). The commonest histology for each mammography sign was: Microcalcification: FCC (40%), papilloma (11%), FA (9%), ADH (8%), CSL (6%); well-defined mass: FA (28%), FCC (25%), papilloma (18%), CSL (10%); architectural distortion: CSL/radial scar (78%), only 16% in FCC with 6% in FA.

Conclusion: This study confirms that modern breast biopsy techniques decrease the need for surgery for benign lesions, particularly microcalcifications due to FCC. A further decrease in the need for surgical biopsy may be anticipated as techniques improve and data showing the effectiveness of non-operative diagnosis of such lesions as CSL/radial scar and papilloma becomes available.

C-0181

Controversial issues in atypia of the breast diagnosed by stereotactic 11-gauge vacuum-assisted biopsy: Systematic surgery or mammography assessment?

C.A.S. Labbe-Devilliers, P. Meingan, D. Loussouarn, L. Campion, M. Ricaud-Couprise; Nantes Saint-Herblain/FR

Purpose: To determine if some atypical lesions: Atypical ductal hyperplasia (ADH) and columnar cell with atypia (CCA), diagnosed at stereotactic 11-gauge vacuum-assisted biopsy (VAB) can avoid surgical excision and to define which patients may not need excision?

Methods and Materials: We reviewed retrospectively 570 patients who underwent VAB for breast microcalcifications, only 80 had atypical lesions alone ADH or CCA. We reviewed many characteristics for each patients about clinical presentation, mammography findings, histologic biopsy and the corresponding surgically excised tissue features. Because surgical excision was not performed or they were lost to follow-up, 26 patients were excluded.

Results: The 54 patients who subsequently underwent excision were the subject of this study. Data were statistically analyzed with the chi-2 test. Surgical excision of 54 atypical lesions revealed 19 missed carcinomas (35%). Four variables revealed higher-risk lesions on excision: Tumor size, number of specimens with microcalcifications, percentage of lesion removed and number of atypical foci. Whatever the combination of variable is, the rate of carcinoma involvement is still greater than 10%.

Conclusions: We recommend surgical excision for atypical lesions found after VAB.

C-0182

Can core biopsy be used instead of surgical biopsy in the diagnosis and prognostic factor analysis of nonpalpable breast cancer?

A. Özdemir, N.K. Voyvoda, N. Üzüm, A. Dursun; Ankara/TR

Purpose: To investigate the efficacy of US guided core biopsy (CB) in the diagnosis and prognostic factor analysis of nonpalpable breast cancer.

Materials and Methods: US guided CB was performed in 136 nonpalpable breast lesions, using 14 g semi-automatic needles. Mean number of core samples was 3.5 (range 3 to 6). Malignant lesions diagnosed with CB underwent therapeutic

Scientific and Educational Exhibits

surgical excision (SE). CB and SE results were compared for histological type, grade, estrogen and progesterone receptors (ER and PR), and c-erb-B2.

Results: Fifty-one lesions were malignant in CB (37.5%), with mean size of 17.8 mm (range 6 to 50 mm). Concordance between CB and SE was 83.9% (26/31) for histological type, 67.9% (19/28) for grade, 30.4% (7/23) for ER, 26.1% (6/23) for PR and 47.8% (11/23) for c-erb-B2. CB was insufficient to determine the histological type in four cancers (12.9%) which were reported as "infiltrating malignant." SE yielded positive (when negative on CB) or higher rates in 39.2% for ER, 34.8% for PR, 17.4% for c-erb B2 and 21.4% for grade. CB yielded positive (when negative on SE) or higher rates in 30.4% for ER, 39.1% for PR, 34.8% for c-erb B2 and 10.7% for grade.

Conclusion: Core and surgical biopsies demonstrated high concordance for histological type, moderate-to-high concordance for grade, moderate concordance for c-erb-B2 and low concordance for ER and PR. Relatively poor concordances may be related to tumor heterogeneity and may be decreased by increasing the sample number in core biopsy.

C-0183

SDAV percutaneous biopsy as an alternative to surgical biopsy in breast lesions with 12 G core biopsy disagreement

S. Sánchez, P. Martínez-Miravete, M. Sainz, M. Torres, E. Lag; Logroño/ES

Purpose: To show our experience with 11 and 8 gauge vacuum-assisted breast biopsy as an alternative to surgical biopsy, in breast lesions with 12 G core biopsy with disagreement result.

Methods and Materials: From January 2003 to August 2004, 607 core biopsies were performed. Rebiopsy with vacuum-assisted device was performed in 61 cases (10%): 6% with 8 G and 94% with 11 G. Fifty (90%) under ultrasound guidance and 6 (10%) with upright digital stereotactic device.

Results: Of the 61 lesions, the imaging finding were: 14 architectural distortion (23%); 8 asymmetric density (13%); 39 ultrasound nodules (64%). The degree of suspicious was: 1.5% BI-RADS™ 2; 41% BI-RADS™ 3; 56% BI-RADS™ 4 and 1.5% BI-RADS™ 5. Three cancers were diagnosed by SDAV (5%), just one was suspicious with core biopsy (1.5%), so there were two underestimations. Five lesions underwent surgical biopsy due to radio-pathologic disagreement. One new cancer was diagnosed (both systems were false negative). Fifty-three lesions were benign on percutaneous biopsy. After twenty months follow-up none of them required rebiopsy. There were 8 minor complications: 4 haematomas, 1 vasovaginal reaction, 1 traumatic skin lesion and 2 arterial bleeding.

Conclusion: 1. Vacuum-assisted breast biopsy is a valid alternative to surgical biopsy in lesions with radio-pathological disagreement at core biopsy. 2. It is a feasible technique with infrequent complications. False negatives and surgical biopsies can be avoided with a integrated radio-pathologic team approach.

C-0184

Psychological adjustment of stereotactic breast biopsy instrumentation procedures: About 73 cases

B. Barreau, S. Tastet, V. Picot, C. Henriquès, F. Valentin, R. Gilles, M.-H. Dilhuyd; Bordeaux/FR

Purpose: The objective was to investigate patient perceptions after stereotactic breast biopsy instrumentation, after the procedure and after the results.

Methods and Materials: From March 2002 to March 2003, a questionnaire (response type Likert) on stress was given to 73 patients who had breast biopsies procedures. The first time at the end of the procedure (T1) and after the histological diagnosis (T2). There are two groups of women: The first group (G1) corresponds to patients with a benign diagnosis ($n = 32$) and the group (G2) to patients with malignant diagnosis ($n = 32$).

Results: The questionnaire has been validated (analysis of principal component with varimax rotation). Three factors were identified: Procedure, quality of life, information and perception after biopsy. The responses were analysed with Chi-square. Only the "procedure" factor was different at T1 and T2 ($p = 0.022$). Compression was painful: 11% at T1 versus 21% at T2. Women were disturbed by local anaesthesia: 26% at T1 versus 21% at T2. Biopsy was painful: 6% at T1 versus 13% at T2. Examination is too long: 24% at T1 versus 35% at T2. The procedure is uncomfortable: 52% at T1 versus 54% at T2. Information satisfied patients in 90% cases. There was no statistically significant difference according to procedures and histological disease ($p = 0.0357$).

Conclusion: Information and medical empathy conditioned patients' perceptions. Patients tolerated the procedures well.

Breast

Digital mammography

C-0185

Computer aided detection (CAD) results for mammography in a diagnostic center environment

R. Salvador, F. Ramírez, X. Martínez, M. Salvador, D. Coll, R. Salvador Jr; Barcelona/ES

Purpose: The aim of this study is to review the results of a new CAD system applied to breast diagnosis.

Methods and Materials: We reviewed 48 patients consecutively sent to our institution for a core-biopsy sample on a BI-RADS 4 and 5 lesion found in a mammography previously obtained in our center. The CAD system was set at three different levels (high, medium and low threshold sensitivity) for each one of the two parameters evaluated (Tumor and Microcalcification clusters) were analyzed. All the marks were considered to obtain the NPV, PPV, sensitivity and specificity. The results were compared to the pathology analysis in the 22 infiltrating carcinomas (IC), 3 ductal carcinoma in situ (DCIS), 3 atypical ductal hyperplasias (ADH), and 20 benign conditions. A positive result was considered in three different scenarios, one IC, DCIS and ADH; two IC and DCIS; and three IC.

Results: The values for sensitivity at the higher level were 39.3%, 44% and 45.5% respectively for each scenario. Specificity 55%, 60.9% and 61.5%. PPV 55%, 55%, and 50%. NPV 39.3%, 50%, and 57.1%. Medium level values were sensitivity 39.3%, 44%, and 40.9%. Specificity 70%, 73.9% and 69.2%. PPV 64.7%, 64.7% and 52.9%. NPV 45.1%, 45.1% and 58%. And at the lower level sensitivity 53.6%, 60% and 59%. Specificity 55%, 60.9% and 57.9%. PPV 62.5%, 62.5% and 54.1%. NPV 45.8%, 58.3% and 62.5%.

Conclusion: The most advantageous setting was medium level of threshold and the scenario in which IC and DCIS were considered as a positive result.

C-0186

Clinical implication of phase contrast digital mammography using practical mammography equipment

T. Tanaka, K. Tsuchiya, N. Nitta, A. Furukawa, M. Takahashi, K. Murata; Otsu/JP

Purpose: To estimate clinical advantages of digital full-field phase contrast mammography (PCM) using a practical mammography equipment by comparing the digital mammograms printed in 25 micrometer pixels with conventional contact screen-film (S/F) mammography.

Methods and Materials: Our clinical tests have been conducted in a MLO direction on one side breast for PCM and S/F mammography. The mammography equipment used was customized for PCM so as to set an imaging plate of computed radiography away from an object by 49 cm, keeping the distance between a focal spot of X-ray tube and an object to be as 65 cm as in the conventional contact mammography. Focal spot size of molybdenum X-ray tube for PCM was 100 micrometers nominally, while focal spot size in S/F mammography was 300 micrometers. Each set of PCM and S/F mammograms for 38 patients was read independently by three qualified radiologists with expertise in mammography so as to evaluate each detectability of micro-calcification and nodules. The collected data was analyzed with ROC method.

Results: For micro-calcification, Az values are 0.9657 for PCM and 0.8874 for S/F. For nodule, those are 0.9651 for PCM and 0.9546 for S/F. Glandular architecture was depicted in PCM more clearly than in S/F.

Conclusions: Detectability for both micro-calcification and nodule in PCM are better than one in S/F. Clear depiction of glandular architecture in PCM suggests that PCM would be advantageous in dense breast mammography.

C-0187

Dose reduction and diagnostic accuracy in full-field digital mammography: A clinical study

G. Gennaro¹, H. Souchay², C. di Maggio¹, L. Katz², M. La Grassa¹, L. Pescarini¹, C. Alberelli²; ¹Padua/IT, ²Buc/FR

Purpose: Evaluate lesion classification changes with dose level in a diagnostic population undergoing direct digital mammography examinations.

Methods and Materials: A sample of 305 cases was collected, including 56 cancers, 153 benign lesions and 96 negative cases. Each patient had one view double-exposed with a full-field digital mammography unit (GE Senograph 2000D): One image at standard dose and another reducing dose. On basis of results from a previous phantom study, dose was reduced by 30% to 50% ac-

Scientific and Educational Exhibits

cording to breast thickness and composition. All images were anonymized for patient names and dose levels. Three experienced and independent radiologists using soft-copy reading, recorded findings of localization, type and confidence of presence. Images were classified using an extended 7-step BI-RADS scale. Lesion classifications were compared with the truth (histology or 2-years follow-up) and assessment differences between standard and reduced dose were evaluated.

Results: BI-RADS classifications at standard and reduced dose, referred to the truth, were not statistically different. P-values were 0.37 and 0.33, 0.69, 0.84 for overall and each individual radiologists, respectively. The applied dose reduction had no effect on false negatives, false positives, sensitivity and specificity.

Conclusion: Changes in lesion classification with FFDM dose reduction were not statistically significant in the population sample. The reader interpretation variability is much greater than the effect of dose reduction. Results support the opportunity of reducing dose in digital mammography without significant impact on clinical decision.

C-0188

Diagnostic pitfalls in digital mammography using a computerized assisted diagnosis (CAD) system

V. Annibale¹, F. Crinò¹, F. Bosurgi², A. Gambaro¹, F. Travaglini¹, A. Carriero¹; ¹Novara/IT, ²Siderno/IT

Purpose: To report our experience about diagnostic accuracy and CAD dependent pitfalls in a group of patients with breast cancer.

Methods and Materials: From January 2003 to August 2004, 83 consecutive patients with breast cancer, diagnosed by mammography and histologically confirmed, were studied both with digital mammography and with CAD. Patients were classified in three groups: Group A (CAD negative in both crano-caudal and oblique projections), group B (CAD negative either in crano-caudal or in oblique projection), group C (CAD positive in both projections).

Results: 71/83 (85%) of patients were considered positive by CAD system (group C), 9 (11%) partially negative (group B) and 3 (4%) completely negative (group A). 2 cases in group A presented as a nodule and 1 patient showed an area of parenchymal distortion. 5 patients in group B resulted negative in oblique projection and 4 resulted negative in crano-caudal projection. In the same group 4 cases presented as a nodule, 4 cases as nodules and calcifications and 1 case both parenchymal distortions and calcifications. In group C, 40 patients presented with mammary nodule, 7 microcalcifications, 17 parenchymal distortions and 6 combined lesions (ie. nodule with calcifications).

Conclusions: In our experience the use of CAD system in digital mammography resulted in uncertain help for the radiologist. In particular, the report of CAD assessed mammography can only be considered as a diagnostic aid and can not replace the complete clinical-diagnostic evaluation.

Breast

Magnetic resonance

C-0189

Locally advanced breast cancer: Magnetic resonance imaging versus clinical examination, mammography and ultrasonography in evaluation of residual disease after primary chemotherapy

M. Bodini, U.P. Marini, C. Fiorentino, L. Olivetti; Cremona/IT

Purpose: Primary chemotherapy (PC) is essential in the treatment of patients with locally advanced breast cancer. Magnetic resonance imaging (MRI) is the better tool for distinguishing fibrosis from richly vascularised neoplastic tissue and for evaluating tumour response to chemotherapy, namely tumour debulking and residual viability. The accuracy of MRI versus clinical examination, mammography and ultrasonography is evaluated.

Methods and Materials: Seventy-three patients with T2-T4, N0, M0 breast cancer were treated with 3-4 cycles of single agent epirubicin before definitive surgery. All patients were evaluated after PC with clinical examination and MRI. Forty out of 73 patients underwent also to mammography and ultrasonography. Size of any residual pathologic tissue was measured and the clinical and imaging dimension of the residual tumour were correlated with the pathologic specimen.

Results: Residual tumor assessed by MRI correlated with pathologic measurements (Spearman's $r=0.72$) better than residual tumor assessed by clinical palpation (Spearman's $r=0.58$). MRI attained better correlation to pathologic findings (Spearman's $r=0.74$; $p < 0.001$) than US ($r=0.55$; $p < 0.001$) and mammography ($r=0.32$; $p = \text{n.s.}$).

Conclusions: As compared to pathology specimens, MRI is able to represent the extent of cancer more accurately than clinical examination, mammography and ultrasonography. MRI is a promising technique in assessing the response of locally advanced breast cancer to PC. The current limit of MRI is the low specificity in predicting the nature of residual disease.

C-0190

Magnetic resonance imaging (MRI) in detecting early breast implant rupture: Report in 467 cases

S. Montemezzi, F. Fornasa, G. Barbazi, G. Puppini, A. Battistoni, A. Marchi, G. Gortenutti; Verona/IT

Purpose: To evaluate MRI accuracy in detecting early implant rupture as well as silicone gel bleeding.

Methods and Materials: From November 2000 to July 2004, 467 patients underwent MRI implant evaluation. MRI was performed by using Magnetom Symphony 1.5 Tesla (Siemens): The imaging protocol included Fast Spin EchoT2 weighted images and Turbo Inversion Recovery weighted images for silicone. 65/467 patients underwent surgery: MRI findings were correlated to surgical reports. 370/467 untreated patients were evaluated by clinical and/or MRI follow-up.

Results: MRI diagnosed implant rupture in 45 cases and gel bleeding in 7 cases. Surgery assessed implant rupture in 43/45 cases and gel bleeding in 7/7 cases; surgery showed a hematoma between the external shell and the capsule in 1/2 Patients who resulted MRI false positive for implant rupture. MRI did not assess implant rupture in 373/467 patients of whom 14 underwent surgery (negative in 11cases; early gel bleeding in 3cases): The retrospective analysis of those cases, detected as negative by MRI, showed a loose implant shell, assessed as radial fold, distinct from the capsule by a small silicone amount. MRI sensitivity, specificity, positive predictive value, negative predictive value and accuracy were respectively 94.3%, 99.4%, 96.1%, 99.1% and 98.8%.

Conclusion: In our experience, MRI has been effective in detecting early implant rupture. MRI diagnostic accuracy may be improved by assessing early silicone gel bleeding as well as differentiating between silicon gel bleeding and initial implant rupture, even if the latter is not clinically important because in both cases surgical removal of the implants is required.

C-0191

MR mammography of enhancing breast masses: Can MR predict carcinomas with a fibrotic focus?

M.L.A. Van Goethem¹, K. Schelfout¹, C. Colpaert¹, E. Kersschot², I. Verslegers¹, I. Biltjes¹, A. De Schepper¹, J. Weyler¹, P. Parizel¹; ¹Antwerp/BE, ²Aalst/BE

Purpose: To study whether dynamic MR mammography can predict the presence and the diameter of a fibrotic focus (FF) in breast carcinoma.

Methods and Materials: In a prospective study, 233 consecutive women with a

Scientific and Educational Exhibits

suspicious lesion underwent preoperative dynamic MR and 403 enhancing lesions were detected; 337 of them were masses. Enhancement pattern (homogeneous, non homogeneous, the presence of a less or later enhancing centre) and kinetic features of the masses were correlated with histopathological examination. **Results:** The prevalence of an FF in cancers with homogeneous enhancement, non homogeneous enhancement and cancers presenting with a centre was respectively 0%, 14.3% and 64.6%. Kinetic features did not help in the diagnosis of FF. Correlation of the diameter of the FF between MR and pathology was 0.616 (Spearman Rank) ($p < 0.0001$).

Conclusion: The presence of a less or later enhancing centre in a carcinoma on MR corresponds to FF in 64.6%. Assessment of the diameter of an FF on MR was good.

C-0192

Contrast enhanced magnetic resonance mammography (CE-MRM) in the evaluation of suspected microcalcifications at mammography

F. Pediconi, C. Catalano, F. Venditti, A. Roselli, E. Moriconi, R. Passariello; Rome/IT

Purpose: To evaluate the role of CE-MRM in the evaluation and characterization of breast lesions associated with microcalcification diagnosed by mammography.

Methods and Materials: Thirty women with suspected or unclear microcalcifications at mammography, underwent CE-MRM with a 1.5 T magnet using a bilateral breast surface coil. The CE-MRM protocol comprised a T2-weighted STIR sequence and 3D dynamic T1-weighted FLASH sequence before and after (four measurements) the administration of 0.1 mmol/Kg of Gd-BOPTA. At mammography microcalcifications were evaluated by LeGal and BI-RADS classifications. Criteria for lesion evaluation included site, number, morphological patterns, margins and dimensions of all enhancement areas at CE-MRM. All suspected lesions were classified according to BI-RADS classification. Bi-RADS scores of lesions detected at mammography and at CE-MRM were compared. All results were correlated with histopathological specimen.

Results: At histopathological examination, 17/30 lesions were invasive carcinomas, 9/30 were ductal carcinomas in situ and 4/30 were benign lesions. Almost perfect agreement was seen between Bi-RADS scores of lesions detected at mammography and at CE-MRM. A good correlation between CE-MRM findings and histopathological specimens was obtained.

Conclusions: CE-MRM showed high values of sensibility, specificity and accuracy in the evaluation and characterization of microcalcification.

C-0193

3 T-magnetic-resonance-elastography of the breast: Technical feasibility

K. Meyer, R. Sinkus, M. Kaul, J. Lorenzen, G. Adam; Hamburg/DE

Purpose: MR-elastography of the breast has been technically established at 1.5 T. At 3 T difficulties are encountered due to shortened T2-relaxation times and prolonged MR echo-times caused by increased pulse-duration (SAR). This leads to signal loss that is not compensated by the gain due to increased field-strength. The aim was to overcome these limitations.

Methods and Materials: Mechanical excitation frequency remains at 50 Hz, because higher values would lead to strong attenuation effects of the wave providing insufficient penetration. This frequency leads to a TE of about 60 ms for the motion-sensitised spin-echo-sequence. Shortening of this prohibitive long echo-time is achieved by running the sequence at twice the mechanical excitation frequency. Consequently, the sensitivity to detect motion is reduced by a factor of about two. Loss in SNR is compensated by introduction of an EPI-readout and a signal-average of two. 10 healthy volunteers were examined in a 3 T MR system in prone position with a four-element breast coil. Reconstruction of elasticity and viscosity was performed after.

Results: EPI-readout did not lead to any significant image distortions. The shortened TE (30 ms) led to sufficient SNR within the parenchyma. 50 Hz-oscillation provided a sufficient penetration of the wave into the breast. Reconstructed images of shear modulus did not show any suspect regions of enhanced elasticity.

Conclusions: MRE of breast at 3 T is technically feasible. An efficient insertion of the waves into breast was achieved. EPI-readout provided a successful data acquisition.

C-0194

Pre-operative MR imaging localization of breast cancer in supine position using a newly developed marking net

K. Oikado¹, H. Tsunoda-Shimizu¹, T. Kazama², S. Nakamura¹, H. Suzuki¹, M. Kikuchi¹, Y. Numaguchi¹; ¹Tokyo/JP, ²Chiba/JP

Purpose: To determine whether MR imaging in supine position with a newly developed marking net can be used reliably to localize preoperatively breast cancer with intraductal component.

Methods and Materials: Our study included 25 patients with breast cancer having intraductal components detected by mammography or ultrasound (mean age 50, 31-65). Breast conserving surgery was elected for these patients using a newly developed marking net filled with contrast media for precise localization of tumor extension. Twenty-six breast lesions of 25 patients underwent pre-operative localization in the supine position. Coronal fat-suppressed T1-weighted images with and without contrast enhancement were obtained and MIP reconstruction was performed. All patients underwent partial mastectomy and the range of resection was decided with the markings on MR imaging. Comparison of radiological and pathological findings was made using operated specimens.

Results: Twenty-two lesions were clearly defined on MR imaging and resection was relatively feasible with the use of a marking net. Evaluation of tumor extent was impossible in 4 patients due to enhancement of mastopathy or normal breast tissue. Eleven lesions of 22 showed tumor free on frozen section. The other 11 lesions showed tumor cells at the resected margin. However, in 10 of the 11 lesions, tumor cells were of non-invasive ductal component. Additional slightly wider resection was performed for these patients and no tumor cells were detected at resected margin.

Conclusion: Pre-operative MR imaging localization of breast cancer using a newly developed net may help pre-operative evaluation of tumor extent.

C-0195

Role of Gd-BOPTA-enhanced MR mammography in the evaluation of neoadjuvant chemotherapy response in patients with breast cancer

F. Pediconi, C. Catalano, F. Venditti, E. Moriconi, S. Padula, R. Passariello; Rome/IT

Purpose: Assess accuracy of MR mammography (MRM) for evaluation of size and changes in contrast agent uptake pattern in patients with invasive breast cancer after neoadjuvant chemotherapy.

Methods and Materials: Thirty women with core biopsy-confirmed invasive breast cancer underwent MRM prior to neoadjuvant chemotherapy and surgical excision. MRM protocol comprised a T2-weighted STIR sequence and a flash 3D T1-weighted sequence acquired before and at 2, 4, 6, 8 and 10 min after the administration of Gd-BOPTA at 0.1 mmol/Kg. Interval between pre-operative MRM examination and surgery was less than two weeks. Diameter of the tumor and pattern of dynamic contrast agent uptake on the MRM images after chemotherapy were evaluated against histological specimen.

Results: Four patients were excluded because surgery was performed more than two weeks after the last MRM; 26 patients were classified as either complete responders (n = 3), partial responders (n = 16) or non responders (n = 7) on basis of therapy response as indicated on the MRM images. Three complete responders and 3 of the 16 partial responders on MRM imaging showed no residual disease at pathology. Good correlation was found between tumor diameter measured on pre-operative MRM images and on the surgical specimen. MRM assessment had a slight tendency toward overestimation of lesion size compared with pathology. Reduction of tumor size after chemotherapy was associated with decreased contrast agent uptake and modification of dynamic uptake pattern.

Conclusion: MRM is appropriate to evaluate therapeutic effects of neoadjuvant chemotherapy in large breast tumors and permits an accurate assessment of residual breast tumor diameter.

C-0196

An advanced method of computer aided evaluation applied to breast MR imaging: A useful tool both for the radiologist analysis and for the diagnostic accuracy

J.C. Vilanova, J. Barcelo, M. Villalon; Girona/ES

Purpose: To analyze and compare a new method of computer aided evaluation for breast MR imaging and a standard MR imaging software analysis: For diagnostic accuracy, registration of data to correct patient movement-related artifact and the usefulness for the radiologist who interprets MR breast examinations.

Methods and Materials: We evaluated 36 subjects retrospectively from a consecutive series of breast cancer MR imaging patients (GE, Signa LX 1.5T). We

Scientific and Educational Exhibits

performed a comparative study between a commercially available automatic CAD system (CADstream) and standard software for MR imaging. We determined lesion size, morphology, kinetic enhancement, and additional lesions on MR imaging, quality of image correction of subtracted images by CAD and, time for study analysis on each system.

Results: CAD's automatic measurements showed higher tumor size correlation (0.92) with histologic analysis than with the manual standard software (0.86). The morphology and kinetic enhancement patterns did not show significant differences between CAD and standard MR imaging software. Both systems detected additional lesions in 10 patients (28%). Corrected subtraction series from CAD were chosen as better registered data for patient movement-related artifact than uncorrected subtraction images in 83% of cases. The mean analysis time for breast MR imaging on the CAD system was 12 minutes and for standard MR imaging software of 19 minutes.

Conclusion: The automatic CAD system shows an accurate diagnostic method for breast cancer MR evaluation with high histologic correlation. CAD system shows a significantly reduction in artifacts for the subtraction series and saves a substantial amount of time for the analysis and interpretation of MR processed images.

C-0197

MR imaging findings of breast implants complications

A. Roma, B. Ubeda, P. Nin, R. Rotger, R. Ramos, A. Palacio; *Barcelona/ES*

Learning Objectives: MR imaging features of normal breast silicone implants. MR imaging technique in the evaluation of breast implants. Description of the most common complications.

Background: Breast augmentation can be performed with the injection of foreign materials into the breast tissue, transplantation of autogenous tissue and use of prosthetic devices. Breast implants include silicone gel, saline, biocompatible gel, double-lumen and tissue expanders. The implant can be placed in a retroglandular or submuscular position. MR is an accurate technique to diagnose the type and extent of breast implants complications.

Imaging Findings: MR for breast implants evaluation is performed with a breast-dedicated coil with FSE T2, STIR, FSE T2 with silicone-suppressed and STIR with water-suppressed sequences in two or more planes. We describe the main features of normal breast silicone implants and the most common complications including capsule folds and contracture, herniation, fluid periprosthetic collections and intra and extracapsular ruptures.

Conclusion: MR imaging is an accurate technique for evaluation of breast implants and depicting its complications. Special sequences are useful for demonstration of extracapsular silicone. It also provides an overview of the breast, the axilla and the chest wall.

C-0198

A model for reporting dynamic breast MR imaging

A. Fausto, F. Sardanelli; *Milan/IT*

Learning Objectives: To propose a model for reporting breast MR imaging.

Background: High sensitivity and good specificity can be reached with dynamic breast MR, when integrating morphologic and dynamic criteria. The technique is mainly based on a predynamic unenhanced (2D T2-weighted fast spin-echo or STIR) and a dynamic 3D T1-weighted gradient-echo acquisition. Postprocessing: Image subtraction; MIP, MPR; percent enhancement versus time curves for targeted regions of interest. How to report the exam?

Procedure Details: Our model of report: *History* (2-4 lines). Hereditary predisposition to breast cancer; menarche age; oral contraceptives, pregnancy and lactation history; date of last menses or menopausal age; hormone replacing therapy. Breast symptoms; previous examinations (date and synthesis of findings). Clinical query for current MR exam. *Technique* (2 lines). Type/orientation of predynamic and dynamic sequences; type/dose of contrast agent; short description of postprocessing. *Results* (2-8 lines). Breast pattern (fatty, scattered fibroglandular, homogeneously glandular); possible diffuse signal alterations on predynamic scans. For any detected lesion: side/location (in correlation with previous examinations); size (mm in maximal diameter); signal intensity on predynamic scans; shape, margins, homogeneity and pattern of contrast enhancement; dynamics of percent enhancement (continuous increase, plateau, or wash-out); level of suspicion according to BI-RADS or similar score. *Conclusions* (1-3 lines). Synthesis of diagnosis and indications for further action (second look ultrasound; repeat MR; biopsy; surgery, etc.) or follow-up with conventional imaging or MR.

Conclusion: A standardized report can summarize in about 7-18 lines the information to be transmitted to other physicians not expert in breast MR.

C-0199

MR imaging in ductal carcinoma in situ (DCIS) with mammographic appearance of microcalcifications

A. Cilotti, C. Marini, C. Giacconi, D. Francesca, D. Mazzotta, A. Vaccaro, C. Della Pina, C. Bartolozzi; *Pisa/IT*

Purpose: To evaluate MR imaging performance in ductal carcinoma in situ (DCIS) with mammographic appearance of microcalcifications.

Methods and Materials: MR imaging examinations of 73 patients with histologic diagnosis of DCIS having microcalcifications were revalued. According to Fisher's score, MR imaging was classified in a 3-points scale for malignancy (BI-RADS).

Results: MR imaging revealed these types of enhancement: Dendritic (50 cases), nodular (23 cases), diffuse with sectorial shape (58 cases) and focal (15 cases). Time-intensity curves were type I (16 cases), type II (41 cases) and type III (16 cases). According to BI-RADS category MR imaging was classified as B3 (score 0-3) in 14 cases, B4 (score 4-5) in 37 cases and B5 (score 6-7) in 22 cases. Sensitivity was 84%. This data can increase if we contemplate Fisher's score 3 as suspect (BI-RADS B4).

Conclusion: The more available MR imaging findings in DCIS were: Dendritic enhancement (68%), quickly wash-in (78%), sectorial shape enhancement (79%), while contrast enhancement distribution is difficult to evaluate in small lesions, particularly if dendritic enhancement is present. On the contrary quickly wash-out, usually present in 90/95% of infiltrative cancer, was present only in 22% of DCIS. In score Fisher 0-3 category of DCIS, relative to False Negative at MR imaging, the most common data was the presence of more findings in a quadrant with diffuse/sectorial shape (incidence 75%). MR imaging is not a diagnostic technique in DCIS but the presence of reported findings as dendritic enhancement, quickly wash-in and sectorial shape can be suggestive of DCIS.

C-0200

Characterization of pure high grade DCIS on magnetic resonance imaging using the evolving breast MR lexicon terminology: Can it be differentiated from pure invasive disease?

A.M. Groves, R.M.L. Warren, S. Godward, P.S. Rajan; *Cambridge/UK*

Purpose: Magnetic resonance imaging (MRI) is now a recognized method of imaging the breast. Unfortunately, there is lack of standardization in the MRI terminology used to characterize the appearance of breast lesions. Moreover, cases of mixed histologies are often imaged. We retrospectively identified cases of pure high grade ductal carcinoma in situ (DCIS) and using the recently introduced Breast MRI Lexicon, characterized the lesions in order to try and identify features that might distinguish high grade DCIS from invasive disease.

Materials and Methods: A five-year review of our institution's database revealed 637 patients underwent gadolinium enhanced breast MRI examination. After excluding patients with previous chemotherapy or inadequate MRI examination, 13 patients with histologically proven high grade DCIS were analyzed and compared to the 13 most recent cases of pure invasive breast carcinoma. The morphological and dynamic features were then compared.

Results: DCIS cases were significantly more likely to show focal branching pattern ($P = 0.03$) and to have an irregular contour ($P = 0.03$), compared with invasive disease. Although of marginal statistical significance, DCIS lesions are more likely to have a lower morphological score than invasive carcinoma ($P = 0.06$), whilst the latter is more likely to show ring enhancement ($P = 0.07$).

Conclusions: Use of breast MRI for staging at our institution shows that pure high grade DCIS and pure invasive cancers are both rare entities. Despite the relatively limited numbers we identified features that would help to differentiate high grade DCIS from invasive carcinoma on MRI, as well as those characteristics that did not contribute.

C-0201

Magnetic resonance imaging of breast implant ruptures

A. Magistrelli, M. Costantini, M. Romani, R. Masetti, P. Belli; *Rome/IT*

Learning Objectives: To illustrate magnetic resonance imaging (MRI) findings of breast implant ruptures.

Background: The number of women with breast implants is estimated between 4 and 6 million of the world population. In these patients, mammography and sonography have a lower diagnostic accuracy. MRI plays a major role in breast implants evaluation, especially in diagnosis of complications. The incidence of silicon breast implant rupture varies with implantation time and type of implant. The rupture rate increased significantly with increasing implant age and double-lumen implants were associated with substantially lower rupture risk than single-

Scientific and Educational Exhibits

lumen implants. Implant rupture occurs in 15-20% of cases between the 3rd and 10th year after implantation. Both intracapsular (80-90%) and extra capsular (10-20%) rupture required explantation.

Procedure Details: From January 2000 to September 2004, we studied 47 asymptomatic women with implant rupture who subsequently had the implant surgically removed. We describe the most common MRI signs of rupture: "Linguine sign", "teardrop sign" and "C sign". For correct diagnosis, the radiologist should be familiar with all implant types. When a periprosthetic mass is associated with an undamaged implant, MRI allows the differential diagnosis between herniation, irregular fibrous capsule and breast cancer.

Conclusion: According to literature data, our study confirms the high MRI sensitivity and specificity in the evaluation of breast implant rupture. However an integration with clinical information and conventional imaging is useful to improve MRI diagnosis.

Differentiation of benign and malignant solid breast masses: Real-time spatial compound imaging versus conventional ultrasound

J. Cha¹, W. Moon¹, Y. Koh¹, J.-E. Cheon¹, J. Park², B.-K. Han¹, Y. Cheo¹;
¹Seoul/KR, ²Wisconsin, WI/US

Purpose: To compare the diagnostic performance of real-time spatial compound imaging (SCI) with that of conventional US in the differentiation of benign and malignant solid breast masses.

Methods and Materials: Seventy-five solid breast masses were prospectively evaluated using conventional US and SCI (ATL HDI 5000) with a 5-12 MHz transducer. Of 75 lesions, 21 were cancerous and 54 were benign masses, confirmed by surgical excision or percutaneous needle biopsy. Each image set was masked and randomized. Three experienced radiologists who had not performed the examinations independently analyzed the US findings of the lesion and provided a level of suspicion to indicate the probability of malignancy without information of physical examinations and mammograms. Results were correlated with histologic findings and evaluated with receiver operating characteristic (ROC) analysis.

Results: Regarding the description of US findings, punctate calcifications within the mass was mostly discordant between conventional US and SCI followed by echotexture, boundary echo, width/AP ratio, echogenicity, shape, margin and posterior acoustic transmission. Az and $\text{Az}_{0.90}$ of the conventional US and SCI for each reader were 0.79, 0.85 and 0.29, 0.29 for reader 1; 0.88, 0.88 and 0.69, 0.65 for reader 2; and 0.82, 0.89 and 0.39, 0.39 for reader 3. Diagnostic performance of the two techniques was not significantly different.

Conclusion: There was a remarkable difference in the description of US findings between conventional US and SCI. However, the performance of the radiologists in the characterization of solid breast masses did not change significantly with the use of SCI.

C-0203

Differentiation of benign and malignant solid breast masses: Tissue harmonic imaging versus conventional ultrasound

J. Cha¹, W. Moon¹, Y. Koh¹, J. Cheon¹, J. Park², B.-K. Han¹, Y. Cheo¹;
¹Seoul/KR, ²Wisconsin, WI/US

Purpose: To compare the diagnostic performance of tissue harmonic imaging (THI) with that of conventional US in the differentiation of benign and malignant solid breast masses.

Methods and Materials: Ninety-one solid breast masses were prospectively evaluated using conventional US and THI (LOGIQ 700; GE) with a 13 MHz transducer. Of 91 lesions, 30 were cancerous and 61 were benign masses, confirmed by surgical excision or percutaneous needle biopsy. Each image set was masked and randomized. Three experienced radiologists who had not performed the examinations independently analyzed the US findings of the lesion and provided a level of suspicion to indicate the probability of malignancy without information of physical examinations and mammograms. Results were correlated with histologic findings and evaluated with receiver operating characteristic (ROC) analysis.

Results: Regarding the description of US findings, echogenicity was mostly discordant between conventional US and THI followed by echotexture, margin, calcifications, posterior acoustic transmission, boundary echo, shape and width/AP. Az and $\text{Az}_{0.90}$ of the conventional US and THI for each reader were 0.8390, 0.8316 and 0.5889, 0.5886 for reader 1; 0.8677, 0.8979 and 0.7445, 0.7454 for reader 2; and 0.7682, 0.7838 and 0.2896, 0.2930 for reader 3. Diagnostic performance of the two techniques was not significantly different.

Conclusion: There was a remarkable difference in the description of US findings between conventional US and THI. However, the performance of the radiologists in the characterization of solid breast masses did not change significantly with the use of THI.

C-0204

US depiction and pathologic outcome of suspicious breast lesions additionally detected on MR imaging

J. Shin, B.-K. Han, Y. Choe, K. Ko; Seoul/KR

Purpose: The purpose of our study was to assess the feasibility of ultrasonographic (US) depiction of suspicious breast lesions additionally detected on magnetic resonance (MR) imaging of patients with breast cancer and to investigate their pathologic outcome.

Scientific and Educational Exhibits

Methods and Materials: We retrospectively reviewed 300 consecutive breast MR examinations with sagittal dynamic sequences performed for preoperative evaluation of patients with breast cancer from January 2002 to January 2004. We found 26 patients with 33 unexpectedly enhancing lesions on MR in addition to known focus of cancer and recommended to look for a US correlate amendable to biopsy or localization. These patients were reviewed for imaging findings and histopathologic findings from subsequent biopsy or surgery.

Results: Ninety one percent (30/33) of all additionally detected breast lesions on MR imaging were histologically confirmed. An US correlate was identified in 25 (75.8%) of all additionally detected lesions. Carcinoma was found in 17 (68%) of these lesions, of which 7 were invasive carcinoma and 10 were ductal carcinoma in situ (DCIS). Among 8 lesions without an US correlate, 3 (37.5%) yielded carcinoma, of which one was invasive carcinoma and two were DCIS.

Conclusion: Although additionally detected suspicious breast lesions on MR imaging were not evident on US, these had a higher possibility of carcinoma in those with underlying primary breast carcinoma. Additionally enhancing lesions with a US correlate were more prone to be malignant lesions.

C-0205

Possibility of the US-detection of clustered microcalcifications of female breast

H. Shevchenko; Moscow/RU

Purpose: To evaluate the US-changes in area of clustered microcalcifications (c.m.).

Methods and Materials: 147 patients (mean age = 58 y.o.) with cancer-suspicious c.m. detected mammographically have been examined with 7.5-12 MHz linear transducer (HDI-5000 ATL Philips) in B-mode and Sono CT. 90 cancers and 57 benign lesions were found. Mean diameter of calcifications was 1.7 mm (0.4-8 mm) and 0.15-0.8 mm when using X-ray. The diameter varied due to inability of US (even high-resolution) to detect c.m. as a group of microcalcifications, and not as a single one.

Results: C.m. were visualized with help of US only in 25% of all cases (37 patients). However, in X-ray-detected c.m., malignant lesions could be found only with help of US in 96% of all cases (86 cancers). X-ray-detected c.m. had intermediate concern or high probability of malignancy (cat. 4 and 5 BI-RADS). Their quantity varied from 1 to 30 per cm². US-detected calcifications were visible when their concentration lied in-between 5 and 20 per cm² (namely cat. 5 BI-RADS).

Conclusion: Detection of c.m. by US-scanning was possible only in 25% of all cases and only if their density was relatively high (> 5). Specificity of US-examination is 96%. The size and quantity of c.m. cannot be evaluated by means of X-ray. C.m. was seen as single big calcification in 25% of all cases.

C-0206

Is the echogenicity of a mass influenced by its morphology? An in vitro model

E. De Luis, J.J. Noguera, M. Pons, P.D. Domínguez, L.J. Pina, F. Martínez Regueira; Pamplona/ES

Purpose: Malignant hyperechoic masses are rarely found on breast ultrasound exams. These findings are frequently associated with infiltrating lobular carcinomas. Pathology of these lesions may show multiple layers of tumoral cells (Indian rows) mixed with normal adjacent fatty tissue. Our purpose was to evaluate if the echogenicity of a mass was influenced by its shape, using an in vitro model.

Methods and Materials: Two models of fatty breasts were created, using 500 ml of olive oil in hermetic plastic bags. Two beef pieces of meat (10 g each one) were used to simulate breast masses. Both pieces were introduced inside the bags. The morphology of both specimens was different. In model 1, the specimen was a round homogeneous mass, and in model 2 the specimen was mashed up and torn with a knife. Mammography and ultrasonography were performed.

Results: *Mammographic findings:* In model 1 the specimen appeared as a round, homogeneously dense mass with well-circumscribed margins. In model 2 the specimen was shown as an irregular heterogeneous mass, with small fatty densities inside. *Ultrasonographic findings:* In model 1 the specimen was shown as a hypoechoic well-circumscribed mass, while in model 2 it was shown as an irregular hyperechoic mass.

Conclusion: The echogenicity of a lesion may be influenced by its morphology. An heterogeneous mass with small fatty spaces inside is more echogenic than an homogeneous mass. This might justify the hyperechoic pattern of some infiltrating lobular carcinomas.

C-0208

Assessment of clinical outcomes and the sonographic criteria in benign and malignant solid breast masses

A. Özdemir, Z.Ö. Karadag, B. Coskun; Ankara/TR

Purpose: To assess the appropriateness of radiological diagnosis and the sonographic criteria in benign and malignant solid breast masses.

Methods and Materials: "Probably benign", "suspicious" or "probably malignant" 646 solid breast masses in 421 patients, biopsied or followed up between March 2000 and February 2004 were retrospectively analyzed. Radiological suspicion was based on mammographic and sonographic findings in 254 (39.3%) and only on sonographic findings in 392 (60.7%) lesions. Accordingly, 530 lesions (82%) were "probably benign", 55 lesions (8.5%) were "suspicious" and 61 lesions (9.4%) were "probably malignant".

Results: The final diagnosis was obtained through biopsy (30.9%) or periodic follow-up of at least 2 years (69.1%). Seventy-two lesions (11.2%) were malignant and 574 (88.8%) were benign. Ppv of the "probably malignant", "suspicious", and "probably benign" diagnoses were 91.8%, 21.8% and 0.75%, in order. Sensitivity, specificity, ppv and npv of US were 94.4%, 91.6%, 58.6% and 99.2%, respectively. Five cancers were diagnosed only with US (6.9%). The most useful US criteria in differential diagnosis were contour morphology (OR 26.9), transverse-to-anteroposterior diameter ratio (OR 5.4), shape (OR 4.2) and matrix echogenicity (OR 3.1). In retrospect, 3 of 4 cancers in the "probably benign" group could have been diagnosed by more strict use of the US criteria, providing a ppv of 0.19 instead of 0.75. Follow-up instead of biopsy saved 26,100 € and 55,500 €, compared to core and surgical biopsies, respectively.

Conclusion: Ppv for each diagnostic category was within best ranges. Strict use of US criteria can improve the diagnostic sensitivity.

C-0209

Elastosonography of benign and malignant nodular breast lesions: First experience review

A. Martegani, L. Aiani, L. Tufarulo, R. Campi, M. Ciancio, F. Mascheroni; Como/IT

Learning Objectives: Showing how to perform elastosonographic scan on breast nodules and provide a first image gallery based on Ueno's score.

Backgrounds: 121 nodular lesions (benign and malignant) in 89 patients were evaluated from November 2003 to August 2004 with an ultrasound examination followed by elastography, both performed by EUB-8500/Logos-Hitachi Japan, equipped with different linear electronic 7.5-13 MHz transducers with a dedicated device applied on the probe surface in order to improve the contact with the skin. The first 13 cases were propaedeutic.

A short, careful training is necessary for the operator to learn properly to perform the acquisition, that usually lasts only few minutes (2 - 5 minutes).

Breast nodules were classified according to the morphological elastographic Ueno scores. Cytohistologic biopsy, surgical specimen and follow-up were considered as gold standard.

Imaging Findings: A short demonstration showing how to perform the elastographic scan is provided. Some reproducible elastographic patterns found both in cystic lesions and in large (> 2 cm) malignancies are hereby proposed, with an image gallery of the most typical elastographic patterns based on Ueno's score. Elastographic behaviour of small benign and malignant nodules (up to 2 cm) seems to be more uniform compared to those larger than 2 cm. Some examples are shown.

Conclusion: A broadening of clinical studies is crucial for a definitive validation of the method. Our first experience demonstrates the diagnostic reliability of Elastosonography in characterising breast nodular lesions, especially if smaller than 2 cm.

Real-time spatial compound ultrasound with XFOV imaging in the evaluation of breast lesions

K. Chatzimichael, G. Economou, M. Kampanarou, G. Dimitrakopoulou, D.A. Kelekis; *Athens/GR*

Purpose: To assess the diagnostic role of real-time spatial compound Ultrasound (US) with extended field of view (XFOV) imaging of breast lesions as compared with this of conventional B-mode US.

Methods and Materials: 30 women with breast abnormalities in screening or symptomatic mammography underwent both conventional high resolution B-mode US and real-time spatial compound XFOV imaging. Scans were performed with a SEQUOIA 512 ACUSON scanner under standarized examination settings. Subsequently images were evaluated independently by two radiologists experienced in breast US according to a multistage scoring system with regard to the presence of artifacts, margin definition, matrix definition and overall quality. We assessed also whether the compound XFOV images improved the localization of lesions and the demonstration of the large lesions.

Results: Our comparison of conventional US and compound XFOV imaging confirms a statistically significant reduction in speckle and clutter artifacts accompanied by improved definition of margins and matrix echotexture of both solid and cystic lesions. Compound XFOV technique was found to increase image quality and provide better information about lesion localization, as well as improve the demonstration of the large lesions.

Conclusion: For the time being our results have shown that compound XFOV imaging when compared with conventional US provides better information in localization and matrix characterization of breast lesions and may further improve the diagnostic role of breast US.

Imaging of late recurrence in invasive breast cancer

P. Meingan, C. Labbe-Devilliers, I. Doutriaux-Dumoulin, C. Digabel-Chabay, M. Ricaud-Couprise; *Nantes Saint-Herblain/FR*

Purpose: 1) to describe the appearances of late recurrence (occurring more than 10 years after the initial diagnosis) in invasive breast cancer. 2) to evaluate the prevalence of the sites involved, local or distant. 3) to estimate the frequency of recurrences heralded by symptoms.

Method and Materials: The data of 2923 patients referred in our institution between 1982 and 1991 for a breast invasive carcinoma were reviewed. We noted for each patient the presence or not of late recurrence (occurring more than 10 years after the initial diagnosis with an interval free of disease). We evaluated the mode of detection of recurrences, clinical or on follow-up imaging. We describe the radiological features of these recurrences and evaluate the prevalence of the sites involved.

Results: 3% of patients developed late recurrence. 45% of these recurrences concerned the initially treated breast, 27% the contralateral breast and 28% affected a distant metastatic site. The most common sites involved were bone (18%), lung (10%), and pleura (4%). 66% of recurrences were heralded by symptoms and 34% were detected on follow-up imaging studies.

Conclusions: Late recurrences in breast carcinoma are rare but not uncommon and occur particularly in the initially treated breast or the opposite breast. Distant metastatic recurrences are observed in one third of the cases and consist mainly of bone metastases. Two-thirds of recurrences are heralded by clinical symptoms.

C-0212

Phyllodes tumors: Benign and malignant findings

W. Kwon¹, K.K. Oh², M.S. Kim¹; ¹Wonju/KR, ²Seoul/KR

Purpose: To characterize the mammographic and sonographic findings of pathologically confirmed benign and malignant phyllodes tumors.

Methods and Materials: Imaging findings were reviewed in 51 patients with 56 phyllodes tumors that were confirmed by histopathology. Fifty-one tumors (36 benign and 15 malignant) were reviewed using mammography and forty-two tumors (29 benign and 13 malignant) with sonography. The mammographic and sonographic features were analyzed.

Results: Sonography showed low-echoic cystic areas in 11 (84.6%) cases of malignant tumors and 5 (17.2%) cases of benign tumors with statistical significance ($p < 0.001$). Hypoechoic echogenicity ($p = 0.002$) and heterogeneous echotexture ($p < 0.001$) were seen in 13 cases (100%) of malignant tumors. Calcification within the tumor showed a higher frequency in malignant tumors (6 cases, 40%) than benign tumors (3 cases, 8.8%) with statistical significance ($p = 0.013$). Benign phyllodes tumors measured 3.25 cm and malignant tumors 5.57 cm in mean diameter ($p = 0.005$). The mean age of the malignant tumor patients (41 years old) was older than the benign tumor patients (33 years old) ($p = 0.007$). The benign and malignant phyllodes tumors showed a similar frequency of lobular shape in 61.1% and 73.3% ($p = 0.527$) and a circumscribed margin in 41.7% and 60% ($p = 0.356$), respectively.

Conclusion: Imaging cannot reliably separate malignant from benign phyllodes tumor. However, it appears that size, cystic areas, and a heterogeneous echotexture are associated with a higher likelihood of malignancy.

C-0213

Breast microcalcifications: Benign or malignant. Ready for a challenge?

A.R. Sever¹, S. Villan¹, F. Batmaz², N.A. Mounter¹, P. Mills¹, J.B. Schofield¹, S.E. Jones¹, P.A. Jones¹; ¹Maidstone/UK, ²London/UK

Learning Objectives: To study the spectrum of breast microcalcifications in the form of a self assessment test.

Background: Breast lesions consisting of microcalcifications only, with no accompanying mass, impose a challenge to breast radiologists in the decision making process. As these lesions are usually impalpable and rarely visible on ultrasound, an accurate mammographic evaluation is crucial in assessing the need of an immediate biopsy, follow-up or no follow-up. A programme is conceived as an interactive training session to practise with a set of mammograms designed for radiologists in training as well as breast screening radiologists.

Procedure Details: Maidstone Breast Unit has a large digital library of mammograms consisting of more than 600 cases with microcalcification only lesions which were biopsied using Vacuum-Assisted Mammatome device under stereo-

Scientific and Educational Exhibits

tactic guidance. In co-operation with GULEN Information Consultancy we designed a computer programme to review this teaching file in the form of a test. The test involves three sections. The first section is an introduction and a demonstration of the test consisting of three cases. Second section is the test itself consisting of 40 cases of mammograms including magnification views. The attendees will be asked to select a box indicating either benign or malignant for each case. The third section will give the statistical score of the test in terms of accuracy, sensitivity and specificity and the answers of each case including histopathology images and a brief explanation.

Conclusion: This test will be educational for residents in training and for radiologists to refresh their skills.

C-0214

Breast cancer in women 40 years of age and younger

J. Calbo, M. Castro, M. Carnero, L. Perez, N. Picazo, I. Gonzalez; Alicante/ES

Purpose: To review the clinical, radiological and histopathological findings, including biopathological parameters, in breast cancer diagnosed in women 40 years of age and younger.

Methods and Materials: We made a retrospective review of 71 cases. All the selected patients had radiologic studies (mammography and/or sonography) and histopathologic confirmation.

Results: A total of 1231 patients with breast cancer were studied, 71 of which were 40 years old or younger. In 89% a palpable mass was the clinical presentation. The most frequent mammographic finding was as a nodular lesion. Mammography did not find anomalies in 21% of the cases. By sonography, a hypoechoic nodule was the most frequent presentation (40%). Histologic findings revealed infiltrating ductal carcinoma in 82% of tumours, with a high incidence of poorly differentiated forms (GII - GIII). We observed lymphovascular invasion in 56% of the patients.

Conclusion: Breast cancer is a rare condition in adolescents and young adults. Invasive breast cancer occurring at a young age has more aggressive biological behaviour and is associated with a worse prognosis. In our series, we found a high incidence of poorly differentiated (GII-III) ductal carcinomas and more than 50% had lymphovascular invasion at diagnosis. Most of the patients had a positive clinical examination as a palpable mass. The accuracy of mammography is inferior in young women, who have denser breast tissue. In a fifth of our patients, mammography did not show the lesion, which was detected by sonography.

C-0215

Fat necrosis in TRAM flaps mimicking malignancy

A. Roditi, R. Arkun; Izmir/TR

Learning Objectives: To illustrate the mammographic spectrum of fat necrosis in patients with transverse rectus abdominis myocutaneous (TRAM) flaps and the challenge to differentiate these benign changes from malignancy.

Background: Fat necrosis in breasts with TRAM flaps has a wide spectrum of mammographic findings and these findings may occasionally mimic malignancy. With the use of mammography in TRAM flaps, radiologists are becoming aware of the different findings in these patients, and especially of fat necrosis. In a five year period of follow-up, the spectrum of fat necrosis changing from a bandlike increased density with accompanying pleomorphic calcifications to posttraumatic coarse heterogeneous calcifications are discussed.

Procedure Details: As part of the routine radiological workup of patients with TRAM flaps, mammography of the flap is being performed regularly in some institutions. The mammographic exam is performed with the routine projections used in screening mammography which are the craniocaudal (CC) and the mediolateral oblique (MLO) projections.

Conclusion: It is important to be aware of the reasons and frequent sites of complications occurring in TRAM flap patients and also the diversity of mammographic findings ranging from fat necrosis to malignancy. One should search diligently for all changes that may be a sign of early malignancy and all efforts should be used in the differentiation of fat necrosis from malignancy without compromising the cosmetic results.

C-0216

Diagnostic value of FDG PET-CT for detecting primary breast malignancy: Comparison with other image modalities and histopathologic correlation

N. Jung, J. Lee, S. Kim, B. Song, S. Jung, J. Byun; Seoul/KR

Purpose: To compare the diagnostic value of 18F-FDG PET-CT in detecting the primary breast malignancy with other imaging modalities and to determine whether detectability of PET-CT depends on any factors.

Methods and Materials: We retrospectively evaluated pathologically proven 36 lesions in 34 patients who underwent preoperative FDG PET-CT during the past 9 months. Other imaging modalities were also evaluated: Mammography (N = 32), US (N = 28) and MR imaging (N = 10) in the same population. Sensitivities of each modality were obtained. We also statistically analyzed PET-CT positive and negative groups in relation to SUV, size, nuclear grade and differentiation.

Results: 35 lesions among 36 were malignant breast lesions. Sensitivities of FDG PET-CT, mammography, US, and MR imaging for detecting malignant breast mass were 74% (26/35), 81% (27/33), 100% (29/29) and 91% (10/11) respectively. SUV(P) and SUV(M) in PET-CT positive group were significantly higher than those of PET-CT negative group [p < 0.0001 for SUV(P) and p = 0.0002 for SUV(M)]. The size of the mass in PET-CT positive group was also significantly larger than that in PET-CT negative group (p = 0.0090). Nuclear grade of the tumor was significantly different (p = 0.1265) between the two groups if the significance level of the test was set to 0.15. However, the tumor differentiation was not significantly different between two groups (p = 0.8507).

Conclusion: The sensitivity of the FDG-PET in detecting primary breast cancer is lower than those of other imaging modalities. The detectability of the FDG PET-CT might be degraded when the tumor is small in size and/or has a low nuclear grade.

C-0217

Breast manifestations in patients with systemic lupus erythematosus (SLE)

M. Kim¹, H. Kim¹, H. Yoon², S. Kim¹, W. Moon¹, S. Chung³, D. Kim¹, H. Shin¹, J. Park⁴; ¹Seoul/KR, ²Bucheon/KR, ³Bundang/KR, ⁴Madison, WI/US

Learning Objectives: To learn various radiological findings of the breast in patients with SLE. To understand the mechanisms of breast manifestations in patients with SLE.

Background: SLE may cause variable clinical presentations and pathologic patterns. Breast involvement with SLE is not frequent. We observed 15 patients with breast manifestations of SLE during the recent 5 years. In this exhibit, we will describe the breast manifestations in patients with SLE.

Procedure Details: Real-time ultrasonography of both breast and axilla and routine mammography (craniocaudal and mediolateral oblique view) were performed in these patients with SLE. Findings of breast manifestations of SLE included lupus mastitis and panniculitis with dystrophic calcifications (n = 3), bilateral or unilateral (dependent) breast edema due to heart failure or chronic renal failure (n = 3), benign tumors (n = 4), axillary lymphadenopathy (n = 2), breast cancer (n = 2) and infection due to steroid therapy (n = 1).

Conclusion: Various radiologic findings of breast manifestations of SLE including primary and secondary consequences of the disease will be exhibited with clinical and pathologic correlation.

C-0218

Male breast cancer: Retrospective analysis of 58 patients

D.N.D. Freitas¹, L. Orvalho²; ¹Funchal/PT, ²Lisbon/PT

Purpose: Male breast cancer is a rare cancer in men representing less than 1% of all breast cancer. A review of clinical aspects, risk factors, imaging, treatment and outcome was performed.

Methods and Materials: A 10 year list of male patients with breast cancer treated in Instituto Português de Oncologia de Lisboa was requested from ROR-Sul (Oncology registry). Clinical files were reviewed for relevant information.

Results: Average age on presentation was 66 years, (range 35-85). Most patients (75.9%) reported a nodule in the breast. Only 11% had family history of breast cancer. On mammography, a nodule was the most frequent finding, microcalcifications represented only 4%. The left breast accounted for 59% of cancers and the central region harboured 75% of cases. Staging revealed 36% of patients in stage II, 38% stage III, 7% stage IV and only 17% stage I. Invasive ductal carcinoma represented 86%. Treatment included modified radical mastectomy (65% of patients), radiotherapy (65%), hormone therapy (70%) and chemotherapy (48%). After treatment 52% remained cancer free, whereas 24% had distant metastases and 10.3% had another cancer. Most metastases were located in bone and lungs.

Conclusion: Male breast cancer is diagnosed in aged patients, mostly for a nodule in the breast. Neither family history nor risk factors were seen in the majority of patients. Male breast cancer is diagnosed in more advanced stages. Male breast cancer has a survival rate equal to breast cancer in women when adjusted for staging, but advanced staging implies worse prognosis in men.

Scientific and Educational Exhibits

C-0219

Evaluation of the use of MammoTool: An interactive, web-based, educational approach for the interpretation of mammographic studies
L. Bacigalupo¹, E. Soldi¹, P. Bonetto¹, G. Gozzi², A. Ganzetti², G.M. Conti³,
¹Genoa/IT, ²Como/IT, ³Parma/IT

Purpose: Among the causes of missed breast cancer there are lack of perception and incorrect interpretation. We designed MammoTool (MT), a web-based, interactive software for mammographic teaching files, aimed at training radiologists to correctly read mammograms. MT presents the user a set of cases. The user is expected to: Interpret each case (also with the use of a magnifying lens and other image manipulation tools), provide a grade of certainty with which he evaluates the image as being normal or abnormal and mouse-click on the possible lesion (only malignant lesions are considered in this study). We tested MT to evaluate the performance of a group of radiologists.

Methods and Materials: We tested MT on 67 radiologists. Each radiologist had to interpret 20 cases sorted randomly out of a database containing 68 cases (50% positive for malignancy and 50% negative for malignancy). Questionnaires were collected from these radiologists regarding their seniority, expertise and the use of MT.

Results: MT was user-friendly and no particular problems occurred during the test. We observed that the best results were obtained by radiologists who read more than 4000 mammographic studies every year. The years of expertise were less well correlated with the results.

Conclusion: The radiologist with MT can learn to interactively analyze mammographic teaching files with different image manipulation tools. After evaluating a series of cases, they will be able to assess their skills and performance, in terms of ROC and IROC curves. They may finally review the resolved cases and comprehend the errors.

C-0220

Radiologic evaluation of the inflammatory breast disorders
J. Sabate, M. Clotet, V. Villalba, T. Salinas, A. Gomez; Barcelona/ES

Purpose: To describe the radiological features in these entities that very infrequently involve the breast.

Methods and Materials: We include cases of: sarcoidosis, Wegener granulomatosis, amyloidosis, tuberculosis, Churg-strauss disease, Necrobiotic xantogranulomatosis and diabetes mastopathy. Image diagnostic Methods: mammography (M), ultrasound (US) and MR with pathological correlation have been obtained.

Results: Wegener granulomatosis may manifest as an irregular high-density mass simulating breast cancer. Sarcoidosis use to be a well-defined mass usually accompanied by lymph node enlargement. Amyloid tumor manifests as a calcified mass. Tuberculosis usually simulates malignancy. Churg-strauss disease manifests with diffuse and bilateral involvement. Diabetic fibrous mastopathy presents as a very dense breast tissue at M, suspicious of malignancy at US. Necrobiotic xantogranulomatosis of the breast manifest as a multiples ill-defined masses at M and hypoechoic at US. Granulomatous lobular mastitis presents as a mass suspicious of malignancy.

Conclusions: Radiologist should know the findings of these entities specially when malignant appearance is encountered.

C-0221

Use of macroaggregates of TC-99m labelled human serum albumin (MAA) for non palpable breast lesions marking. An easy new technique with minimum surgical invasion.

M. Ruiz, C. López, M. Valle, M. Cortés, R. Pardo, C. Pastor, T. Cañuelo, C. Martínez, C. Molino; Ciudad Real/ES

Purpose: Radioguided occult lesion localisation (ROLL) using MAA is proposed to replace standard techniques (wire hook localization) to biopsy non-palpable breast lesions. MAA is a radiotracer with large particles that cannot migrate rapidly by lymphatic and it is useful for marking.

Methods and Materials: From May 2003 to August 2004, 44 patients suspected to have occult breast carcinoma (BIRADS 4-5) were enrolled in the study. Three hours before surgery, 300-500 µCi in 0.1 ml of volumen were injected into the center of the lesion using stereotactic mammographic or ultrasound guidance. After that, anterior and lateral scintigraphy were obtained. All patients underwent open surgical biopsy guided by gamma probe and the specimen was radiographed to verify complete removal of the lesion.

Results: Radiological findings suspected of carcinoma were: Irregular cluster microcalcifications (21), nodules (5), spiculated lesions (17) and architectural distortion (1). We injected radiotracer under US guidance in 3 patients and under

stereotactic guidance in 41. Mammography and scintigraphy revealed that the radiotracer was correctly positioned in a small area in 42/43. The rate of confirmation of lesion removal was 100%. Pathological results were: 19 benign lesions, 3 atypical ductal hyperplasia and 22 infiltrating carcinoma.

Conclusion: ROLL with MAA is an alternative technique to be used for marking occult breast lesions that allows an easy and accurate removal with a directed surgical access avoiding displacement and migration associated with traditional methods.

C-0222

The role of CT in local staging of breast cancer

T. Uematsu, S. Yuen, H. Ikuma, A. Seki, T. Aramaki, N. Morimoto, M. Endou, H. Furukawa; Shizuoka/JP

Learning Objectives: 1) To describe the MDCT techniques used for local staging of breast cancer. 2) To illustrate the MDCT findings compared to MR imaging findings in breast cancer local staging. 3) To discuss the consequences of these findings on treatment and outcome. 4) To discuss both the additional value and the pitfalls of MDCT in breast imaging.

Background: The occurrence of local tumor recurrence after breast-conserving treatment is related to microscopic margin involvement. An adequate excision of the tumor may be necessary to obtain optimal local tumor control. CT can reveal the accurate determination of disease extent within the breast that is not detected on mammography, ultrasonography, or physical examination. Therefore, CT has become an important part of work up of these patients in some institutions. However, still uncertainty exists concerning the additional value of CT compared to MR imaging staging in determining tumor extent and the consequence of these findings on treatment choice and outcome.

Procedure Details: Based on our experience in over 100 patients with breast cancer, we will illustrate the CT findings compared the MR imaging findings in breast cancer local staging.

Conclusion: We discuss the consequences of the CT findings compared the MR imaging findings, with emphasis on the additional value and pitfalls of CT in local staging of breast cancer.

C-0223

Alternative utilities of a breast marking coil

J.J. Noguera, P.D. Dominguez, E. De Luis, L. Diaz, L.J. Pina, G. Zornoza; Pamplona/ES

Learning Objectives: To review the main indications for breast marking coils. To show alternative uses for breast marking coils.

Background: Breast markers have been widely used after vacuum-assisted biopsies if the lesion was completely removed. Also these markers have played an important role in marking breast tumours that undergo neoadjuvant chemotherapy, in order to localize the tumour bed if the lesion could not be macroscopically identified.

Procedure Details: We use the marker IDL-19.5-9.0-4-U-DM (Cook, Bjaevskov, Denmark). This marker may be guided by stereotaxis or ultrasound. The alternative utilities of this coil are: a) to mark an ultrasound detected lesion in order to correlate it with mammographic findings; b) to mark the tumour bed after breast conserving therapy in order to facilitate posterior interstitial radiation therapy; c) to mark a lesion only seen in one view in order to facilitate the most appropriate approach. Thirty markers were employed. One of them could not be properly delivered. The remaining cases were successfully performed. No displacement was observed in any case.

Conclusion: This procedure is effective in order to mark breast lesions, allowing posterior interventional procedures or to correlate ultrasonographic and mammographic findings.

C-0224

Concordance of the breast imaging reporting assessments and final diagnosis for diagnostic mammography and sonography.

J.H. Lorenzen, A.K. Wedel, B.W. Lisboa, G. Adam; Hamburg/DE

Purpose: To assess the final clinical outcome of BI-RADS categories for diagnostic mammography and sonography.

Methods and Materials: We analysed 632 mammography and sonography examinations from women with diagnostic indications (age: 23-100, mean 58) performed during 2001 and 2003. Final clinical outcome (Histology: 502; follow-up: 130) was ascertained in each case and concordance of BI-RADS-categories for mammography and sonography and final diagnosis were analysed.

Results: Final diagnosis yielded 231 benign lesions (37%) and 401 cancers (63%).

Scientific and Educational Exhibits

Concordance of BI-RADS Assessment and final outcome was documented in 542 cases (85.8%). There were 11 category 1 and 2 assessments and the positive predictive value was 0% (0 malignant lesion of 11 cases). 140 lesions were classified with BI-RADS 3. The PPV was 3% (5 of 140 lesions). There were 267 category 4 lesions (42%) with a PPV of 77% (186/267) and finally 214 BI-RADS 5 lesions with a PPV of 98% (210/214). Overall sensitivity of mammography was 93% with specificity of 72% and for sonography 86% and 74%. The highest correlation between BI-RADS category and final outcome was documented for the diagnostic combination of mammography and sonography with a kappa-value of 0.806 ($p < 0.001$), followed by mammography (kappa: 0.677) and sonography (kappa: 0.624). The overall correlation was 0.673 ($p=0.000$).

Conclusion: BI-RADS assessments of diagnostic mammography and sonography yields a higher cancer detection rate, especially for category 4, compared with screening examinations. Combination of mammography and sonography for diagnostic indications showed substantially the highest concordance of BI-RADS category and final diagnosis.

C-0225

Unusual breast lesions: Radiologic-pathologic correlation

M. Bernathova, M. Dünser, G. Retzl, G. Bodner, B. Zelger; Innsbruck/AT

Learning Objectives: To show the imaging findings in uncommon breast lesions and provide a radiologic-pathologic correlation.

Background: Unusual breast lesions can present a diagnostic challenge. Imaging findings in these entities are nonspecific, the benign lesion can clinically and radiologically mimic malignant tumour. The exact diagnosis is usually made by excisional biopsy.

Procedure Details: Retrospective review of radiologic findings in 20 patients with uncommon breast lesions examined during March 2000 and March 2004 was performed. Patients underwent diagnostic mammography, breast sonography and breast MR imaging. We chose 7 uncommon benign and malignant conditions (primary non-Hodgkin lymphoma of the breast, pseudolymphatic infiltration of the nipple, granular cell tumour, metastasis of the bronchial carcinoma to the breast, primary angiosarcoma of the breast, mucinous carcinoma with large cystic dilatation of the duct and tubular carcinoma) where the correct diagnosis was done by core needle biopsy and describe the radiological and pathological findings.

Conclusion: Learning the histological appearance helps to understand the radiological finding. Familiarity with variety of uncommon breast lesions is important for correct clinical management of disease.

C-0226

Unusual presentations of ductal carcinoma in situ: Radiological and pathological correlation

D.M. Duke, M.K. Kennedy, J. Kerr, E. Doyle, M.M. McNicholas, H.M. Fenlon, F. Flanagan; Dublin/IE

Learning Objectives: Our exhibit will review unusual clinical and radiological manifestations of breast ductal carcinoma in situ (DCIS) with the findings at mammography, sonography and magnetic resonance imaging being presented. Pathological correlation will also be outlined with particular reference to the incidence of concurrent carcinoma in situ.

Background: DCIS is heterogeneous in its mammographic, clinical and histological presentation and consequently its biological behaviour. It is most commonly diagnosed in asymptomatic women after the detection of micro-calcifications on screening mammograms. However, it may present as a palpable mass, spontaneous nipple discharge or Paget's disease. On mammography it may be detected as a noncalcified, macrolobulated mass with partially distinct margins, a spiculated mass, distortion or parenchymal asymmetry. This spectrum of DCIS manifestations presents a diagnostic dilemma for clinicians, radiologists and pathologists.

Procedure Details: Since its inception in 2000, the Eccles unit of the Irish National Breast screening programme has invited in excess of 70,000 women, aged 50-64, for mammography. 110 of these have been diagnosed with DCIS. We identified a subgroup of these patients who did not have the classical imaging features of microcalcifications on mammography. The imaging findings of these patients were correlated with pathological findings and clinical outcome. A pictorial review of our results will be displayed.

Conclusion: Unusual manifestation of DCIS causes a diagnostic dilemma for all involved in the management of breast cancer. It must be included as a differential diagnosis for a spectrum of mammography and clinical findings in order to correctly identify and treat these patients.

Cardiac

C-0227

MR and CT imaging of partial and total cavo-pulmonary connections: A guide to assessment of the fontan circuit for the uninitiated

A. Crean, Y. Provost, N. Paul, N. Merchant; Toronto, ON/CA

Learning Objectives: 1. To illustrate the range of cavopulmonary connections in existence. 2. To illustrate potential complications of the Fontan circuit. 3. To illustrate the relative merits of MR vs CT in this patient group.

Background: The Fontan procedure (cavo-pulmonary anastomosis) is used worldwide for the augmentation of pulmonary blood flow in the setting of tricuspid or pulmonary atresia. The original operation has been superceded by a number of variants which can confuse the uninitiated. Radiologists need to appreciate the diversity of cavopulmonary connections when planning and reporting studies in these patients. This exhibit reflects our experience with this patient population over the last 5 years.

Imaging Findings: We discuss: a) types of cavo-pulmonary connection. b) pitfalls in the assessment of Fontan (and/or pulmonary) thrombosis. c) what imaging sequences are most appropriate for full evaluation of the Fontan circuit, including how to quantitate cavopulmonary flow. d) how to recognise the "failing Fontan".

Conclusion: We aim to demystify the Fontan procedure for general radiologists and provide sufficient instruction to enable competent assessment of the functional status of the Fontan circuit.

C-0228

Feasibility of rapid-sequence ^{31}P -MRS of the heart in cardiac patients

K. Chida, H. Otani, H. Saito, T. Nagasaki, Y. Kagaya, M. Kohzuki, M. Zuguchi, S. Takahashi, K. Shirato; Sendai/JP

Purpose: The most critical element impeding the routine use of human cardiac phosphorus-31 magnetic resonance spectroscopy (^{31}P -MRS) is its low S/N ratio and consequent long examination time. The purpose of this paper was to determine the clinical feasibility of rapid-sequence ^{31}P -MRS of the heart in cardiac patients using a 1.5-Tesla clinical MR instrument.

Methods and Materials: The rapid-sequence ^{31}P -MRS procedure using a two-dimensional phosphorus chemical-shift imaging sequence in combination with 30-mm axial slice-selective excitation was phase encoded in arrays of 8x8 steps with an average of four acquisitions. Its acquisition time ranged from 3 to 5 minutes, depending on the heart rate. Twenty-three cardiac patients (dilated cardiomyopathy (DCM): 13 cases, hypertrophic cardiomyopathy: 3 cases, hypertensive heart diseases: 3 cases, aortic regurgitation: 1 case, and old myocardial infarction (OMI): 3 cases) were examined using rapid cardiac ^{31}P -MRS. The student's *t* test was used to compare phosphocreatine (PCr) / adenosine triphosphate (ATP) ratios from the cardiac patients with those of the control subjects ($n = 13$).

Results: The myocardial PCr/ATP ratio obtained by rapid ^{31}P -MRS was significantly lower ($p < 0.001$) in DCM patients (1.82 ± 0.33 , mean \pm SD), and in patients with global myocardial dysfunction (combined data for 20 patients (except OMI): 1.89 ± 0.32), than in normal volunteers (2.96 ± 0.59). These results are similar to previous studies. The anterior-septal myocardial PCr/ATP ratio was also lower (1.54) than in the patients with inferior infarction (3.17) and posterior infarction (2.31).

Conclusion: Rapid-sequence ^{31}P -MRS may be a valid diagnostic tool for patients with cardiac disease.

C-0229

Characteristics of myocardial enhancement in dilated cardiomyopathy with contrast-enhanced MR imaging

J. Nam, B. Choi, J. Seo, Y.-J. Kim, T. Kim, K. Choe; Seoul/KR

Purpose: With contrast-enhanced MR imaging (ceMRI), atypical patterned enhancement of myocardium has been reported in non-ischemic dilated cardiomyopathy (DCMP). We studied the characteristics of enhancement in DCMP by ceMRI.

Methods and Materials: Thirty nine patients (mean 59 ± 12 yrs) with DCMP and normal coronary arteries proven by conventional coronary angiography underwent ceMRI with 10-minute delay after contrast administration of Gd-DPTA at 0.2 mmol/kg. Thirty patients with myocardial infarction underwent ceMRI with the same protocol for comparison. The signal intensity of skeletal muscles on the chest wall (Slsm) was used as reference in the same patient. Sls of hyperenhanced infarcted myocardium (Slhm), remote myocardium (Slrm) from hyper-

Scientific and Educational Exhibits

hanced infarction, abnormally enhanced myocardium (SI_{em}) in DCMP, nonenhanced myocardium (SI_{nem}) in DCMP were measured and analyzed.

Results: Visual assessment of the myocardium in patients with DCMP resulted in no enhancement in 13 (33%) patients, and enhancement in 26 (67%), while all patients with infarction showed hyperenhancement on the infarcted region. The SI_{em}/SI_{nem} in DCMP was 4.02 ± 2.46 , SI_{nem}/SI_{em} 0.79 ± 0.67 , SI_{hm}/SI_{em} 6.73 ± 3.68 , SI_{re}/SI_{em} 0.79 ± 0.91 . Enhancement in DCMP was mild to moderate in 18 (70%), strong in 4 (15%) and both in 4 (15%). The most characteristic pattern were enhancement at base (42.3%), septum (42.3%), middle layer (34.6%), and enhancement with diffuse transmural pattern (46.2%). EF and EDV showed no significant correlation with the abnormal myocardial enhancement in DCMP.

Conclusions: The mild to moderate degree of diffuse transmural or middle layer enhancement especially on the basal septum is a frequent and characteristic enhancement pattern of myocardium in DCMP patients.

C-0230

Noninvasive investigation of cardiac metabolism in patients with hypertensive heart disease (HHD) by ^{31}P -MR spectroscopy

R. Rzanny, J.-P. Heyne, A. Hansch, U. Leder, J.R. Reichenbach, W.A. Kaiser; Jena/DE

Purpose: Hypertension with chronically increased blood pressure can induce left ventricular hypertrophy and fibrosis and is one of the most common risks for the development of a congestive heart failure. In this study the correlation between changes in the ^{31}P -metabolism and left ventricular end-systolic volume (LVEF) in patients with HHD was investigated non-invasively by ^{31}P -MRS.

Method/Materials: 36 patients with HHD and 20 volunteers without any symptoms of myocardial disease were examined at 1.5 T using a surface coil (300 mm \times 300 mm) and a ECG-gated ^{31}P -CSI sequence (voxel size measured: 40 x 40 x 100 mm³; reconstructed: 20 x 20 x 100 mm³). 24 patients had normal ventricle sizes and ejection fractions (EF) (compensated HHD), whereas 11 patients had a restricted EF (decompensated HHD).

Results: In all patients a decreased PCr/ γ -ATP ratio was observed. However in patients with a decompensated HHD the PCr/ γ -ATP ratio was lower than in patients with compensated HHD ($p = 0.012$). The PCr/ γ -ATP showed a linear correlation with the LVEF for all patients (Pearson coefficient: 0.39; $p = 0.025$). In addition, a decreased PDE/ γ -ATP ratio was observed in patients with decompensated HHD compared to volunteers.

Conclusions: The present results support the hypothesis of an altered energy metabolism in HHD. The small but significant linear correlation of our estimated PCr/ γ -ATP ratios with the LVEF supports the assumption that left ventricular dysfunction is related to impairments of the energy metabolism. The reduced PDE/ γ -ATP ratio in patients with decompensated HHD can be interpreted as a sign for hypertrophic growth.

C-0231

MR imaging for the diagnosis and follow-up of myocarditis

M.M. Huguet, J. Vila, N. Oller, C. Moure, P. Lozano, E. Delgado, G. Sabin; Barcelona/ES

Purpose: To evaluate the potential of ECG-gated breath-hold MR imaging in diagnosing acute myocarditis. Myocarditis is under-diagnosed with clinical criteria generally used for diagnosis. Diagnostic tools currently available are unsatisfactory. We tested the hypothesis that inflammation is reflected by signal changes in contrast-enhanced magnetic resonance imaging.

Material and Methods: We assessed 21 consecutive patients with symptoms of chest pain and altered ECG. Fifteen had elevated troponin I as indicator of myocardial damage. Coronary heart disease was excluded in 19 patients. One patient with coronary disease required a QCTP. MR images were performed at 1.5 T CVI (GE). Both cine and contrast-enhanced short axis CMR images were performed. Cine CMR was performed using a steady-state free-precession sequence. Contrast CMR images were acquired on average 5 to 10 minutes after contrast (0.2 mmol/Kg Gd-DTPA), using a segmented IR-GRE technique. Five patients were re-examined by MR imaging 3 months later.

Results: Contrast enhancement was present in 16 patients of 21 (76%). Regions of contrast enhancement has a subepicardial distribution and were most frequently located in the lateral wall (12 cases) and less frequently in the inferior wall (4 cases). No wall motion abnormalities were found. CMR at follow-up three months after the initial CMR, demonstrate a mild decrease in the average area of enhanced tissue.

Conclusion: Subepicardial enhancement is a frequent finding in cases of acute myocarditis. Contrast media-enhanced MR imaging visualizes the localization, activity, and extent of inflammation and may serve as a powerful noninvasive tool in the diagnosis and follow-up of myocarditis.

C-0232

Magnetic resonance imaging and non-compaction of the ventricular myocardium: Unusual or underdiagnosed disorder?

G. Garcia Continente, T.M. De Caralt, J.R. Ayuso, C. Pare, M. Sitges, C. Ayuso, R.J. Perea, J. Ramirez, A. Tomasello; Barcelona/ES

Learning Objectives: To illustrate typical morphological features by cardiac magnetic resonance imaging in non-compaction ventricular myocardium.

Background: Non-compaction of the myocardium is a rare unclassified congenital cardiomyopathy. The etiology is not clear but an arrest of intrauterine myocardial morphogenesis is the accepted basic mechanism. Early diagnosis is important in order to prevent the high incidence of cardiovascular complications such us heart failure, systemic embolism and arrhythmias. The increasing use of magnetic resonance in the study of cardiac diseases has lead to an increment in the recognized cases of this rare disorder. Therefore, to have knowledge of the imaging findings of this process is an important issue for radiologists working on cardiac magnetic resonance.

Imaging Findings: We report eight patients who were diagnosed of non-compaction left ventricle myocardium by contrast-enhanced echocardiography, and confirmed by cardiac magnetic resonance. T1-weighted spin-echo image (black blood) demonstrated two layer structure: a thin low intensity compacted epicardial portion and a thicker high intensity endocardial layer with prominent trabeculations and deep intertrabecular recesses which were filled with blood. Cine-MR gradient-echo sequences allow functional qualitative assessment: in all cases the prominent trabecular meshwork was more evident during diastole, and also revealed hypokinesia of the non-compacted ventricular wall.

Conclusion: Cardiac magnetic resonance imaging is a non-invasive method which provides high-resolution imaging of non-compaction myocardium, and permits us to confirm and evaluate the severity and prognosis of this cardiac disorder.

C-0233

CT and MR imaging of pericardial disease

S.P. Prabhu¹, A. Neelakantan²; ¹Bristol/UK, ²Hereford/UK

Learning Objectives: 1. To illustrate the utility of computed tomography (CT) and magnetic resonance (MR) imaging in the evaluation of pericardial disease. 2. To demonstrate the anatomy of normal pericardium and show how CT and MR imaging enable exquisite delineation of pericardial anatomy. 3. Illustrate examples where CT and MR imaging have assisted in noninvasive evaluation of loculated or hemorrhagic pericardial effusions, constrictive pericarditis and pericardial masses including congenital and neoplastic lesions. 4. Elaborate CT and MR imaging diagnostic criteria for pericardial constriction.

Background: Both CT and MR imaging are being increasingly used either as an adjunct or as a substitute to echocardiography as they provide a larger field of view and allow visualisation of the entire chest and associated abnormalities in the mediastinum and lungs. The main advantage of CT and MR imaging is the excellent soft-tissue contrast.

Procedure Details: Using examples from our tertiary care institution archives, we illustrate various examples of pericardial pathology investigated by CT and MR imaging. Anatomy of normal pericardium and associated cardiac structures are explained followed by description of pathological entities and criteria for their diagnosis on CT and MR imaging.

Conclusion: It is important to understand the normal anatomy and pathological appearances of the pericardium even for the general radiologist as there will be an increasing demand for imaging of the pericardium in the near future.

C-0234

Catheter deployed devices in adults with congenital heart disease:

A radiological perspective of normal appearances and complications

V.S. Warbey, M. Mullen, S.P. Padley; London/UK

Learning Objectives: To appreciate the range of catheter deployed devices available in the management of adults with congenital heart disease. To understand the indications for each device and the normal post-deployment radiological appearances. To recognise complications that may arise following device placement.

Background: Congenital heart disease (CHD) is common, occurring in approximately 0.8% of newborn infants. The success of paediatric cardiology programs has created a growing population of young adults who may require further intervention. Increasingly, these interventions may involve catheter deployment of a range of new devices. Radiologists should be able to recognise such devices and may be asked to perform additional cross-sectional imaging to evaluate device efficacy.

Scientific and Educational Exhibits

Procedure Details: Catheter interventions are undertaken to close abnormal vascular communications including atrial and ventricular septal defects, patent foramen ovale and ductus arteriosus. In addition, occlusion of coronary artery fistulae, postoperative fenestrations and aortopulmonary collaterals may be undertaken. Dilatation and stent placement is employed in conditions such as aortic coarctation and pulmonary artery stenosis, and to increase flow through surgical conduits and venous baffles. The indications for use, devices available and outcomes will be illustrated in each case.

Conclusion: The role of the chest radiograph is central to the management of adults who have undergone catheter intervention for congenital heart disease. Recognition of the normal and abnormal appearances following deployment of these devices is increasingly important as they become more frequently encountered in radiological practice.

C-0235

CT and MR imaging of benign primary cardiac neoplasms with echocardiographic correlation

F. Todua, M. Razmadze, G. Tsivtsivadze, S. Kakhadze; *Tbilisi/GE*

Purpose: Analyze the advantages and disadvantages of CT, MR imaging and transthoracic echocardiography (TE) in the assessment of heart neoplasms.

Material and Methods: 46 patients (age 8-68 years) with suspected heart neoplasms were examined with TE, CT and MR imaging. Examinations were performed under clinical indications in preparation for surgery or to obtain a precise diagnosis.

Results: In 37 patients the diagnosis of intracardiac tumor (21 myxomas, 6 rhabdomyomas, 5 lipomas, 3 fibromas, 2 cardiac echinococcosis) was confirmed pathologically. In 9 patients echocardiographic diagnosis was not confirmed. In these cases MR imaging and CT revealed an anatomic variant or other abnormality that had been interpreted as a probable mass on the echocardiogram.

Conclusion: All methods allow evaluation of tumor size, location and structure. TE is the primary modality for imaging of intracardiac disease. It provides high-resolution, real-time images, especially improved with the introduction of new ultrasonographic imaging techniques such as tissue harmonics. The resolution of CT and MR imaging is superior to that of TE, and both modalities proved to be useful for detection of the tumor, depiction of contour, relation with other cardiac structures, also allowing imaging of the entire mediastinum and evaluation of the extracardiac extent of disease. In comparison to MR imaging, CT is capable of detecting calcifications, which is an important variable in the differential diagnosis of cardiac neoplasms. In addition, CT is faster, easier to perform, and generally has more reliable image quality. MR imaging has better soft-tissue contrast than CT and allows much greater flexibility in the selection of imaging planes.

C-0236

Measurement of cardiac high-energy-phosphate metabolites in dilated cardiomyopathy (DCM) by ^{31}P -MR spectroscopy

A. Hansch, R. Rzanny, J.-P. Heyne, U. Leder, J. Reichenbach, J. Boettcher, W.A. Kaiser; *Jena/DE*

Introduction: Dilated cardiomyopathy (DCM) is accompanied by an impaired cardiac energy metabolism. The aim of this study was to investigate whether the PCr/ATP-ratio is reduced in patients with DCM by using spectroscopic chemical shift imaging (CSI). Additionally, we evaluated how this index correlates with the left ventricular ejection fraction (LVEF) as an established prognostic factor of heart failure.

Methods and Materials: This study involved 20 volunteers and 15 patients with severe symptoms and 10 patients with moderate symptoms of DCM. Cardiac ^{31}P -MR measurements were performed with a 1.5 T whole body scanner. Peak areas were evaluated for cardiac high-energy phosphates (PCr, ATP), as well as for 2,3-diphosphoglycerate (2,3-DPG) and phosphodiesters (PDE).

Results: PCr/ γ -ATP ratio was significantly decreased in patients with moderate and severe DCM (PCr/ γ -ATP in severe DCM 1.31 ± 0.38 , PCr/ γ -ATP in moderate DCM 1.63 ± 0.33 , PCr/ γ -ATP in volunteers 2.07 ± 0.17). PCr/ γ -ATP ratios showed a linear correlation with reduced left ventricular ejection fractions. PDE/ γ -ATP ratios were significantly increased in patients with severe DCM (mean PDE/ γ -ATP = 1.49 ± 0.56) as compared to volunteers (PDE/ γ -ATP = 1.07 ± 0.27).

Discussion: Applying ^{31}P -MRS with commonly available 2D-CSI sequences is a valuable technique to evaluate DCM by determining PCr/ATP ratios non-invasively. In addition to reduced PCr/ATP ratios observed in patients suffering from DCM, significantly increased PDE/ATP ratios were found in patients with severe DCM.

C-0237

MR imaging of cardiac and paracardiac masses: A pictorial review

G.K. Schneider, R. Seidel, P. Fries, I. Kindermann, M. Boehm, H. Winter; *Homburg a.d. Saar/DE*

Learning Objectives: Based on typical MR findings algorithms that include other diagnostic modalities like findings on catheter angiography or perfusion measurements will be presented to give the reader a maximum spectrum of findings to characterize cardiac and paracardiac masses.

Background: Although cardiac masses are most frequently detected on echocardiography, MR imaging is the method of choice to accurately evaluate and further characterize cardiac tumors. However the maximum information about a suspected cardiac mass is gained if all clinical information together with results of echocardiography, computed tomography, catheter angiography and endomyocardial biopsy are taken into consideration.

Imaging Findings: Case studies presented include common and rare benign and malignant tumors as well as tumor-like lesions with correlation to histology and surgical images. MR imaging results will be presented and discussed together with findings in other imaging modalities and typical and atypical manifestations of the different tumors will be discussed.

Conclusion: MR imaging has a major impact on the work up of cardiac and paracardiac masses as an accurate diagnostic tool for further characterisation and therapy planning.

C-0238

Utility of myocardial edema to differentiate between acute and chronic myocardial infarctions (MIs) and its correlation with the extension of necrosis: A T2-weighted and delayed enhancement (DE) cardiovascular-MR (CMR) study

M. Francone, I. Carbone, K. Lanciotti, E. Algeri, A. Ascarelli, M. Cavacece, F. Fedele, R. Passariello; *Rome/IT*

Purpose: Previous studies have shown that myocardial edema typically appears in the acute phase of MI after reperfusion and gradually resolves with infarct healing. Therefore, we intended to investigate the feasibility of T2-weighted CMR to discriminate acute from chronic MIs and to correlate the extension of edema with DE findings.

Materials and Methods: Forty-one patients with a previous history of MI were included in the study; 19 were studied in the acute phase (< 14 days) after MI, 22 had a chronic history of MI (> 30 days). In all patients a CMR protocol including T2-weighted black-blood and DE sequences was acquired using a 1.5-T CMR-system. In order to discriminate acute from chronic MI, the presence of edema and DE was visually assessed by two blinded observers. When detected, the volume of edematous myocardium was correlated with the extension of necrosis as shown by DE acquisitions.

Results: After images analysis, myocardial edema was detected as a transmural area of hyperintense T2-weighted signal in 19/19 patients with acute MI and 2/22 chronic patients. The combined assessment of T2-weighted and DE images yielded a specificity of 91% to differentiate acute from chronic lesions. The volume of edema was significantly larger than necrosis in all cases (mean +18.6%, p < 0.05) and a good correlation was found between edema and extension of MI ($r = 0.86$, p < 0.01).

Conclusions: Our study suggests that a combined approach of T2-weighted and DE CMR-sequences enables differentiation of acute from chronic MIs; T2-weighted images can depict the presence of edema in acute patients overestimating the extension of necrosis.

C-0239

Magnetic resonance for follow-up after orthotopic cardiac transplantation

G. Puppini, S. Quintarelli, L. Tomasi, M. Iafrancesco, G. Destro, S. Montemezzi, G. Gortenutti; *Verona/IT*

Purpose: Patients who underwent orthotopic cardiac transplantation (OCT) require several evaluations of myocardial function and of morphology of caval anastomosis (CA). The aim of this work is to determine whether magnetic resonance (MR) might be useful as a one-step technique to evaluate patients who underwent OCT.

Methods and Materials: 31 patients underwent MR evaluation (1.5 T) at least 12 months after OCT to assess cardiac morphology and function. We used T1-weighted sequences in order to analyze the morphology of anastomoses involving aorta, pulmonary artery and cava veins. We measured ejection fraction (EF) and regional function (RF) of left ventricle (LV), performing short-axis dynamic sequences. Segmental wall thickening was scored 0 if normokinetic, 1 if hypokinetic and 2 if dyskinetic. Data are expressed as mean \pm SD.

Scientific and Educational Exhibits

Results: Morphologic assessment was feasible for all vascular anastomoses, in particular for the caval ones which are not easily determined by either ultrasound or angiography. The diameter of postcaval anastomoses is 19.5 ± 4.2 mm (9 ± 1.7 mm/m²), while the diameter of precaval anastomoses is 16.6 ± 3.1 mm (9 ± 1.7 mm/m²). Out of 496 segments 487 (98.1%) are normokinetic, 9 (1.9%) hypokinetic and there are no dis/akinetik segments (mean score = 0.018 ± 0.13). We find a trend toward a correlation between the diameter of postcaval anastomosis and EF ($p = 0.05$), while there seems to be no link among EF, diameters of cavae, regional function in relation to the time from OCT.

Conclusions: We suggest that MR be considered as a potential one-step alternative tool for follow-up after OCT.

C-0240

MR assessment of nonischemic dilated cardiomyopathy: Correlation of left ventricular wall motion and delayed myocardial enhancement

J.-W. Lee, J. Seo, Y. Kim, B. Choi, K. Choe; Seoul/KR

Purpose: To evaluate and analyze the left ventricular (LV) wall motion in patients with nonischemic DCMP related to the presence of delayed myocardial enhancement.

Materials and Methods: Thirty-one consecutive patients (male: 20, female: 11, mean age: 54.1 years) with nonischemic DCMP and confirmed unobstructive coronary arteries were enrolled. MR imagings with short-axis myocardial tagging and delayed contrast enhancement were performed. With the myocardial tagging images, circumferential myocardial shortening (ECC) and radial myocardial thickening (ERR) were calculated by HARP analysis. The strains of ECC and ERR taken in every segments were analyzed related to myocardial enhancement.

Results: Fourteen patients revealed delayed enhancements of LV myocardium and seventeen patients did not. All patients showed marked regional heterogeneity of LV wall motion and regional paradoxical motion (19/31) by HARP analysis. Reduced wall motion of LV in septum and preserved wall motion in lateral wall were easily detected by HARP analysis. The LV myocardial wall motions by ECC and ERR at each segments were not significantly different in segments with and without delayed myocardial enhancement (ECC < mean p-value = 0.289 >, ERR < mean p-value = 0.455 >, $p < 0.05$) except for anterior wall at the middle and basal LV on ECC.

Conclusion: Short-axis tagged MR imaging and HARP analysis showed delicate regional heterogeneity and paradoxical motion in nonischemic DCMP patients. The tagged MR imaging and HARP analysis can be applied to analyze delicate and complex LV wall motion in nonischemic DCMP patients.

C-0241

Delay hyperenhancement by contrast-enhanced MR imaging: Clinical application of various cardiac disease

D. Kim, S.-I. Choi; Seoul/KR

Learning Objectives: The purpose of this study was to exhibit delayed enhancement of various cardiac diseases on MR imaging.

Background: Clinical applications of contrast-enhanced MR imaging in defining viability are evolving with the advantage of excellent spatial resolution. The value of delay hyperenhancement imaging is accurate identification of infarcted myocardium with resolution that allows the transmural extent of myocardial injury to be determined. Also, non-ischemic patterns of myocardial injury such as dilated or hypertrophic cardiomyopathy have been reported in other disease states. Delay hyperenhancement may have an additional role in guiding management or determining prognosis in diseases such as myocarditis.

Imaging Findings: In this exhibit, we will demonstrate clinical application of delay hyperenhancement in various cardiac diseases such as myocardial infarction including RV infarction, microvascular obstruction, non-ischemic cardiomyopathy such as dilated cardiomyopathy, and myocarditis on the basis of our experience.

C-0242

Use of positron emission tomography and [13N]-ammonia to estimate the relationship between regional myocardial blood flow and coronary artery stenosis severity in patients with coronary heart disease

D.V. Ryzhkova, M.I. Mostova, O.G. Zverev, L.A. Kofal, L.A. Tyutin; St. Petersburg/RU

Purpose: The purpose of this study was to determine the relationship between coronary artery stenosis (CAS) severity and regional myocardial blood flow (MBF) in patients with coronary artery disease (CAD).

Materials and Methods: 21 patients with angiographically confirmed CAD were included in the study. None of them had a clinical history or electrocardiographic

evidence of previous myocardial infarction, significant myocardial hypertrophy or valvular disease; no patient had evidence of complete coronary occlusion by angiography examination. 11 normal subjects served as controls. MBF at rest and during dipyridamole induced hyperemia was evaluated by [13N]-ammonia dynamic positron emission tomography ("HR+", Siemens). The coronary flow reserve (CFR) was defined as the ratio between MBF stress and MBF rest. Selective angiography of coronary arteries was performed according to the Judkins technique.

Results: MBF at rest was similar in the patients and controls (69.7 ± 15.4 mL/min/100 g. vs 71.7 ± 17.7 mL/min/100 g., NS). During hyperemia MBF significantly decreased in the regions supplied by diseased coronary vessels in the patients (76.6 ± 17.6 mL/min/100 g. vs 206.5 ± 63.5 mL/min/100 g., $P < 0.001$). It revealed a significant correlation between MBF during hyperemia and CAS degree ($r = -0.76$; $P < 0.05$). CFR began to decrease when CAS degree was equal 50 percent or more of the luminal diameter and approached unity (1.01 ± 0.17) when CAS was equal or greater than 80 percent.

Conclusion: MBF at rest remains constant despite increasing of CAS severity. Whereas, MBF during hyperemia begins to progressively decline if CAS degree is more than 50 percent. CFR approaches unity when CAS is 80 percent or greater.

C-0243

Tissue MR imaging of subacute myocardial infarction correlates with B-Type natriuretic peptide and tissue Doppler imaging

B.P. Paelinck¹, C.J. Vrints¹, J.J. Bax², J.M. Bosmans¹, A. de Roos², H.J. Lamb², ¹Edegem/BE, ²Leiden/NL

Purpose: B-type natriuretic peptide (BNP) is an amino acid protein released from the cardiac ventricles in response to myocyte stretch. BNP has been correlated to left ventricular (LV) filling pressures in patients with LV dysfunction and has been used to improve management of these patients. Combining Doppler assessed early diastolic mitral flow velocity (E) with early diastolic mitral annular velocity (Ea) has been correlated with both LV pressures and BNP. Phase-contrast MR imaging allows velocity encoding of both moving structures (tissue MRI) and blood. The study was aimed to investigate whether tissue MR Imaging assessed E/Ea correlates with BNP.

Methods and Materials: 14 patients in the subacute phase (5.9 ± 2.7 days) of Q-wave myocardial infarction (mass index: 83 ± 14 g/m², ejection fraction: $44 \pm 12\%$) underwent consecutive measurement of mitral inflow and mitral annular velocities with Doppler and phase-contrast MR imaging. The data were correlated with BNP.

Results: There was a strong relation between MR imaging (12.5 ± 6.3) and Doppler (12.6 ± 5.6) assessed E/Ea ($r = 0.89$, $P < 0.0001$) and between MR imaging (1.8 ± 0.8) and Doppler (1.5 ± 0.8) assessed E/A (A = late diastolic mitral velocity; $r = 0.92$, $P < 0.0001$). BNP ranged from 39.5 to 2380 pg/ml. E/A related strongly to BNP (MR: $r = 0.72$, $P = 0.004$ and Doppler: $r = 0.66$, $P = 0.014$). Best relation was found between E/Ea and BNP (MR: $r = 0.74$, $P = 0.002$ and Doppler: $r = 0.88$, $P < 0.0001$).

Conclusions: Tissue MR imaging has the ability to measure E/Ea. Tissue MR Imaging assessed E/Ea correlates with BNP in patients with subacute myocardial infarction.

C-0244

Comparison of delayed enhancement MR imaging and thallium SPECT for the assessment of myocardial viability

L. Klzo, M. Solar, J. Zizka; Hradec Kralove/CZ

Purpose: To compare delayed contrast enhancement MR imaging with thallium 201 single photon emission computed tomography (SPECT) in the evaluation of myocardial viability.

Methods and Material: Forty patients with ischemic cardiomyopathy (defined by significant coronary artery disease and systolic dysfunction with ejection fraction < 45%) were evaluated by both imaging techniques.

Results: Mean ejection fraction was $31.7\% (\pm 7.2\%)$. Totally, 1332 left ventricular segments were evaluated. An agreement in the assessment of myocardial viability was observed in 540 segments (41%): 415 segments were fully viable, 62 showed signs of impaired viability and 63 were non-viable. 285 segments (21%) with no signs of viability on SPECT showed some viable tissue on MR imaging: this finding was most common at the posterolateral left ventricular wall. 461 segments (35%) fully viable on SPECT showed non-transmural extent of enhancing scar on MR imaging. In 31 segments (2%) with impaired viability on SPECT, MR imaging did not reveal any non-viable tissue. 15 segments (1%) with signs of viability on SPECT were defined as non-viable on MR imaging.

Conclusion: When comparing delayed enhancement MR imaging with thallium

Scientific and Educational Exhibits

SPECT for the assessment of myocardial viability, MR imaging shows signs of viability in the segments that were defined as viable on SPECT. However, many segments (35%) with normal thallium uptake on SPECT show signs of irreversible myocardial injury on MR imaging. On the contrary, significant number (21%) of non-viable segments on SPECT shows signs of viability on MR imaging. Delayed enhancement MR imaging thus seems to be more accurate in the assessment of myocardial viability than thallium SPECT.

C-0245

Whole heart coronary MR-angiography: Presentation of a new technique and report of initial results

M. Ozgun, A. Hoffmeier, R.M. Botnar, W. Heindel, R. Fischbach, D. Maintz; Münster/DE

Purpose: To evaluate a new coronary MR angiography technique covering the whole coronary artery tree in one data set acquisition.

Material and Methods: 5 healthy volunteers and 15 patients with CAD were examined with navigator gated and corrected free-breathing 3D-balanced-gradient-echo sequence covering the whole heart (WH-MRA) (TR = 5.4, TE = 2.7, SENSE factor = 2, 160 slices, 0.75 mm reconstructed slice thickness, in-plane resolution = 0.99x0.99 mm, scan-time = 14 min and a vessel targeted 3D-balanced-gradient-turbo-field-echo (BTFE-MRA) sequence (TR = 5.6, TE = 2.8, 20 slices of 1.5 mm reconstructed slice thickness, in-plane resolution = 0.99 x 0.99 mm, scan-time = 7 min)). Subjective image quality (4 point scale) and objective image quality parameters including vessel sharpness, vessel diameter, SNR and CNR were calculated for WH-MRA and BTFE-MRA. In patients, accuracy for detection of stenoses larger than 50% was compared to X-ray coronary angiography, which was considered the goldstandard.

Results: WH-MRA demonstrated good vessel visibility in healthy subjects (100%) whereas in patients, vessel visibility was limited (78% in an 8 segment evaluation). Vessel sharpness was inferior to BTFE-MRA in patients (37% vs. 42%) but equal in healthy subjects (42%). Vessel diameters did not differ significantly between WH-MRA and BTFE-MRA. SNR and CNR were significantly reduced for the WH-MRA (SNR: 12.1 vs. 19, CNR 7.4 vs. 11.5). Diagnostic accuracy for the detection of CAD was inferior for WH-MRA (78%) when compared to CTA (84%) and comparable to BTFE-MRA (79%).

Conclusions: We successfully demonstrate the use of WH-MRA for coronary visualization in healthy subjects. In patients, subjective/objective image quality and accuracy for detection of CAD was inferior to BTFE-MRA.

C-0246

MR imaging evaluation of patients undergoing radiofrequency catheter ablation of atrial fibrillation: A preablation comprehensive approach

V. Katsiva, A. Katsivas, M. Douskou, C. Vasilopoulos, S. Mavrogeni, G.A. Michailidis, M. Tibshirani; Athens/GR

Learning Objectives: To briefly describe the use of radio-frequency catheter ablation (RFCA) of the distal pulmonary veins (PVs) and posterior left atrium in the treatment of atrial fibrillation. To define an optimized preablation MR imaging study protocol and analysis. To illustrate normal anatomy and anatomic variations of left atrium-PVs.

Background: Pulmonary vein (PV) isolation is considered the treatment of choice in patients undergoing RFCA of atrial fibrillation. Detailed knowledge of the left atrium-PVs anatomy is required for procedural success.

We investigated with MR imaging 26 patients with paroxysmal atrial fibrillation who were treated with catheter ablation. The protocol was designed to assess: patent foramen ovale, intraatrial thrombus and the anatomy of PVs-left atrium. The following anatomic features were described: number, size, location and shape of the PVs ostia, intervenous saddle distances, shape and orientation of the PVs trunks and branching pattern with emphasis on the presence of ostial branch.

Procedure Details: On a 1.5-T MR imager, a cine mode true-FISP sequence was acquired. Three-dimensional gadolinium-enhanced MR angiography was performed, in the coronal plane centered on the left atrium after intravenous bolus injection of gadolinium-based contrast material. Postprocessing of MRA data generated 2D multiplanar reformatted and 3D epicardial and intracardial images of the left atrium and distal PVs. A delayed contrast enhanced inversion recovery sequence was acquired 5 to 10 minutes following contrast administration.

Conclusion: Conventional PV anatomy was encountered in 14/26 patients. A common left PV, an additional PV, early branching pattern, ostium diameter > 25 mm or < 10 mm were the most important anatomic variants.

C-0247

Tc99m-Myoview and Ga-67-Citras combined SPECT imaging for diagnosis of cardiac sarcoidosis

A.N. Yalfimov, D.V. Ryzhkova, L.A. Tyutin, O.P. Baranova; St. Petersburg/RU

Purpose: Sarcoidosis is the multisystem disease of unknown etiology which is characterized long asymptomatic course. Cardiac sarcoidosis results in dilated cardiomyopathies, fatal ventricular tachyarrhythmia or blockade of conducting heart system. The aim of this study was to assess the diagnostic advantage of Tc99m-Myoview and Ga-67-Citras combined SPECT imaging for detection of myocardial involvement with sarcoidosis.

Methods and Materials: 24 patients with suspicion of cardiac sarcoidosis were included in the study. All the patients had no evidence of coronary artery disease and myocardial infarction history. Tc99m-Myoview and Ga-67-Citras SPECT (E. cam var, Siemens) were performed on different days. The intrabronchial myocardial biopsy was carried out in all cases.

Results: The patients were classified into two groups according the presence or absence of histological evidence of cardiac sarcoidosis. 11 patients with histologically proven cardiac sarcoidosis (the 1st group) had abnormal Ga-67-Citras uptake in the heart. The myocardial regions with abnormal Ga-67-Citras uptake corresponded with those with perfusion defects in all patients. Tc99m-Myoview SPECT revealed perfusion abnormalities in myocardial regions without high Ga-67-Citras uptake in 4 patients. Sarcoidosis lesions were not observed in those areas according the myocardial biopsy. 13 patients without histological evidence of cardiac sarcoidosis were classified into the 2nd group. In the 2nd group none had perfusion defects and abnormal Ga-67-Citras uptake.

Conclusion: Tc99m-Myoview and Ga-67-Citras combined SPECT imaging is a reliable protocol for cardiac sarcoidosis detection and allows avoidance of intrabronchial myocardial biopsy.

C-0248

Diagnosis of arrhythmogenic right ventricular cardiomyopathy: A modified magnetic resonance imaging scoring system

R. Maksimovic¹, T. Dill², G. Bachmann², P. Seferovic¹, S. Stankovic¹, H. Pitschner²; ¹Belgrade/YU, ²Bad Nauheim/DE

Purpose: Diagnostic value of magnetic resonance imaging (MRI) in patients with arrhythmogenic right ventricular cardiomyopathy (ARVC) has not been well established. This study aims to evaluate an MRI based scoring model formation and assess its diagnostic significance in patients with suspected ARVC.

Materials and Methods: 53 patients with myocardial abnormalities in the RV verified on MRI were included and divided into two groups: group 1 (17 patients) with ARVC and group 2 (36 patients) with other RV arrhythmias. Decision tree learning (DTL) and linear classification (based on a modified ARVC scoring model of major and minor criteria) were used to identify and assess MRI criterion information value, and to induce ARVC diagnostic rules.

Results: All major ARVC criteria were more frequent in group 1. Among minor criteria, regional RV hypokinesia, mild segmental RV dilatation and prominent trabeculae were more frequent in group 1 while mild global RV dilatation was more frequent in group 2. Diagnostic rules defined by DTL yielded a mean predictive accuracy of 76.8% and RV aneurysm emerged as a key criterion in the diagnosis of ARVC. Optimal diagnostic accuracy (sensitivity 93.3%, specificity 89.5%) was achieved when the value of the modified scoring model was equal to four, which corresponds to the following criteria combinations: two major, or, one major and two minor, or four minor criteria.

Conclusions: Accurate diagnostic rules based on MRI were derived with a RV aneurysm as the most important criterion. Combinations of major and minor criteria contributed to a statistically valid model for ARVC diagnosis.

C-0249

Cine-MR imaging: Morphologic analysis of congenital heart diseases

C. Barrera¹, C. Gervas¹, J. San Vicente¹, A. Cabrera², M. Izquierdo¹, E. Fernandez¹; ¹San Sebastian/ES, ²Bilbao/ES

Learning Objective: To illustrate the ability and contribution of cine-MR imaging sequences in the depiction of congenital heart diseases' morphologic alterations.

Background: Cine-MR imaging allows analysis of cardiac cavities, valves and blood flow in movement. In addition, high quality anatomic images with excellent contrast between blood flow (bright blood) and adjacent structures are obtained. These sequences help precise evaluation of the anatomy of congenital heart diseases (venoatrial and atrioventricular connections, ventriculoarterial alignment anomalies, atrial or ventricular septal defects, ...) and to obtain valvular information. They are very useful in the analysis of surgical conduits and anastomosis, as well as the presence of flow distal to a stent or valvular pathology.

Scientific and Educational Exhibits

Procedure Details: 102 cardiac MR imaging studies of 90 patients referred to our hospital for cardiac congenital anomaly analysis were retrospectively reviewed, 51 studies for the diagnosis and 51 after surgical treatment. 79 included cine fast gradient echo (GE) sequences, 34 magnetization prepared GE and 45 steady state coherent GE. The examinations which did not include cine-MR imaging sequences corresponded to pre and postsurgical aortic coarctation and pulmonary venous anomalous connections. We display different image examples where cine-MR imaging was useful for diagnosis.

Conclusion: In addition to the great value in functional analysis of congenital heart diseases, cine-MR imaging contributes to morphological evaluation of these pathologies because of the anatomic quality of the images, the excellent contrast and the ability to visualize the anatomical structures in movement.

C-0250

MR imaging of cardiomyopathies: A pictorial review

X. Merino-Casabiel, R. Dominguez-Oronoz, E. Castella-Fierro, V. Pineda, A. Evangelista; Barcelona/ES

Learning Objectives: To review and illustrate the MR imaging findings of cardiomyopathies.

Background: Cardiomyopathy is an important cause of morbidity and mortality. Myocardial diseases present clinically in a variety of forms ranging from a- or oligosymptomatic to fulminant cardiac failure. Diagnosis is based on patient's symptoms, cardiac imaging, laboratory test and endomyocardial biopsy. MR is well suited to evaluation of myocardial diseases and provides accurate and reproducible morphologic and dynamic images of the myocardium.

Procedure Details: Retrospective review of our cardiac MR exams database over last 5 years was made, selecting the most demonstrative examples of cardiomyopathies including primary cardiomyopathies (dilated, hypertrophic, restrictive and arrhythmogenic right ventricular dysplasia), specific cardiomyopathies (ischemic, valvular, infective inflammatory (myocarditis), noninfective inflammatory (connective tissue disorders), infiltrative (hemochromatosis), fibroplastic (Löfller disease) and unclassified cardiomyopathies.

Conclusion: MR imaging is a useful tool in the diagnosis and evaluation of severity of heart abnormalities in patients with cardiomyopathies.

C-0251

Using cardiovascular MR imaging to understand and simplify the chest radiograph for congenital heart disease

S.P. Prabhu, K. Burney; Bristol/UK

Learning Objectives: 1. Develop a systematic approach to the chest radiograph taken to evaluate congenital heart disease. 2. Narrow the differential diagnosis and guide further investigation. 3. Understand pathophysiology of common congenital heart disorders better using the help of MR imaging.

Background: The chest radiograph for congenital heart disease has always been seen by residents to be difficult to master. However, it is still the commonest investigation performed to investigate congenital heart disease throughout the world. With the advent of cross-sectional imaging modalities, it has become easier to understand pathophysiology of complex congenital heart disease. We have found that correlation of MR imaging images of patients with congenital heart disease are very useful to understand the chest radiographs. This review aims to elaborate on this correlation.

Imaging Findings: We reviewed data from patients who underwent MR imaging for congenital heart disease in our institution in the last 24 months. We obtained a chest radiograph taken as close to the date of the MR imaging as possible. We identified the pathology on these radiographs that could be illustrated in a three dimensional plane and correlated this to the chest X-ray findings. Normal cases are used to illustrate normal anatomical structures and accepted nomenclature in cardiac radiology. Case studies include both simple, isolated anomalies like coarctation of the aorta, septal defects and valvular stenosis and complex, multiple anomalies like tetralogy of Fallot and variants of transposition of the great arteries.

Conclusions: MR imaging can be used to enhance understanding of the chest radiograph for congenital heart disease.

C-0252

Fetal heart tumors

D. Elias, P. Marantz, M. Guerchicoff, A. Gutierrez, A. Villa, J. San Roman; Buenos Aires/AR

Purpose: To determine prevalence and natural history of heart tumors in patients referred for fetal echocardiography.

Methods and Materials: From May 1998 to December 2003, 7 fetuses with cardiac tumors have been sent to fetal echocardiography out of 9866 obstetric US studies.

Results: Four patients had multiple rhabdomyomas. Three of them had tuberous sclerosis (TS) with intracerebral tumors detected by MR imaging. Cardiac tumors regressed during first year of life and children were asymptomatic. Another fetus presented a single tumor with a rhabdomyoma appearance at US attached to the interventricular septum. At 5 months of life this mass became smaller. Another patient had a large left ventricular mass with US appearances of a fibroma, which required early surgery. This tumor was almost completely resected, and 4 years later a small residual mass has not grown. Histopathological exams revealed cardiac fibrosarcoma. The last fetus with a single intraseptal tumor with US appearances suggestive of a large fibroma, died at 7 months old with low cardiac output. MR imaging did not identify brain tumors. Autopsy was not authorized by parents.

Conclusion: (1) Prevalence of fetal cardiac tumors in our hospital was 0.05% and represented 7.5% of congenital heart disease in a 5-year period. (2) Rhabdomyomas were most frequent with spontaneous regression after birth. (3) Multiple rhabdomyomas were associated with TS. (4) No death occurred during fetal life in this series. (5) Fetal echocardiography provides an accurate diagnosis, allowing pregnancy follow-up and parental counseling.

C-0253

Characterization of acute and chronic myocardial infarcts by multidetector CT. Comparison with contrast-enhanced MR

B.L. Gerber, E. Coche, B. Belge, P. Lim, A. Pasquet, J.-L. Vanoverschelde; Brussels/BE

Background: Gd-DTPA contrast-enhanced (CE) MR imaging reveals patterns of hypoenhancement early and of hyper-enhancement late after contrast injection in myocardial infarction (MI). We evaluated whether the injection of iodated contrast at the time of non invasive coronary imaging might also allow infarct characterization by multidetector CT (MDCT).

Materials and Methods: Nineteen patients with acute MI and 14 patients with chronic dysfunction and suspected MI underwent MDCT and CE-MR imaging. CE patterns on short-axis tissue MDCT images acquired at the time of coronary imaging and 10 minutes after contrast injection were compared with MR.

Results: Early MDCT images demonstrated areas of reduced contrast enhancement in infarcted areas in 15 patients with acute infarct and in 4 patients with chronic infarct. The location of areas of early hypo-enhancement by MDCT was similar to those of MR. Size of early hypo-enhanced areas by MDCT and MR (4 ± 8 vs. $6 \pm 9\%$, $p = NS$) were similar and highly correlated ($r = 0.89$, $p < 0.001$). On late MDCT images all patients with acute infarcts and 10 patients with chronically dysfunctional myocardium had areas of increased contrast-enhancement (hyper-enhanced areas). Again, the location and size of late hyperenhanced areas by MDCT and CE-MR were similar (25 ± 18 vs. $22 \pm 16\%$, $p = NS$) and well correlated ($r = 0.78$, $p < 0.001$).

Conclusions: MDCT can characterize acute and chronic MI with similar contrast-enhancement patterns, i.e. hypoenhanced area on early images, and hyper-enhanced area on late images, as CE-MR. The technique can thus provide important information on tissue viability at the time of non-invasive coronary imaging.

C-0254

The complex of myxomas, spotty skin pigmentation and endocrine overactivity: Carney complex Imaging findings

N.A. Courcoutsakis¹, P. Prassopoulos¹, J.A. Carney², C.A. Stratakis³; ¹Alexandroupolis/GR, ²Minnesota, MN/US, ³Bethesda, MD/US

Learning Objectives: To illustrate the spectrum of the manifestations and corresponding imaging findings of "The Complex of Myxomas, Spotty Skin Pigmentation, and Endocrine Overactivity" or Carney Complex (CNC).

Background: CNC is a familial multiple neoplasia and lentiginosis syndrome. CNC is inherited by an autosomal dominant manner and it is genetically heterogeneous. CNC features overlapped with those of McCune-Albright syndrome and other multiple endocrine neoplasia (MEN) syndromes.

Imaging Findings: Spotty skin pigmentation is the major clinical manifestation of the syndrome, followed by multicentric heart myxomas, which occur at a young age and are the lethal component of the disease due to brain embolic episodes. Myxomas also occur in the skin (eyelid, external ear canal and nipple) and the breast. Breast myxomas, when present, are multiple and bilateral among female CNC-patients ("breast-myxomatosis"). Affected CNC-patients often present tumors in two or more endocrine glands, including primary pigmented nodular adren-

Scientific and Educational Exhibits

o cortical disease, growth hormone or prolactin producing pituitary adenomas, thyroid adenomas or carcinomas, testicular neoplasms (large-cell calcifying Sertoli cell tumor) and ovarian lesions. Infrequent but characteristic tumors in CNC patients include psammomatous melanotic schwannoma, breast ductal adenoma with tubular features, and osteochondromyxoma or "Carney bone tumor". Mammography or breast MR imaging, cardiac US or MR imaging, CT or MR imaging evaluation of the adrenals, pituitary gland, testicles or ovaries are important diagnostic tools for detecting tumors associated with CNC.

Conclusion: Patients with suspected CNC should undergo a thorough imaging evaluation to define to establish diagnosis and to disclose tumors associated with CNC.

C-0255

Magnetic resonance detection of subclinical cardiac impairment in patients with systemic sclerosis

E. De Cicco, S. Casanova, M. Gravano, G. Molinari; Genoa/IT

Purpose: Aim of our study was to assess myocardial involvement in patients suffering from Systemic sclerosis (SSc) with no apparent symptoms or instrumental detection of cardiac impairment.

Methods and Materials: Forty-six SSc consecutive patients, (55.5 ± 14.1 yrs; 40 females, 6 males) underwent cardiac MR imaging at 1.5-T (Magnetom Vision, Siemens). Ten healthy volunteers, matched for age and sex, were enrolled as control group. All patients with SSc were asymptomatic with an unremarkable physical examination and in sinus rhythm. A segmented ECG-gated breath hold cine gradient echo sequence (TR/TE = 100/6.1 msec; FA = 25°, thickness = 10 mm) to encompass both ventricles (from basis to apex) was used. Diastolic and systolic volumes as well as ejection fractions for both ventricles were evaluated.

Results: All patients had left ventricle ejection fraction (LVEF) ($61.5 \pm 6.1\%$) in the normal range and nobody presented left ventricle kinetic abnormalities. Thirty patients had a reduced right ventricle ejection fraction (RVEF) ($42.5 \pm 4.4\%$) with LVEF of $57.9 \pm 6.7\%$ and sixteen patients had normal RVEF ($55.2 \pm 4.1\%$) with a LVEF of $66 \pm 4.4\%$.

Conclusion: Impairment of RVEF was found in patients suffering from SSc, even if they were not symptomatic for cardiac involvement. Compared with control group, SSc patients had significative reduction in RVEF ($p < 0.05$). these preliminary data suggest that MR imaging could be a potentially predictive method in evaluating early myocardial damage in SSc.

C-0256

Assessment of right ventricular function with magnetic resonance.

Preliminary report

D. Piotrowska, L. Kownacki, M. Golebiowski, L. Krolicki; Warsaw/PL

Purpose: Magnetic resonance (MR) is a well established "golden standard" in the assessment of left ventricular (LV) function. However evaluation of function of the more complex-shaped right ventricle (RV) is still uncertain. We aim to determine the feasibility and accuracy of right ventricular volume, function, and mass measurements with MR in comparison with corresponding LV values.

Materials and Methods: 12 healthy volunteers, 4 patients with ventricular hypertrophy and 7 with history of MI (19M,4F;20-70 yrs. median 28) were examined. A ECG-gated cardiac CINE TFE sequence was used (TR = 9.5[ms], TE = 4.5[ms], Flip angle = 30[deg],matrix:256x256 [pixels],slice thickness:8[mm], phases:10-13, number of slices:8-10). The images obtained were analysed on workstation with MASS software.

Results: The global calculated values were: RVmass [g], RVEDV [ml], RVESV [ml], RVSV [ml], RVEF [%], LVmass [g], LVEDV [ml], LVESV [ml], LVSV [ml], LVEF [%]. RV analyses were successfully performed in all subjects. RVSV was nearly identical to LVSV ($R = 0.96$, $p < 0.0001$), with a mean difference between RVSV and LVSV of 1 ml in the whole group as well as in the subgroups. As expected the subjects with history of MI have significantly lower LVEF. However there were no differences in RVSV and RVEF. 6 subjects (body-builders) out of the 12 healthy volunteers have significantly higher LVmass, RVEDV (175.6 ml vs 136.7 ml) RVESV (91.8 ml vs 54 ml) and lower RVEF (48% vs 60%).

Conclusion: TFE cine MR imaging enables accurate quantification of RV function in healthy subjects, patients with HCM and patients with history of MI using MASS software.

Multidetector CT (MDCT)

C-0257

ECG-gated 16-slice CT of coronary arteries: Assessment of image quality and accuracy in detecting stenoses

O. Luz, M. Heuschmid, A. Kuettner, S. Schroeder, A. Kopp, C.D. Claussen; Tübingen/DE

Purpose: Aim of this study was to investigate image quality and diagnostic accuracy in detecting coronary artery lesions using a 16-slice multidetector CT scanner.

Material and Methods: 37 patients underwent non-contrast spiral scan and MDCT angiography of the coronary arteries. After oral beta-blockade, scans were obtained in a single breath-hold with a 16-slice scanner using ECG-gating. Image quality was assessed in terms of artifacts and segment visibility by two reviewers. Stenosis severity was compared with results of conventional coronary angiography.

Results: Data evaluation of image quality was based on 488 segments. 380 segments were considered to have diagnostic image quality. 108 segments (22.1%) could not be sufficiently evaluated because of severe calcifications (35 segments) and motion artifacts (73 segments). The mean calcium score (Agatston Score Equivalent, ASE) was 524.3 ± 807.6 . 28/37 (75.7%) patients had an ASE < 1000 (mean ASE: 90.8 ± 152.3) and 9/37 (24.3%) patients had an ASE ≥ 1000 (mean ASE: 1761.0 ± 637.6). For detecting lesions $\geq 50\%$, the overall sensitivity, specificity, positive predictive value and negative predictive value were 59%, 87%, 61% and 87%. When limiting the number of patients to those with a calcium score < 1000 ASE, the threshold-corrected sensitivity for lesions $\geq 50\%$ was 93%, specificity 94%, positive predictive value 68% and negative predictive value 99%.

Conclusions: In patients with no or moderate coronary calcification, MDCT of coronary arteries using 16-slice technology allows the reliable detection of coronary artery stenoses with high diagnostic accuracy. An initial non-contrast scan was found to be mandatory to avoid useless examinations in patients with severe calcifications.

C-0258

Low-attenuation of myocardium with contrast-enhanced multi-detector CT: Hypoperfusion or fat deposition?

J. Nam, B. Choi, J. Seo, Y.-J. Kim, T. Kim, K. Choe; Seoul/KR

Purpose: Recently, acute myocardial infarction has been reported to show low-attenuated myocardium due to hypoperfusion in contrast-enhanced CT. We investigated low-attenuation of myocardium in patients who underwent coronary artery angiography with multi-detector CT.

Methods and Materials: In total 655 patients (mean age 61 ± 10) underwent contrast-enhanced coronary CT angiography for evaluation of native coronary artery in suspicion of coronary artery disease (NCA group, n = 275) or patency of coronary artery bypass graft (CABG group, n = 380) with multidetector CT. They all underwent non-enhanced CT (NECT) with a protocol for coronary calcium scoring. If a low-attenuation region was detected in NECT, it was considered due to fat deposition. The degree of enhancement of the low-attenuation area was measured and compared to that of normally enhanced myocardium.

Results: Seventy two (11%) patients showed low-attenuation area of myocardium with CECT. Sixty patients (15.8%) in CABG group and 12 patients (4.4%) in NCA group showed low-attenuation area of myocardium in CECT. In NECT, fat deposition was noted in 61 (85%) of patients in the same areas as with CECT. In the 12 patients with low-attenuation areas in the NCA group, a history of previous myocardial infarction was present in 4 patients, but not in 8. CT attenuation value of low-attenuated myocardium in NECT and CECT was -24.1 ± 33.4 and -8.5 ± 33.9 HU and that of normal myocardium was 44.3 ± 15.4 and 111.9 ± 23.9 HU, respectively.

Conclusion: Chronic myocardial infarction or ischemia frequently shows low-attenuation in CECT by either hypoperfusion, fat deposition, or by both. Therefore, low-attenuated myocardium in CECT should be carefully interpreted.

C-0259

Occlusive myocardial infarction on sixteen-slice multi-detector row helical CT in a rabbit model: Radiologic-pathologic correlation according to infarct age

J. Lee, Y. Kim; Seoul/KR

Purpose: To evaluate imaging finding and diagnostic accuracy for myocardial infarct (MI) on sixteen-slice multi-detector row helical CT (MDCT) in rabbits with radiologic and pathologic correlation.

Scientific and Educational Exhibits

Materials and Methods: MI was induced in 20 rabbits by ligation of coronary arteries. MDCT was obtained at 1 minute (early) and 6 minutes (delayed) after intravenous contrast injection. Rabbits were sacrificed according to infarct age, acute or chronic. Sliced cardiac specimens were stained for gross and microscopic examination. Agreement of scored transmural extent of MI between MDCT and specimens was statistically analyzed.

Results: MI was demonstrated in 13 rabbits on specimens and MDCT. Infarcted myocardium was demonstrated as a low-attenuation area on early scan and a low-attenuation area with enhancement along periphery on delayed scans. There was excellent agreement in transmural extent of MI between specimens and MDCT in early phase and fair to good in delayed phase. Histopathologic examination revealed myocardial necrosis with granulation along periphery of necrotic myocardium, corresponding to low-attenuation area on early phase. Peripheral enhancement on delayed phase could correlate with the area of granulation. Granulation tissue in specimens and peripheral enhancement on delayed phase were increased with ageing of infarct.

Conclusion: MDCT was useful in the diagnosis of MI and the early phase was more accurate than delayed in evaluation of transmural extent. In histopathologic examination, infarcted myocardium consisted of myocardial necrosis with granulation along periphery of infarcted myocardium, which could match the low-attenuation area and peripheral enhancement on delay phase. Granulation and peripheral enhancement were increased with the ageing of infarcts.

C-0260

Imaging of atrioventricular septal defect (AVSD) with multidetector-row CT angiography

R.L. Hallett, M.D. Hiatt, D. Fleischmann, J.C. Hellinger, G.D. Rubin, F.P. Chan; Stanford, CA/US

Learning Objectives: To explain in detail our technique for acquisition of ECG-gated multidetector row CT (MDCT) angiography in children with congenital heart disease. To illustrate the spectrum of AVSD as depicted by MDCT angiography in infants through adolescents.

Background: ECG-gated MDCT has evolved into a viable problem-solving tool for the assessment of congenital abnormalities of the heart and great vessels. ECG-gated MDCT provides excellent spatial resolution and facilitates acquisition of volume data with acceptable temporal resolution, even at high heart rates. Short exam times, decreased anesthesia needs, and safe performance in patients with pacemakers are additional benefits. AVSD arises when the endocardial cushions fail to meet the septum primum, resulting in a spectrum of abnormalities from primum ASD to complete AVSD. Various AV valve abnormalities also coexist. The Rastelli classification of complete AVSD is useful for surgical planning. Diagnosis is often made by echocardiography, but MDCT angiography provides additional information including true 3D and 4D datasets for depiction of complex native and post-operative cardiac anatomy, mass, and function.

Imaging Findings: ECG-gated MDCT acquisition technique and contrast medium delivery methods will be described in detail. Dose-reduction techniques will be discussed. The anatomic structures important for characterization will be clearly demonstrated. A wide spectrum of AVSD including native and post-operative anatomy and associated cardiovascular anomalies will be presented.

Conclusion: AVSD is a spectrum of cardiac malformations. ECG-gated MDCT angiography is a useful problem-solving tool for evaluation of native and post-operative anatomy and function, and helps guide surgical planning and post-operative follow-up.

C-0261

Anomalous origin of coronary arteries: Demonstration with MSCT coronary angiography

Z. Wang, Z. Yang, J. Shen, H. Zhu, X. Zhou, W. Fang; Dalian/CN

Learning Objectives: To illustrate the ability of MSCT coronary angiography in the detection of anomalous origin of the coronary arteries. To demonstrate the ability of MSCT coronary angiography in the further evaluation of patients with chest pain in whom a coronary anomaly is suspected.

Purpose: To describe the value of multislice spiral CT (MSCT) coronary angiography in the detection of anomalous origin of the coronary arteries.

Materials and Methods: During three years, the 3010 subjects underwent MSCT coronary angiography (retrospectively ECG-gating; 0.5 s rotation; one-sector reconstruction algorithm; intravenous contrast agent).

Results: The anomalous origin of coronary artery was incidentally found with a multislice spiral CT in 22 patients (0.73%). There were 10 patients with an anomalously high origin of the right coronary artery. There were 9 patients with anomalous origin of the right coronary artery from left coronary sinus. In 2 patients, the

circumflex artery arises from the right coronary sinus and behind the aorta to reach the left atrioventricular groove. There was 1 patient with anomalous origin of the right coronary artery from posterior coronary sinus. These signs were better shown by MSCT coronary angiography.

Conclusions: MSCT coronary angiography is a useful adjunctive technique to invasive coronary angiography in the evaluation of anomalous origin of the coronary arteries.

C-0262

Assessment of mitral valvular replacement with chordal preservation using multidetector row computed tomography

D. Kim¹, S. Ryu², B.-H. Ahn²; ¹Seoul/KR, ²Gwang-Ju/KR

Background: The efficacy of multidetector row computed tomography (MDCT) for evaluating mitral valvular replacement (MVR) with chordal preservation has not been reported. The advanced diagnostic technique, MDCT may enable us to evaluate the cardiac function and morphology of MVR with chordal preservation. In this study, we demonstrated various MDCT images for the evaluation of MVR with chordal preservation in patients with mitral stenosis.

Materials and Methods: Twelve patients with MVR with chordal sparing or reconstruction were evaluated using MDCT. Nine patients underwent MVR with chordal reconstruction. Three patients underwent MVR with native chordal preservation. Four patients underwent partial preservation or reconstruction of chordae, two underwent preservation of the posterior leaflet chords only. Images of MDCT were recorded and measured according to echocardiographic view and criteria. Short-axis, two-chamber, four-chamber views, and three-dimensional images were processed for evaluating cardiac morphology and ventricular function.

Results: MDCT images were obtained successfully. Two-chamber and four-chamber views were useful in visualizing the papillary muscles and chordae. Short-axis view was most helpful in evaluating cardiac function. Three-dimensional images were used for evaluation of cardiac morphology.

Conclusion: MDCT can be another useful diagnostic modality for the cardiac function and morphologic evaluation of MVR with chordal preservation.

C-0263

Imaging of atrial septal defects (ASD) with multidetector-row CT (MDCT) angiography

S. Poplaw, J.C. Hellinger, M.D. Hiatt, F.P. Chan, D. Fleischmann; Palo Alto, CA/US

Learning Objectives: To review the embryology, anatomy and pathophysiology of atrial septal defects. To illustrate the MDCT findings, with echocardiographic and MR correlation.

Background: ASDs account for approximately 1% of congenital heart disease (CHD), but are the most common CHD in adults older than 20 years of age. MDCT acquisition speed has become so fast, that routine MDCT angiography (MDCTA) through the chest may depict ASD. It is paramount for the radiologist to detect and accurately classify these congenital abnormalities because of the associated complications (i.e. pulmonary hypertension, infective endocarditis, atrial dysrhythmias, and heart failure).

Imaging Findings: Ideal acquisitions require retrospective ECG-gated technique. However, as will be shown, routine MDCTA thin section technique can lead to the diagnosis. With robust technique MDCTA can demonstrate all anatomical types of ASD, associated congenital abnormalities, and the sequelae from ASD. At times, compared to echocardiography and MR imaging, MDCTA can more reliably depict ostium secundum, ostium primum, sinus venosus, and coronary sinus defects. At present, while complete volume acquisitions cannot demonstrate flow, identifying a CT shunt sign can localize a defect.

Conclusion: MDCTA is a valuable imaging modality for diagnosis of all types of ASD. Radiologist can play a significant role in minimizing the associated morbidity and mortality.

C-0264

Comparison between multi-detector CT and electro-anatomical mapping for evaluation of left atrium and distal pulmonary veins anatomy in atrial fibrillation patients

M. Centonze, M. Del Greco, M. Marini, S. Della Sala, P. Peterlongo; Trento/IT

Purpose: Aim of this study was to compare the results of left atrium (LA) and PVs reconstructions between CARTO™, an electro-anatomic navigation system used for atrial fibrillation (AF) radio-frequency catheter ablation (RFCA), and Multi-Detector 16 slices computed tomography (MDCT).

Method and Materials: 20 patients with drug refractory AF underwent PVs RFCA

Scientific and Educational Exhibits

guided by the CARTO™ maps of the LA and PVs ostia. MDCT examinations were performed after the procedure (> 1 month) for recognition of such potential complications as PVs stenosis. The following parameters were compared between MDCT and CARTO™: antero-posterior (AP), crano-caudal (CC) and late-ro-lateral (LL) axis of LA and number of right (RPVs) and left PVs (LPVs).

Results: The median values of LA axis were as follows: AP axis 37 mm CARTO™ versus 39 mm MDCT; CC axis 60 mm versus 65 mm; LL axis 81 mm versus 64 mm.

RPVs number concordance between CARTO™ and MDCT was found in 5/20 cases while in 13/20 cases CARTO™ overestimated the PVs number due to the presence in all of the cases of a branching less than 10 mm from the PVs ostium. Only in 2 cases CARTO™ failed to identify the PVs due to a small middle RPV. LPVs number was the same in 12/20 cases while in 8/20 cases CARTO™ overestimated due to the presence of a short common pulmonary trunk (7) or a branching less than 10 mm from the PV ostium (1).

Conclusion: MDCT defines the LA and PVs anatomy better than CARTO™ maps, providing useful information necessary for successful RFCA.

C-0265

The relationship between coronary calcium score and myocardial perfusion

I.E. Itsikovich, D.V. Ryzhkova, L.A. Tiutin, E.V. Rozengaouz, L.A. Kofal;
St. Petersburg/RU

Purpose: To estimate the relationship between coronary calcium score and myocardial perfusion in patients with coronary artery disease.

Materials and Methods: Full-scale examination was performed for 63 patients (47 males and 17 females; 37 - 75 years). Calcium score (CS) measurement was performed in 252 coronary arteries according to Agatstone's technique by Volume-Zoom CT scanner (Siemens) with retrospectively ECG-gating image reconstruction. 13N-ammonia PET scans were acquired at rest and during pharmacological test using "HR+" (Siemens) to assess the myocardial perfusion.

Results: All coronary arteries were divided in 4 groups depending on the value of CS. 198 coronary arteries with a low value of CS (10 units and less) were classified in the first group, 28 arteries with moderate CS (11 - 100 units) - in the second group, 13 arteries with mean CS (101 - 400 units) - in the third group and 7 arteries with high CS (over 400 units) - in the fourth group. Reversible perfusion defects were revealed in myocardial segments supplied by 18 (9.1%) coronary arteries of the first group, by 9 (32%) arteries of the second group, by 3 (23.1%) arteries of the third group, by 4 (57.1%) arteries of the fourth group. The flow-limiting stenoses (over 50%) were revealed in the mentioned arteries according MSCT coronary angiography.

Conclusion: Coronary artery calcification does not always result in myocardial ischemia. The perfusion abnormalities may be observed in territories supplied by coronary arteries with a low or zero CS.

C-0267

Visualisation of coronary artery stent patency with 64-slice computed tomography

F. Cademartiri, N.R. Mollet, G. Runza, M. Belgrano, M. Midiri, R. Pozzi Mucelli, G.P. Krestin; Rotterdam/NL

Learning Objectives: 1. Describe the technical features of a new generation of multislice CT scanner. 2. Describe the issues and the solutions adopted to improve the visualisation of coronary artery stents. 3. Provide cases that show the clinical impact of the technical improvements.

Background: 16-slice Computed Tomography (CT) has showed great potential in the visualization of significant stenosis in coronary artery. Coronary artery stents are difficult to image with CT because of their high density and the associated "blooming" effect due to volume averaging and interpolation. In addition, residual motion due to insufficient temporal resolution can deteriorate the image quality. For these reasons, the direct visualisation of stents is limited to large (> 3 mm diameter) stents with a relatively low attenuation. Based on this observation a better scanner should provide both improved spatial and temporal resolution.

Imaging Findings: We describe a multislice CT scanner able to scan 64 slices per rotation with a voxel size of 0.3x0.3x0.4 mm, and a rotation time of 0.33 s (effective temporal resolution up to 165 ms). Schemes of the main technical issues and solutions will be displayed as well as several clinical examples of coronary stents with conventional coronary angiography correlation.

Conclusion: The new 64-slice CT allows improved visualisation of coronary artery stents.

C-0268

16-row multidetector CT in the detection of coronary anomalies

P.M. Carrascosa, C. Capuñay, M. Ulla, P. García Merletti, E. Martín López, J. Carrascosa; Buenos Aires/AR

Learning Objectives: To illustrate the spectrum of coronary arteries anomalies. To outline the advantages of this non-invasive technique. To be familiar with these vascular findings to avoid diagnostic mistakes.

Background: Coronary artery anomalies (CAA) are anatomical variants that occur in 0.3-1.3% of patients. They can be related to syncope, dyspnea, ventricular fibrillation, angina, myocardial infarction, atrio-ventricular block or even sudden death. The purpose of this paper is to evaluate the usefulness of Multidetector CT (MDCT) in the evaluation of CAA. A total of 30 patients with CAA diagnosed by digital angiography (DA) were evaluated with CT coronary angiography between April and August 2004. There were 1 right coronary artery arising from main left coronary artery, 7 independent origins of the LAD and circumflex, 3 right side circumflex, 1 left coronary artery fistula into the pulmonary trunk, 14 intra-myocardial bridging and 4 intra-muscular coronary segments.

Procedure Details: CTs were performed with a 16-row CT scanner (Brilliance 16; Philips Medical Systems) with slices of 0.8 mm thickness, 0.4 mm reconstruction interval, gantry rotation time of 420 msec. An enhanced acquisition was performed with 120 ml of contrast. During the scan, the ECG's of the patients were recorded. The vascular analysis, the origin and cause of the CAA were performed using axial images, multiplanar reconstructions and volume rendering reconstruction.

Conclusion: Most anomalies are harmless but some of them require aggressive intervention. MDCT can accurately detect the origin and cause of CAA as well as the anatomical relationships to adjacent cardiac structures with high image resolution.

C-0269

Multidetector CT evaluation of congenital heart disease

M. Ledermann, V. Latrabe, M. Montaudon, O. Corneloup, F. Laurent; Pessac/FR

Learning Objectives: Based on the analysis of a series of 44 patients, the aim of this exhibit is to assess the capabilities of multidetector CT scan in exploring congenital heart diseases. The spectrum of congenital heart diseases will be reviewed and illustrated by numerous examples. Advantages and disadvantages of CT will be discussed.

Background: Echocardiography remains the initial imaging modality for diagnosis and follow-up of congenital heart diseases. However it suffers from some limits: operator-dependence, a small field of view, and problems relating to acoustic window. Multislice CT scan appears to be a valuable alternative for the morphologic evaluation of congenital heart disease.

Imaging Findings: 44 patients underwent multislice CT scan using a low-dose protocol. All these exams were performed after inconclusive echocardiography in exploring congenital heart diseases (tetralogy of Fallot, pulmonary atresia with ventricular septal defect, transposition of great vessels, tricuspid atresia, double-outlet right ventricle, partial anomalous pulmonary venous return, coarctation of the aorta, truncus arteriosus). All studies were requested to answer to specific anatomic questions, either prior to surgical management, or in the post-operative follow-up of these patients.

Conclusion: Multidetector CT scan is a useful noninvasive technique for evaluating congenital heart diseases. Compared with MR imaging, CT requires markedly decreased sedation time as it produces images with increased speed. Spatial resolution is clearly better, allowing valuable assessment of right outflow tract, coronary arteries, systemic artery collaterals, and surgical procedures. Finally, CT scan provides images of lung parenchymal structures.

C-0270

Evaluation of global left ventricular myocardial function using retrospectively ECG-gated 16-slice multidetector computed tomography: Comparison with magnetic resonance imaging

M. Heuschmid¹, J. Rothfuss¹, S. Schroeder¹, M. Fenchel¹, N. Stauber¹, A. Kuettner¹, M.D. Seemann², A.F. Kopp¹, C.D. Claussen¹; ¹Tübingen/DE, ²Munich/DE

Purpose: To assess the quantitative measurement of left ventricular functional parameters using retrospectively ECG-gated multidetector computed tomography (MDCT) and to compare the results with magnetic resonance imaging (MRI).

Methods and Materials: 52 patients (pts) with suspected coronary artery disease were included in the present study. 16-slice MDCT scans were performed using retrospective ECG-gating (0.75 mm collimation, 2.8 mm table feed/rota-

Scientific and Educational Exhibits

tion, 0.42 s rotation time). Based on the CT dataset, short axis reformats of the left ventricle were performed for the functional analysis. End-diastolic volume (EDV), end-systolic volume (ESV) and stroke volume (SV) as well as ejection fraction (EF) were calculated from MDCT data according the modified Simpson's method and compared to MRI results (1.5 T scanner).

Results: Comparing MDCT with MRI, the results for the determination of EDV, ESV, SV, and EF were as follows: EDV: MDCT 140.6 ± 40.0 ml vs. MRI 125.5 ± 29.4 ml, $r = 0.83$, [$p < 0.0001$], mean difference (MD) 15.1 ± 22.80 ; ESV: MDCT 75.0 ± 33.7 ml vs. MRI 64.4 ± 26.1 ml, $r = 0.90$, [$p < 0.0001$], MD 10.6 ± 15.5 ; SV: MDCT 65.6 ± 15.3 ml vs. MRI 61.1 ± 13.2 ml, $r = 0.66$, [$p = 0.008$], MD 4.5 ± 11.9 ml; EF: MDCT $48.0\% \pm 9.3\%$ vs. MRI $49.6\% \pm 9.6\%$, $r = 0.88$, [$p = 0.0072$], MD $-1.8\% \pm 4.7\%$.

Conclusion: Cardiac MDCT with retrospective ECG-gating displayed a high correlation of left ventricular functional parameters compared to MRI. Thus, important additional information with clinical and prognostic relevance can be achieved. However, although a high correlation was found, EDV, EVS and SV were overestimated and EF underestimated in MDCT which have to be taken into account when applying this technology in clinical practice.

C-0271

Whole heart coronary MR-angiography: Value for the detection of coronary artery stenoses in comparison to MSCT-angiography

D. Maintz¹, M. Ozgun¹, A. Hoffmeier¹, W. Heindel¹, R. Fischbach¹, R. Botnar²;
¹Münster/DE, ²Boston, MA/US

Purpose: To compare steady-state-free-precession whole heart coronary magnetic resonance imaging (MRI) with multidetector coronary computed tomography angiography (CTA) for the detection of coronary artery disease (CAD).

Material and Methods: Twenty patients with CAD were examined with navigator gated/corrected free-breathing 3D balanced-gradient-echo whole heart coronary MRI and coronary CTA. Subjective overall image quality (4 point scale, 1 = excellent), visibility of vessel segments and accuracy for the detection of significant coronary stenoses (> 50%) were compared to coronary X-ray angiography by two blinded readers.

Results: Average subjective image quality was 2.7 for MRI and 1.7 for CTA. Of a total of 209 segments, 67 segments (32%) had to be excluded from the evaluation by MRI (61 due to insufficient image quality and 6 due to stent artifacts). In CTA, 31 segments (15%) had to be excluded from the evaluation (12 due to insufficient image quality, 15 due to severe calcifications superimposing the vessel lumen and 4 due to stent artifacts). Within the evaluated segments, the prevalence of significant CAD was: MR imaging 23%, CTA 18%. Segment-based values for the detection of $\geq 50\%$ diameter coronary X-ray angiographic stenoses were: sensitivity: MRI 88%, CTA 95%; specificity: MRI 82%, CTA 84%; accuracy: MRI 87%, CTA 93%; positive predictive value: MRI 68%, CTA 77% and negative predictive value: MRI 94%, CTA 95%.

Conclusions: Coronary WH-MRI was inferior to coronary CTA regarding image quality and number of evaluable segments, but both had similar diagnostic value for the detection and exclusion of CAD when only evaluable segments were included.

C-0272

64-slice CT in coronary artery disease

B. Jankharia, P. Krishnan, K. Rajpal; Mumbai/IN

Learning Objectives: To illustrate the usefulness of 64-slice CT in the evaluation of coronary artery disease.

Background: Multi-slice CT is now a recognized modality for the evaluation of coronary artery disease. The faster the scanner, the easier it normally is to scan the coronary arteries. A new 64-slice CT (Sensation Cardiac, Siemens, Erlangen) has been recently introduced with a rotation time of 330 ms with an effective temporal resolution of 165 ms. The spatial resolution is 0.4 mm in the z-axis. This is a 32-detector row with double sampling in the z-axis with a flying focal spot. These improvements are expected to produce superior images of the coronary arteries, as compared to earlier 16-slice CT scanners.

Imaging Findings: Using a robust technique, diagnostic quality images can be obtained in the vast majority of patients. Normal studies exclude coronary artery disease with a high degree of confidence. Coronary artery lesions such as stenoses and plaques, both calcified and non-calcified can be seen well. Visualization of intra-stent pathology is also possible.

Conclusion: With a robust technique, coronary artery disease can be well appreciated using a 64-slice CT.

C-0273

Understanding ECG gated reconstruction by scanning diagram

N. Akino, K. Tsujikawa, Y. Takahashi, M. Niwa, Y. Uebayashi;
Toyoake-city Aichi/JP

Purpose: It is very difficult to understand the ECG gated reconstruction in multi slice CT scanning. In this report we would like to introduce a movie we have developed for educational use to help any operator easily understand what the ECG gated reconstruction is like.

Method and Materials: The scan diagram has X-ray revolving angles at the vertical axis and body axis direction's positions on the horizontal axis. The heart rate signals have been added to this in order for viewers to visually understand the ECG gated reconstruction. We performed a simulation on the time resolution, the space resolution and the image noise.

Results: We easily obtained understanding of the ECG gated reconstruction with help from the scanning diagram movie.

Conclusions: Understanding the ECG gated reconstruction is indispensable for performing best possible CT scanning inspections. We are sure that the educational movie of the reconstruction is helpful to radiologists and radiological technologists.

C-0274

Noninvasive assessment of in-stent restenosis of coronary artery with multi-detector row CT

J.-W. Lee, E. Yoo, B. Choi, J. Nam, J. Seo, Y.-J. Kim, K. Choe; Seoul/KR

Purpose: To assess the usefulness of 16-slice spiral CT for evaluation of restenosis of coronary artery stents.

Methods and Materials: 36 consecutive patients (mean 58 yrs) with coronary artery stents ($n = 48$) were enrolled. Sixteen-slice CT and invasive coronary arteriography were performed with interval from 1 to 22 days (mean 9 days) and were compared. All patients were pre-treated with propranolol (30-60 mg) prior to CT scan. Reconstruction window was tailored to individuals. Restenosis of in-stent lumen in CT was decided by presence of lower density of in-stent lumen than that of the proximal opacified vessel lumen with assessors being unaware of the results of invasive coronary arteriography.

Results: Three stents (6%) of total 48 stents could not be evaluated with CT because of motion artifact ($n = 2$) or complete obliteration of in-stent lumen by severe beam-hardening effect of stent ($n = 1$) and were excluded. Twelve (26%) of 45 stents revealed restenosis by invasive coronary arteriography. Nine of twelve restenosis were correctly diagnosed with CT (Sensitivity 75%). These 9 stents showed lower in-stent density ($n = 9$), severely degraded shape of stents ($n = 2$), and absence of distal segment enhancement ($n = 1$). One of 33 stents without restenosis was falsely diagnosed as restenosis with CT by equivocal lower density of in-stent lumen (Specificity 97%). The accuracy and positive and negative predictive value were 91% (41/45), 90% (9/10), and 89% (32/36), respectively.

Conclusions: Visual assessment with measurement of in-stent luminal density is useful to evaluate the restenosis of coronary artery stents with 16-slice spiral CT.

C-0275

Anomalous coronary anatomy using multi detector computed tomography

P.M.A. van Ooijen, J. Dorgelo, F. Zijlstra, M. Oudkerk; Groningen/NL

Purpose: The purpose of this study was to evaluate the usefulness of multi detector computed tomography (MDCT) for the evaluation of coronary anomalies.

Materials/Methods: MDCT was obtained in 13 patients (9 male, mean age 49.5 y.o.), following a standard protocol on a Sensation16 Cardiac (Siemens Medical Systems, Erlangen, Germany). All patients obtained the CT on clinical indication after a non conclusive conventional catheter angiogram. After acquisition of the data during recording of the ECG signal datasets were reconstructed retrospectively and transmitted to a special purpose visualization workstation (Vitrea, Vital Images, Plymouth, MN, USA).

Results: In the 13 patients, 6 different coronary anomalies were diagnosed (separate ostium of LAD and LCX (2), single vessel LCA (1), LCA from RCA (3) of which two followed a course between the RVOT and aorta, RCA from LCA (6), double LAD (1)). Two observers scored diagnostic quality at a 5 point scale (0 = non diagnostic, 5 = excellent quality) resulting in a mean quality of 3.73.

Conclusion: Multi detector computed tomography provides us with a high quality and accurate modality to visualize and diagnose coronary anomalies. Origin and course of all anomalous coronary arteries was visualized clearly with a high average diagnostic image quality. Shortcomings in conventional catheter coronary angiography, such as uncertainty of the proximal course and the inability to selectively catheterize the anomalous coronary artery are overcome by using contrast enhanced computed tomography.

C-0276

Study of CABG with MDCT: Something rather than patency, stenoses or obstruction!

C. Delgado Sánchez, G. Fernández, E. Santos-Armentia, C. Trinidad, M. Velasco, F. Tardáguila; Vigo/ES

Purpose: To learn other information present on MDCT angiography apart from the assessment of bypass graft patency that the radiologist must know and report.

Methods and Materials: 347 patients were studied with 16-MDCT coronary angiography. 21 patients with total of 54 bypass grafts (22 artery grafts and 32 venous grafts) were also evaluated.

Results: Calcified plaques in supraaortic branches must be reported because surgical cardioplegia predisposes to higher risk of cerebrovascular strokes. The location of coronary arteries close to the sternum is important to avoid injuries during the median sternotomy. Also, the surgeon needs to know if the aorta is free of atherosomatic plaques, calcium or other pathologies because this will be necessary to make an anastomosis in the wall of the proximal aorta. Radiological information regarding atherosomatosis within the distal coronary vessels or intramyocardial pathway of coronary vessels will be important. Description of the aortic valve will be appreciated in order to repair it in the same intervention. The radiologist must also be familiar with grafts used in CABG. Newer surgical techniques are also performed in CABG. Minimally invasive direct coronary artery bypass allow the practice of anastomoses with bypass particularly in the LAD. It can be performed with robotic instruments guided with endoscopic video.

Conclusion: The radiologist can provide very valuable information even in MDCT studies where patients may be candidates for surgery (information prior to surgery) and in relation to the surgical technique performed in CABG or what different grafts were used.

Receptorial (Tc99m-Depreotide scintigraphy) and morphological (CT scan) imaging in the non-invasive characterization of lung nodules

P. Sullo, G. Mazzarella, E.M. Covelli, R. Cioffi, G. Belfiore; Caserta/IT

Purpose: Lung nodule (LN) assessment is based on CT, PET, bronchoscopy and histology. Malignant lung tumor cells overexpress somatostatin receptors (SSTR). Tc99m-Depreotide, a synthetic analog peptide which selectively binds to SSTR, has been proposed to differentiate indeterminate LN. We aimed to investigate Tc99m-Depreotide scintigraphy in the characterization of LN using morphological CT imaging and histology as reference.

Materials and Methods: Nineteen patients (16M, 3F; mean age 67 years) with CT-suspected malignant LN underwented Tc99m-Depreotide tomographic chest and whole-body scintigraphy 2 hours after tracer injection. Each study was considered positive for malignancy when significant uptake was present in CT-detected nodules. Conventional skeletal scintigraphy was also performed in 8 patient. All patients underwent CT-guided transthoracic needle and/or broncoscopic biopsy, and diagnosis was established by histology.

Results: Histologically proven lung cancer was diagnosed in 18 (95%) patients, 7 with squamous cell carcinoma, 5 adenocarcinoma, 5 poorly differentiated non-small cell cancer and 1 lymphoma. In 1 patient cancer was ruled out. Tc99m-Depreotide chest tomography correctly detected malignant LN in all patients with CT and histology suggestive for lung cancer (sensitivity 100%), and was negative in the inflammatory disease patient. Moreover, skeletal scintigraphy was positive in 4 patients detecting 21 metastatic bone lesions; Tc99m-Depreotide whole-body scintigraphy showed significative increased uptake in 12/21 (57%) bone metastases.

Conclusion: Tc99m-Depreotide imaging is an accurate method in the non-invasive diagnostic characterization of LN, complementary to CT scan. Therefore, it might be helpful in the management of LN, especially when invasive procedures are not indicated and/or PET is not available.

C-0278

CT-related prognosis in surgically treated bronchial carcinoid tumors

A. Bray; Rome/IT

Purpose: To define the CT findings at diagnosis and follow-up influencing the long-term survival of patients surgically treated for bronchial carcinoid tumors (BCT). To determine whether BCT show a favourable outcome.

Methods and Materials: A retrospective, single-centre review of 163 patients (86 men and 77 women with a mean age of 49.5 ± 11 years) surgically treated is reported. The cases were segregated into typical and atypical carcinoids. Symptoms were present in 29 patients (17.8%). Pre-operative radiological staging (chest X-ray and total body CT) was performed in all patients. Operations included 145 formal lung resection (89%), 10 wedge resections (6.1%) and 8 sleeve lobectomies (4.9%) plus radical mediastinal lymphadenectomy in all cases.

Results: Histology showed 121 (74.2%) typical carcinoids and 42 (25.8%) atypical carcinoids. Typical and atypical BCT have similar imaging features. The mass appear radiologically as a well-defined, round or ovoid (lobulated) lesion. Nodular calcification is a common CT finding. Atelectasis, air trapping, obstructing pneumonitis and mucoid impaction were usually associated with central BCT (80%). Peripheral BCT (20%) appeared as solitary nodules. Overall 5-year survival was 90.3% (mean 139 months): 100% of NO typical or atypical BCT, 90% in N1 typical BCT and 78.8% in N1 atypical BCT, 22.2% in N2 atypical BCT.

Conclusions: Prognosis in BCT is mainly related to nodal status rather than to histological subtype. In N0 and N1 BCT, no statistical significant difference has been found between typical and atypical subtypes. N2 BCT show a dismal prognosis. Accurate N staging with CT helps optimize surgical planning for BCT.

C-0279

Thoracic tumors and pseudo-tumors associated with interstitial lung diseases: HRCT findings with pathologic correlation

A. Giménez, T. Franquet, A. Hidalgo, T. Salinas, S. Valverde, R. Bordes; Barcelona/ES

Learning Objectives: To review the characteristic HRCT findings of a variety of malignancies and pseudotumors in patients with interstitial lung diseases. To understand the radiologic manifestations on the basis of the different histopathologic features.

Scientific and Educational Exhibits

Background: The purpose of this exhibit is to illustrate the spectrum of thoracic malignancies and non-malignant disorders (pseudotumors) related to a variety of underlying interstitial pulmonary diseases.

Imaging Findings: A wide spectrum of radiographic and CT findings of common and uncommon neoplasms are demonstrated including, among others: BALTo-ma and thymoma in Sjögren's syndrome; bronchioloalveolar cell carcinoma in progressive systemic sclerosis; squamous cell carcinoma in UIP and occupational lung disorders; non-Hodgkin's lymphoma in SLE; mesothelioma and rounded atelectasis in asbestosis; and focal amyloidosis in Sjögren's syndrome.

Conclusion: Because many of these diseases have a highly characteristic CT appearances, this exhibit will aid the practising radiologist in better understanding and recognition of these complications. The pathologic basis for the radiographic findings and correlation with gross or microscopic pathology will be discussed in appropriate cases.

C-0280

Staging of primary non-small cell lung cancer with CT, MR imaging and PET

S.A. O'Keeffe, A. McGrath, S. O'Brien, R. McDermott, F. O'Connell, J.F.M. Meaney; Dublin/IE

Learning Objectives: 1. To describe staging of primary non-small cell bronchogenic carcinoma with CT, MR imaging and PET scanning. 2. To describe an efficient pathway (CXR, CT, bone scanning and MRI) to allow most effective use of PET scanning. 3. To highlight the value of PET scanning in patients with solitary pulmonary nodules without a proven histological diagnosis of lung cancer. 4. To illustrate the role of CT in selecting patients for mediastinoscopy and for eliminating the need for mediastinoscopy in patients with obvious N3 disease. 5. To illustrate the features that designate Stage IIIB (irresectable by conventional criteria but eligible for radical radiotherapy) and Stage IV disease (distant metastases).

Background: The prognosis in patients with non-small cell lung cancer is poor. A primary aim of imaging is to eliminate unnecessary thoracotomy in patients in whom resection is not possible. Traditionally, stage has been determined by a combination of CXR, CT, MR imaging (occasionally) and mediastinoscopy. However, for CT sensitivity, specificity and negative predictive value are all approximately 60%. PET has significantly improved the staging of lung cancer, by enabling the detection of regional lymph node metastases, detecting spread in patients with apparently localized disease, and by demonstrating that a solitary pulmonary nodule probably represents a malignant lesion.

Imaging Findings: A comprehensive review of the findings on CXR, CT, MR imaging and PET scanning that differentiate resectable from irresectable disease is presented.

Conclusion: In this e-poster, we demonstrate combined modality imaging of lung cancer with CT, PET and MR imaging.

C-0281

Clinical validation of automated calculations of emphysema volumes

E. Dharaiya¹, R. Gilkeson², L. Ciancibello¹, K. Subramanyan¹, J. Durgan¹, S. Pohlman¹, A. Vlassenbroek¹; ¹Highland Heights, OH/US, ²Cleveland, OH/US

Purpose: This abstract compares the results of an automatic and manual method for calculation of emphysema.

Method: The study involved 17 patients. In the manual method a 3-D volume rendered image of the lung was created. The lung volume was calculated at a threshold of -750. Emphysema was calculated at a threshold of -950. A 3-D volume rendered image of the emphysema-affected tissue was obtained at the threshold. The automatic algorithm required no user interaction. It automatically aggregated the volumes in airway and lung tissue and labelled them accordingly. The high contrast vascular networks, myocardium, tissues in mediastinum, and lung walls were also labelled. The emphysema regions are characterised as small volumes of air trapping. By subtracting the airway out of lung volume, and subsequently summing all the air-trapped volumes, a total emphysema volume was determined. The algorithm also segmented the right and left lungs, displayed the emphysema distribution in each lung and calculated emphysema volumes in each lung separately.

Results: The emphysema values calculated manually and automatically at a threshold of -950 were 2850.34 ± 1448.55 and 2747.71 ± 1405.52 respectively. The coefficient of correlation between the two methods was 0.9997. The average emphysema volumes for right and left lungs were 1508.99 ± 716.24 and 1238.72 ± 721.47 respectively. The manual procedure takes approximately 10-15 mins while the automatic method takes about 1 min.

Conclusion: Emphysema quantification is very important in planning the surgical procedures for treatment of the disease. The automatic method provides a fast and close estimation of the emphysema and eliminates user variability.

C-0282

Qualitative and quantitative analysis of contrast enhancement maps for pulmonary nodule characterization

I. Petkovska, S.K. Shah, M.F. McNitt-Gray, H.J. Kim, J.G. Goldin, D.R. Aberle; Los Angeles, CA/US

Purpose: To determine whether quantitative and qualitative texture features derived from contrast enhancement maps, acquired on indeterminate lung nodules, can distinguish benign from malignant nodules.

Materials and Method: Thin section, contrast-enhanced CT (baseline and post-contrast series acquired at 45, 90, 180, and 360 seconds following IV contrast administration) was performed on 29 patients with lung nodules (14 benign, 15 malignant). A thoracic radiologist manually identified the boundary of each nodule and selected the axial slice with the greatest diameter on the baseline series. The post-contrast series with maximum enhancement was volumetrically registered to the baseline series. Corresponding axial images from the two series were subtracted and the difference voxels were quantized into 7 color-coded bins to create the contrast enhancement map. A thoracic radiologist visually scored each map for: magnitude, extent, and heterogeneity of enhancement on a 5-point scale. Also 14 quantitative texture features were calculated for each map. All features were analyzed for differences between benign and malignant nodules.

Results: Malignant nodules demonstrated a more heterogeneous pattern of enhancement ($p < 0.01$). Neither magnitude nor extent of enhancement was significant. A statistical analysis was performed to combine the 14 texture features to a single factor, which was significantly different between benign and malignant nodules ($p = 0.010$).

Conclusion: These maps may provide a richer understanding of nodule behavior giving information of contrast media spatial distribution. Heterogeneity may relate to the interplay between host stromal elements and neovascularity. Further studies are necessary to determine whether these patterns correlate with the biological behavior of neoplasms.

C-0283

CT findings of gefitinib-related interstitial pneumonitis in 65 patients: Multi-institutional analysis of West Japan Thoracic Oncology Group (WJTOG)

M. Endo¹, T. Johkoh², K. Kimura³, N. Yamamoto¹, ¹Shizuoka/JP, ²Osaka/JP, ³Kobe/JP

Purpose: To clarify the image characteristics of interstitial pneumonitis (IP) induced by the newly-developed molecular-targeting drug gefitinib.

Materials and Methods: In a total of 1,976 patients with non-small cell lung cancer, to whom gefitinib was administered from August to December 2002, 102 were suspected of having IP. 65 of these patients had undergone CT as well as chest roentgenogram at onset. Based on the findings of chest roentgenogram and CT, reviewed and analyzed by three radiologists, the final definitive diagnosis of gefitinib-related IP was determined, adding clinical data in the medical records. Moreover, CT findings were classified into four patterns: Pattern A: non-specific areas with ground-glass attenuation; B: multifocal areas of airspace consolidations; C: patchy distribution of areas with ground-glass attenuation accompanied by interlobular septal thickening, such as seen in acute eosinophilic pneumonia; and D: extensive bilateral areas with ground-glass attenuation or airspace consolidations with traction bronchiectasis, such as seen in acute interstitial pneumonia.

Results: Seventy patients were diagnosed as having gefitinib-related IP. The diagnostic images were classified as pattern A in 29 patients, B in 3, C in 7, D in 20 and others in 11. 24 patients with pattern A, 1 with pattern B, 7 with C and 12 with D were classified into a single pattern by CT findings. The patients dying due to gefitinib-related IP were significantly more frequent in pattern D.

Conclusion: Gefitinib is considered to induce IP in a certain proportion of patients, and the imaging findings are similar to drug-induced pneumonitis caused by conventional anticancer agents.

C-0284

Neuroendocrine proliferations of lung: Spectrum of diseases

A. Hidalgo, T. Franquet, A. Giménez, G. Sánchez, C. Blancas, R. Bordes; Barcelona/ES

Learning Objectives: To review the radiologic and pathologic appearance of neuroendocrine proliferations of the lung. To learn how to deal with problems related to diagnosis and classification of these tumors.

Background: Neuroendocrine proliferations of the lung are a heterogenous group of tumors of varying biological potential. The recent classification of these tumors includes 6 entities: Small cell lung carcinoma, Large cell neuroendocrine carcinoma,

Scientific and Educational Exhibits

noma, Carcinoid, Atypical carcinoid, Neuroendocrine hyperplasia and Tumorlet.

Procedure Details: We review the radiological findings of these processes including chest radiographs, CT and MR imaging. We correlate the images with bronchoscopic and pathologic findings. SCLC often present with bulky hilum and mediastinal lymph node masses. LCNC appears as a well-defined and lobulated tumor with no air-bronchograms or calcification. The differentiation between typical and atypical carcinoid tumor is based mainly on the mitotic count. Neuroendocrine hyperplasia and tumorlets are characterized by mosaic perfusion due to air trapping, airway wall thickening, and small nodules on HRCT.

Conclusion: Radiologists have to be aware of these tumors and to suggest a diagnosis based on imaging findings.

C-0285

Volumetric expiratory high-resolution CT of the lung: Basics and clinical applications

M. Nishino, M. Kuroki, V. Raptopoulos, J.F. Copeland, P.M. Boiselle, H. Hatabu; Boston, MA/US

Learning Objectives: To become familiar with 1) technical aspects of volumetric expiratory high-resolution CT (VEHRCT) 2) usefulness of contiguous scans, coronal and sagittal reformats, and 3) clinical application of VEHRCT in various diffuse lung diseases.

Background: Expiratory HRCT is a powerful adjunct to inspiratory HRCT in detecting various small airway diseases. We have developed a new VEHRCT which allows volumetric data acquisition of the lungs both at end-inspiration and end-expiration, with equivalent radiation dose compared to the standard non-contiguous expiratory HRCT. VEHRCT has been applied in patients with diffuse lung disease with small airway abnormalities.

Imaging Findings: The contiguous axial HRCT images enabled better identification of the conducting airway to the areas of air trapping ($p < 0.0001$). The coronal reformats provided added value by clearer visualization of the borders of air trapping over contiguous axial images ($p = 0.001$). Sagittal reformats provided significant additional information compared to axial images ($p = 0.004$). The volume rendering of the lungs at end-inspiration and end-expiration demonstrated changes in volume and attenuation after expiration in a three-dimensional manner, allowing for easy recognition of air trapping. In patients with emphysema, asthma, bronchiectasis or sarcoidosis, VEHRCT demonstrated representative findings in a multiplanar and 3 dimensional manner, providing added value over contiguous axial images.

Conclusion: VEHRCT with multiplanar reformats provides additional information in evaluating areas of air trapping and their conducting airways, and is clinically useful in evaluating diffuse lung diseases with small airway abnormalities. Further possibilities include quantitative analysis of lung biomechanics using computational analysis.

C-0286

Correlation between lymph node metastasis and the ratio of high attenuation area to tumor diameter by HRCT in adenocarcinoma of the lung of 3 cm or less

R. Nishio¹, S. Acata², N. Ikeda², K. Saito¹, H. Kotake¹, H. Kato², K. Abe²; ¹Ibaraki/JP, ²Tokyo/JP

Purpose: Limited resection of the lung can improve post-operative QOL, but it requires the absence of lymph node metastases. Early adenocarcinoma usually appears as ground-glass attenuation. We studied adenocarcinoma of the lung of 3 cm or less in diameter to determine whether or not there is a correlation between the ratio of high attenuation area to the tumor diameter (H/T ratio), and the presence of lymph node metastasis.

Method and Materials: From January 1996 to June 2004, we studied 281 patients with adenocarcinoma of the lung (≤ 3 cm) by pre-operative HRCT. The correlation between the H/T ratio and the presence of lymph node metastasis was evaluated. HRCT images were evaluated by two radiologists.

Results: None of the patients with tumors of ratios of 60% or less (33.5% of all cases) had lymph node metastasis. In contrast, tumors at H/T ratio of 100% had lymph node metastasis even if the diameter was only 6 mm. In tumors with H/T ratio greater than 60%, 16.6% had lymph node metastasis.

Conclusion: If the H/T ratio is around 60% or less, the likelihood of lymph node metastasis is nil, and prognosis may be considered to be extremely favorable. This data may be useful when considering limited resection.

C-0287

Spectrum of CT features in cavitary or cystic pulmonary metastases:

Correlation with primary and histologic types of the tumor

T. Koyama, S. Umeoka, T. Kubo, K. Tamai, H. Ueda, H. Kobayashi, H. Wada, T. Saga, K. Togashi; Kyoto/JP

Purpose: The purpose of this study is to investigate common histologic types and primary sites for cavitary and/or cystic pulmonary metastases, and to describe the spectrum of CT features in correlation with the primary and histology.

Methods and Materials: CT images in 57 patients with cavitary/cystic pulmonary metastases (age: 27-87, mean: 62.7) were retrospectively reviewed by two radiologists, for the size, margin of the largest lesion, the number of the cavitary/cystic lesions, and associated other CT findings. More than ten lesions were regarded as multiple. CT findings were correlated with histologic subtypes and primary.

Results: Histology included 32 adenocarcinoma (colon:13, pancreas:7, lung:5, biliary tract:4, others:3), 12 SqCC (head&neck:6, esophagus:3, others:3), 3 TCC (all urinary tract) and 10 sarcomas. Cystic metastases were seen in 9 patients, including one adenocarcinoma and 8 sarcomas, 5 of which were associated with pneumothorax. The remaining patients had cavitary metastases. The size of the largest lesions in adenocarcinoma, SqCC, sarcoma and TCC was 13.2 ± 10.2 cm, 28.6 ± 14.2 cm, 15.8 ± 4.1 cm and 23.7 ± 11.5 cm, respectively. The inner surface was irregular in 9 SqCC (75%), 3 TCC (100%), 11 adenocarcinoma (34%). The outer margin was smooth and round in 28 adenocarcinoma (81%), 9 SqCC (75%), 2 TCC (67%), and all sarcomas (100%). Multiple cavitations were seen in 21 adenocarcinoma, 1 SqCC and 7 sarcomas.

Conclusion: In cavitary and/or cystic metastases, adenocarcinoma of colon and lung, SqCC of head & neck, and sarcomas are common. Sarcomas commonly cause cystic metastases associated with pneumothorax. SqCC and TCC tend to form large cavitations with irregular inner surface, while adenocarcinoma tends to cause multiple small cavitation with smooth margin.

C-0288

Mediastinal disease of lymphatic tissue: Imaging findings with histopathologic correlation

T.U. Kim, Y.J. Jeong, K.-I. Kim, T.Y. Moon; Busan/KR

Learning Objectives: 1. To describe the categories of mediastinal disease of lymphatic tissue and their imaging findings with histopathologic correlation. 2. To provide the means of differential diagnosis between the various diseases.

Background: Mediastinal lymphadenopathy is a not uncommon radiologic finding on helical CT scan. Various diseases result in mediastinal lymphadenopathy, including neoplasms, infectious and inflammatory disease, and lymphoproliferative disorders. Differential diagnosis of mediastinal disease of lymphatic tissue is a challenging process, because radiographic appearances are variable and non-specific.

Procedure Details: Mediastinal diseases of lymphatic tissue are classified into three categories: neoplasms (lymphoma, bronchogenic cancer, metastasis), infectious and inflammatory disease (tuberculosis, sarcoidosis, amyloidosis), and lymphoproliferative disorders (Castleman's disease, angiolymphoblastic lymphadenopathy, infectious mononucleosis, Kikuchi disease). We describe the imaging findings of histologically proven mediastinal disease of lymphatic tissue in 275 patients, in terms of predominance of involved lymph node, nodal enhancement and morphology, and internal characteristics and correlate them with histopathologic findings.

Conclusion: Awareness of specific patterns of predominance of involved lymph node, nodal enhancement and morphology, and internal characteristics helps in the differential diagnosis and optimal treatment of mediastinal disease of lymphatic tissue.

C-0289

The spectrum of CT findings in pleural mesothelioma

A. Massuet, X. Gallardo, E. Castañer, J. Mata, D. Gil; Sabadell/ES

Learning Objectives: To describe the computed tomography (CT) features of malignant pleural mesothelioma (MPM). To illustrate the typical and atypical CT findings for this tumour. To describe the different ways that this tumour can spread.

Background: MPM is an uncommon neoplasm that arises from the pleura. Most cases are associated with prior asbestos exposure. Histologic evaluation is required to reach the definitive diagnosis. CT, MR and PET in combination are crucial in staging and determining the most appropriate treatment option for patients with this tumour. CT is the modality most frequently employed for the initial study; MR and PET are helpful in delineating the extent of disease.

Scientific and Educational Exhibits

Procedure Details: We reviewed the CT findings of 50 patients with pathologically confirmed MPM diagnosed at our center between 1990 and 2004. We present the most representative cases of typical MPM presentation with incipient signs that suggest the diagnosis. We also present selected cases of atypical presentation simulating pulmonary or chest wall lesions or a mediastinal mass. We show different kinds of local and distant dissemination, such as hilar and mediastinal adenopathies, pulmonary metastases, metastasis to the liver, to the brain and to the bone, as well as cases of carcinomatous lymphangitis and peritoneal carcinomatosis.

Conclusion: CT is usually the primary imaging technique used when this disease is suspected, so it is important to recognise how this tumour presents in this imaging modality. Although the definite diagnosis requires histopathologic evaluation, CT can be helpful in suggesting this malignant pleural disease.

C-0290

CT evaluation of non-malignant tracheal stenosis: What the surgeon needs to know

M.A. Molla Landete, F. Ferrando Valls, H. Benlloch, V. Tarazona Hervas, J. Palmero da Cruz; Valencia/ES

Learning Objectives: To demonstrate the application of MDCT with multiplanar and 3D reconstruction in the evaluation of non-malignant focal tracheal stenosis before surgical procedures. To describe the procedure and show its contribution to such surgical techniques.

Background: Benign tracheal stenosis is a rare condition, being mostly a complication of endotracheal intubation or placement of a tracheostomy tube. Bronchoscopy remains the primary procedure for the diagnostic work-up of this disease. However, evaluation with CT may aid in planning of surgical procedures particularly for tracheal resection with end-to-end anastomosis. Between Jan 1999 and Aug 2004, 18 patients with benign tracheal stenosis were diagnosed in our center. In all cases CT studies were performed before planning therapy.

Procedure Details: The scanned area was from 1-2 cm below carina to laryngeal ventricles in a caudo-cranial acquisition. Laryngeal cartilage integrity and vocal cord position were evaluated. Oblique axial images to the tracheal lumen assessed the shape, width and integrity of cartilaginous wall and submucous tissue. These images were the most accurate in measuring lumen diameter. Oblique coronal images along tracheal lumen are needed to measure distance from vocal cords to the most proximal altered tracheal wall and from distal end of the abnormality to the carina. Healthy tracheal length above and below the pathologic area must measure at least 7 cm.

Conclusion: MDCT can be helpful in determining the grade and extension of benign tracheal stenosis. Preoperative studies must include tracheal wall characteristics and exact length of healthy trachea from larynx to carina in order to allow surgical reconstruction.

C-0291

Lung nodule analysis software: Is what you see really what you get?

S.M. Ellis, M. Roddie, L. Honeyfield, J. Dehmeshki; London/UK

Purpose: To test the ability of 4 lung nodule analysis programs (3 commercially available) to accurately extract nodules from normal anatomical structures.

Materials and Methods: A lung phantom (QRM, Moehrendorf, Germany) was scanned on Phillips and Siemens 16 slice multislice CT scanners. The phantom contained 40 spherical nodules: 8 that were freestanding, 7 encasing and 9 adjacent to simulated vessels, 8 adjacent to and 8 arising from the chest wall. Analysis of each nodule yielded a 3D representation, which was used to determine the success or failure of the program under test to extract the nodule alone.

Results: All the nodule analysis programs successfully "extracted" the freestanding nodules. The commercial programs failed to exclude vessel or chest wall from those nodules adjacent to or intimately associated with these structures. The in-house software accurately extracted 40% of such nodules automatically and, with the ability to semi-automatically alter the detection algorithm, successfully extracted all but one.

Conclusion: Once a nodule analysis program has failed to exclude adjacent normal structures from a nodule, the resulting volume of that analysis will be flawed. There is certainly room for improvement in currently available nodule analysis software and the ability to semi-automatically alter the detection algorithm rendered a definite advantage to the in-house software.

C-0292

How many biopsies are necessary in pulmonary nodules to obtain an adequate diagnostic accuracy?

M. Wehrschaetz, H. Deutschmann, U. Aldrian, M. Tillich; Graz/AT

Purpose: To determine the frequency of biopsies in pulmonary lesions that is necessary to obtain adequate (the highest possible) accuracy in histological work up.

Materials and Methods: 260 patients suffering from thoracic lesions underwent computer tomography (CT)-guided core-cut biopsy using coaxial technique, from January 1999 to April 2004. These were evaluated retrospectively. Overall 669 adequate biopsies were taken (from one to five biopsies in each setting). The specimens were marked sequentially. Histological work up was performed on each biopsy. All biopsies were performed using a 19 gauge introducer needle and a 20 gauge core cut biopsy needle in all patients. The biopsy results were correlated to histology after surgery or autopsy. The number of biopsies was determined that is necessary to achieve the highest possible accuracy in diagnosing pulmonary lesions. Written informed consent was given by all patients.

Results: In 591 of 669 biopsies (88.3%) there were positive results. The accuracy was 87.4%. In 193 of 260 patients (74.2%), a suspected malignancy was confirmed. In 50 of 260 patients (19.2%), a benign lesion could be diagnosed. 17 (6.5%) patients were lost to follow-up. The first, second and third biopsy had an accuracy of 63.6%, 89.2% and 91.5%, respectively. More biopsies did not show any higher impact on accuracy.

Conclusion: To reach adequate diagnostic accuracy with CT-guided core cut biopsy, three adequate specimens are recommended.

C-0293

Cytomegalovirus pneumonia in immunocompromised patients with haematological disease: Correlation of HRCT findings with clinical outcome

M.S. Horger, C.A. Pfannenberg, H. Einsele, H. Hebart, R. Beck, C.D. Claussen; Tübingen/DE

Objectives: To assess correlation between HRCT findings of Cytomegalovirus (CMV) pneumonia in haematological patients and outcome.

Materials and Methods: We retrospectively evaluated the CT scans of 36 patients with CMV positive culture from broncho-alveolar lavage (BAL), with respect to CT morphology, and correlated these results with the outcome, also taking into consideration other risk factors including: underlying disease, CMV seropositivity, time of onset of antiviral therapy and presence of graft versus host disease (GvHD). The patients included 22 men and 14 women ranging in age from 26-80 years (mean age, 42 years). CT morphology of pulmonary infiltrates was classified into: ground-glass opacities (GGO), nodular, reticular or reticulonodular infiltrates and patchy areas of consolidation.

Results: 18 patients showed focal pulmonary abnormalities, whereas 18 patients had diffuse bilateral infiltrates. 19 patients demonstrated larger areas of GGO, 9 patients showed focal parenchymal consolidation, 7 patients presented with nodular opacifications and 1 patient showed only reticulation. 13 patients died during the acute episode of CMV pneumonia despite antiviral therapy. 12 of them belonged to the group showing either diffuse, or patchy GGO. 1 patient presented initially a small nodular CT pattern, which developed at follow-up into a patchy consolidation pattern as observed in the rest of the patients with fatal outcome, despite intensive ongoing antiviral therapy.

Conclusion: Initial HRCT findings in immunocompromised patients with CMV pneumonia seem to have an impact on patient outcome, being unfavourable in those forms of disease beginning as bilateral, diffuse or patchy ground-glass opacities followed by progressive consolidation, and in those where the CT morphology changes at follow-up to diffuse GGO and consolidation.

C-0294

Imaging of malignant pleural mesothelioma using morphological and functional MR imaging

C. Plathow, C. Fink, A. Sandner, M. Klopp, M. Puderbach, C. Thieke, A. Schmähl, H.-U. Kauczor; Heidelberg/DE

Learning Objectives: To introduce a routine state-of-the art protocol for morphological and functional MR imaging of pleural mesothelioma and illustrate typical findings.

Background: The interest in pleural mesothelioma has markedly increased in recent years because of the expected increase in incidence of more than 50% in the coming decade, and because of new therapeutic strategies that have become available. A correct and early histologic diagnosis, a complete and accurate staging of the tumor, and the differentiation between residual tumor and pleural fibrosis are essential to evaluate the efficacy of new therapeutic strategies.

Scientific and Educational Exhibits

Procedure Details: The imaging protocol at 1.5 T includes breathhold T1 and T2 weighted morphological MR imaging with and without ECG and respiratory gating. For the assessment of vascular invasion, contrast-enhanced 3D MR angiography with parallel imaging techniques is performed. Functional measurements include contrast-enhanced 3D perfusion with high temporal resolution as well as dynamic cine-MR imaging to assess infiltration of the diaphragm and the chest wall. The protocol takes about 30 minutes. Typical imaging findings are correlated to CT findings and discussed with regard to the TNM-classification.

Conclusion: While CT is the most frequently applied diagnostic tool, MR imaging using parallel imaging techniques gives more information, especially in terms of infiltration of the diaphragm and the spinal canal, but also in differentiating pleural mesothelioma from other malignancy or from benign pleural disease.

C-0295

The value of emergency room (ER) chest radiographs in patients with unsuspected thoracic pathology

M.G. Skilakaki, J.V. Kalogeropoulos, P. Galina, P. Polyviou, P.N. Piperopoulos; Athens/GR

Purpose: This study investigated the role of plain chest film in the evaluation of patients admitted to ER without any symptoms or clinical signs of thoracic pathology.

Methods and Materials: Conventional chest radiograph (PA or AP projection) was performed in 418 consecutive patients (age 32-96 years) without any history of respiratory disease (patients with fever and no other symptoms from the respiratory system were also excluded) and in 404 consecutive patients (age 37-89 years) in whom the possibility of the thoracic pathology was considered in their differential diagnosis.

Results: Of the subjects with no clinical signs of intrathoracic disease 86 (20.6%) had positive findings on their chest plain film: 62 patients (14.7%) had active disease of the lung parenchyma or/and the mediastinum, 18 patients had findings of old granulomatous disease or emphysema and 3 patients had metastatic bone lesions of unknown primary tumor. Further investigation in these cases included lateral chest radiograph (6 cases) and/or chest CT (46 cases). Of the subjects with possible thoracic pathology 224 had findings on chest radiograph and in 180 the plain chest film was normal.

Conclusion: Although positive history is statistically a very strong indication ($p < 0.001$) for performing chest radiograph, our study revealed a high percentage (20.6%) of positive findings in asymptomatic patients. We suggest that conventional chest radiograph (PA or AP projection) should be included in the investigation protocol of all patients admitted to ER.

C-0296

Multislice CT and SPECT-CT: Correlation in diagnosis of pulmonary nodules

G. Sergiacomi, M. Leporace, M. Cariani, F. Laviani, A. Bartolomucci, O. Schillaci, G. Simonetti; Rome/IT

Purpose: To demonstrate the validity and efficacy of ms-CT and Spect-CT in the assessment of pulmonary lesions.

Methods and Materials: 46 patients (34 males, 12 females; age range: 59-82 years) with solitary pulmonary nodules demonstrated on CT examination, underwent spect-CT after Tc-99m SESTAMIBI i.v. injection. Tc-99m SESTAMIBI is a lipophilic cation that is accumulated in areas where there is increased cellular metabolic activity. We used ms-CT LightSpeed 16 (GE Medical Systems) and a dual-head γ -camera Millennium (GE Medical Systems). To evaluate the diagnostic accuracy, a further ms-CT control was performed 4 months later.

Results: In 36 patients with 8-12 mm lesions at the first CT examination with positive scintigraphy, at the 4 months follow-up, CT demonstrated a volumetric increase, while histological examination revealed malignant lesions: 22 adenocarcinomas, 10 bronchogenic carcinomas, 2 large cell carcinomas and 2 metastases. Two false negative cases were adenocarcinomas with unclear CT characteristics, low tracer up-take at scintigraphy and a volumetric increase at the 4 month CT examination. Two false positive cases were granulomas with dubious CT characteristics and positive scintigraphy without significant volumetric increase (> 20%) at follow-up. 6 cases were diagnosed histologically as hamartomas, CT yielded dubious results with absence of radiotracer up-take and no significant volumetric increase at follow-up.

Conclusion: Scintigraphic evaluation revealed sensitivity of 0.95 and specificity of 0.75. Our study proposes a diagnostic protocol for the early diagnosis of pulmonary nodules with the aim of anticipating the surgical treatment of suspicious lesions at their first identification at CT.

C-0297

Multislice CT with retrospective ECG gating in the evaluation of central lung tumours

G. Sergiacomi, M. Cariani, M. Leporace, M. Sperandio, A. Romagnoli, G. Simonetti; Rome/IT

Purpose: To evaluate the efficacy of retrospective ECG gating in the assessment and diagnosis of central pulmonary tumours with possible hilar and parahilar structures involvement.

Methods and Materials: 50 patients (32 males and 18 females, age range 45-72) with central pulmonary tumours previously suspected on chest X-ray examinations (28 in the right lung and 22 in the left lung) were selected. Beta-blocker therapy was applied in 26 patients to reduce heart rate. The study was performed with a 16-row ms-CT with retrospective ECG gating after administration of contrast medium and saline flush. The axial images were reformatted using MPR, MIP and VR algorithms and evaluated independently by 2 experienced cardio-thoracic radiologists. Readers recorded their degree of diagnostic confidence for suspected involvement of the hilar and parahilar structures in each case on a 5 point scale. Twenty patients with central lung cancer studied without ECG gating were used as controls.

Results: Retrospective ECG gating significantly improves ($p < 0.05$) the assessment of hilar and parahilar tumour involvement. Without ECG gating the two readers recorded the maximum score on the confidence scale in 49% and 52% of cases respectively. With ECG gating the maximum score was recorded in 75% and 80% of cases respectively.

Conclusion: Retrospective ECG gating, thanks to reduced cardiac motion artefacts, allows a better evaluation of hilar and parahilar vascular and bronchial structures and optimal visualization of possible neoplastic pericardial and myocardial involvement, and can therefore be a valid tool in the evaluation of central pulmonary tumours and in planning a therapeutic approach.

C-0298

Characteristic high resolution computed tomography findings of pulmonary tuberculosis in patients with smear-positive sputum

N. Kosaka, T. Sakai, H. Uematsu, H. Kimura, M. Hase, M. Noguchi, H. Itoh; Fukui/JP

Purpose: To characterize the high-resolution computed tomography (HRCT) findings that can predict the infectivity of pulmonary tuberculosis.

Methods and Materials: HRCT images in 48 patients (age range: 21-92 years; mean age 58 years; 14 females, 34 males) with active pulmonary tuberculosis were retrospectively reviewed in this study. The 48 patients were divided into two groups: sputum-smear positive ($n = 25$) and negative ($n = 23$). HRCT (slice thickness: 2 mm) findings of these two groups were independently reviewed by two experienced radiologists, focusing on the presence or absence of nodular opacity, ground-glass opacity, cavitation, centrilobular opacity, bronchial wall thickening, and air-space consolidation.

Results: The frequency of air-space consolidation in the smear-positive group was significantly higher than that in the smear-negative group ($P < 0.005$), while its overall frequency was the lowest of the frequencies we measured. The frequencies of cavitation and ground-glass opacity in the smear-positive group were also statistically higher than those in the negative group ($P < 0.05$). The frequency of bronchial wall thickening, centrilobular opacity, and nodular opacities were not statistically significant between the two groups.

Conclusion: HRCT findings such as air-space consolidation, cavities, and ground-glass opacities have a significant correlation with smear-positivity in pulmonary tuberculosis. Therefore, HRCT may be useful to evaluate the infectivity of pulmonary tuberculosis, in addition to the establishing the diagnosis of active pulmonary tuberculosis.

C-0299

Computer-aided diagnosis: Differentiation between malignant and benign solitary pulmonary nodules using quantitative measures of shape

S. Iwano, T. Nakamura, Y. Kamioka, T. Ishigaki; Nagoya/JP

Purpose: To determine whether digital image analysis could differentiate between benign and malignant solitary pulmonary nodules (SPNs) based on morphological classification of high-resolution CT (HRCT) images.

Methods: HRCT images (0.5-mm or 1-mm slice thickness) of 97 solid SPNs were obtained. The diagnoses of these 97 cases (54 benign and 43 malignant) were determined from either radiological follow-up or pathological specimens. HRCT images were binarized with predefined threshold values (-300 HU), and the desired pulmonary nodules were extracted on image processing computer

Scientific and Educational Exhibits

software. From these binary image data, circularity ($= 4\pi \cdot \text{Area}/\text{Perimeter}^2$) and 2nd-moment of each nodule were calculated as quantitative measures of shape, to differentiate malignant and benign.

Results: Malignant nodules had lower measures in both circularity and 2nd-moment. Those nodules with circularity ≤ 0.75 and 2nd-moment ≤ 0.18 , had a high probability of malignancy, although several malignant nodules had high 2nd-moment measure because of emphysema, pleural indentation or air-bronchogram. Using these threshold values results in a sensitivity of 81.4%, specificity of 81.5%, positive predictive value of 77.8%, negative predictive value of 84.6%, and accuracy of 81.4%.

Conclusion: HRCT image analysis on a computer could differentiate between malignant and benign pulmonary nodules using quantitative measures of shape. This method could be applied to computer-aided diagnosis.

C-0300

Visualization of aberrant bronchial arteries and their anatomic course by CT bronchial angiography

S.M. Shin, Y.J. Jeong, K.I. Kim, C.W. Kim, T.Y. Moon; Busan/KR

Purpose: To evaluate the ability of multi-detector CT (MDCT) to identify aberrant bronchial arteries and their course.

Materials and Methods: Bronchial arteries (BA) were evaluated with MDCT bronchial arteriography (CTBA) in 83 patients with hemoptysis. CTBA was performed with 2.5 cc/sec injection rate of 100 cc non-ionic contrast agent and 1.25-2.5 mm collimation with a pitch of 6. Based on the original images and coronal reformats, two independent observers recorded the type of bronchial arteries (Classification of Cauldwell et al: type I-IV) and the presence of aberrant bronchial arteries. If aberrant bronchial arteries were present, the origins of the aberrant bronchial arteries were also recorded. Results on CTBA were compared with those of conventional bronchial arteriography (CBA).

Results: CTBA showed 61 (73%) type I, one (1%) type II, three (5%) type III, one (1%) type IV, seven (8%) common trunks of both BA, and nine (11%) aberrant bronchial arteries. Of nine aberrant bronchial arteries demonstrated on CTBA, three originated from the left internal mammary artery, two from the right subclavian artery, two from the aortic arch, one from the right bronchial artery, and one from the left thyrocervical trunk. The anatomic course of aberrant bronchial arteries on CTBA was correctly classified in nine of ten patients (90%) on CBA. Only one aberrant left bronchial artery, arising from the right bronchial artery, was not correctly identified on CTBA.

Conclusion: MDCT bronchial arteriography is a reliable, non-invasive technique to identify aberrant bronchial arteries and their course prior to arterial embolization in patients with hemoptysis.

C-0301

Differential CT features of focal pneumonia versus mucinous bronchioloalveolar carcinoma (BAC) mimicking pneumonia

T. Kim¹, S. Kim¹, S. Chung², B. Choi¹; ¹Seoul/KR, ²Yongin/KR

Purpose: To assess the characteristic CT findings of focal pneumonia versus mucinous BAC mimicking pneumonia, which were located at the lung periphery.

Methods and Materials: Two radiologists in consensus reviewed the thin-section CT findings in 47 patients with a focal area of parenchymal opacification, confirmed as a focal pneumonia or mucinous BAC, at the lung periphery. We evaluated presence of ground glass attenuation, marginal conspicuity, CT angiogram sign, air bronchogram sign, a bubble-like low-attenuation area, adjacent pleural thickening and retraction, pleural effusion, extra-pleural fatty hypertrophy, presence of bronchial wall thickening proximal to the lesions, and air-trapping in the adjacent normal lung. We used Chi-square test to evaluate the statistically significant differences between focal pneumonia and mucinous BAC mimicking pneumonia. A *p* value of < 0.05 was considered as being statistically significant.

Results: Twenty-nine patients had a focal pneumonia including pulmonary tuberculosis in 6 patients, and 18 patients were confirmed as a mucinous BAC or mixed adenocarcinoma with a predominant BAC pattern. The latter displayed the presence of a bubble-like low-attenuation area, whereas the former displayed bronchial wall thickening proximal to the lesions and adjacent pleural thickening surrounding the lesions. There were no significant differences in other CT findings.

Conclusion: A focal area of parenchymal opacification on the thin-section CT scans may suggest a focal pneumonia rather than a mucinous BAC when it shows bronchial wall thickening proximal to the lesions and adjacent pleural thickening surrounding the lesions.

C-0302

HRCT in differential diagnosis of types of interstitial pneumonia

A.L. Yudin, Y. Abovich; Moscow/RU

Purpose: To identify specific CT patterns of the different histologic types of interstitial pneumonias and create algorithms for differential diagnosis.

Methods and Materials: Between January 1998 and February 2004, 312 patients with diffuse infiltrative lung diseases were examined in our department. 137 patients had interstitial pneumonia, of whom 97 had idiopathic interstitial pneumonia with histologic verification (24 - UIP, 30 - NSIP, 17 - AIP, 14 - DIP, 12 - COP). HRCT features and their combinations were analyzed to reveal specific patterns.

Results: Different combinations of HRCT features determined positive predictive index for UIP - 100%, NSIP - 95%, AIP - 92%, DIP - 78%, COP - 67%. On the basis of specific patterns we created an algorithm for differential diagnosis of interstitial pneumonias. With the help of this algorithm independent experts were able to state true diagnoses in 88% of cases.

Conclusion: HRCT provides radiologists with ample opportunity to differentiate interstitial pneumonias without histologic verification.

C-0303

"Halo sign" on pulmonary CT: Radiologic-pathologic correlation

M. Parrón, M. Navarro, M. Pardo, I. Torres, M. Fernández-Veilla, J. Echeveste; Madrid/ES

Learning Objectives: To describe and illustrate the spectrum of diseases that can cause pulmonary nodules with the "halo sign" on thoracic computed tomography (CT). To show the correlation of the "halo sign" with pathologic findings.

Background: The "halo sign" consists of a halo of ground glass attenuation surrounding a pulmonary nodule. The "halo sign" has been demonstrated in a number of conditions associated with haemorrhagic nodules, and occasionally, with non-haemorrhagic pulmonary nodules. In the appropriate clinical setting, it is considered an early sign of pulmonary aspergillosis. The CT scans of patients with pulmonary nodules from our thoracic pathology database were reviewed and those with "halo sign" were selected. Diagnosis was always obtained by means of laboratory, cytologic, histological or microbiological tests. The pathology basis of this sign is discussed, and shown in appropriate cases.

Imaging Findings: The "halo sign" was found in association with four different pathological entities: haemorrhagic pulmonary nodules of infectious aetiology (invasive pulmonary aspergillosis, viral pneumonia, mucormycosis, cryptococcosis, candidiasis, tuberculosis, septic pulmonary embolism); haemorrhagic pulmonary nodules of non-infectious aetiology (Wegener granulomatosis, Kaposi sarcoma, haemorrhagic pulmonary metastasis); pulmonary nodules with halo due to neoplastic cell infiltration (bronchiolo-alveolar carcinoma, lymphoma, and other primary or secondary pulmonary tumours); and pulmonary nodules with halo due to non-haemorrhagic inflammatory injuries (sarcoidosis, inflammatory pseudotumor, organizing pneumonia, actinomycosis).

Conclusion: The "halo sign" is a non-specific but useful finding. A number of diseases can exhibit pulmonary nodules with a "halo sign" on the thoracic CT, displaying different pathological features, not only haemorrhagic nodules.

C-0304

Single versus four-level tumour perfusion measurement using dynamic helical contrast enhanced multi-detector computed tomography (MDCT):

Effect on measurement agreement and potential for whole tumour assessment

Q.S. Ng¹, V. Goh¹, E. Klotz², H. Fichte², D. Carnell¹, M. Saunders¹, P.J. Hoskin¹, A.R. Padhani¹; ¹Northwood/UK, ²Forchheim/DE

Purpose: To assess measurement agreement of single versus four level CT perfusion measurements using a novel dynamic helical technique.

Materials and Methods: Ten patients with lung cancer were examined using 16-detector row CT (Sensation 16, Siemens). 90 s dynamic acquisitions were obtained through the entire tumour following IV contrast infusion, and repeated within 24 hours. Median tumour permeability (0.5 ml/min/100 ml) and relative blood volume (0.1%) were determined (Patlak analysis; Functional CT, Siemens) on a pixel-by-pixel basis for a single 10 mm central axial image, and for three further adjacent slices. Measurement agreement was assessed using Bland-Altman statistics, following natural logarithmic transformation of values where necessary.

Results: Mean difference (95% limits of agreement) for permeability and blood volume were -0.07 (-0.74 to +0.60) and 20.2 (-39.7 to +80.1) respectively for one level, and 0.02 (-0.40 to +0.45) and 12.9 (-36.2 to +62.1) respectively for four levels. Intraclass correlation coefficients were 0.8 and 0.3 respectively for one

Scientific and Educational Exhibits

level, and 0.9 and 0.5 for four levels. Within subject standard deviation (within patient coefficient of variation) were 0.24 (27%) and 25.0 (40%) respectively for one level, and 0.15 (16%) and 19.2 (31%) respectively for four levels. For therapeutic response assessment, in a single patient, a permeability change of -48% to +92%, and blood volume of \pm 111% is required to be significant for a single level, compared with -33% to +50%, and \pm 86% respectively for four levels.

Conclusion: Perfusion CT measurement agreement is improved using multiple slices. We have established the degree of change required for therapeutic response.

C-0305

Pulmonary sequestration: A pictorial review

B.J. Op de Beeck¹, R. Salgado¹, L. Trappeniers², F. Vandenbroucke², K. de Jongh¹, P. Parizel¹; ¹Edegem/BE, ²Brussels/BE

Learning Objectives: To demonstrate the various appearances of pulmonary sequestration. To outline the advantages and limitations of HRCT, MDCT and MR imaging for differentiating intralobar from extralobar sequestration.

Background: A pulmonary sequestration is a portion of pulmonary tissue that does not have communication with the tracheobronchial system through a normal bronchus and is supplied by anomalous systemic arteries. Pulmonary sequestrations are anatomically divided into two categories, intralobar and extralobar. An intralobar sequestration lies within the pleural cavity of the normal lung. An extralobar sequestration has its own visceral supply. In this exhibit we will describe the diagnostic clues of the different imaging modalities.

Imaging Findings: Various parenchymal abnormalities have been observed, including cysts, soft tissue masses, emphysema surrounding the cysts or masses, and hypervascularity of a region of lung. Imaging findings depend on the volume and the presence or absence of infection. If infection is present, a fluid-filled pattern is seen. If cystic in nature, air trapping is seen on expiratory scans. When the sequestered lung becomes infected, it often appears to be a chronic pulmonary abscess. The caliber of the anomalous artery in intralobar sequestration is usually large, and venous drainage generally occurs through the pulmonary vein. The caliber of the anomalous artery is usually small; venous drainage is usually into a systemic vein, such as the azygous vein.

Conclusion: Meticulous vascular evaluation is mandatory. Diagnosis of pulmonary sequestration is related to the detection of an anomalous systemic artery. Different venous drainage is noticed in intra- and extralobar types.

C-0306

CT lung cancer screening supported by CAD system on Italian traffic policemen: One year preliminary results

F. Fraioli, C. Catalano, L. Bertoletti, P.G. Nardis, R. Passariello; Rome/IT

Purpose: To illustrate a one-year experience of lung cancer CT-screening on a large high risk population, supported by CAD.

Materials and Methods: Clinical study was approved by institutional review board and performed on 1000 traffic-policemen. Study-selection included people > 50 years, smokers and with 15 years working outside on the street. MDCT parameters were: 140 kVp; 20 mAs; sl.collimation: 1 mm; sl. Thickness 1 (kernel B60) and 5 mm (kernel B30). No i.v. contrast agent was administered. Algorithm for post HRCT classification includes 7 options: 1) inadequate examination; 2) negative examination; 3) negative examination for neoplastic lesion but with other benign findings; 4) < 5 mm suspicious solitary pulmonary nodules; 5) > 5 mm suspicious pulmonary nodule; 6) nodules found only by CAD; 7) multiple (> 7) nodules with diameter less than 5 mm. Categories 2-3-7 have been considered as non-neoplastic and will be recalled for a second screening after 2 years. Categories 4-5-6 will be recalled after 3-6 months.

Results: Preliminary results revealed 714 subjects in categories 2-3-7; 144 in category 4; 49 in category 5; 77 nodules in category 6; ten in category 1. 6 patients presented lung cancer; 4 with a well defined burden 3 cm lung cancer, and 2 neoplasms considered as 3b-stage.

Conclusion: Data are preliminary and need confirmation on the next follow-up study. Nevertheless, in a selected high risk population, a lung cancer screening programme can be applied to reduce mortality. In addition, because of high speed nodule detection of the CAD system, it can be used for diagnosis and can reduce false negative rates of the physicians.

C-0307

Cavitory lesions in the lung: Radiographic and CT findings

M. Mereu, F. Guido, B. Feragalli, A. Travaglini, C. Torrione, M. Storto; Chieti/IT

Learning Objectives: 1) To describe the radiographic and CT findings of the most common cavitary lesions in the lung. 2) To review the radiographic and CT

criteria most useful in the differential diagnosis between benign and malignant cavitory lesions.

Background: The term "cavity" is used to describe an air-containing lesion characterized by a > 4-mm thick wall or an air-containing lesion within a mass or a surrounding infiltrate. Cavitory lesions can be observed in patients with a number of pulmonary diseases including neoplasms, infectious processes, infarcts, septic embolism, congenital abnormalities, collagen vascular diseases, and progressive massive fibrosis occurring with pneumoconiosis.

Procedure Details: The most commonly encountered radiographic and CT findings of these different diseases will be illustrated and discussed together with some basic information that may help differentiate benign from malignant lesions.

Conclusion: Cavitory lesions of the lung are quite common and can be benign or malignant. Malignancy is commonly the first diagnosis to consider for a cavitory lesion, particularly in a middle-aged or older adult with a history of cigarette smoking. In contrast in patients with AIDS, cavitory lesions are usually caused by infections including bacteria, mycobacteria, *P. carinii* and other fungi, and cytomegalovirus. The clinical context is clearly of importance in prioritizing diagnostic possibilities.

C-0308

Peripheral lung cancer: Screening and detection with low dose helical CT. Toshima trial

H. Tajima, T. Kumazaki, S. Murata, K. Nakazawa, T. Fukunaga, J. Watari, M. Machida, K. Yamamoto, H. Fukasawa; Tokyo/JP

Purpose: To evaluate low dose helical CT for the screening and detection of small peripheral lung cancers at Toshima ward, Tokyo.

Methods and Materials: Low dose helical CT (Asteion, Toshiba) was obtained from May 2000 to Feb 2003 in 3953 participants. The parameters were 120 kVp, 50 mA, 10 collimation, and 2:1 pitch.

Results: Peripheral lung cancer was detected in 24 out of 3953 examinations (0.60%). Cell types were as follows: squamous cell tumor, 2; adenocarcinoma, 20; large cell tumor, 1; mucoepidermoid tumor, 1. The mean size of the lesions was 18.1 mm (range 7-40 mm). Twenty (83%) out of the 24 tumors were stage I.

Conclusion: Low dose helical CT can depict early-stage lung cancers.

C-0309

Recurrent lung cancer at the bronchial stump site: CT and bronchoscopic findings

W. Kwon, K. Sung, W.-Y. Lee, M. Kim; Wonju/KR

Learning Objectives: To illustrate the spectrum of recurrent lung cancer at the bronchial stump site after lung resection. To outline the advantages and limitations of CT and bronchoscopy. To promote awareness of careful evaluation of the bronchial stump site at CT.

Background: Recurrence at the bronchial stump was seen in 2.2% of all cases of resected lung cancer. There may be tumor recurrence at the bronchial stump, even when the resected margin is sufficiently distant from the tumor and the surgical margin of the resected specimen is negative for cancer. The recurrent mass is commonly located at the site of the bronchial stump. If the recurrent mass is small, not well defined, or does not displace adjacent structures, differentiation from postsurgical fibrosis is difficult.

Imaging Findings: Bronchoscopic findings such as endobronchial mass, ulceration, and submucosal infiltration were correlated with CT findings. The most common finding is endobronchial mass (10/14). Although submucosal infiltration is seen on bronchoscopy, definite recurrent lung cancer can be diagnosed compared with the previous CT scan.

Conclusion: Variable findings of CT and bronchoscopy for recurrent lung cancer are demonstrated. Correlation with bronchoscopic findings and CT findings is helpful in verifying the presence of a recurrent mass.

C-0310

Traumatic diaphragmatic hernia: Comprehensive evaluation using novel MR techniques and multislice CT

H. Yang, K.-H. Do, K.-S. Song, J. Seo; Seoul/KR

Learning Objectives: To know the CT findings of traumatic diaphragmatic hernia. To explain the technique of real-time respiratory dynamic MR imaging. To understand the advantage of the MR and MSCT in the evaluation of traumatic diaphragmatic hernia.

Background: Because the diaphragm is a thin and complex structure which is oriented transversely or obliquely, it is difficult to diagnose diaphragmatic pathology by conventional techniques. Early diagnosis of traumatic diaphragmatic inju-

Scientific and Educational Exhibits

ry is important because the pleuroperitoneal pressure gradient can cause the defects to enlarge over time. However, the diagnosis of diaphragmatic rupture or defect and its functional significance is difficult to assess by conventional techniques. The purpose of this exhibit is to illustrate the usefulness of MSCT and respiratory cine MR technique in the evaluation of traumatic diaphragmatic hernia.

Imaging Findings: We collected 35 cases of traumatic diaphragmatic hernia. Axial CT scans showed various direct and indirect signs suggesting a diaphragmatic defect. Reformatted sagittal or coronal images using MSCT are useful in detection of diaphragmatic defects. Using three dimensional real-time respiratory dynamic MR imaging, it is possible to assess the respiratory motion of the diaphragm and dynamic movement of herniated organs.

Conclusion: Diaphragmatic defects were well demonstrated on three dimensional real-time respiratory dynamic MR imaging and reformatted sagittal or coronal images from MSCT.

C-0311

Assessment of pulmonary nodules on multi-slice CT (MSCT) of the chest: Impact of computer-aided detection (CAD) in the management of oncology patients

G. Bastarrika, P.D. Domínguez, D. Cano, M.J. Pons, I. Vivas,
I. González-Crespo; Pamplona/ES

Purpose: To evaluate the role of a computer-aided detection (CAD) system in the detection and growth assessment of lung nodules on MSCT exams of patients with metastatic cancer.

Methods and Materials: MSCT data sets of 19 consecutive patients with known malignancy (38 exams) were acquired. Scan parameters: 120 kV, 165 mAs, 5 x 2.5 mm collimation, 1.5 mm reconstruction interval. Two experienced readers reviewed each study, considering in their analysis pulmonary nodules of any size. The standard of reference for each nodule was determined by a consensus double read. All studies were processed using a CAD system (ImageChecker CT, R2 Technology, Inc.) and findings were compared with the standard of reference. One radiologist confirmed or dismissed CAD detected lesions. The impact of the CAD in oncology patient management was also analysed.

Results: A total of 121 lung nodules were identified as the standard of reference (mean size: 5.18 mm; SD: 2.75). The CAD system detected 139 lesions - 52 lung nodules (sensitivity: 0.43) and 87 (62.4%) false positives - and did not detect 69 nodules (57%) (false negatives). The CAD detected a total of 2.29 false positives/case; the system did not detect 1.81 nodules/case (mean size: 4.08 mm; SD: 1.73). The CAD allowed assessment of nodule growth in three cases but was not capable of demonstrating progression of the disease in one patient (haematogenous metastatic spread).

Conclusion: Even if accurate and helpful, CAD should be considered as a second reading tool for radiologists in routine clinical MSCT interpretation.

C-0312

CT features of pulmonary hydatid disease

C. Hafsa, M. Golli, S. Kriaa, M. Zbidi, A. Gannouni; Monastir/TN

Purpose: To study the CT features of pulmonary hydatid disease and to specify when we realize the chest CT in hydatid disease?

Methods and Materials: A retrospective study of 250 children with pulmonary hydatidosis is presented. The 250 cases (145 boys and 105 girls aged from 18 months to 14 years) were studied during the period from January 1982 until December 2003. CT of the chest was obtained in 120 cases. Surgery was performed for all patients. Diagnosis was confirmed with serology tests and/or pathological study of resected cysts.

Results: Different sizes and shapes of hydatid cysts were encountered, 44 of them being ruptured. CT density of the cysts varied from -42 to 160 Hounsfield units (HU; median, 15.5 HU). Apart from the classically described features of pulmonary hydatid disease, a crescent-shaped rim of air at the lower end of the cyst (inverse crescent sign) was seen in 10 cysts, and a bleb of air in the wall of five as-yet unruptured cysts (signet ring sign). Thick wall (> 10 mm) was observed in thirty cysts, and each of them had associated evidence of infection.

Conclusions: Inverse crescent sign, signet ring sign, high CT density, and thick wall should be recognized as features of pulmonary hydatid cysts on CT. CT is useful for diagnosis of atypical or complicated lesions and to detect bronchiectasis.

C-0313

Imaging features of mediastinal hydatid cyst

C. Hafsa, M. Zbidi, S. Kriaa, S. Jerbi Ommezine, M. Golli, A. Gannouni; Monastir/TN

Purpose: Hydatid disease is a parasitic infestation caused by larvae of the echinococcus tapeworm. Mediastinal hydatid cyst is uncommon. We present the various radiological aspects of mediastinal hydatidosis based upon a series of 20 cases. The importance of Echocardiography and thoracic MRI and CT will be emphasized.

Methods and Materials: A retrospective study of 20 cases having mediastinal hydatid cyst is reported. Chest radiography, echocardiography and abdominal ultrasound were performed in all cases. CT was performed only in 10 cases. MRI was performed in three cases. Surgery was performed for all patients. Diagnosis was confirmed with serology tests and/or pathological study of resected cysts.

Resultat: Echocardiography showed a multivesicle cyst in the ventricular cavity in 6 cases. Thoracic computerised tomography (CT) and magnetic resonance imaging (MRI) also revealed a hypodense mass in the ventricular cavity. Only four cases have a cyst in the posterior mediastinum. A diagnosis of primary hydatid cyst was confirmed and total cystectomy was performed.

Conclusion: Echocardiography is the best diagnostic procedure for cardiac hydatid disease, although thoracic MR imaging and CT, and abdominal CT, are also necessary for detecting the exact location, size and number of disseminated hydatid cysts.

C-0314

A review of outpatient ventilation-perfusion scintigraphy

B.J. Holloway, P. Struhal; Wolverhampton/UK

Purpose: The aim of this review is to ascertain the outcomes of outpatient V/Q scans and their effect on management. Additionally there has been a more recent implementation of consistent vetting of requests in our institution. This has occurred following an improvement of staffing levels. This review provides an opportunity to analyse the consistency with which this is occurring.

Method: The information was compiled retrospectively for all outpatient V/Q scans performed between 01/01/2002 and 31/12/2003 inclusively. Once the total number was ascertained, the original request cards were obtained to check for vetting. The probability of pulmonary embolus was documented. In results of greater than low probability further information regarding relevant risk factors was sought.

Results: A total of 115 outpatient V/Q scans were performed within the two year time period specified. Documented evidence of vetting of the request cards was seen in 87 examinations (76%). 103 patients (90%) had a probability of pulmonary embolus reported as no greater than low. Of the 12 examinations with probabilities greater than low all had significant risk factors or had an abnormal chest radiograph.

Conclusion: Our review looks in depth at the frequency of, and outcomes in, outpatient ventilation perfusion scanning. We can conclude that in this population the chance of obtaining a high probability result in individuals with a normal chest radiograph and without risk factors such as malignancy and known thromboembolic disease is virtually nil. We have performed a review of the available literature on this subject.

C-0315

Ultrasound guided FNAC of impalpable cervical lymph nodes in lung cancer

L. Chandratreya, M. Cobby, R. Watura; Bristol/UK

Learning Objectives: We aim to demonstrate the anatomy, technique, indications and possible benefits of ultrasonography of impalpable cervical nodes and ultrasound guided fine needle aspiration cytology of these in lung cancer.

Background: The finding of an abnormal cervical lymph node in lung cancer is crucial to its staging and may radically alter management. Although routine scalene node biopsy is no longer performed in impalpable adenopathy by the surgeons in lung cancer, there has been resurging interest in ultrasonography of the neck with ultrasound guided FNAC of abnormal nodes in selected cases.

Technique: Using a 7.5 MHz linear probe we scan the neck from the suprascapular level to the submental and retroparotid regions, longitudinally and transversely, to include the Groups I to V of the cervical lymph node regions bilaterally. When lymph nodes are detected the most abnormal or the largest node is then aspirated by aseptic technique using a 22 G needle and smears are sent for cytological examination.

Conclusion: We have found this to be a safe and simple procedure, requiring no anaesthesia or preparation and can be easily performed on outpatients. This also accurately identifies lymph nodes differentiating them from thrombosed veins, fat

Scientific and Educational Exhibits

and thyroid masses. We firmly believe this is an important pre-treatment evaluation which may spare the patient more invasive and potentially more risky diagnostic procedures like percutaneous lung biopsy and mediastinoscopy.

C-0316

Rare primary mediastinal tumors: Helical CT features and pathological correlation

J.-Q. Yu, Z.-G. Yang, Z.-L. Li; Chengdu/CN

Learning Objectives: 1. To demonstrate the morphologic features of rare mediastinal tumors on helical CT. 2. To correlate the CT features with pathological findings of rare mediastinal tumors. 3. To learn how to differentiate the rare mediastinal tumors on the basis of location, size, shape, and particularly attenuation on un- or enhanced CT images.

Background: Primary mediastinal tumors comprise a diverse group of neoplasms. Some are rare and account for less 5% of primary mediastinal masses, therefore their morphological features are not easily recognized. We try to investigate the characteristics of these rare tumors on CT images.

Imaging Findings: Twenty-five cases with different types of rare mediastinal tumor were observed and analyzed retrospectively. Thymic cysts are round, uniloculated or multiiloculated thin-walled masses on helical CT. Thymic carcinoma and carcinoid show a large, poorly defined, infiltrative anterior mass, frequently associated with pleural and pericardial effusion or hemorrhage and necrosis. Hemangiomas are well-margined and heterogeneous masses on enhanced CT and have punctate or phlebolith calcification. Ganglia tumors are well-margined, homogeneous or heterogeneous, oblong masses with a broad base along the anterolateral aspect of the spine. Malignant fibrous histiocytoma, small cell undifferentiated sarcoma and angiomyolipoma are located in the posterior mediastinum and are heterogeneous masses, which manifest various densities due to different histologic components. The educational exhibit presents the helical CT features and pathology of these tumors.

C-0317

Invasive pulmonary aspergillosis: Significance and predictive value of the "hypodense sign" on unenhanced CT

M.S. Horger, C.A. Pfannenberg, C. Lengerke, H. Hebart, C.D. Claussen; Tübingen/DE

Purpose: To assess the diagnostic value of central hypointensity ("hypodense sign") in lung consolidation on unenhanced CT, in immunocompromised patients, suspected of having invasive pulmonary aspergillosis (IPA).

Material and Methods: Retrospective analysis of serial CT scans of the lung was performed in 43 patients with IPA in order to assess the hypodense sign using standard mediastinal and lung windowing settings, as well as narrower window setting (width, 110-140 HU; level, 15-40 HU). The time between the occurrence of early CT findings of IPA and the appearance of the hypodense sign, as well as between this and the occurrence of the crescent sign, cavitation or reduction in lesion size, was evaluated. In addition, we reviewed CT scans of immunocompromised patients with viral ($n = 45$) or bacterial ($n = 44$) pneumonia, with respect to the presence of the "hypodense" sign.

Results: Unenhanced CT scans revealed the hypodense sign in 13 (30.2%) patients. The mean time delay between the first manifestation of IPA and the hypodense sign was 7.8 days, while the time interval between the hypodense sign and the occurrence of crescent sign, cavitation, or decrease in the lesion's size was 8.3 days. The hypodense sign did not occur in any of the patients with viral or bacterial pneumonia, in the control series.

Conclusion: We consider the hypodense sign to be a supplementary tool in the diagnosis of IPA. Its sensitivity was low in our series, but the high specificity makes it valuable in predicting invasive pulmonary aspergillosis, preceding the occurrence of cavitation or crescent sign.

C-0318

CT diagnosis of pulmonary aspergilloses in hematological diseases

A. Varga, G. Forrai; Budapest/HU

Purpose: To review the spectrum of *Aspergillus*-related pulmonary disease focusing on the CT diagnosis of *Aspergillus* infections in patients with hematological diseases.

Procedure Details: 275 plain and contrast-enhanced helical chest CT examinations and high resolution CT examinations of hematology patients were performed between 1 January 2003 and 27 February 2004.

Background: *Aspergillus fumigatus*, a rare cause of pneumonia in the general population, has an important role in the immunocompromised group of patients,

particularly in patients with lymphoma or leukaemia. The pulmonary aspergilloses are a spectrum of diseases ranging from bronchopulmonary aspergillosis in the hyperimmune host, through pulmonary mycetoma formation in lung cavities of patients with normal immune status, to invasive pulmonary aspergillosis in immunocompromised hosts. The latter may be further categorised as angioinvasive and airway invasive pulmonary aspergillosis. Overlap between these entities occurs ("semi-invasive" pulmonary aspergillosis in chronic cavitary lung disease in patients with mild immunocompromise). In our study CT signs of pulmonary aspergillosis were established in 6.5% of cases (18/275). Differential diagnosis of pulmonary aspergillosis includes other opportunistic infections, pulmonary manifestation of hematological diseases, other neoplasms, drug or radiation induced lung disease. Definitive diagnosis can often only be established by biopsy.

Conclusion: Pulmonary aspergillosis is relatively common in immunocompromised patients with hematological diseases. Complications can result in serious life-threatening conditions, therefore easily accessible non-invasive imaging modalities are necessary. CT plays an important role in differential diagnosis, providing enough informations for most therapeutic decisions.

C-0319

Screening for lung cancer in a high risk population using spiral computed tomography: 3-year results

L. Cardinale, F. Ferraris, F. Perotto, P. Gollini, A. Priola, S. Novello, C. Fava; Orbassano/IT

Purpose: ELCAP and Japanese studies show low-dose-spiral-CT (sCT) detects early-stage lung cancer (LC) in high-risk populations. Our trial was designed to confirm these data, evaluating prevalence of LC at first sCT examination, and to assess the radiological detection during a 5-year follow-up. Our secondary aim was to determine overall resectability of detected LC.

Materials and Methods: We enrolled 519 asymptomatic volunteers, aged > 55 years, who smoked > 20 pack-years; we planned to perform an annual sCT for 5 years.

Results: Baseline sCT detected nodules > 5 mm in 22% of cases, < 5 mm in 25%; 53% were negative. At year 1, 18 patients dropped out: 14 due to personal decision, 4 due to diagnosis of other malignancies. During year 2 sCT detected nodules > 5 mm in 5% of cases. By year 2, 8 LC were diagnosed (5 at baseline, 3 at year 2): 6 stage I, 1 IIIB and 1 IV (adrenal metastases). During year 1, 2 additional cases were resected (1 atypical resection, 1 lobectomy) for bronchoalveolar adenoma. 3 year results are under evaluation.

Conclusion: In terms of LC prevalence/incidence, data from our feasibility trial are comparable to those previously reported and support the use of this screening tool in randomized studies.

C-0320

Virtual bronchoscopy: A new approach to facilitating endobronchial ultrasound-guided transbronchial needle aspiration biopsy

K. Nakatani, S. Morishita, K. Okino, T. Anayama, S. Sasaguri, S. Yoshida; Nankoku/JP

Purpose: Assessment of mediastinal lymph nodes (N2, N3) is one of the most important factors when planning therapy and estimating prognosis in thoracic malignancy. Recently, endobronchial ultrasound (EBUS) guided transbronchial needle aspiration biopsy has often been performed to ascertain lymph node status. The authors have constructed three dimensional images in order to help bronchoscopists.

Methods and Materials: Multidetector computed tomography (Aquilion, 1.0 mm x 16, helical pitch; 15, beam pitch; 0.94, Toshiba, Tokyo, Japan) was performed. Images were transferred to a workstation (Virtual Place Advance, AZE, Tokyo, Japan). Color images were reconstructed to distinguish between mediastinal lymph nodes and the great vessels. In this manner, movie images can be relayed to chest surgeons, enabling virtual bronchoscopy to "see through" the lymph nodes and vessels.

Results: EBUS-guided transbronchial needle aspiration biopsy requires considerable skill, as the bronchoscopist can only visualize 30 degrees in an upward direction and the ultrasound beam is very narrow. Moreover, anatomic position of great vessels differs greatly between individuals. The virtual bronchoscopy method reported herein could help bronchoscopists to gain an accurate understanding of the relationship between the bronchial tree, target lymph nodes, arteries and veins. These images could increase efficiency of the examination and allow it to be performed more safely.

Conclusion: We have developed a virtual bronchoscopy method that enables clinicians to "see through" the lymph nodes and great vessels. These images can help bronchoscopists understand the anatomic relationships and can expedite EBUS-guided transbronchial needle aspiration biopsy.

Scientific and Educational Exhibits

C-0321

CT-guided fine-needle aspiration biopsy in the diagnosis of focal pulmonary lesions

K. Bronisz, J. Wójcicka, P. Czyszkowski, C. Rybacki, T. Szylberg;
Bydgoszcz/PL

Background: The delay in the diagnosis of lung cancer makes the radical treatment of this disease impossible, leading to its becoming generalized. X-ray detection of focal pulmonary lesions ought to result in the establishment of the histopathological diagnosis. It is necessary to collect material from the lesion for microscopic investigation. The results determine the initiation of appropriate treatment. Many focal pulmonary lesions are inaccessible by bronchoscopy, and a biopsy through the chest wall is required.

Purpose: To show the possibilities created by the application of CT-guided FNAB in the diagnosis of focal pulmonary lesions.

Materials and Methods: 585 patients: 427 men (73%) and 158 women (27%). 592 fine-needle aspiration biopsies performed in CT Laboratory of the Radiology Department in the period between 1995 and 2003.

Results: Cytological diagnosis based on the obtained material was possible in 491 cases (82.9%). In 47 cases normal pulmonary cells were found in the material. Of the above-mentioned number of cases, as well as in 54 cases suspected of a tumor, where non-diagnostic material was obtained (blood, necrosis), 39 repeat biopsies were performed. Pneumothorax was the most serious complication after biopsy. It required surgical intervention in 37 cases (6.3%). Mild haemoptysis was observed in 30 cases (5%).

Conclusion: CT-guided FNAB of pulmonary focal lesions is an effective, minimally invasive diagnostic method, allowing establishment of the cytological diagnosis. This method substantially shortens the time between the X-ray detection of the lesion and the initiation of appropriate treatment.

C-0322

Distributional variations of thymic cysts in the mediastinum

T. Kim, S. Kim, S. Chung, B. Choi, K. Choe; Seoul/KR

Purpose: To retrospectively evaluate the distributional variations of thymic cysts in the mediastinum.

Methods and Materials: Twenty-seven patients (9 men, 18 women; mean age, 58.9 years; range, 24-82 years) with thymic cysts were included in this study. Two radiologists retrospectively reviewed the CT features in consensus, which included attenuation values, size and location of the tumors. The tumor location was classified as the anterior, middle, or superior mediastinum. The superior mediastinum was divided into either the anterior or middle compartment on the basis of the relationship with the vascular structures such as carotid and innominate arteries.

Results: The tumors were located in the anterior mediastinum in 22 patients (81.5%), in the middle mediastinum in 2 patients (7.4%), and in the superior mediastinum in 3 patients (11.1%), respectively. The superior mediastinal lesions were located in the anterior, pre-vascular compartment in 2 patients and in the middle, post-vascular compartment in one patient. The size of the tumors ranged from 2.2 to 12 cm (mean, 4.8 cm) at the axial longest diameter. The mean attenuation value was about 8.4 HU on the unenhanced scans and about 9.7 HU on the contrast-enhanced scans.

Conclusion: Thymic cysts are usually located in the anterior mediastinum, but some lesions occur in the superior or middle mediastinum. Therefore, we should include a thymic cyst in the differential diagnosis when cystic lesions are located in the superior or middle mediastinum.

C-0323

Quantitative multi-planar lung cancer perfusion measurement using multidetector row computed tomography (MDCT): Inter and intra-observer agreement

Q.S. Ng¹, V. Goh¹, H. Fichte², E. Klotz², D. Carnell¹, M. Saunders¹, P.J. Hoskin¹, A. Padhani¹; ¹Northwood/UK, ²Forchheim/DE

Purpose: Multi-planar perfusion measurement enables quantitative vascular assessment of an entire tumour, but inter and intra-observer measurement error has not been assessed to date.

Materials and Methods: 11 patients with lung cancer were examined prospectively using MDCT (Sensation 16, Siemens). 90 s helical dynamic acquisitions were acquired repeatedly through the entire tumour following intravenous contrast infusion. Mean tumour permeability (0.5 ml/min/100 ml) and relative blood volume (0.1%) in a central axial and reconstructed coronal plane were determined by two independent observers using prototype software (FunctionalCT,

Siemens). Measurements were repeated by each observer, and inter- and intra-observer agreement was assessed using Bland-Altman statistics.

Results: The mean difference (95% limits of agreement) for inter-observer agreement for permeability and relative blood volume was -0.6 (-6.9 to +5.8) and 1.2 (-10.3 to +12.7) respectively in the axial plane, and -2.1 (-8.6 to +4.4) and -6.5 (-44.4 to +31.5) respectively in the coronal plane. The mean difference (95% limits of agreement) for intra-observer agreement was 0.1 (-0.4 to +0.7) and -1.1 (-6.3 to +4) respectively in the axial plane, and 1.4 (-3.4 to +6.3) and 1.9 (-30.8 to +34.5) respectively in the coronal plane for observer one, and -0.2 (-6.5 to +6.1) and -0.2 (-6.3 to +5.8) respectively in the axial plane and -0.5 (-3.2 to +2.2) and 3.3 (-13.1 to +19.6) respectively in the coronal plane for observer two. Intraclass correlation coefficients ranged from 0.79 to 0.99.

Conclusion: Good agreement between and within observers was found in both planes, which is essential for reliable therapeutic assessment.

C-0324

An audit of percutaneous lung biopsy performed at University Hospitals of Leicester, UK

A. Donuru, V.V.R. Kandula, M. Kumaran, J. Entwistle; Leicester/UK

Learning Objectives: To assess the outcome of CT/USS guided lung biopsy. To determine the success, failure and complication rates of the procedure.

Background: Percutaneous transthoracic lung biopsy is a common procedure used mainly to elucidate the nature of pulmonary masses. Approximately 450 patients are newly diagnosed with lung cancer in Leicester, UK. Published complication rates vary widely. Only one meta-analysis was identified in thorax [1], which suggested local estimation of complication rates. A multidisciplinary team (MDT) should ensure the most appropriate approach to biopsy. Guidelines were published by British Thoracic Society in agreement with Royal College of Radiologists (RCR) in 2003[2]. **Guidelines:** Adequacy of sample should be over 90%. False positives should be < 1%. Sensitivity for malignancy should be 85-90% in lesions over 2 cms. All patients should be discussed at MDT prior to biopsy.

Imaging Findings: 50 patients audited prospectively (Nov'02 to Oct'03). 36 patients (day case), 13 (in-patient) and no record on 1 patient. Only 23 out of 50 patients had documented lung function tests. 94% CT guided and 6% USS guided. 86% lung biopsies and 14% pleural biopsies. 96% diagnostic and 4% non-diagnostic. Complications included pneumothorax (28%), haemoptysis (4%), haemorrhage (12%). No complications in 56%.

Conclusion: Pneumothorax was managed conservatively in all patients. Haemoptysis was mild - none required blood transfusion. No relationship between number of passes and associated complications. Lung function tests should be documented on all patients (as a part of overall risk assessment) prior to performing a biopsy.

C-0325

The thymus: A mediastinal mystery

M. Nishino, S.K. Ashiku, R. Thurer, O.N. Kocher, P.M. Boiselle, H. Hatabu; Boston, MA/US

Learning Objectives: To provide comprehensive understanding of various thymic pathologies, and to describe their characteristic CT and MR findings along with pathological findings.

Background: The thymus is a unique organ which plays an integral role in the immune response via its complex microenvironment. Reaching its maximum weight in puberty and subsequently undergoing fatty involution, the thymus is seldom an eye-catching structure on imaging studies in normal adults. However, once involved in a disease process, it shows a variety of clinical and radiological manifestations which require comprehensive understanding of each entity.

Imaging Findings: In this review, we describe CT and MR imaging findings of a variety of thymic pathologies, including thymoma, thymic carcinoma, thymic cyst, thymic hyperplasia, thymolipoma, etc. The useful imaging findings for differentiating these entities, including shape and location of the lesion, CT attenuation and MR signal intensity, the presence of mediastinal invasion, and pleural metastasis are discussed. Surgical and pathological findings are also presented and correlated with radiological findings, to enhance understanding of the underlying process reflected in the imaging.

Conclusion: The CT and MR imaging findings of the thymic diseases, in correlation with surgical and pathological findings, are useful in differentiating each entity, and enhance our understanding of the variety of thymic pathology.

Congenital and acquired anomalies of the pulmonary arteries in adults:

A radiologic overview

D. Gil¹, E. Castaner¹, X. Gallardo¹, J. Mata¹, Y. Pallardo², J. Perendreu¹, A. Massuet¹; ¹Sabadell/ES, ²Valencia/ES

Learning Objectives: To describe the signs that allow anomalies of the pulmonary arteries to be identified or suspected on chest radiographs. To show the usefulness of CT and MR imaging in confirming the suspected diagnosis. To illustrate a practical approach to anomalies of the pulmonary arteries. To warn of potential complications in some vascular diseases, or infectious settings.

Background: Evaluation of pulmonary arteries is mainly indicated in patients with suspected pulmonary thromboembolism. However, other acquired pathologies can affect pulmonary arteries in the setting of neoplasms, infectious diseases, or inflammatory vascular processes. Some congenital anomalies can also be suspected on chest radiographs.

Procedure Details: We show the most representative cases of pulmonary arteries anomalies, diagnosed at our centre between 1995-2004. First we described the congenital anomalies that can be seen in the adult patient, including idiopathic dilatation of pulmonary artery trunk, pulmonary artery sling, and agenesis of the pulmonary artery. Among the acquired entities that can affect the pulmonary arteries, we include neoplasms (primary pulmonary artery sarcomas and intra-vascular pulmonary metastases), anomalies associated with inflammatory vascular processes (Behcet's disease, Takayasu's arteritis), involvement secondary to infections, pulmonary thromboembolism (acute and chronic) and changes secondary to pulmonary hypertension.

Conclusion: CT angiography and MR angiography are useful in the evaluation of pulmonary artery anomalies. Radiologists should be aware of potential pulmonary artery complications in some vascular diseases or infectious settings. Some congenital anomalies can be suspected on the radiographic findings.

C-0327

Role of D-dimer and pre-test probability scoring in suspected acute pulmonary embolism

G. Annamalai, C. Campbell, P. Duffy; Glasgow/UK

Purpose: To determine the role of D-dimer and pre-test probability (PTP) scoring in the management of suspected acute pulmonary embolism (PE).

Methods and Materials: Prospective study of 70 consecutive patients with suspected acute PE. All patients had D-dimer (Vidas ELISA) and CT pulmonary angiography (CTPA) performed. Pre-test probabilities using validated scoring systems (Wells and Geneva) were categorised as low, intermediate or high. The Geneva PTP scoring system is an objective and therefore reproducible system. The Wells scoring system is more subjective, incorporating clinical judgement.

Results: Prevalence of PE in our study population was 16%. Sensitivity and specificity of D-dimer test were 80% and 28% respectively. Two of 17 patients (12%) with negative D-dimer (< 500 ug/l) had PE confirmed on CTPA. The Wells scoring system performed better at excluding PE. No patients with low Wells PTP score but 13% with low Geneva score had PE subsequently diagnosed. None of the patients with both low Wells PTP score and negative D-dimer had PE.

Conclusion: This study confirms that negative D-dimer alone does not exclude acute PE and D-dimer is not suitable as a routine screening test. However, negative D-dimer in combination with a low Wells PTP is useful in excluding the diagnosis, thus decreasing the need for further imaging for venous thromboembolism.

C-0328

Predictors on CT of hemodynamic improvement after pulmonary thromboendarterectomy

M. Heinrich¹, A. Grgic¹, D. Tscholl¹, B. Kramann¹, H.-J. Schäfers¹, M. Uder²; ¹Homburg a.d. Saar/DE, ²Erlangen/DE

Purpose: To correlate preoperative CT findings in patients with chronic thromboembolic pulmonary hypertension (CTEPH) with pulmonary vascular resistance (PVR) after pulmonary thromboendarterectomy (PTE) and to evaluate the use of CT in predicting hemodynamic improvement.

Methods and Materials: 60 patients who underwent PTE and helical CT were included in this retrospective study. Imaging findings in preoperative chest CT-scans were correlated with postoperative PVR. Patients with a postoperative PVR

higher than 500 dynes * s * cm⁻⁵ were considered to have insufficient hemodynamic improvement and not to have benefited from surgery. Univariate analyses were performed by Mann-Whitney test, Spearman's rank correlation and Fisher's exact test, as appropriate. Multivariate analysis was performed by multiple linear regression analysis.

Results: The presence ($p = 0.008$) and extent of central thrombi ($rs = -0.36$, $p = 0.007$) and the presence of dilated bronchial arteries ($p = 0.03$) was negatively correlated with postoperative PVR. 60% (3/5) of patients without visible central thromboembolic material on CT had an inadequate hemodynamic improvement, in contrast to 4% (2/51) of patients with central thrombi ($p = 0.003$). Preoperative PVR ($rs = 0.31$, $p = 0.018$) and the extent of a mosaic perfusion pattern ($rs = 0.37$, $p = 0.007$) and of peripheral scars ($rs = 0.32$, $p = 0.017$) were positively correlated with postoperative PVR.

Conclusion: Preoperative CT findings can help to predict hemodynamic improvement after PTE. The absence of central thromboembolic material, especially in combination with a mosaic perfusion pattern in all lobes, is a significant risk factor for inadequate hemodynamic improvement after surgery.

C-0329

Perfusion abnormalities in congenital and neoplastic pulmonary disease:

Comparison of ultrafast MR perfusion and multislice CT imaging

D.T. Boll¹, J.S. Lewin², A.J. Aschoff¹, R.C. Gilkeson³, ¹Ulm/DE, ²Baltimore, MD/US, ³Cleveland, OH/US

Purpose: To prospectively assess MR perfusion patterns of chronic, non-embolic pulmonary diseases and to compare the findings visualized with ultrafast MR perfusion imaging to those of pulmonary, contrast-enhanced multislice CT imaging.

Material and Methods: 25 patients underwent concurrent CT and MR evaluation of chronic, non-embolic pulmonary diseases of congenital ($n = 15$) or neoplastic ($n = 10$) origin. Analysis of MR perfusion and CT datasets was realized by defining pulmonary as well as vascular regions-of-interest. Utilizing MR imaging, time-intensity curves were plotted. Analogously, contrast-enhanced CT image datasets provided pulmonary signal-to-noise ratio measurements. Vessel centerlines of bronchial arteries were determined. Perfusion type was determined.

Results: Statistical analysis of pulmonary perfusion type detected 20 pulmonary artery perfusion patterns and five bronchial artery perfusion patterns. In patients with pulmonary artery perfusion, MR and multislice CT imaging differed in only four of twenty patients in not more than one lung segment per patient. In patients with systemic bronchial arterial supply, MR perfusion and multislice CT imaging differed in four of five patients in up to three segments per patient. Patients with systemic bronchial arterial supply had bronchial arteries ranging from 2.0 - 3.6 mm compared to the submillimeter diameters in pulmonary perfusion types.

Conclusion: Congenital and neoplastic pulmonary conditions require ultrafast MR imaging in order to successfully detect subtle and masked changes in lung perfusion patterns, especially in the systemic bronchial arterial supply. Presence of hypertrophied bronchial arteries indicated bronchial arterial perfusion with the subsequent need for high temporal resolution perfusion imaging of the pulmonary parenchyma.

C-0330

Multidetector CT of pulmonary vascular abnormalities in the adult

F. Triviño, A. Benito, G. Pérez, R. Ysamat, L. Zurera, M. Cara, M. Canis; ¹Cordoba/ES

Learning Objectives: To detail the anatomy and radiological features of unusual symptomatic vascular pulmonary lesions in the adult.

To emphasize the ability of multidetector CT in characterizing these lesions, guiding interventional therapy and avoiding unnecessary surgery.

Background: Multidetector CT is the modality of choice in depicting pulmonary vascular abnormalities, allowing their accurate characterization. High resolution enhanced 3D imaging provides a non-invasive method for the diagnosis of these lesions, avoiding the need for conventional angiography unless endovascular interventional procedures are required. Vascular pulmonary lesions in the adult are often symptomatic and can lead to dramatic situations requiring prompt diagnosis and treatment. Understanding the anatomy and radiological appearance of these lesions is essential in making the correct diagnosis.

Procedure Details: We reviewed all pulmonary vascular abnormalities detected in our department in the last four years. Multidetector CT led to the correct diagnosis in all cases. Angiography and interventional therapy was performed when necessary. Specific topics addressed include: intralobar sequestration, congenital pulmonary venolobar syndrome, pseudosequestration, pulmonary arteriovenous malformation, congenital and acquired occult main pulmonary artery, pulmonary

Scientific and Educational Exhibits

artery aneurysm, hematoma of pulmonary artery sheath, pulmonary venous varix, pulmonary vein anomalies and thromboembolic disease. Detailed anatomic-radiologic correlation and specific diagnostic criteria for each topic are revisited. Cross-sectional and 3D images are shown. Arteriography images are included when available.

Conclusion: Multidetector CT allows accurate diagnosis in vascular pulmonary lesions and facilitates optimal patient treatment. Knowledge of the radiological appearance of these entities is mandatory for its correct characterization.

C-0331

Identification of pulmonary vein variants by multidetector CT

C. Capuñay, PM. Carrascosa, M. Ulla, J. Carrascosa; Buenos Aires/AR

Learning Objectives: To illustrate a new application of 3D images in the evaluation of vein anatomy. To outline the advantages of this kind of non-invasive evaluation. To provide an overview of the spectrum of pulmonary vein variants.

Background: Anomalies in number and insertion of pulmonary veins (PV) are frequent in humans and their evaluation prior radiofrequency catheter ablation (RFCA) facilitates this anatomical based procedure.

Procedure Details: The anatomy of the PV were assessed in 110 patients admitted at the institution for coronary artery evaluation. CT scans were performed on a 16-row CT scanner (Brilliance 16; Philips Medical Systems) with the following parameters: 16x0.75 configuration, 1 mm slice thickness, 0.5 reconstruction interval, 140 kV, 450 mAs, pitch 0.24. ECG gated acquisitions were obtained at different moments of the cardiac cycle. Injection of 100 ml of iodinated contrast was performed by power injector.

Images were analyzed by 2D and 3D (volume rendering) reconstructions to assess the anatomy of the PV. Also the ostial diameters and branching patterns were determined.

Results: Sixty patients (54.5%) had two ostia for upper and lower lobe veins on the right side and 89 (81%) had two ostia for upper and lower lobe veins on the left side. 38 patients (34%) had three ostia and 12 patients (11%) 4 ostia on the right side. 18 patients (16.3%) has one ostium and 3 patients (2.7%) 3 ostia on the left side.

Conclusion: Multidetector CT is a valuable tool that allows detection of intra-patient and inter-patient anatomic variants of the PV.

C-0332

Detection of pulmonary embolism with unenhanced CT

R. Cobelli, M. Zompatori, E. Lombardo, C. Bnà, G. De Luca; Parma/IT

Objective: To evaluate the percentage of cases in which emboli can be detected in unenhanced scans and to identify the cases in which they appear hyperattenuating or hypoattenuating in comparison to the circulating blood.

Method: We performed an angio-CT before and after contrast injection on 140 consecutive patients, following clinical suspicion of pulmonary embolism. A radiologist analysed comparatively the examinations thus obtained. We analysed firstly the enhanced scan and, after detecting the thrombus, the unenhanced scan was evaluated.

Results: 51 exams were positive for pulmonary embolism; in 21/51 (41%) cases it was possible to identify the embolus even in the unenhanced scans; in particular in 10/21 (47.6%) cases the clots were hyperattenuating compared to the blood; in 5/21 (23.8%) cases hypoattenuating and in 6/21 (28.6%) cases were mixed hyper-hypoattenuating.

Conclusion: In a relatively high percentage of cases, above all those of central thromboembolism, it is possible to identify and characterize the clots, even in the unenhanced scans. The possibility of diagnosing pulmonary embolism without the use of contrast medium is of clinical importance as it could suggest the presence of pulmonary embolism in patients with non-specific cardiopulmonary symptoms and, through an analysis of the density and the morphology of the clot, similar to what may be observed via transesophageal ultrasound, it can provide information regarding the period in which the pulmonary embolism took place (acute or chronic pulmonary embolism).

C-0333

Evaluation of flow-related artefacts in the study of pulmonary embolism with multislice

R. Cobelli, M. Zompatori; Parma/IT

Objective: To evaluate the flow-related artefacts in CT exams performed to exclude pulmonary embolism.

Materials and Methods: We retrospectively analysed 98 CTs of the thorax performed for clinical suspicion of pulmonary embolism. In particular we analysed

the detection of flow-related artefacts that compromise the possibility of making a correct diagnosis of pulmonary embolism. All the exams were performed using bolus tracking and a collimation of 0.75 mm. The exam technique is described.

Results: Two type of artefacts are detected; the absence of contrast material in the pulmonary artery due to a transient interruption of contrast enhancement related to inspiration (present in 6/98 of the cases); and the second one (2/98) was created by the presence of poorly enhanced blood due to a local increase in vascular resistances (ie: atelectasis or pleural effusion). A complete iconography is illustrated.

Conclusion: In the first group, it was necessary repeat the scan to obtain correct opacification of the pulmonary vessels, while in the second group it is important to recognise the artefact to avoid the misdiagnosis of pulmonary embolism. In both cases it is necessary to repeat the scan to make a correct diagnosis.

C-0334

Elective bronchial artery embolisation for haemoptysis using spherical embolic agents

K. Malagari, D. Antonopoulos, J. Mitromaras, E. Alexopoulou, A. Sissopoulos, D. Shizas, D. Kelekis; Athens/GR

Purpose: To examine the efficacy of bronchial artery embolisation (BAE) with the use of newer embolic material.

Materials and Methods: Thirty-eight patients with a recent severe or massive haemoptysis (23 M, 15 F; mean age 48.3) underwent bronchial arteriography and were subsequently embolised electively. The underlying disease was cystic fibrosis (n = 5), bronchiectasis (n = 16), chronic fibrocystic lung disease (n = 9), complex hepatopulmonary infection (n = 1), postbullectomy (n = 2), and occult (n = 5). Embolic agents used included spherical embolic agents alone > 300 μ in 31 patients (Embospheres; Biosphere, Rockland, MA) combined with Gelatin sponge particles in 7 cases (Gelfoam; Upjohn, Kalamazoo, MI). A microcatheter was used in 9 of the patients while the remaining were catheterised with 4-5 F Cobra-shaped or Simmons catheters. Repeat bronchial arteriography was performed in 15 cases based on initial arteriography findings, extent of initial embolization and CT arteriography findings suggestive of bronchial artery dilatation. In 7 of these patients a repeat embolization was performed. No major complications were observed. Follow-up ranged from 5 to 44 months (mean: 26.2 months).

Results: On follow-up, relapse of haemoptysis was reported in 6 patients (2.3%), in two of whom it was severe. Recurrence after embolisation was correlated to chronic lung disease ($p = 0.04$) and active inflammation ($p = 0.005$).

Conclusion: Elective BAE with the use of newer embolic agents and superselective catheterization has very low intermediate recurrence rates. Active inflammation requires further treatment.

C-0335

Pre-test scores in patients suspected of having pulmonary embolism: Are they really useful before multidetector-CT examination?

A.A. Lemos, R. Castelli, D. Fortis, A. Guariglia, P. Biondetti, F. Porro; Milan/IT

Learning Objectives: To determine the usefulness of the most common clinical probability test performed before MDCT examination for pulmonary embolism.

Background: The high performance of multidetector-CT (MDCT) in the detection of pulmonary embolism (PE) has resulted in an increased workload at our department. In addition, several examinations are not justified because clinical indications are inadequate or insufficient.

Procedure Details: We evaluated 329 patients, 175 males and 154 females, ages 33-85 years (median 59 years) with an initial clinical work-up, which included: ECG, blood gas analysis, chest X-ray, and d-dimer levels. We performed the Wicki's, Well's, and Kline's scale of probabilities. We then obtained confirmation or exclusion of the diagnosis using MDCT and/or pulmonary scintigraphy. We divided the patients in two groups: Those with PE not confirmed (178 patients, group a), and those with PE confirmed (151 patients, group b). Our results were as follows: Wicki's scale: Low probability 29%, intermediate probability 44%, high probability 79%. Well's scale: Low probability 27%, intermediate probability 47%, high probability 82%. Kline's scale: Low probability 32%, high probability 61%.

Conclusion: None of the three scales yielded convincing results, because the percentage of confirmed PE was excessive in patients with low pre-test probability. The high demand for MDCT examinations may be justified in those patients with intermediate and high probabilities in which PE was confirmed.

C-0336

Thromboembolic complications after major orthopedic surgery: A 13-year register of 5607 patients

B. Bjørnarå, T. Gudmundsen, O. Dahl; Drammen/NO

Purpose: Our two recent studies examined "Late occurring clinical DVT in joint-operated patients" and "Risk of non-fatal pulmonary embolism after joint surgery in patients receiving in-hospital low molecular weight heparin prophylaxis". The present study examines the overall risk of venous thromboembolism after major orthopedic surgery.

Materials and Methods: A 13-year prospective registry of all patients undergoing major orthopaedic surgery (nailed hip fracture procedure, total hip and knee replacement surgery) at a Norwegian hospital between 1989 and 2001. Low molecular weight heparin was given routinely for about ten days. Patients with suspected pulmonary embolism underwent VP-scintigraphy or spiral CT. Patients with suspected DVT underwent ultrasonography and, if negative, venography.

Results: Out of 5607 operated patients, 64 had pulmonary embolism (incidence 1.1%) and 86 had DVT (incidence 1.5%). Only 7 patients had both pulmonary embolism and DVT. The overall incidence for thromboembolic complications was 2.6%. Average time to readmission for pulmonary embolism was 42 days after total hip replacement surgery, 25 days after nailed hip fracture procedure and 10 days after total knee replacement surgery. The average time to readmission for DVT was 32 days after total hip replacement, 37 days after nailed hip fracture and 26 days after total knee replacement.

Conclusions: For patients undergoing major orthopaedic surgery and only receiving in-hospital thromboprophylaxis, the incidence of pulmonary embolism and DVT remains elevated for 2-3 months. The different timing for developing pulmonary embolism and DVT suggests that these groups should be considered separately when determining the optimal thromboprophylaxis regimen.

C-0337

Effective dose level from lung screening CT using auto exposure control

T. Koyama, M. Terada, M. Sato, M. Kobayashi, Y. Numaguchi, T. Horiuchi, J. Sekiguchi; Tokyo/JP

Purpose: The purpose of this study is to evaluate the effective dose level from Lung Screening CT using Automatic Exposure Control (AEC). AEC systems for CT are rapidly gaining widespread clinical use. These systems automatically adjust the tube current (mA) to improve dose utilization and/or to reduce variability of patient dependent image noise.

Materials and Methods: CT systems have recently implemented dose information display, such as CTDIvol and the DLP (dose-length product, in mGy.cm) on the operating consoles. The effective dose for CT examination is calculated from the DLP with the factor for converting into effective dose. We prospectively studied over 1,000 participants undergoing lung screening on 16-slice MDCT (Light-Speed16; GE Healthcare, Milwaukee, WI, USA). Each participant underwent scanning at Noise Index=30, single breath-hold, 1.25 x 16 mm detector configuration, 0.5 sec per rotation, pitch of 1.35: 1. Contiguous 2.5 mm thickness images were reconstructed.

Results: We confirmed the CT system provides various mA values along the z-axis during scanning, and maintains constant image noise. In screening exams, average effective dose was approximately 1.3 mSv, and was reduced by 30-40% as compared with fixed mA protocols. The same level of detectability for nodules in LSCT (Lung Screening CT phantom, Kyoto Kagaku) was confirmed with fixed mA and AEC protocols.

Conclusion: We conclude that AEC can achieve a significant reduction in dose without compromising diagnostic image quality. These results showed that AEC protocol produces sufficient diagnostic image quality compared with a conventional fixed mA technique.

C-0338

Diagnostic performance of a computer-aided diagnosis tool (CAD) for the detection of pulmonary nodules in low dose lung cancer screening CT

S. Giunta, S. Canitano, P.L. Ordonez, G. Vallati, M. Benassi, M. Crecco; Rome/IT

Purpose: To assess the diagnostic performance of a CAD system for automatic detection of pulmonary nodules using Multi Detector CT (MDCT) in lung cancer screening.

Materials and Methods: 80 dataset of MDCT (Somatom Plus 4\Volume Zoom, Siemens, Germany) low dose lung cancer screening from the Regina Elena I-ELCAP were submitted to an experimental CAD (syngo Lung Care CT, Siemens, Germany). The cases were reported independently by two chest radiologists in double blind report (DBR) and then in final version after the CAD evaluation. Each candidate nodule marked by CAD was analysed and evaluated as true positive (TP) or false positive (FP) by a consensus panel (CP). The CP was the DBR plus CAD analysis plus a second consensus reading by the two radiologists during the CAD analysis.

Results: The CP evaluated 369 nodules as TP. The CAD tool detected 1314 candidate nodules. 243 (18.50%) were classified as TP and 1071 as FP (81%). 12 nodules detected by CP (3.7%) were not detected by either the DBR or CAD. 67 nodules were detected both by CAD and DBR (18.1%), 176 were detected only by CAD (47.7%) and 114 were detected only by DBR (30.9%). DBR sensitivity was 50%, CAD sensitivity was 68% and system CAD-DBR sensitivity was 97%.

Conclusion: The CAD tool increases the number of pulmonary nodules detected, reducing the number of missed nodules. This method appears to play a supportive role, providing routine real-time clinical assistance to interpret chest MDCT studies of a lung cancer screening program.

C-0339

Microscopic findings in various lung diseases with peripheral lung imaging using micro focus X-ray CT

H. Ikura¹, K. Shimizu², Y. Yasuhara¹, M. Miyagawa¹, T. Mochizuki¹, H. Ebara¹, K. Ueno³, T. Nagareda⁴; ¹Ehime/JP, ²Kanagawa/JP, ³Tokyo/JP, ⁴Hyogo/JP

Purpose: Although synchrotron radiation (SR) CT can visualize fine structures of peripheral lung with approximately 10 µm of spatial resolution, it is difficult to access the largest SR facility. The objective of this study was to evaluate the potential of micro focus X-ray CT (MF-XCT), located in a corner of an ordinary laboratory, for peripheral lung imaging, comparing with pathology and SRCT imaging.

Scientific and Educational Exhibits

Methods and Materials: Postmortem human lungs with normal and pathologic states were inflated and fixed by Heitzman's method. Each specimen was cut down to small cylindrical shape with 6-mm diameter and 20-mm height for adaptation to the FOV of MFxCT system. The CT images were obtained using MFxCT system (MCT-CB100MF, Hitachi Medical Corp., Japan). Thereafter, microscopic sections were obtained with hematoxylin and eosin. Finally, MFxCT images were compared with the microscopic and SRCT images.

Results: MFxCT could clearly visualize the peripheral lung structures including alveolar walls with approximately 10 µm of spatial resolution as well as SRCT. MFxCT also demonstrated the pathologic features (destruction and enlargement of peripheral airspace in emphysema; destruction and micro honey-comb due to fibrosis in pulmonary fibrosis; apparent thickening of alveolar wall and filling within alveoli in pulmonary hemorrhage). Each MFxCT image of the normal and pathologic lung specimen correlated with the corresponding histopathologic and SRCT image, point to point.

Conclusions: MFxCT provided peripheral lung images with approximately 10 µm of spatial resolution non-invasively. Therefore, MFxCT could demonstrate the various diagnosable features in an ordinary laboratory to differentiate on microscopic order.

C-0340

Parallel imaging in lung MR

F. Molinari, S. Gaudino, D. Spina, T. Pirroni, L. Bonomo; Rome/IT

Learning Objectives: 1. To provide an extensive review of all the technical and methodological problems related to lung MR; 2. To illustrate strategies of optimization both for morphologic and functional imaging of lung; 3. To investigate the benefits of using parallel imaging in lung MR and fully explain the technical basis for it.

Background: MR imaging of lung is mainly limited by several technical and methodological problems, including a very weak signal of the lung tissue due to a low proton density, air-tissue interfaces, flow and diffusion, relaxation effects, cardiac and respiratory motion. Very short T2 values are therefore commonly observed, requiring optimised and dedicated sequences to perform both morphologic and functional studies.

Procedure Details: Single-shot Fast Spin Echo (SS-FSE) sequences, either with cardiac or respiratory triggering, are most effective in producing anatomic images of lung parenchyma. MR functional studies of lung, such as oxygen-enhanced MR imaging and non-invasive studies of lung perfusion, can be performed applying Inversion Recovery pulses to SS-FSE sequences. Parallel imaging (PI) represents a useful technical approach to speed up acquisition time and increase spatial resolution of MR images. An exhaustive explanation of potential advantages and limits of implementing PI on lung MR, in both morphologic and functional imaging, will be provided.

Conclusion: Parallel imaging in lung MR, as in other organs, improves image quality and reduces scan time. Despite some PI-related artefacts, this technical approach still provides advantages over conventional methods to overcome the many limitations of lung MR imaging.

C-0342

Automatic exposure control in low-dose chest CT with 16 slice MSCT

S. Gomi, M. Suzuki, S. Doi, H. Daisaki, T. Murano, K. Mayumi, Y. Muramatsu, S. Tsukagoshi, N. Moriyama; Tokyo/JP

Learning Objectives: To determine the optimal scan conditions for CT automatic exposure control (CT-AEC) and to understand how to use a phantom for Low-Dose Chest CT.

Background: Using 16-slice MSCT, Low-Dose Chest CT (scan conditions: 120 kV, 30 mA, 0.5 s/rotation, Pitch factor 11, 1 mm-slice) has been executed at our institution. Image quality depends on the individual patient and slice position. However, CT-AEC is not generally used in medical screening examinations because of the few changes of tube current in Low-Dose CT. Therefore, the present study was conducted to determine the optimal scan conditions for CT-AEC.

Procedure Details: A chest CT phantom (LSCT-001, Kyoto-Kagaku) was scanned to obtain the DLP (Dose Length Product) under routine scan conditions (DLP-routine). Scan conditions equivalent to DLP-routine were obtained using CT-AEC at 80, 100, and 120 kV with or without an additional filter. The phantom was scanned under these conditions to determine the minimum diameter of simulated tumors that could be visualized. And the maximum tumor was measured the CNR (Contrast-Noise Ratio). The minimum diameter of tumors visualized at the lung apex, tracheal bifurcation, and lung base was 4 mm for all scan conditions.

The CNR values in each region were 1.9, 2.6, and 2.9 using routine scan conditions, with high values obtained only with a filter at 100 or 120 kV.

Conclusion: Using CT-AEC, the optimal exposure dose can be obtained at 100 or 120 kV with a filter.

C-0343

Automated diagnosis of disease using texture analysis in CT of the lungs

S.P. Prabhu, J. Malone, L. Carrivick, J. Rossiter, P.R. Goddard; Bristol/UK

Purpose: To evaluate the feasibility of a computer-aided diagnosis (CAD) system to distinguish between normal lung and 5 patterns of disease commonly seen on MDCT scans of the lungs.

Method and Materials: Scans of 100 patients were gathered from daily practice and the lung fields identified using a fully automated segmentation algorithm where possible and semi-automated in the more unusual cases. Representative areas of normal tissue, various degrees of fibrosis, emphysema, consolidation and ground glass opacification were highlighted by radiologists. We used texture analysis to train 3 standard machine learner programmes. Each of the scans were classified in 3 different sized grids. The results from the block sizes of 16, 8 and 4 pixels were fused and a final classified image for each of the scans was produced. The results in each complete set of scans were combined to produce a bullet point report for each subject elaborating location and extent of the disease in question.

Results: We demonstrate 90% accuracy of the CAD programme in cases of normal tissue and severe disease when compared with large areas of selected scans labelled by experts. There is only a 62% agreement in more subtle and equivocal cases. We further compared computer generated bullet point reports to the actual reports and again achieved close to 90% correlation in the more clear-cut cases.

Conclusions: We demonstrate the feasibility of a fully automated system for diagnosis of lung disease on MDCT of the chest.

C-0344

Internet-based tool for differential diagnosis of HRCT findings in non-HIV patients with cancer presenting with lung diseases

C. de Bazelaire, S. Vignot, O. Mathieu, A.-M. Zagdanski, P. Bourrier, E. de Kerviler, J. Frijla; Paris/FR

Learning Objectives: To facilitate interpretation of lung HRCTs in patients with cancer presenting with lung disorders. To propose an internet-based tool for differential diagnosis, according to initial disease, treatments, HRCT patterns, and symptoms.

Background: Lung diseases are common in non-HIV patients under treatment for cancer. HRCT features lack specificity and differential diagnosis is tricky. Radiologists should correlate differential diagnoses (infection, non-infection), side-effects of treatments and clinical findings: gram-negative bacillus infection with potential septic shock occurs in the setting of transient neutropenia, while lymphopenia leads to *pneumocystis jiroveci* or viral pneumonias. HRCT findings should be interpreted carefully: Although nodules surrounded by ground-glass opacities suggest invasive aspergillosis in prolonged and severe neutropenia, halo sign also reflects intracellular bacterial infections (mycobacteria, *legionella*) in prolonged lymphopenia.

Procedure Details: HRCT findings were classified into alveolar consolidation, ground glass opacities, septal thickening, micro-nodules, nodules, and bronchiolar abnormalities. Patients with similar immune defects were pooled, based on type and duration of anticancer-therapy (induction, consolidation chemotherapies, intensification with autologous and allogeneic bone marrow transplants). Clinical course i.e. acute and sub-acute onset, or chronic evolution was also considered. For each subgroup, differential diagnoses seen in our institution or found in literature were recorded. This tool performed an analysis with patient's information and provided relevant diagnoses.

Conclusion: This internet-based educational tool is still evolving, along with inclusion of new patients. This may lead to the addition of new differential diagnoses and refinement of prevalence values. It helps young radiologists in our institution, to avoid uncommon differential diagnoses and to warn when life-threatening conditions are present.

C-0345

Time-resolved parallel 3D MRA of the lung: SNR improvement using correlation analysis

C. Fink, M. Bock, R. Buhmann, S. Ley, M. Puderbach, C. Plathow, H.-U. Kauczor; Heidelberg/DE

Purpose: Time-resolved parallel 3D MRA allows comprehensive imaging of the pulmonary vasculature and lung perfusion. A potential drawback of time-resolved

Scientific and Educational Exhibits

parallel 3D MRA, however, is the low inherent signal-to-noise ratio (SNR), which is further decreased by subtraction of a pre-contrast image. The aim of this study is to assess the SNR increase of a correlation analysis post-processing over conventional image subtraction.

Methods and Materials: 44 patients were examined with a time-resolved parallel 3D MRA (TR/TE/α: 0.8/1.9 msec/40°; GRAPPA; acceleration factor: 2; scan time per 3D data set: 1.5 sec; 0.1 mmol/kg b.w. Gd-DTPA). Pulmonary arteriograms, venograms, and perfusion-weighted data sets of the lung were calculated from the time-resolved MRA data using image subtraction and correlation analysis. In the correlation analysis the unnormalised correlation coefficient of the signal in each pixel and the signal from a manually selected target region (lung artery or vein, lung parenchyma) was calculated. For comparison, the SNR of the processed image data was measured.

Results: Correlation analysis achieved a significantly higher SNR than image subtraction: The mean SNR of the image data computed by correlation analysis and image subtraction was 484 vs. 266 for the arteriograms, 464 vs. 273 for the venograms, and 29 vs. 16 for the perfusion weighted data sets of the lung ($p < 0.0001$).

Conclusion: Correlation analysis is a useful algorithm for the processing of time-resolved parallel 3D MRA data. Compared to simple image subtraction, correlation analysis achieves a ~1.8-fold higher SNR.

C-0346

Correlation between automatic vs. manual lung nodule assessment

C. Capuñay, P.M. Carrascosa, M. Ulla, J. Vallejos, J. Carrascosa;
Buenos Aires/AR

Purpose: To determine the correlation between an automatic lung nodule assessment software and manual measurement.

Methods: Thirty patients with the suspected diagnosis of solitary pulmonary nodule were evaluated. CT exams were performed on a 16-row CT scanner (Brilliance 16; Philips Medical Systems) using 1 mm slice thickness and 0.5 mm reconstruction interval. The images were evaluated in the axial plane to identify the lung nodule and these selected images were then reprocessed on a workstation. Images were analyzed by two different operators. Operator 1 performed the measurement with an automatic nodule assessment software. Operator 2 performed the measurement using bi-dimensional and three-dimensional images. The volume of the nodule and its diameters (x, y, z axis) were determined. The correlation between the two measurements were assessed using the Spearman's rank correlation coefficient (Rho).

Results: Thirty-three nodules were diagnosed. For the volume assessment, Rho was 0.972 (0.945, 0.986). For the x, y and z nodule diameters, Rho was 0.953 (0.907, 0.977), 0.944 (0.888, 0.972) and 0.966 (0.931, 0.983) respectively.

Conclusion: There was good correlation between the manual and automatic lung nodule measurements.

C-0347

Intra-observer variability of automatic lung nodule assessment software

C. Capuñay, P.M. Carrascosa, M. Ulla, J. Vallejos, J. Carrascosa;
Buenos Aires/AR

Purpose: To determine the intra-observer variability of an automatic lung nodule assessment software.

Methods: Thirty patients with the suspected diagnosis of solitary pulmonary nodule were evaluated. CT exams were performed on a 16-row CT scanner (Brilliance 16; Philips Medical Systems) using 1 mm slice thickness and 0.5 mm reconstruction interval. The images were evaluated in the axial plane to identify the lung nodule and these selected images were then reprocessed on a workstation using an automatic nodule assessment software. The volume of the nodule and its diameters (X, Y, Z axis) were determined twice, on different days and by the same operator, using the same baseline parameters. The intra-observer variability of the software was assessed using the kappa coefficient.

Results: Thirty-three nodules were diagnosed. For the volume assessment, kappa was 0.853 (0.633, 1.072). For the x, y and z nodule diameters, kappa was 0.931 (0.716, 1.146), 0.910 (0.691, 1.128) and 0.894 (0.682, 1.106) respectively.

Conclusion: The automatic lung nodule assessment software evaluated was demonstrated to be a reproducible method, with low variability between the two measurements.

F-18 FDG microPET imaging after percutaneous radiofrequency ablation (RFA) in normal rabbit lung

T. Okuma, T. Matsuoka, T. Okamura, Y. Wada, A. Yamamoto, Y. Oyama, K. Koyama, Y. Watanabe, Y. Inoue; Osaka/JP

Purpose: RFA has been recently used to treat unresectable lung cancer. RFA causes inflammatory change in surrounding normal tissue. Therefore we evaluated thermal effects of normal rabbit lung after RFA using FDG microPET which has a high resolution (1.85 mm).

Methods and Materials: Twenty-one Japanese white rabbits received CT-guided RFA. A LeVeen Needle Electrode was inserted and ablated until maximum impedance. Eleven rabbits underwent microPET scan on day 1, weeks 1, 2, 4, and 8, after RFA. The other 10 rabbits were followed by CT. For microPET, following transmission scan, emission data were acquired at early phase (40-60 min) after intravenous 18F-FDG injection. Ablated lesion-to-muscle (A/M) ratio was calculated to evaluate microPET images. We compared FDG uptake, CT image and pathological findings after RFA.

Results: A/M ratio on day 1, in weeks 1, 2, 4, and 8, after RFA was 2.7 ± 0.73 , 3.47 ± 0.09 , 3.37 ± 1.14 , 2.57 ± 0.42 , and 1.73 ± 0.01 , (mean \pm SD), respectively. A/M ratio at 1 and 2 weeks was significantly higher than at 4 and 8 weeks ($P < 0.05$). 1 and 2 weeks after RFA, ablated lesions showed rounded opacity on CT, and coagulation necrosis, hemorrhage, and inflammation on histology. 4 and 8 weeks after RFA, opacity decreased on CT and inflammation was reduced on histology.

Conclusion: Thermal damage of normal lung due to RFA affects FDG uptake 1 and 2 weeks after RFA. Decreases in FDG uptake on follow-up microPET correlated with pathological findings after normal lung RFA.

C-0349

CT-guided radiofrequency thermal ablation (RFA) of primary and metastatic lung tumours

L. Thanos, S. Mylona, N. Sakaridis, E. Karahaliou, A. Kokkinaki, N. Batakis; Athens/GR

Purpose: To present the technique, the effectiveness and the possible complications of RFA of primary and metastatic lung tumors.

Materials and Methods: During an eighteen-month period, we performed 65 RFA sessions under CT-guidance in 48 lesions (25 metastatic and 23 inoperable primary) on 35 patients with lung tumors. We used two different types of generators, RITA (hooked electrode) and MIRAS (spiral electrode). The ablation lasted 15-18 minutes.

The procedure was performed after analgesic treatment and local anaesthesia at the point of entry. Follow-up with dual-phase contrast enhanced spiral CT was performed immediately after the procedure and at 1-, 6- and 12-month intervals.

Results: Total necrosis was observed in 19 (82.6%) primary and in 19 (76%) metastatic lesions. In 4 (17.4%) patients with primary and in 6 (14%) with metastatic lesions that demonstrated partial necrosis, we proceeded to a second session. The 6-month CT follow-up demonstrated recurrence in 7 (14.5%) lesions (4 primary and 3 metastatic), which were treated with a new RFA session. We had minimal complications of two pneumothoraces and one hemorrhage. Two patients died after one year.

Conclusion: CT-guided RFA may provide a safe and effective alternative treatment as well as a good quality of life in patients with lung tumors.

C-0350

F-18 FDG-microPET evaluation after CT-guided radiofrequency ablation (RFA) in rabbit VX2 lung tumor model

T. Okuma, T. Matsuoka, T. Okamura, Y. Wada, A. Yamamoto, Y. Oyama, K. Koyama, K. Nakamura, Y. Watanabe, Y. Inoue; Osaka/JP

Purpose: To evaluate therapeutic effects of RFA for implanted lung VX2 tumor, using FDG microPET with a high resolution.

Methods and Materials: Six Japanese white rabbits received RFA for normal lung and underwent microPET on 1 day after RFA (group A). VX2 was implanted into 11 rabbits lung divided into 2 groups, 6 underwent microPET without RFA (group B), and 5 had microPET on day 1 after RFA (group C). For RFA, a LeVeen Needle Electrode was inserted and ablated until maximum impedance. For microPET study, dynamic emissions were acquired for 120 minutes after 18F-FDG

Scientific and Educational Exhibits

injection. Images were reconstructed at early (40-60 min.) and delayed phases (100-120 min.), and ablated lung-to-muscle (A/M), tumor-to-muscle (T/M), and ablated tumor-to-muscle (TA/M) ratios were calculated. FDG uptake and pathological findings were compared.

Results: In early phase, A/M, T/M, and RFA central and peripheral zone of TA/M ratios were 2.7 ± 0.73 , 6.05 ± 1.82 , 0.76 ± 0.33 , and 3.01 ± 0.79 , and in delayed phase, 2.9 ± 0.53 , 7.6 ± 2.26 , 0.84 ± 0.58 , and 3.54 ± 1.12 (mean \pm SD), respectively.

In groups A and C, histological findings were central coagulation necrosis, and peripheral inflammation, and A/M and TA/M ratios between early and delayed phases were not significantly different. A/M and peripheral zone of TA/M ratios were not significantly different. In group B, histology showed viable cells. T/M ratio of delayed phase was significantly higher than that of early phase. TA/M ratio of central zone was significantly lower than T/M ratio ($P < 0.05$).

Conclusion: Change in tumor FDG uptake on microPET was useful for evaluating early therapeutic effects after RFA.

C-0351

Chest MR imaging in post-mortem examinations: Autopsy imaging system

S. Kandatsu, R. Kishimoto, S. Komatsu, H. Ezawa, H. Tsuji; Chiba-ken Chiba-shi/JP

Purpose: To evaluate the diagnostic accuracy of chest MR and CT imaging performed immediately after death.

Materials and Methods: Twenty-five patients with malignant diseases underwent whole body MR and CT imaging within 24 hours after death. We autopsied them immediately after the examinations. They included 8 cases of hepatoma, 7 cases of lung carcinoma, 3 cases of head and neck melanoma, 2 cases of uterine carcinoma, 2 cases of pancreas carcinoma, one case of head and neck adenocarcinoma, one case of esophageal carcinoma, and one case of chondrosarcoma, respectively. We compared the images of MR and CT with the results of the autopsies.

Results: We precisely found pleural effusion, pulmonary nodules of more than 5 mm in diameter, hemorrhage, chest wall tumor invasion, mesenchymal thickening, and bone invasion on chest MR imaging. Almost all of abnormal lesions recognized on CT imaging were found on MR imaging. On MR imaging, we recognized more abnormal lesions which were not found on CT imaging.

Conclusion: Post mortem chest MR imaging in autopsy imaging system has diagnostic value and is superior to chest CT imaging.

C-0352

A comparative experimental study of the in-vivo efficiency of saline-enhanced bipolar versus monopolar pulmonary radiofrequency ablation

S.-H. Park, G.-Y. Jin, Y.-M. Han, H.-H. Park; Jeon-ju/KR

Purpose: To compare the in-vivo efficiency of a saline-enhanced bipolar radiofrequency (RF) system with monopolar RF by assessing the variable factor and dimensions of RF-created coagulation necrosis in rabbit lung.

Materials and Methods: In 15 rabbits, 15 RFA lesions were produced using a one or two 16-gauge open-perfused electrodes with a 1-cm active tip at an interelectrode distance of 1 cm. Rabbits were assigned to one of five groups: Group A ($n = 3$), 0.9% NaCl at a rate 30 cc/hr in monopolar mode; Group B ($n = 3$), 5.8% NaCl at a rate 30 cc/hr in bipolar mode; Group C ($n = 3$), 5.8% NaCl at a rate 15 cc/hr in bipolar mode; Group D ($n = 3$), the 0.9% NaCl at a rate 30 cc/hr in bipolar mode; Group E ($n = 3$), 0.9% NaCl at a rate 15 cc/hr in bipolar mode. RF energy was applied for 5 minutes and the temperature of the electrode tip was automatically measured. The dimensions of the thermal lesions in gross specimens were compared between the groups.

Results: The mean diameter of the thermal lesions was larger in the bipolar mode (30.9 ± 4.4 mm) than in the monopolar mode (22.5 ± 3.5) and the difference was statistically significant ($p < 0.05$). In bipolar mode, the dimensions of the thermal lesions was larger at a rate 15 cc/hr (34.2 ± 4.0 mm) than at a rate 30 cc/hr (27.6 ± 0.1 mm) and the difference was statistically significant ($p < 0.05$).

Conclusions: Using an open perfusion system, bipolar RFA more efficiently created larger area of thermal ablation than monopolar RFA.

C-0353

Saline-enhanced radiofrequency ablation for treating inoperable non-small cell lung malignancy

G.-Y. Jin, Y.-M. Han, Y.-C. Lee, C.-S. Kim, G.-H. Chung, S.-H. Chung, Y.-G. Kim; Jeon-ju/KR

Purpose: To assess the technical feasibility, safety, and complications of saline-enhanced radiofrequency (RF) ablation for treating inoperable non-small cell lung malignancy.

Materials and Methods: From December 2003 to February 2004, eleven patients (mean age, 73.5 years; range, 67-77 years) who had non-small cell lung malignancy ($n = 10$) or metastatic lung tumor ($n = 1$) underwent RF ablation with HiTT system (Berchtold®) under CT guidance. Patients were either non-surgical candidates because of advanced stage and/or co-morbid processes ($n = 10$), or refused surgery ($n = 1$). Tumor diameter ranged from 2 cm to 6 cm (4.1 ± 1.34 cm). The procedure was performed as palliative therapy for 11 patients. Contrast-enhanced CT was performed immediately, at 1 month, and at 3 months to evaluate response to RF therapy.

Results: The total duration of RF application ranged from 12 minutes to 70 minutes (mean: 32.5 ± 7.5 minutes) per each session. The mean numbers of needle electrode insertions through the mass was 1.9 (range: 1-3). The diameter of the treatment zone was larger (4.78 ± 1.30 cm) than that of the tumor, as ablated adjacent lung tissue had a similar appearance to the ablated tumor (initially 4.1 ± 1.34 cm). There were two major complications (2/11: 18.2%) including hemoptysis, and one hemothorax that required thoracostomy.

Conclusion: In this preliminary study, saline-enhanced RF ablation appears to be a safe and time-saving procedure for the treatment of inoperable non-small cell lung malignancy.

Computer Applications

C-0354

Towards standardization of hanging protocols for imaging display

E. Avraham; Plano, TX/US

Learning Objectives: To demonstrate limitations of current propriety hanging protocols (HP) for laying medical images on display workstations. To present the new standardization of "Hanging Protocols" for automatic layout of the medical Images based on user preferred methods, and display workstation capabilities. To demonstrate HP clinical use cases for chest X-ray and neurosurgery planning. To elucidate needs and opportunities to optimize the medical imaging reading workflow via standardized HP.

Background: Current propriety HPs aren't supporting all the user preferred layout methods. The supported HP varies among vendors, so there is no consistent imaging layout among different display workstations. The DICOM standard HP supplement resolves these HP limitations and optimizes automatically and consistently the medical imaging orientation and display positioning. The viewing methods are selected upon user layout preference and display device capability. **Procedure Details:** This educational exhibit includes but isn't limited to (1) demonstrating current propriety HP limitations, (2) presenting the DICOM standard HP supplement for automatic & consistent medical imaging layout, (3) demonstrating examples for X-ray imaging layout and Neurosurgery planning, (4) Proposing innovation for the current standard HP data model to support 3D imaging layout and orientation.

Conclusion: This HP standardization improves the medical imaging reading practice in several domains: 1. Orienting properly images before displaying. Lays out images automatically, based on user preferences, and displays device capabilities. 2. Standard HPs can be reused on different workstations (from different vendors) with similar capabilities, keeping the consistency on layout images on different display devices.

C-0355

Computer-assisted diagnosis of thyroid nodules malignancy risk

S. Tsantis¹, D. Glotso², I. Kalatzis², N. Piliouras², P. Spyridonos², N. Dimitropoulos², G. Nikiforidis², D. Cavouras²; ¹Patras/GR, ²Athens/GR

Purpose: To provide definite diagnosis of thyroid nodule malignancy risk factor, ultrasound scans are usually combined with the invasive Fine Needle Aspiration (FNA) examination. To prevent unnecessary invasive interventions, a computer-assisted diagnosis system is introduced for the automatic discrimination of low from high-risk thyroid nodules based solely on the quantitative analysis of ultrasound images.

Methods and Materials: Clinical material comprised of 120 ultrasound images from 120 pathologically confirmed cases of thyroid nodules (74 low-risk and 42 high-risk). An experienced physician (N.D) delineated the boundary of each nodule employing a custom developed in C++ software. Tumour malignancy was encoded in a set of 40 textural features, which fed a Probabilistic Neural Network classifier, designed to automatically discriminate low from high-risk cases.

Results: Maximum accuracy (96.7%) was obtained using three textural features (namely mean value, contrast and sum of squares variance) that describe nodule echogenicity, the presence or absence of calcifications and the intra-nodular vascular spots. Sensitivity (detection of high-risk cases) was 98.7% whereas specificity (discrimination of low-risk cases) was 92.8%.

Conclusion: The proposed system could be used as a second opinion tool to the radiologist for avoiding the risk of excessive FNA examination, thus decreasing the time/cost of diagnosis and the need for patients to undergo invasive examination.

Acknowledgements: The present research was carried for the project "Computer-based system for the automatic diagnosis of thyroid nodule cancer" co-funded by 75% from the European Union and 25% from the Greek Government under the framework of the Education and Initial Vocational Training Program "Archimedes".

C-0356

Three-dimensional stereoscopic abdominal MR angiography as an educational tool for medical students

T. Yamagishi¹, K.H. Höhne², K. Abe¹; ¹Tokyo/JP, ²Hamburg/DE

Purpose: It is important task for medical school lecturers to teach thorough knowledge of three-dimensional (3D) extent of the vascular structure. While in classical medicine, anatomical knowledge is represented in textbooks and atlases,

present-day computer assisted technique allows precise and realistic rendering of the morphological structure. We made use of MR angiography data of clinical cases and created stereoscopic images for the purpose of practical education.

Methods and Materials: Clinical image data of 10 examinees were obtained by routine abdominal 3D-VIBE (volumetric interpolated breath-fold examination) protocol (arterial phase after dynamic infusion of Gd-DTPA). A Siemens Avanto (1.5 T) scanner was used. Data sets were imported into the VOXEL-MAN program (Institute of Medical Informatics, University Hospital Eppendorf, Hamburg, Germany). Stereoscopic surface-rendered images were created from the segmented volume data. The panoramic sequential stereoscopic images of 3D angiography were evaluated for the value of educational benefits by a questionnaire survey, which was done by forty medical students.

Results: Ninety-three percent of the students evaluated the resulted images as excellent for medical education. The most advantageous benefit was getting a chance to know well about the 3D extent of the interested vascular structures. Most of them pointed out that these kinds of knowledge could hardly be grasped by non-stereoscopic image presentation.

Conclusion: Stereoscopic viewing yielded an exact 3D observation of the abdominal vascular structure. Real time rendering of the stereoscopic images could be performed by VOXEL-MAN. Using the data of clinical cases gave an impact on medical students. We could achieve improved educational outcome.

Virtual contrast injection: A software tool for selective visualization of vessel structures

A. Löfväng¹, X. Tizon², A. Persson¹, G. Wiklund¹, Ö. Smedby¹; ¹Linköping/SE, ²Uppsala/SE

Learning Objectives: To understand the basic principle and potential clinical use of the virtual contrast injection algorithm (concurrent greyscale connectedness) for separation of overlying vessel structures from each other.

Background: When applying rendering methods like Maximum Intensity Projection (MIP) in both Computed Tomography Angiography (CTA) and Magnetic Resonance Angiography (MRA), a frequent problem is the superposition of adjacent vascular structures, e.g. arteries and veins in contrast-enhanced MRA or coronary arteries and heart chambers in CTA. The virtual contrast injection is a post-processing algorithm for such situations that allows unwanted vascular structures to be eliminated.

Procedure Details: The input data demonstrated here are high-resolution CTA images of the heart. In an interactive seeding step, the user marks with "seeds" in different colours, both coronaries, the heart chambers and surrounding structures. As the algorithm is started, the colours of the seeds are propagated between adjacent voxels, along with the grey-scale values of voxels passed on the way, until each voxel is labelled with the colour of the seed with which it is most strongly connected. Each vessel tree may then be displayed separately, and the most appropriate projection may be selected. In this exhibit, the viewer is able to interactively choose his/her favourite projection with the mouse (using Quicktime VR).

Conclusion: Virtual contrast injection can be used for display of vessels such as the coronaries in an angiographic format familiar from invasive angiography. The ability to interactively selecting optimal projections angles after the examination makes CTA an attractive alternative to invasive angiography.

C-0359

EMIT: Digital multilingual medical radiation physics dictionary

M. Stoeva¹, S. Tabakov²; ¹Plovdiv/BG, ²London/UK

Purpose: The main objective for the development of the Digital Multilingual Medical Radiation Physics and Engineering Dictionary was to provide a common tool for better understanding and improvement of the quality of the education and service in the field of Medical imaging.

Methods and Materials: Based on a case study, several thousand most common terms covering ionising and non-ionising radiation were collected by an interdisciplinary team. The further development of the software was conducted using MS Visual Basic 6. The Medical Physics Dictionary was developed under the European Medical Imaging Technology Training (EMIT) project, supported by Grant 308 of the EC program Leonardo da Vinci.

Results: The dictionary incorporates a large database of medical radiation terms in 5 European languages (English, French, German, Italian, Swedish). It also

Scientific and Educational Exhibits

provides tools for cross translation, sorting, typing prediction, analysis of coincidence, user's manual and help modules. The dynamic structure can easily be modified to broaden the range of the terms and languages. The Medical Physics EMIT Dictionary is now available on CD.

Conclusion: The ongoing process of development of common European standards for education and training in the field of medical radiation serves as a basis for the development of the Digital Medical Radiation Physics EMIT dictionary. The dictionary is now available throughout the world in all 65 countries using the EMIT training materials.

C-0360

Integration of electrical mapping and multi-detector CT imaging of left atrium and pulmonary veins for atrial fibrillation ablation

M. Centonze, A. Cristoforetti, F. Ravelli, M. Del Greco, F. Dalla Palma, G. Nollo; *Trento/IT*

Purpose: Correlation of electrical patterns and real anatomical structure of the atria remains an important challenge for successful radio-frequency ablation of atrial fibrillation. Aim of this study is the three-dimensional (3D) anatomic reconstruction of the left atrium (LA) and pulmonary veins (PVs) and its fusion with LA electrical maps.

Method and Materials: The LA and PVs of nine consecutive patients with atrial fibrillation (9 men, 56.9 ± 9 years) undergoing electrophysiological study for PVs ablation were previously examined with 16-slices spiral CT (MX 8000 IDT, Philips). Source images (0.75 mm slice thickness) were acquired by retrospective ECG-gating (75% of cardiac cycle) with temporal resolution = 210 ms. A specific method based on marker-controlled watershed segmentation was developed for 3D cardiac reconstruction. This allowed to separate the surface rendering of LA and PVs proximal branches from the other overlapping structures of the heart. Successively, electro-anatomic mapping (CARTO®, Biosense Webster) of LA and PVs ostia was performed.

Results: CARTO® maps were successfully registered on the 3D LA inner surface minimizing the residual error by a stochastic relaxation approach with a final error (distance of CARTO® coordinates to 3D LA surface) ranging from 2.03 to 3.00 mm. The fusion of the electrical maps with the 3D LA reconstruction was achieved by radial basis function interpolation.

Conclusion: Fusion of 3D anatomical images of LA and PVs with electrical maps is feasible. Pre-ablation procedure Multi-Detector CT examination may constitute a significant support for mechanism investigation and treatment of atrial fibrillation.

C-0361

Computed tomography angiography of the coronary arteries with virtual contrast injection

A. Löfving¹, X. Tizon², A. Persson¹, G. Wiklund¹, Ö. Smedby¹; ¹*Linköping/SE*, ²*Uppsala/SE*

Purpose: Computed Tomography Angiography (CTA) is an attractive non-invasive alternative to invasive angiography but has had limited use in the coronary arteries due to resolution and visualization difficulties. Maximum intensity projection (MIP) is frequently used in other domains but is difficult to apply in the heart with numerous overlying contrast-filled structures. The purpose of this feasibility study was to ascertain whether virtual contrast injection, originally proposed for MR angiography, can visualize the coronaries in CT datasets.

Methods: Ten patients were examined after i.v. contrast injection in a 16-detector CT scanner (Siemens Sensation 16) with collimation 16×0.75 mm, reconstructed slice thickness 1 mm and increment 0.5 mm. The virtual contrast injection (concurrent greyscale connectedness) was implemented in Java on a standard PC using the open-source ImageJ platform. Rendering of the right and left coronary separately was made with MIP and volume rendering (VRT).

Results: Images similar to invasive angiography were obtained in all 7 projections used in the clinical routine of our institution (3 for the right and 4 for the left coronary). In addition, the observer has the possibility to freely select an optimal projection (as demonstrated interactively in this digital poster). Typical time for interaction (vessel seeding) was 30 min and for processing 10-15 min.

Conclusion: CTA with subsequent virtual contrast injection can visualize coronary arteries in a mode similar to invasive angiography. After validation in larger materials, this may become a clinically useful non-invasive alternative for examination of coronary artery morphology. (Supported by Siemens Medical)

C-0362

Open source DICOM archive

V. Porod, J. Novotny, D. Vedlich, D. Kautznerova, M. Hajek; *Prague/CZ*

Purpose: This work describes building of the full-functional DICOM archive using open source applications.

Methods and Materials: All applications, which are necessary for DICOM files archiving are available as Open Source. The Open Source means, that you can download the source code of this applications. Having the source code, you can change the functionality of the application to fit your own requirements. For operating DICOM we used DICOM TOOLKIT from Oldenburger Forschungs- und Entwicklungsinstitute für Informatik-Werkzeuge und Systeme (OFFIS). To keep the database of pictures we used MySQL database server and for the web based pictures access we used Apache web server with PHP module. We also used the very popular open source operating system LINUX. The archiving software was running on DELL server with 2 Xeon (3 GHz) processors, 2 GB RAM and the external harddisk array with total capacity 3 TB. The source of DICOM data was CT SIEMENS SENSATION 16, with the output size approximately 180 000 GB per month. CT was connected with archive through 100 Mbit/s hospital network.

Results: All above mentioned applications were connected to build the DICOM archive with web based access. The time to archive 100 CT pictures was approximately 12 s and the download of 100 pictures to workstation took 9 s.

Conclusion: We presented the possibility of building Open Source DICOM archive. The fact, that we have the source code of all needed applications is useful for example to make a connection with hospital information system.

C-0363

Optimizing material management in interventional radiology departments through the introduction of a materials management system

D.-A. Clevert¹, N. Rupp², M.F. Reiser¹; ¹*Munich/DE*, ²*Passau/DE*

Objective: A cost analysis was performed to assess options of reorganizing material supplies and reducing radiology division costs through the introduction of a materials management system.

Materials and Methods: A materials management system (Piranha, Boston Scientific) was installed on an existing computer system. All consumables were inventoried and entered into the system. An ABC analysis determined further action. On the basis of order frequencies and availability requirements for emergencies, safety levels were agreed with physicians and other medical staff. Inventory costs were computed using these data. The interest rate for these calculations was 8% per year.

Results: The inventory showed that the capital tied up in stocks was 260,000 € in 2001 and 190,000 € in 2002. A change in supply strategy reduced inventory cost in 2001 and 2002. Annual interest expense was lowered by 18,420 €. Another saving of 2,700 € was achieved by a reduction in storage cost. Annual inventory turnover totaled 298,000 €. The total cost cut through improved inventory management was 21,120 € per year equivalent to 7% of annual expenses. Adding the decline in the cost of shelf time overruns equal to 5% of annual expenses, the saving was approximately 12% of total interventional radiology cost in 2001 and some 11% in 2002.

Conclusion: Flexible supply strategies and the introduction of a materials management program can help to reduce inventory costs in interventional radiology divisions without any impact on service levels.

C-0364

PACS in your pocket? The PDA as imaging tool of the future

C.P. Meehan, C.G. Cronin, D.J. Lohan, P.A. McCarthy; *Galway/IE*

Learning Objectives: To illustrate the emerging role for Personal Data Assistant technology in radiology practice. To enumerate technical challenges, hardware options and software developments which allow reporting of digital imaging via handheld computers.

Background: PACS technology is the favoured means of storing, viewing and archiving radiologic imaging data on a department-wide basis. However, this does present limitations. Workstations are costly and therefore of restricted access. Clinicians require access to imaging studies for review and for patient education at the bedside. Handheld computers, or Personal Data Assistants (PDAs) have been commercially available since the 1980s. However, from the late 1990s latter generations of these devices have undergone rapid development in terms of processing power, screen quality and user interface. There are now available software programs for viewing, manipulation and storage of medical imaging data, including the DICOM format. We have conducted a literature and internet search

Scientific and Educational Exhibits

to identify desired hardware specifications for effective image interpretation, and software currently available for this task.

Procedure Details: Several hardware criteria are important: screen dimensions and resolution, processor speed, storage capacity, battery life and interconnectivity using wireless communication standards. Commercially available software packages offer image storage and manipulation capabilities. We have illustrated the current state of the art, and point out technical challenges to the adoption of PDAs into everyday practice.

Conclusion: The current generation of PDAs already incorporates features well suited to interpreting medical imaging. As the technology evolves, more powerful dedicated handheld devices may be developed specifically for incorporation into a hospital-wide system.

C-0365

A multilingual radiological database on the web for medical students

J.C. Hellund, N. Kløw; Oslo/NO

Learning Objectives: To illustrate how a radiological database, founded on a problem-based learning model is made; including good image quality and integration of clinical and radiological data. To show how a monolingual text can be adapted into other languages.

Background: A no password limited radiological database, with images and readings, is for the medical students an opportunity to self-study and continuous education and distance learning. Multi-lingual editions give other nationalities a possibility to access the information.

Procedure Details: The images were digitized and metadata were appended to make search and retrieval possible. Each case was given a history, a examination description and a detailed reading. A case consists of images from one examination. The background data, thumbnails, text and metadata are stored in an Oracle database, the larger pictures are stored in the file system of the server. WebObjects, an object-oriented, java-programming tool for WWW applications, is used to access and display the data. The database is found at www.radiologi.net, where the Norwegian version has been translated to English during spring 2004, a Russian version is being made during the autumn of 2004. The translated text is uploaded during a common interface.

Conclusion: With a radiological database on the web, students report a high level of satisfaction with the educational method. During the 3 years with the Norwegian version, there were an average of 78.152 requests for pages/month with an average registrations of 423 distinct hosts servers. The programming tool makes the technical handling of translated text easy.

C-0366

SMARTDOC: A new system for real-time consultation and interaction of complex medical data over the internet on low end hardware

A. Persson, S. Palmberg, M. Ranlöf, M. Jern; Linköping/SE

Learning Objectives: Experience how to interact in a high quality medical 3D image incorporated in a Microsoft Word or PowerPoint document. Interact between PCs with voice communication over the Internet on standard software developed for collaborative games. The real-time interactivity and user-friendly interface will be demonstrated.

Background: The next decade will bring widespread, networked multimedia interpersonal computing into the Radiology world. Three-dimensional study has been increasingly used in medical diagnosis and treatment. We have developed web based application components for 2D and 3D visualization of medical data with support for peer-to-peer collaborative sessions on PC desktops and laptops. SMARTDOC's distributed architecture is based on "Application Component Sharing" and a network abstraction system for games providing real-time data interactivity and voice communication. SMARTDOC goes beyond the traditional hospital workflow management and allow the information integration, access and distribution which leads to a more effective patients' treatment.

Procedure Details: The technology and network infrastructure are based on available Microsoft technology. The distributed architecture is based on "Application Component Sharing" providing real-time data interactivity, reducing the load on the network and with zero administration client deployment. The innovation can be summarized as the integration of network technology used in collaborative games with 3D data navigation techniques.

Conclusion: SMARTDOC makes remote visualisation of medical 3D data over the Internet possible with low end computers with standard cost-effective software. The solution will assist in education and knowledge exchange regarding the interpretation of medical images.

C-0367

Context-enhanced detection of electrophysiology catheters in X-ray fluoroscopy images

E.M. Franken¹, M.A. van Almsick¹, P.M.J. Rongen², B.M. ter Haar Romeny¹; ¹Eindhoven/NL, ²Best/NL

Purpose: Cardiac catheter ablation is a minimal invasive medical procedure to treat patients with arrhythmias. For this purpose, special catheters are navigated through the patient's vascular system under continuous X-ray guidance. Our goal is to develop robust image analysis techniques that can detect catheters under fluoroscopy imaging conditions, and that may assist the doctor during the treatment.

Methods and Materials: Traditional image processing methods detect line structures with filters that utilize only small spatial neighborhoods, leading to bad performance in noisy images. Inspired by the biological visual system we use context filters, which enhance elongated structures in an image based on a model of line continuation. We use an adapted version of the tensor voting technique by Medioli et al. This technique makes the final extraction of the catheters easier and more robust.

Results: We compared the performance with and without the use of tensor voting on a test set consisting of 50 clinical images. The success rate of catheter tip extraction increased from 57% to 80% for low noise images. For high noise images the success rate improved from 43% to 72%.

Conclusion: Using tensor voting leads to an increased extraction performance. We expect that further refinement of context enhancement methods will improve existing methods for detecting elongated structures. These new developments in image analysis are applicable to a lot of other medical image analysis problems.

C-0368

Image compression in chest radiography: To the limit and beyond

C. Lefort, A. Merlin, O. Hurtier, P. Petitbon, G. Frija; Paris/FR

Purpose: To evaluate image quality after compression using the wavelet technique, in order to develop teleradiology.

Methods and Materials: 120 plain chest radiographies (60 normal, 60 pathological) were analyzed retrospectively by four radiologists. Each radiography was presented in six different formats: native, compressed with no loss of information, and four different levels of compression (20, 40, 60 and 80). The images were read on a 21-inch 1K cathodic screen, and were rated 'normal'/pathological'. Statistics were performed using the Cochran test.

Results: There was no statistically significant impact on diagnosis of the compression of the images, compared to native images. There was a good intra-observer correlation, independently of the level of compression. Specifically, the number of false negatives was identical for all types of images. However, there was a bias to the study, for example, the image was recognized the second time it was presented to the reader, pathology was not sufficiently diversified.

Conclusion: There was no statistical difference concerning diagnostic quality for the different levels of compression up to 80. These preliminary results need to be confirmed by a study on a larger population of images.

C-0369

Preoperative delineation of intracranial aneurysm's topography during surgery using CT angiography

M.T. Karamessini, G.C. Kagadis, D. Karnabatidis, D. Konstantinou, T. Petsas, G. Nikiforidis, D. Siablis; Patras/GR

Purpose: To describe a technique that tries to delineate intracranial aneurysm's topography during surgery, using volume rendering techniques (VRT) in spiral CT angiography data.

Methods and Materials: Thirty-four patients with ruptured intracranial aneurysms in the ACoA and MCA identified by both CTA and DSA, were included in our study group. The demonstration of the most important features of an aneurysm during surgery was efficient after rotation of the reconstructed image of the patient's head. Its optimal position was then recorded (standardized) by the implementation of a virtual three dimensional coordinate system. Each aneurysm possessed a unique orientation, given in degrees on each virtual axis. In the operating table the patient's head was fixated with the Mayfield device, applying the set of coordinates given in the three axes by the preoperative reconstructed VRT image.

Results: The application of the proposed technique was successful in all cases. Using standard anatomical landmarks in the head correspondingly to each virtual axis, the reproduction of the technique during surgery was easily feasible. In a total of 24 ACoA and 14 MCA aneurysms, we observed a range of rotation de-

Scientific and Educational Exhibits

grees around which our patients' optimum values ranged. There was a good correlation between the VRT reconstructed images and the intraoperative findings. **Conclusion:** The results of our study support the conclusion that the preoperative delineation of intracranial aneurysm's topography during surgery using CTA data is feasible and facilitates aneurysm surgery, especially for complex cases such aneurysms of the ACoA or MCA.

C-0370

Assessment of hip joint structural alterations in osteoarthritis using image texture analysis

I. Boniatis¹, L. Costaridou¹, D. Cavouras², E. Panagiotopoulos¹, G. Panayiotakis¹; ¹Patras/GR, ²Athens/GR

Purpose: Osteoarthritis is a condition characterized by structural and functional alterations of synovial joints. Radiographic Hip Joint Space (HJS) narrowing is regarded as the hallmark for monitoring of osteoarthritis progression. In this study, the potential capacity of computer-based texture analysis in evaluating structural alterations related to hip osteoarthritis was investigated.

Methods and Materials: Forty eight HJS ROIs were obtained from the digitized standing A-P pelvic radiographs of 24 patients with verified unilateral hip osteoarthritis. ROIs were obtained by means of a custom developed computer-aided cropping technique; first an adaptive wavelet enhancement algorithm was applied to emphasize the articular margins of the hip joint and next the HJS outline was manually delineated by an expert physician. A number of textural features regarding image pixel fluctuations were extracted from each segmented HJS region using first and second order statistics. Additionally, an index expressing textural differentiation between osteoarthritic and contralateral control HJS was computed for each patient and compared to a relative index reflecting HJS area decrease.

Results: Statistically significant differences ($p < 0.05$) between the osteoarthritic and the contralateral control Hip Joint were found for the HJS areas and the textural feature of Run Length Non Uniformity. The index expressing HJS narrowing correlated highly with the pathological HJS area ($r = -0.964$, $p < 0.001$), while the two indices (HJS narrowing and textural differentiation) were also highly correlated ($r = 0.976$, $p < 0.001$).

Conclusion: Texture analysis of the radiographic HJS has a potential value in evaluating structural changes associated with the progression of hip osteoarthritis.

C-0371

Web technology and wireless application in the management of radiological images and data

V. Panebianco, C. Catalano, A. Laghi, R. Ferrari, V. Campanella, P.G. Nardis, R. Passariello; Rome/IT

Objective learning: To increase productivity and make quickly radiological workflow and to cut in film and printing costs.

Background: Web technology in association with wireless application make the film-less enterprise a reality; our aim was currently satisfied by a recent project, which is an integrated system of multimedia different component for effectively managing electronic patient's images.

Details: System is composed by: - PACS and RIS system (Ferrania Imaging Technologies); - system for diffusion of images and data via Intranet (LAN) with wireless application (WLAN) and via Internet (web) technology; - high (2.5 k) and medium (standard PC) resolution workstations; - Laptops, Tablet PCs and pocket PCs; - Security systems: computer certification, VPN (virtual private network). A local area network (LAN) and a wireless local area network (WLAN), connected with the regular intranet, can grant network access practically everywhere. Laptops, Tablet PCs and pocket PCs, with embedded wireless card can be transferred everywhere in the same way as a film folder and gives immediate access to the PACS/RIS database. This system is able to manage electronically the complete exam workflow according to standard protocols (DICOM, HL7 and IHE) and to distribute the information through the web.

Conclusion: Web-applications are the most efficient to run over a wireless device. A web application is a program that have all the processing component at the server side and allows the access to each device, using simply the web browser.

C-0372

Improvement of visibility of the lentiform nucleus in CT images for diagnosis of acute middle cerebral artery infarction

N. Takahashi¹, Y. Lee², D.-Y. Tsai², S. Kamio¹; ¹Sendai-shi/JP, ²Niigata/JP

Purpose: The obscurity and partial disappearance of lentiform nucleus are early signs of acute middle cerebral artery infarction (AMCAI) in CT images. However,

the detection of obscure lentiform nucleus is considerably difficult. In this study, a method for improving the visibility and detectability of lentiform nucleus is presented. This approach is considered as the first step for computer-aided diagnosis in AMCAI

Method and Materials: Since the brain region of a head CT image is fairly rough, the contours of lentiform nucleus are generally obscure. In order to improve the visibility of lentiform nucleus, an image processing being able to reduce local noise while maintaining the contrast of contours and edges is desirable. To cope with this issue, an adaptive partial smoothing filter (APSF) was devised. The APSF is a specifically designed filter used to perform local smoothing using a variable filter size determined by the distribution of pixel values of contours or edges in the region of interest. By adjusting 3 major parameters which exist in the APSF, an optimal condition for image enhancement can be obtained.

Results: The APSF was applied to clinical CT images having AMCAI. Our preliminary results showed that the visibility of the lentiform nucleus is much improved. To validate the usefulness of the proposed method, a commonly used low-pass filter was also used for comparison. The results demonstrated the superiority of the APSF.

Conclusion: The APSF can improve the visibility of the lentiform nucleus resulting in the increase of detectability of AMCAI.

C-0373

Pulmonary nodule detection in CT images using ellipsoid models

S. Matsumoto¹, Y. Ohno¹, H. Watanabe², T. Higashino¹, K. Sugimura¹; ¹Kobe/JP, ²Akashi/JP

Purpose: To develop a new scheme for automatic nodule detection in chest CT images.

Methods and Materials: The scheme delineates nodule candidates utilizing deformable ellipsoid models and computes 7 newly devised features for each nodule candidate. After the number of nodule candidates is reduced using a cutoff value for each feature, nodule candidates are classified based on linear discriminant analysis (LDA). The scheme was evaluated using data sets of 52 cases each of which had 1-2 nodules suspected to be lung cancer. The data sets consisting of images of 5-mm slice thickness harbored 60 such nodules (effective diameter of 5-35 mm, mean 19 mm) of which 47 were pathologically proven to be primary lung cancers. LDA was carried out using the whole array of features as well as its subsets consisting of 2-6 features. Appropriate subsets were selected using scatter matrices. The performance of LDA was assessed by means of free-response receiver operating characteristic methodology. In addition, an individual feature itself was also evaluated as a final classifier using the same methodology.

Results: LDA gave similar performance whether it was based on the whole array of features or on one of its selected subsets, showing a sensitivity of 90% with 2.2-3.0 false positives per case. The performance of a single feature approached that of LDA, yielding 3.0 false positives per case at the same sensitivity.

Conclusion: These results indicate the feasibility of the new scheme. A high discrimination power of a newly devised feature was also demonstrated.

C-0374

Are small-matrix (256x256 pixels) images of emergency CT examinations good enough for teleradiology diagnosis?

A. Gmur¹, P. Zdunek², R. Pacho³; ¹Pszczyna/PL, ²Bielsko-Biala/PL, ³Warsaw/PL

Learning Objectives: To describe the method of shortening teleradiology data transmission time of emergency CT examinations with the use of small-matrix image reconstruction. To assess the diagnostic value of 256x256 pixels images in comparison with 512x512 pixels images.

Background: Teleradiology becomes an accepted method for distant consultations of difficult cases. However, the amount of data which has to be sent immediately remains a problem in emergency teleradiology. Instead of rising transmission speed, the reducing of data volume (e.g. image matrix size) can be done. Because small matrix affects quality we assessed the diagnostic value of 256x256 and 512x512 pixels images.

Procedure Details: 50 CT examinations of emergency patients were reconstructed on both matrixes. Two experienced radiologists evaluated the examinations independently: one of them assessed 512x512 images, the second - 256x256 images. In the next step, both radiologists reviewed all the examinations together to establish, whether differences in their diagnoses came from poor image quality or from overlooking.

Conclusion: Full compliance between both radiologist was noticed in 92% of examinations in the first step of assessment followed by 100% in the second. All clinically significant changes were visible on 256x256 pixels images, but the eval-

Scientific and Educational Exhibits

uation of these images was found to be more difficult. It was estimated that CT images reconstructed on 256x256 matrix can be used in after-hours emergency teleradiology for initial assessment, however, the examinations should be reviewed with the use of full-matrix images before making the final diagnosis (e.g. next day morning).

C-0375

Electronic thoracic atlas generated from high resolution computed tomography: Use in minimally invasive cardiothoracic surgery planning
A. Aziz, S.K. Venkatesh, G. Xiao, E.K.W. Sim, W.L. Nowinski, S. Wang;
Singapore/SG

Learning Objective: To develop a digital thoracic model using data from diagnostic high resolution CT for planning of minimal invasive cardio-thoracic surgery (MICTS).

Background: Successful MICTS depends on training of the surgeon and proper planning of the procedure. Surgeons select port locations using external anatomical landmarks as an estimate of patient's internal anatomy. The port location directly influences the access to surgical sites and maneuvering of the instruments. This clinical method is often inaccurate and external landmarks may not correspond to patient's internal anatomy. It is desirable to have digital thoracic model, which can be used for training and planning of MICTS.

Procedure Details: Data available with contrast enhanced high resolution CT is first segmented according to the tissues of interest into chest wall (bone and soft tissue) and mediastinum (blood vessels, heart and soft tissue). This process is done rapidly and semi-automatically using segmentation algorithm developed by us (patent pending). A 3D rotatable, deformable thoracic model is constructed that represents each segmented entity and is labeled in an atlas format. The system interface is well rendered and is easy to use. The port placement is then simulated considering the target internal anatomy.

Conclusion: A high-resolution digital thoracic model in atlas format can be readily obtained with segmentation algorithm and can be developed to form the basis for a virtual reality based simulation system for training and planning of MICTS.

C-0376

Network vulnerability management: Protecting a better view of life
D. Han, L. Van Nostrand; Plano, TX/US

Learning Objectives: To illustrate a network vulnerability management process suitable for medical system manufacturers to resolve malicious software (malware) and vulnerability issues.

Background: Malicious software (malware), in the forms of virus or worm, attacks vulnerabilities in operating systems and their bundled utility programs, and it can cause interruptions to smooth medical system operations. Medical system manufacturers are facing increasing challenges in trying to satisfy customer demands for the establishment of self-contained programs that will protect hospital enterprises from these threats, and, meanwhile, complying with the regulatory guidelines to validate medical software product. It has become imperative for every manufacturer to define an internal process to identify, evaluate, remediate system vulnerabilities, and prevent new threats before they materialize. In this exhibit, we will describe a network vulnerability management process that will help medical system manufacturers reduce the risk of new threats and improve customer satisfaction.

Procedure Details: This network vulnerability management process consists of three sub-processes: *Identification*, *Action*, and *Prevention*. These sub-processes work together to provide maximum protection against threats and vulnerabilities, and they construct a proper solution to secure medical systems.

Conclusion: This network vulnerability management process has been practiced within Kodak Health Imaging. It has proven effective in dealing with threats and vulnerabilities that affect Kodak Health Imaging products. A system like this is recommended to promote rapid-response and preventive activities to ensure the highest standard of quality and safety and to achieve customer satisfaction by testing and deploying appropriate patches in a timely manner.

C-0377

Towards an automatic segmentation of liver tumours in contrast enhanced ultrasound images

A.A. Kissi¹, L. Pourcelot¹, S. Cormier², F. Tranquart¹; ¹Tours/FR, ²Reims/FR

Doppler has been used for many years for cardiovascular exploration in order to visualize the walls and anatomical or functional diseases. The use of ultrasound contrast agents makes it possible to improve ultrasonic information. Nonlinear imaging is an application of this adaptation. It is a powerful technique which images perfusion of an organ. The visualization of flow and perfusion provides im-

portant information for the diagnosis of various diseases and for the detection of tumors. However, the images are buried in noise, the speckle, inherent in the image formation. Furthermore at portal phase, there is often an absence of clear contrast between the lesions and the surrounding tissues because the organ is filled with contrast agents. In this context, we propose a new method of automatic liver lesions segmentation in non linear imaging sequences for the quantification of perfusion. Our method of segmentation is divided into two stages. Initially, we developed an anisotropic diffusion step which raises the structural characteristics in order to eliminate the speckle. Then, a fuzzy competitive clustering process allows us to delineate liver lesions. This method has been used to detect focal hepatic lesions (focal nodular hyperplasia, adenoma). Compared to medical expert's report obtained on 15 varied lesions, the automatic segmentation allows to identify and to delineate the hepatic lesions during the portal phase. Our results show that the inclusion of this method makes it possible to improve the recognition of focal hepatic lesions.

C-0378

Teleradiology volume analysis of CT and MR imaging
D.J. Gardeur, C. Leprince, H. Baekeland; Paris/FR

Purpose: Volume analysis and MIP-CTA or MRA are now routinely performed with MDCT and 3D MR imaging. Teletransmission of hundreds of full DICOM images per exam is very long. As wavelet-JPEG 2000 is commonly used for teleradiology diagnosis, we have studied the feasibility and quality of post processing from the wavelet compressed volume images.

Method and Material: 200 exams-120 CT and 80 MR imaging-were loaded on a web based PACS server (DIAM GIOL) including both DICOM and wavelet images. Wavelet basic compression ratio was 15:1, optional 10:1 and 5:1. The software included an e-viewer with some volume analysis: MPR, MPVR (slab) with MIP, minIP and average slab processing; and volumeMIP. A comparison was performed between full dicom and wavelet-based volume analysis.

Results: In 89% of cases, the diagnostic quality was similar between dicom and wavelet-based post processing images, even for high resolution CT of lung and bones. Lesser diagnostic quality, with some blurring and bone related artifact was observed in posterior fossa CT, circle of Willis CTA, some supratentorial brain CT and FLAIR MR imaging. CTA of the circle of Willis is of good quality at a compression ratio of 10:1. For posterior fossa volume CT and FLAIR MR imaging a compression ratio of 5:1 must be used.

Conclusion: Using new generation web based PACS with wavelet compression and e-viewer, it is feasible to perform teleradiology volume analysis (MPR, MPVR, MIP) from MDCT, 3D MR imaging, CTA and MRA. A wavelet compression ratio up to 15:1 can be used without diagnostic loss of information in the majority of cases. For posterior fossa MDCT, CTA of the circle of Willis and some MR sequences, we recommend a compression ratio of 5:1.

C-0379

Image analysis of CT data of the paranasal sinuses for computer-assisted operational planning
D. Apelt¹, B. Preim², G. Strauss³, I. Hertel³; ¹Bremen/DE, ²Magdeburg/DE, ³Leipzig/DE

Purpose: Planning for endoscopic interventions of the paranasal sinuses (PNS) is supported by a patient-individual processing of the CT-data with image analysis and visualization methods. A segmentation procedure for separating the interesting anatomical and pathological structures was developed.

Methods and Materials: 7 CT datasets with different anatomical and pathological conditions were segmented (resolution between $0.275 \times 0.275 \times 1.000$ and $0.447 \times 0.447 \times 1.000 \text{ mm}^3$). For separating objects, barriers in the form of outlines are drawn by the user roughly around the object on selected slices. Outlines on layers in-between are generated by interpolation. Bone-segmentation is accomplished with the Interactive Watershed Transformation (IWT). For the segmentation of the soft parts an interval-based IWT is used. The segmentation-process is realized in the application RhinoVision (MeVis, Bremen). The visualization of the segmented objects is done with the InterventionPlanner (MeVis, Bremen).

Results: Segmenting the paranasal sinuses, optic nerves and soft parts was performed in less than one hour. In all cases the structures relevant for planning could be identified and delineated. In the examination of the different data sets a strong dependence of the work expended - particularly with the generation of the outline barriers - of the available CT data regarding the anatomical and pathological conditions of the patient showed up.

Conclusion: The procedure does not make assumptions about the shape of the objects and is therefore suitable for the coverage of all anatomical and pathological variations. A clinical evaluation of the prototype is accomplished currently.

Scientific and Educational Exhibits

C-0380

Psychophysical analysis of the DICOM grayscale standard display function

M. Yamaguchi¹, H. Fujita¹, T. Hirano², Y. Okura³, M. Matsumoto⁴, T. Johkoh⁴, Y. Asai⁵; ¹Habikino Osaka/JP, ²Sapporo Hokkaido/JP, ³Kurashiki-shi, Okayama/JP, ⁴Suita Osaka/JP, ⁵Sayama Osaka/JP

Purpose: Consistency in displaying the image over a wide variety of devices with different characteristics is essential for the DICOM Grayscale Standard Display Function (GSDF). The purpose of the present study was to evaluate the consistency of image display of GSDF with psychophysical analysis.

Methods and Materials: A monochromatic 3M Liquid Crystal Display (LCD) flat panel monitor with 8 bit visible gray shades (FC-2091, Eizo Corp., Ishikawa, Japan), which could be displayed with GSDF, CIELAB and gamma 2.2 functions, was used. The calibrated max luminance of this monitor was 480 cd/m². A photo sensor (Sequel Imaging Corp, USA) and calibration software (DR Kal) were used for monitor calibration. The procedure for this analysis was described as following four steps; (1) Calculation of physical gradient value (G) of each display function from characteristic curves after display calibration. (2) Calculation of psychophysical gradient (δ) from G. The psychophysical gradients obtained by $\delta = G/\Delta L_{min}$, where ΔL_{min} is the minimum perceptible luminance contrast as defined by the Barten model, and (3) Statistical analysis of δ regarding these display functions.

Result: δ value of GSDF was significantly greater than those of CIELAB and Exponential 2.2 ($P < 0.001$, by Wilcoxon Matched-Pairs Ranks test) in the range of digital driving level from 53 to 255 and almost constant (i.e., the mean of $\delta = 0.51$).

Conclusion: Although the psychophysical gradients of above three representative display functions were significantly different, from the viewpoint of image consistency, GSDF is considered to be superior.

C-0381

Real-time and interactive remote radiology/radiotherapy conference system using remote desktop software

Y. Baba, Y. Yamashita, S. Morishita, R. Murakami, E. Tomitaka; Kumamoto/JP

Purpose: To describe the implementation and use of a real-time radiotherapy conference system between university hospital and a regional hospital.

Materials and Methods: Remote desktop software was used to share the computer screen (desktop) and to operate the radiotherapy planning system in the regional hospital. Two hospitals were connected by the ADSL (12 Mbps) network. To secure the data, virtual private network (VPN) protocol was used. In the regional hospital, ECLIPSE (Varian Medical system) radiotherapy planning system and remote desktop server software was installed. In the university hospital, remote desktop viewer was installed in an Windows based PC; radiotherapy planning system was not installed. To reveal the usefulness of this system, the time to open a radiotherapy plan, and time to modify the plan was measured using 11 cases.

Results: Sharing the same computer screen between regional hospital and university hospital enabled real-time and interactive remote radiotherapy conference. Eight to 16 seconds was needed to send the computer screen data. The time to open a radiotherapy plan, 6.4 ± 2.5 minutes was needed. To modify the radiation plan, additional 3.8 ± 1.6 minutes /field was needed.

Conclusions: Remote radiotherapy conference system using the remote desktop software was a real time, easy to use, low-cost, and useful system. Using the relatively slow network system (ADSL 12 Mbps; up-word speed 512 kbps), the discussion was concluded within 20 minutes for a patient in most cases. We recommend the optical fiber network to reduce time lag.

C-0382

Computerized method for analysis of magnetic resonance (MR) cardiac perfusion images. Preliminary report

L. Kownacki, M. Orzech, D. Piotrowska, A. Cieszanowski, M. Golebiowski; Warsaw/PL

Introduction: Magnetic resonance (MR) plays a significant role in modern cardiac diagnosis. This method allows morphological and functional imaging as well as perfusion assessment of the heart. MR perfusion images are usually assessed qualitatively and thus the results can be operator-dependent.

Aim: To develop a semi-quantitative method for automatic assessment of MR myocardial perfusion images.

Material and Method: The method was developed for analysis of myocardial perfusion images obtained with Philips Gyroscan ACS 1.5 T system. ECG-gated TFE sequence was used for imaging (TR = 4.2[ms], TE = 2.1[ms], FlipAngle

= 15[deg], TI = 400[ms]). 3 crossections (short axis view) were imaged simultaneously during first-pass of injected contrast medium (Gd-DTPA). 10 series of T1 images were created and qualitatively assessed. Semiquantitative analyses were performed using custom written computer software working in MathLab environment. SVD algorithm was used for calculations. Mean signal intensity curve from left ventricular lumen was used as arterial input function (AIF). Color-coded maps and graphs were created for each image series.

Results: Ten maps were created representing crossections with normal and abnormal perfusion. All the results on maps matched the qualitative assessments performed by two operators.

Conclusion: The custom written computer software is useful for MR cardiac perfusion assessment, however its evaluation with more series of images must be performed.

C-0383

Precession measurement of angular and linear segmental lumbar motion by means of image registration

R. Irwan, L. Penning, M. Oudkerk; Groningen/NL

Purpose: Measurement of segmental lumbar motion by manual superimposition (MS) of flexion and extension radiographs is inaccurate due to differences in cortical outline of the corresponding vertebral bodies. A computerised superimposition ('matching') of digital vertebral body images by means of image registration (IR) is presented. By choosing the whole vertebral body image, and not only its cortical outline, as region of interest, more accurate matching and hence more precise measurement can be expected.

Methods and Materials: Five digital lumbar flexion-extension sets of five consecutive orthopaedic patients suspected of lumbar instability due to old L₁ fracture, spondylolytic spondylolisthesis and degenerative anterolisthesis, were used. Two computer experts A and B performed five IR measurements of each of the five lumbar motion segments in each of the sets. Both angular and linear motion were measured. For comparison a radiologist, experienced in the MS method, performed the same repeated measurements with the MS method. Measurement time for each single investigation was registered.

Results: Pooled SD with 95% CI for the IR method was 0.44 (0.39-0.51) degree, and 1.54 (1.35-1.78) degree for the MS method. Measurement time for the IR method (of angular and linear motion) was 2-3 minutes and for the MS method (of angular motion only) 3-6 minutes.

Conclusion: Measurement error of the IR method proved to be significantly smaller ($p < 0.005$) than that of the MS method. Additionally, the IR method is less time-consuming. We hope the new method will renew interest in diagnosis of abnormal segmental mobility and vertebral instability.

C-0384

A computer based examination for the assessment of reasoning skills in radiology

O. Dicle, M. Yazicioglu, M. Sevil; Izmir/TR

Purpose: Clinical reasoning is one of the most important practices of the radiologist. These kinds of professional skills should be assessed with the help of convenient assessment methods. Conventional assessment methods, like oral examinations have several limitations to make a valid, reliable and objective evaluation of these kinds of professional skills of the radiologists. In recent years clinically oriented reasoning examinations (CORE) have been developed to overcome the problems of conventional oral examinations. In our study we will explain the CORE and its use in radiology. We will also present a computer program that we have developed to perform such examinations by CORE type questions.

Method and Materials: A program was written to stimulate a CORE on a personal computer. Microsoft Office Excel was utilized as a base and several macros were prepared to run the program. Some text and JPEG type of files were used in the program. All the steps, including the timing and the evaluation was made automatically with the help of the program.

Results: The program was used in a simulation examination in four different stations. In all stations candidates those who had no previous knowledge about the program successfully ran the program and it worked without any problems. All the feedbacks from candidates were positive.

Conclusion: With the help of a simple program, interpretation, differential diagnosing and clinical reasoning skills of the radiologists can be successfully assessed. This program can also be used for self assessment processes.

Scientific and Educational Exhibits

C-0385

Transition to digital technology as method for enhancement of efficiency of screening radiographic systems using

N. Hnid¹, B. Tsvigun¹, Y. Kovalenko²; ¹Kamenec-Podolskiy/UA, ²Kiev/UA

Purpose: The purpose of this work was the comparative assessment of film and filmless technology using in preventive chest radiography of people that is the basic method for early revealing of pulmonary tuberculosis in adult population in the Ukraine.

Materials and Methods: The comparative analysis of the data received during preventive examinations of people in fluorography room at the municipal polyclinic in 2002-2003 was made. By the end of 2002, the fluorography room was put to numeral technology by means of additional equipping of 12F7 photofluorograph (Aktyubrentgen, Kazakhstan) with numeral receiver "Alpha" (Teleoptic, Ukraine) having resolving ability 2.5 line pair per millimeter.

Results: After transition to numeral technology, the number of examinations using of photofluorograph increased by 31.42%. On the one hand, it is achieved due to increased productivity of a room because the diagnostic image is available for analysis to radiologist in 15 seconds after exposure. As far as the self-descriptiveness of the digital image is comparable to survey on chest film radiography, and radiation-absorbed dose to the patient in digital radiography is less, the number of diagnostic X-ray inspections made together with phthisiotherapists, oncologists and other specialists rose 20 times. Thanks to that, in 2003 more than USD 9 thousand were saved on expendables only, and this is more than 17% of costs spent for transition to digital technology.

Conclusions: Transition to digital technology allows to lower the cost price of preventive X-ray examinations keeping the same quality of diagnostic images.

Contrast Media

C-0386

Intraindividual comparison of 1.0 M gadobutrol and 0.5 M gadopentetate dimeglumine for time-resolved contrast-enhanced 3D magnetic resonance angiography of the upper torso

C. Fink, M. Puderbach, S. Ley, F. Risse, T.A. Kuder, M. Bock, J. Thaler, C. Plathow, H.-U. Kauczor; Heidelberg/DE

Purpose: To compare the signal characteristics and bolus dynamics of 1.0 M gadobutrol and 0.5 M Gd-DTPA for time-resolved contrast-enhanced 3D MRA of the upper torso.

Methods and Materials: Ten healthy volunteers were examined with time-resolved contrast-enhanced 3D MRA (scan time per 3D data set: 0.86 sec; voxel size: 3.6x2x6.3 mm). Each volunteer underwent 8 individual exams after intravenous injection of 0.05 and 0.1 mmol/kg body weight (b.w.) of 1.0 M gadobutrol and 0.5 M Gd-DTPA using two injection rates (2.5 and 5 ml/sec). The data analysis included quantitative measurements of the peak signal-to-noise ratio (SNR) and bolus dispersion (full-width at half maximum) in the pulmonary artery, left atrium, thoracic and abdominal aorta.

Results: No significant differences of the peak SNR and bolus dispersion were observed between gadobutrol and Gd-DTPA for all dose levels and injection rates in any of the vascular segments. For both contrast agents a dose of 0.1 mmol/kg b.w. injected with 5 ml/sec achieved the highest SNR in all vascular segments.

Conclusion: Higher concentrated gadolinium chelates seem to offer no relevant advantages for time-resolved contrast-enhanced 3D MRA protocols of the upper torso.

C-0387

Incidence of contrast media induced nephropathy in different diagnostic procedures

M. Heinrich¹, A. Grgic¹, M. Heckmann¹, B. Kramann¹, M. Uder²;

¹Homburg a.d. Saar/DE, ²Erlangen/DE

Purpose: To compare the incidence of contrast media induced nephropathy (CIN) in different diagnostic procedures.

Methods and Materials: 17694 consecutive patients who underwent examination with X-ray contrast media (RCM) from 01/2003 to 05/2004 were retrospectively identified in the radiology information system. 6779 patients were excluded because of a lack of creatinine values (3002), repeated RCM-examinations within 4 weeks (3472) and a creatinine value ≥ 5 mg/dl before RCM-application (305). The examinations of the remaining 10915 patients consisted of 4854 cardiac catheterizations, 4742 contrast-enhanced CT scans, 753 intravenous pyelographies (IVP), 494 angiographies and 62 phlebographies. We used two definitions for CIN. Definition#1: Increase in serum creatinine ≥ 0.5 mg/dl or $\geq 25\%$ over baseline value to at least 1.0 mg/dl within 10 days after receiving RCM. Definition#2: Increase in serum creatinine ≥ 0.5 mg/dl or $\geq 25\%$ over baseline value to at least 2.0 mg/dl.

Results: According to definition#1, 1485 patients developed CIN including 19.8% of the patients who underwent cardiac catheterization, 16.4% of the patients who underwent angiography, 8.4% of the patients who underwent CT, 6.5% of the patients who underwent phlebography and 5.3% of the patients who underwent IVP. 421 patients were detected with CIN according to definition#2 including 6% of the patients who underwent cardiac catheterization, 6.1% of the patients who underwent angiography, 1.9% of the patients who underwent CT and 0.8% of the patients who underwent IVP.

Conclusion: Not only the definition of CIN but also the type of RCM-examination seems to influence the incidence of CIN.

C-0388

Microvascular imaging with contrast-enhanced ultrasound

M. Krix, H.-U. Kauczor, S. Delorme; Heidelberg/DE

Learning Objectives: To learn about the possibilities of contrast-enhanced ultrasound techniques for the visualization and quantification of tissue perfusion. Techniques and methods for microvascular imaging using contrast-enhanced ultrasound are presented and possible clinical indications are discussed.

Background: Functional imaging has gained critical importance in recent years. Perfusion, i.e. the blood flow per tissue unit including capillary flow, is an important functional parameter. Pathological changes of tissue perfusion can be found in various clinical diseases like in infarction, inflammation or neoplasia. Novel ultrasound contrast agents and low mechanical index ultrasound techniques al-

Scientific and Educational Exhibits

low for a sensitive detection of microvascularity in real-time. Furthermore, quantification of perfusion is achieved by analysing replenishment kinetics of the contrast agent.

Procedure Details: Technical requirements and examination protocols to use contrast-enhanced ultrasound in the detection of microvascularity are described. Procedures for quantification of perfusion are explained, in particular analysis of replenishment kinetics of ultrasound contrast agents. Fields of possible clinical applications for perfusion imaging with contrast-enhanced ultrasound are discussed.

Conclusion: Contrast-enhanced ultrasound allows sensitive detection and quantification of perfusion, and is a promising functional imaging method for various clinical applications.

C-0389

Gd-IDA derivatives as potential hepatobiliary contrast media for MR

imaging: Experimental studies on rats

M. Studniarek¹, E. Mikiciuk-Olasik², M. Retkowski¹, T. Wierzba¹, M. Sidorowicz¹, ¹Gdansk/PL, ²Lodz/PL

Purpose: Assessment of biodistribution of Gd-IDA (iminodiacetic acid) compound as a potential hepatobiliary MR imaging contrast agents. These substances are known to be specifically taken up by hepatocytes and excreted into bile.

Methods and Materials: Four rats were examined after i.v. injection of 10 mg Gd-IDA derivative (structural formula $C_{38}H_{66}GdN_4NaO_{10}$ and molecular weight 729.868). Continuous acquisition of T1 FSE and MTC sequences (in 2 min loops) before and immediately after c.m. administration was performed during 60 minutes in 2 min loops on 1.5 T MR imaging scanner. Percent of injected Gd dose accumulated in rat liver and enhancement were calculated and time/intensity curves were drafted for liver, kidney, heart, muscle and fat tissue.

Results: Enhancement in the liver reached the peak (100-150%) in 19-33 min p.i. which was followed by plateau with slight signal intensity decrease. The liver accumulation amounted to 60% of administrated Gd-dose. Time/intensity curve in the kidney was similar to typical renogram with the maximal enhancement of 19-39% in 4-6 min. That one for the heart presented exponential decrease of signal intensity when the curves for the muscle and fat tissue were flat.

Conclusions: Gd-IDA derivatives are the promising group of hepatotropic contrast media for MR imaging.

C-0390

Placental perfusion assessment with MR imaging using contrast agents in a mouse model

L.J. Salomon¹, N. Siauve¹, D. Balvay¹, C.A. Cuénot¹, C. Vayssettes¹, A. Luciani¹, G. Fréja¹, Y. Ville², O. Clément¹; ¹Paris/FR, ²Poissy/FR

Learning Objectives: To quantitatively analyze placental perfusion by using MR imaging with contrast agents in a mouse model.

Background: Thirty six Balb/c pregnant mice at 16 days of gestation were injected IV with either a conventional gadolinium chelate or a macromolecular gadolinium chelate and 1.5 Tesla single-slice T1-weighted 2D Fast SPGR sequential MR imaging was then performed for 14 minutes. Images were analyzed qualitatively and parametric map analysis were performed on the 25 mice finally included in the study. Signal intensity was measured in the maternal left ventricle (input function), the placenta and the fetus. After converting signal intensity into contrast agent tissue concentrations, a three-compartment model was developed. Placental perfusion was calculated for conventional ($n = 12$) and macromolecular gadolinium chelates ($n = 13$). Finally, placental and fetal gadolinium concentrations were assayed by means of atomic emission spectrophotometry ($n = 15$).

Imaging Findings: Based on a constant transfer parameter, estimated placental perfusion did not differ between procedures with conventional and macromolecular gadolinium chelates (0.99 ± 0.5 ml/min/g and 1.28 ± 0.6 ml/min/g, respectively, $p = 0.22$). Likewise, mean placental gadolinium concentrations did not differ after conventional and macromolecular chelates injection. In contrast, the mean fetal gadolinium concentration was $9.83 \pm 0.4 \mu\text{M}$ after conventional chelate injection and below the detection limit after macromolecular chelate injection.

Conclusion: Placental perfusion can be calculated by using dynamic contrast-enhanced MR imaging. If this approach is feasible and safe in humans, it may have potential for investigating the origin and course of intra-uterine growth restriction and for the management of compromised pregnancies.

C-0391

A new MR findings: Decrease of signal intensity of myometrium after iv USPIO administration

P. Paolantonio, A. Laghi, C. Miglio, M. Rengo, V. Vergari, S. Ciccarelli, A. Guerrisi, R. Passariello; *Rome/IT*

Purpose: To evaluate the diagnostic advantages of intravenous USPIO administration on T-staging of uterine carcinoma.

Methods and Materials: Seventeen female patients referred for gynecological carcinomas, 11 with corpus uterine cancer and six with cervical carcinoma, underwent MR scan of the pelvis on a 1.5 T magnet. GRE T2*W sequences (TR/TE/FA/matrix/acq. time: 1800 msec/15 msec/30°/230x512/13.51 min) were acquired on multiple planes before and 24 hours after iv administration of 2.6 mg/kg of body weight of Sinerem (Guerbet, Paris, France). Image analysis were performed by consensus by two radiologists and it included qualitative and quantitative analysis of signal intensity (SI) of both normal myometrium and neoplastic lesions before and after Sinerem administration. S/N and C/N were calculated. Modification of T-staging in images obtained after Sinerem administration was also evaluated. Statistical analysis was performed using Wilcoxon test ($p < 0.05$).

Results: Qualitative analysis showed a significant decrease of SI of normal myometrium after Sinerem administration leading to a better lesion conspicuity. Quantitative analysis showed a statistically significant difference between SI of myometrium on plain and Sinerem-enhanced MR images assessed by means of t-test. C/N between lesion and normal myometrium significantly increased following Sinerem administration. In 13 patients Sinerem-enhanced images provided additional information leading to more accurate T staging.

Conclusions: Intravenous injection of Sinerem provides a significant decrease of SI of normal myometrium with higher C/N between neoplastic lesion and normal myometrium increasing the conspicuity of neoplastic lesions.

C-0392

Small well-differentiated hepatocellular carcinoma and atypical adenomatous hyperplasia (≤ 2 cm) evaluated with contrast-enhanced dynamic CT and ferucarbotran-enhanced MR imaging

T. Touan¹, K. Fujimoto², S. Azuma¹, M. Uchida², N. Hayabuchi², N. Ono¹, S. Matsushita¹; ¹Chikugo city/JP, ²Kurume city/JP

Purpose: To compare between contrast-enhanced dynamic CT and ferucarbotran-enhanced MR imaging in the detection of small (≤ 2 cm) well-differentiated hepatocellular carcinomas (HCCs) and atypical adenomatous hyperplasias (AAHs) and to evaluate the signal intensity change of small HCCs and AAHs.

Methods and Materials: We identified 15 patients with pathologically confirmed 18 well-differentiated HCCs and 4 AAHs (median, 11 mm; range, 5-20 mm in the largest diameter) who underwent both dynamic CT and ferucarbotran-enhanced MR imaging. Conventional sequences of T2*-weighted gradient-echo (cT2*-GRE = TR280 ms/TE14 ms, FA: 60°) and specific sequences of T2-weighted gradient-echo (sT2-GRE = TR140 ms/TE8 ms, FA: 30°) images were obtained before and after administration of ferucarbotran. To assess the effect of ferucarbotran, the tumor-liver signal contrast-to-noise ratio (tumor-liver-CNR) was calculated.

Results: There was excellent interobserver agreement for the presence of nodules on each modality (kappa statistic, 0.9-1.0). The detection rates of nodules were 50% (11/22) on dynamic CT, 59% (13/22) on cT2*-GRE sequences with ferucarbotran and 68% (15/22) on sT2-GRE sequences with ferucarbotran. None of 4 AAHs were detected on dynamic CT; in contrast, 2 of 4 AAHs were detected on sT2-GRE sequences with ferucarbotran. There was no significant difference in the tumor-liver-CNR between HCCs and AAHs and 9 of 15 detected nodules revealed signal hypointensity compared to hepatic parenchyma on sT2-GRE sequences with ferucarbotran.

Conclusion: Small well-differentiated HCCs showed ferucarbotran uptake (presence of Kupffer cell phagocytic activity) as well as AAHs. In the detection of small well-differentiated HCCs and AAHs, sT2-GRE sequence with ferucarbotran is superior to dynamic CT and T2*-GRE sequence with ferucarbotran.

C-0393

Atherosclerotic plaque imaging of ApoE-deficient mice with gadofluorine M

M. Shimada¹, K. Yoshikawa¹, H.J. Weinmann², T. Tatebe¹, T. Morita¹, T. Ookubo¹, A. Senoo¹, Y. Inoue¹, S. Hayashi¹; ¹Tokyo/JP, ²Berlin/DE

Purpose: The study of atherosclerotic plaque using Watanabe rabbit was common. In our research, possibility as agents of new atherosclerotic plaque MR imaging of Gadofluorine M in apoE-deficient mice was examined.

Methods and Materials: Total 16 mice (BW:25 gr) were used. Items were apoE-deficient mice of high-cholesterol diet ($n = 8$) and apoE-deficient mice of normal

Scientific and Educational Exhibits

(n = 8). Femoral vein was exposed and catheter was inserted. Each 0.01 ml intravenous injection of Gadofluorine M (250 µmol/ml) was made. T1 WSE (TR:500 ms TE:15 ms) axial thin (2 mm slice) images and fat saturate T1 WSE (TR:500 ms TE:15 ms) were performed before and at 24 hrs after contrast media. Delineation of aortic wall atherosclerotic plaque was examined.

Results: In all apoE-deficient mice of high-cholesterol diet (8/8), enhanced atherosclerotic plaque which spread to whole tunica intima of aortic arch and to a dorsal part of tunica intima of thoracic descending aorta was clearly detected in T1 weighted SE sequence and fat saturate T1 weighted SE. Fat saturate T1 weighted SE sequence was more excellent in the delineation of the arteriosclerosis than T1 weighted SE. However, there were no plaques in abdominal aorta (8/8). In all apoE-deficient mice of normal diet, we can not detect contrast enhanced atherosclerotic plaque in aortic arch, thoracic aorta and abdominal aorta (8/8).

Conclusion: Using Gadofluorine M, we were able to perform good atherosclerotic plaque imaging in apoE-deficient mice of a high-cholesterol diet using fat saturate T1 weighted SE images. ApoE-deficient mice of high-cholesterol diet was a good new model of atherosclerotic plaque in MR imaging.

C-0394

Analysis of an automatic ultrasound image registration system to improve contrast quantification for hepatic perfusion assessment

E.A. Gardner¹, T.S. Sumanawera¹, M.N. Woelmer², R.W. Steins¹, E. Leen³;

¹Mountain View, CA/US, ²Ann Arbor, MI/US, ³Glasgow/UK

Purpose: To assess an ultrasound image registration method that uses nonaffine transforms in order to eliminate movement in the image.

Methods and Materials: Using a destruction/reperfusion technique, contrast-enhanced image sequences of the liver acquired from 14 patients with focal hepatic tumours using contrast pulse sequences (CPS) on a Siemens Sequoia(R) ultrasound system, were analyzed using an online quantification package (Autotracking Contrast Quantification). The quantification parameters, i.e. baseline intensity, enhancement amplitude and the wash-in constant (Bl, A, and β respectively) resulting from using the warping registration method on this system, were compared with those acquired without any motion compensation. The correlation coefficient of this parameterization was recorded as the goodness-of-fit (GOF). Manual image alignment was used as a standard of reference.

Results: There was significant difference in the β between no-alignment and automatic alignment as well as manual alignment (0.5 significance level). The GOF produced using automatic alignment was significantly better (0.5 significance level) than when no alignment was used but was significantly worse than when manual alignment was used. The GOF was never reduced by using automatic alignment and the percentage of cases with a GOF > 0.9 improved from 36% to 64% when using automatic alignment. 71% of manually aligned cases had GOF > 0.9.

Conclusions: The automatic alignment method tested provided consistent and significant improvement in contrast quantification for perfusion assessment. Whilst the performance of manual alignment was not matched, automatic alignment is quick and more practical clinically.

C-0395

Quantitative, contrast-enhanced ultrasound to detect pathologic skeletal muscle perfusion in patients with inflammatory myopathies: Initial results

M. Krix, M.-A. Weber, H.B. Huttner, U. Jappe, U. Meyding-Lamadé, M. Hartmann, M. Essig, H.-U. Kauczor, S. Delorme; Heidelberg/DE

Purpose: To evaluate whether contrast-enhanced ultrasound (CEUS) is able to determine pathologic muscle perfusion in patients with myositis and thereby non-invasively confirm the suspected diagnosis.

Methods and Materials: Skeletal muscle perfusion was quantified using contrast-enhanced (10 ml Levovist® i.v.), intermittent power-Doppler ultrasound applying a modified model analyzing replenishment kinetics of microbubbles. For validation, CEUS perfusion parameters of the right forearm flexor muscles at rest and after defined exercise were compared with venous-occlusion plethysmography (VOP) in 10 healthy volunteers. In 21 patients with suspected myositis, CEUS of the right biceps muscle was performed, and findings were compared with muscle biopsy, and MR imaging at 1.5 T using fat-suppressed T2w, STIR, and contrast-enhanced fat-suppressed T1w sequences.

Results: CEUS allowed for perfusion quantification in different skeletal muscle groups and was able to depict the physiological large variability of muscle perfusion at rest ($3.0 \pm 2.3[\sim\text{ml}/\text{sx}100 \text{ ml}]$) compared to the results after exercise ($22.9 \pm 11.0[\sim\text{ml}/\text{sx}100 \text{ ml}]$). VOP perfusion significantly correlated with the CEUS parameters perfusion ($r = 0.81$, $p < 0.001$) and blood volume ($r = 0.82$, $p < 0.001$). In 8 patients, myositis was confirmed histologically, and CEUS showed signifi-

cantly higher perfusion, blood volume and blood flow velocity values (all $p < 0.01$) than in non-myositis patients. In contrast, contrast enhancement in MR imaging was found in only 57% of the affected muscles, whereas an increased signal intensity on T2w images was found in all myositis patients.

Conclusion: CEUS is a sensitive, cost-saving method in a clinical setting to quantify skeletal muscle perfusion. CEUS is able to non-invasively demonstrate increased perfusion of involved muscle groups in patients with myositis.

C-0396

Everything you always wanted to know about iodinated contrast media interactions with other drugs, but you were afraid to ask

A.N. Chalazonitis, J. Tzovara, S. Velitsista, S. Giannou; Athens/GR

Learning Objectives: 1) To help the participant to understand why and when other drugs may increase the potential risk of adverse reaction to the administered iodinated contrast media. 2) To evaluate the risk of anaphylaxis or nephrotoxicity following interactions between iodinated contrast media and other medications given during hospitalization. 3) To provide guidelines for recommend precautions to prevent possible adverse iodinated contrast media reactions.

Background: Patients undergoing radiographic studies often have coexisting diseases or taking other drugs that increase the potential risk of adverse reaction to the administered iodinated contrast media. Drug interactions occur at varying rates in these patients. Unfortunately, the causative agents cannot be identified in all cases. Most of these drug interactions are pharmacokinetic and can be classified as alterations in absorption or elimination, protein-binding effects and changes in drug metabolism.

Procedure Details: The aim of this exhibit is to illustrate a list of the drugs that can potentially lead to interactions with administrated iodinated contrast media, to describe this pharmacokinetic mechanism after their initiation and to provide guidelines for necessary precautions and recommend actions.

Conclusion: The goal of radiologists and other personnel administering intravascular iodinated contrast material should be to utilize these agents appropriately and properly, so that imaging studies are optimized and risk to the patient is minimized.

C-0397

Basic examination of photoirradiation for possible control of angiogenesis by HP-denatured type IV collagen complex dissolution

M. Machida, K. Kameyama, A. Shimizu, N. Machida, H. Tajima, T. Kumazaki, N. Moriyama, Z. Naito; Tokyo/JP

Purpose: Hematoporphyrin (HP) accumulates selectively in cancer tissue and is used for photodynamic diagnosis and therapy. We have been focusing on HP present in the extracellular matrix between swollen collagen type IV (type IV) and lipid, and have previously reported a similarity between arteriosclerotic lesions and a lipid-protein complex model. Denatured type IV was recently shown to be an angiogenetic factor. In this study we observed the photoreaction of denatured type IV-lipid complex by using HP. We also examined the validity of this approach for the treatment of vascular matrix lesions and the control of angiogenesis.

Methods and Materials: We made a mixture of HP, type IV, and liposomes containing cholesterol, and examined the agglutination state of the collagen-lipid complex as follows. We first irradiated the complex with pulses of 680nm light from a LED source for one hour, then measured the circular dichroism (CD) spectrum and scattered light spectrum. We further inspected the complex using high-sensitivity CCD and electron microscopy.

Results: The structure of type IV collagen was confirmed by CD spectrometry. The denatured collagen was combined with HP. An increase in the scattered light spectrum was observed after light irradiation. The fluorescence spectrum of HP changed from a combined arteriosclerotic pattern to a solitary HP pattern after light irradiation.

Conclusion: The state of the type IV collagen-HP complex changes after weak light irradiation. Irradiation of HP with weak light may be useful for the diagnosis and treatment of angiogenetic lesions as well as vascular matrix lesions.

C-0398

Cytogenetic effects of diagnostic X-rays and contrast media in human peripheral blood lymphocytes

L. Popova¹, V.B. Hadjidekova¹, A. Karadjov¹, B.S. Rao², V.G. Hadjidekov¹; ¹Sofia/BG, ²Mumbai/IN

Purpose: To investigate the induction of cytogenetic damage as chromosomal aberrations and micronuclei formation in peripheral blood lymphocytes of patients undergoing cerebral and renal arteriography.

Scientific and Educational Exhibits

Methods and Materials: Peripheral blood samples were taken from 21 patients undergoing DSA-arteriography (11 male and 10 female, aged between 13-65 years) before the procedure, immediately after and 24 hours later. The skin dose obtained during the whole procedure X-ray exposure was measured by thermoluminescent dosimeters and varied between 0.04-0.30 Gy. Both low and high osmolarity contrast media were used. Cytogenetic analysis of chromosomal aberrations and micronuclei were applied for detection of genotoxic effects of angiographic procedures involving X-rays and iodinated contrast media. Aberrations were scored in 200-400 cells for each patient.

Results: The estimated frequencies of chromosomal aberrations and micronuclei show a significant increase of chromosomal damage after angiographic examination in comparison to the level before the diagnostic exposure. For all 21 patients, the mean frequency of cells carrying chromosomal aberrations after arteriography nearly double the value before X-ray and contrast media exposure, i.e. 1.48-2.54% and remained constant at 24 h analysis. There is no correlation between the increase in cytogenetic damage and entrance dose of X-rays nor the concentration of contrast medium.

Conclusion: Diagnostic procedures involving X-rays and iodinated contrast media as angiography cause a significant increase in cytogenetic damage in peripheral human lymphocytes. These results suggest the need of limitation of contrast media overdosing without compromising the image quality and further studying of their radiosensitivity property.

C-0399

The value of contrast enhanced US imaging in the reduction of TRUS-guided biopsies and minimization of complications: Impact on prostate cancer detection

D. Alexopoulos, A. Filippidou, I. Theotokas, A. Plagou, S. Faitaki, D. Leli, A. Stefanaki, P.S. Zoumpoulis; Athens/GR

Learning Objectives: To survey the physics and technology of US contrast agents and their role in the localization of prostate cancer. To demonstrate the procedure of contrast enhanced targeted biopsy of prostatic lesions. To compare USCA targeted biopsy with conventional TRUS guided biopsy in terms of cancer detection rates and incidence of complications.

Background: Prostatic cancer lesions are not always easily detected by TRUS. Contrast enhancement of these lesions aids in their detection and accurate sampling.

Procedure Details: The low sensitivity of B-mode and color Doppler TRUS in prostate cancer detection renders necessary the performance of systematic prostate biopsy with a frequently low yield. Contrast enhanced TRUS improves detectability of malignancy by revealing regions of increased vascularity, which may be targeted selectively to obtain biopsy specimens. In our study, contrast enhanced targeted biopsy was performed on 90 patients after IV administration of the US microbubble contrast agent SonoVue® (Bracco International). Comparison of cancer detection rates for USCA targeted biopsies and conventional systematic biopsies (control group) indicated improved yield with targeted biopsies. Furthermore, the frequency and severity of complications were reduced when the biopsy was performed under contrast enhancement direction. These initial results demonstrate the potential of contrast enhanced TRUS to decrease the number of biopsy cores and improve the sensitivity of prostate cancer diagnosis.

Conclusion: Despite certain restraints, USCA are most helpful in detecting prostate cancer lesions that are not easily visible on TRUS. This provides for a smaller number of samples and for precision sampling.

C-0400

Uncommon applications of contrast enhanced ultrasound

S.D. Yarmenitis, A. Bakantaki, C. Kourieraki, C. Fragos, T. Maris, N. Gourtsoyiannis; Iraklion/GR

Learning Objectives: To present clinical cases, beyond the established applications, in which contrast enhanced ultrasound (CEUS) proved to be helpful or decisive in the management of the patients.

Background: CEUS is an accepted technique that has entered the field of medical imaging with promising results. The vast majority of applications involve the focal lesions and trauma of the solid abdominal viscera, the study of renal transplants and the study of vesicoureteral reflux. However many other abnormalities may be diagnosed by CEUS. Between June 2003 and August 2004, 70 patients were examined with CEUS for conditions that are never or rarely investigated with this method. The techniques and the specific findings are illustrated.

Procedure Details: Our uncommon CEUS applications comprised cases of dissecting aneurysms of the abdominal aorta, uncertain diagnosis of abdominal and peripheral venous thrombosis, uncertain extent of arterial plaques or paten-

cy of arterial grafts, patency of TIPS, bowel inflammatory disease or bowel inflammatory masses, neoplastic bowel masses, ovarian or testicular torsion, neoplasms of the gallbladder, distal common bile duct and the papilla, neoplasms of the chest wall and studies of the urinary collecting system (UCS). Contrast was administered in standard dose intravenously in all applications except in these of the UCS where intervention route, already available, was used and the material was further diluted in saline.

Conclusions: CEUS is applicable in several uncommon conditions. It may solve the underlying problem, limit the use of more complicated procedures or successfully tailor-up further management of the patients.

C-0401

Effect of ultrasound contrast medium on human CD4⁺ lymphocytes in vitro culture

G. Caruso, G. Salvaggio, G. Fatta, N. Caccamo, C. La Mendola, F. Dieli; Palermo/IT

Purpose: Aim of this study was to investigate the effects of ultrasound contrast medium (SonoVue, Bracco, Italia), with and without ultrasound exposure, on normal release of Interferon-γ (IFN-γ) by human CD4⁺ T lymphocytes.

Methods and Materials: Cells were cultured in complete medium and split into 5 groups of samples as below: One exposed to ultrasound (2 minutes at 3.5 MHz) only, one to contrast medium (0.02 ml) only, one first to contrast medium and then to ultrasound, one first to ultrasound and then to contrast medium and the fifth as control. The supernatants were assayed for IFN-γ production by ELISA technique.

Results: CD4⁺ T cells exposed to ultrasound contrast medium with and without ultrasound exposure, after 48 h of in vitro culture, showed a decreased release of IFN-γ, with respect to cells exposed only to ultrasound and to control group.

Conclusion: Contrast medium ultrasound has a toxic effect on CD4⁺ T cell culture, independently to ultrasound exposure.

C-0402

Biliary strictures following orthotopic liver transplantation: Evaluation with mangafodipir trisodium-enhanced MR cholangiography

P. Boraschi, F. Donati, R. Gigoni, A. Volpi, L. Urbani, F. Falaschi; Pisa/IT

Purpose: To determine whether mangafodipir trisodium-enhanced MR cholangiography (MRC) could improve the diagnostic confidence provided by conventional T2w MRC in patients with suspected biliary strictures after liver transplantation.

Methods and Materials: Eleven liver transplant subjects with suspected biliary strictures underwent MR imaging and MRC at 1.5T device (Signa, GE Medical System) using a phased array coil. After the acquisition of axial T1w and T2w sequences, conventional MRC was performed through a respiratory-triggered, thin-slab (2 mm), heavily T2w fast spin-echo sequence and a breath-hold, thick-slab (10 and 40-50 mm), single-shot T2w sequence in the coronal plane. In each patient a further coronal T1w fat-suppressed breath-hold 3D gradient-echo imaging (FAME) was obtained 30-40 minutes after intravenous administration of mangafodipir trisodium (Mn-DPDP, Teslascan; GE Healthcare; 0.5-mL/Kg body weight). All source images and 3D reconstructions were reviewed in conference by two observers that were asked to determine presence and site of biliary tract strictures. Imaging results were correlated with surgery, direct cholangiography and/or follow-up.

Results: Patients were affected by non-anastomotic strictures (n = 8), anastomotic strictures (n = 3) and inflammatory ampullary stenosis (n = 1). Mangafodipir trisodium-enhanced MRC tended to outperform conventional MRC in delineating slight anastomotic stenoses and strictures involving the hepatic bifurcation and the biliary tree of the graft (ischemic-type biliary lesions).

Conclusion: Our preliminary results suggest that mangafodipir trisodium-enhanced MRC seems to improve the diagnostic performance of MRC in the evaluation of biliary strictures in liver transplant recipients.

C-0403

Comparison between concentration dependent relaxivity of gadopentetate dimeglumine (Magnevist®), gadobutrol (Gadovist®) and gadobenate dimeglumine (MultiHance®) in human blood plasma at 0.2 T, 1.5 T and 3.0 T

P. Martirosian¹, J. Pintaske¹, H. Graf¹, G. Erb², K.-P. Lodemann², C.D. Claussen¹, F. Schick¹; ¹Tübingen/DE, ²Konstanz/DE

Purpose: MR contrast media (CM) can interact with blood proteins leading to modified relaxivity. Effects of 3 different Gd-CM on T1 and T2 relaxation of blood were tested using in vitro human-plasma preparations at 37° C.

Methods: Samples containing Magnevist®, Gadovist® and MultiHance® were

Scientific and Educational Exhibits

prepared with concentrations in 14 logarithmic steps in a range between 0.01 mM and 64 mM. Measurements were performed at 0.2, 1.5, and 3.0 Tesla. T1 was measured by inversion recovery imaging with fast spin-echo readout (inversion time range: 23-8000 ms). Extremely short T1 of samples with high Gd-concentrations were assessed by measuring flip angle dependent signal intensities of a 3D gradient echo sequence with minimal echo time. T2 was assessed by multi-echo spin-echo sequences with equidistant TE between 8 and 256 ms, or 16 and 512 ms.

Results: Relaxivity data were nearly linearly dependent on CM concentrations for Magnevist® and Gadovist®. MultiHance® provided higher T1 and T2 relaxivity at all field strengths and for all concentrations than the other CM, but concentration dependence was not strictly linear. Smaller concentrations of MultiHance® led to most increased T1 and T2 relaxivity. For all three contrast media, T1 relaxivity decreased from 0.2 to 1.5 Tesla (21-29%) and from 1.5 to 3 Tesla (22-33%). T2 relaxivity decreased significantly from 0.2 to 1.5 Tesla for all three contrast media, whereas no further decrease from 1.5 to 3 Tesla was observed.

Conclusion: In human plasma MultiHance® was the most effective Gd-based CM for T1-imaging at field strengths from 0.2 to 3.0 Tesla.

C-0404

Hypervasculat focal liver lesions: A pictorial essay using SonoVue

C. Avigo, P. Cabassa, L. Romanini, L. Grazioli, M. Cristinelli; Brescia/IT

Learning Objectives: 1) to illustrate the range of focal liver lesions that enhance at CEUS. 2) to understand how to avoid the pitfalls. 3) to highlight the differences between CEUS and CT/MR.

Background: CEUS is very sensitive in the assessment of vascularization of focal liver lesions. This educational exhibit will show the wide range of lesions that enhance with the administration of SonoVue with a special focus on arterial phase. The spectrum of diseases include well known hypervasculat lesions at like HCCs, FNHs, hemangiomas and hypervasculat metastases as well as lesions that normally doesn't typically enhance at cross sectional imaging (CT/MR) like so called hypervasculat metastases and cholangiocarcinomas.

Procedure Details: CEUS was performed with second generation contrast media (SonoVue, Bracco) at the standard dose of 2.4 ml with continuous real time scanning at low mechanical index. Images and videos of each lesion pre and post contrast were recorded digitally.

Conclusions: Knowledge of the vascular patterns of enhancement could help in the differential diagnosis of focal liver lesions at CEUS.

Molecular Imaging

C-0405

Endothelial cell-targeted MR imaging using the anti-VEGFR2 and ICAM-1 antibody-conjugated Gd-DTPA

K.-H. Yoon, E.-A. Kim, J.-M. Hur, S.-H. Kim, Y.-H. Lee, K.-S. Choi; Iksan, Jeonbuk/KR

Objectives: We designed blood vessel endothelial cell-targeted MR contrast agents which were prepared with bioconjugation of gadolinium diethylenetriaminepentaacetic acid (Gd-DTPA) and anti-VEGFR2 or ICAM-1 antibody.

Methods and Materials: The anti-VEGFR2 and ICAM-1 antibodies were purified from the culture supernatant of rat hybridomas using the protein A/G-coupled affinity chromatography. The endothelial cell-specific contrast effect was assessed by the MR imaging of its differential contrast effects to human umbilical vein endothelial cells and non-endothelial cells (human fibrosarcoma cell line). The Gd-DTPA-antibody complexes (10 µg/ml) were added to the cell and placed at 4 °C for 4 hrs. MR image was obtained by the 1.5 T module with a microscopic coil. The endothelial cell-specific binding of the Gd-DTPA-antibody conjugates was also confirmed by immunofluorescence staining.

Results: The antibodies were conjugated with Gd-DTPA in an about 50% yield based on the protein content of the Gd-DTPA-antibody complex. The Gd-DTPA-anti-VEGFR2 antibody complex displayed endothelial cell-specific contrast effects in MR imaging. Immunofluorescence assay also showed that Gd-DTPA-anti-VEGFR2 antibody conjugates stained the endothelial cells but not fibrosarcoma cells. Gd-DTPA-anti-ICAM-1 antibody complex exhibited predominant binding to the endothelial cells which were stimulated with 2nM TNF-alpha, a potent inducer of ICAM-1 on endothelial cells.

Conclusion: We suggest that Gd-DTPA-anti-VEGFR2 antibody conjugates selectively detect the vessel endothelial cells and give endothelial cell-specific MR image. Moreover, Gd-DTPA-anti-ICAM-1 antibody complex appears to specifically bind the ICAM-1-expressing endothelial cells which is a typical characteristic of the inflammation, suggesting that Gd-DTPA-anti-ICAM-1 antibody is a useful MR contrast agent for the inflammatory tissue.

C-0406

In-vivo tracking of genetically engineered, anti HER2/neu directed natural killer cells to HER2/neu positive mammary tumors with magnetic resonance imaging

H.E. Daldrup-Link¹, R. Meier², M. Rudelius², G. Piontek², S. Metz², C. Uhreik³, W. Wels³, J. Schlegel², E.J. Rummeny²; ¹San Francisco, CA/US, ²Munich/DE, ³Frankfurt a. Main/DE

Purpose: To optimize labelling of human natural killer (NK) cells with iron oxide contrast agents and to monitor the in vivo distribution of genetically engineered NK cells, directed against HER2/neu receptors, to HER2/neu positive mammary tumors with magnetic resonance (MR) imaging.

Methods and Materials: Parental and genetically modified HER2/neu specific NK-92-scFv(FRP5)-zeta cells, expressing a chimeric antigen receptor specific to the tumor-associated HER2/neu antigen, were labelled with Ferumoxides and Ferucarbotran using simple incubation, lipofection, and electroporation. Labelling efficiencies were determined by spectrometry. Subsequently, Ferucarbotran-labelled NK-92-scFv(FRP5)-zeta or parental NK cells were intravenously injected into six mice with implanted HER2/neu positive mammary tumors. The tumor accumulation of the NK cells was monitored with MR before and 24 hours (h) after cell injection (p.i.). MR data were correlated with histopathology.

Results: Parental and genetically modified NK-92-scFv(FRP5)-zeta cells could be labelled with Ferucarbotran and Ferumoxides by lipofection and electroporation, but not simple incubation. The cytoplasmatic iron uptake was significantly higher after labelling with Ferucarbotran than Ferumoxides ($p < 0.05$). After injection of NK-92-scFv(FRP5)-zeta cells into tumor bearing mice, MR showed a significant signal decline in HER2/neu positive tumors 24 h p.i. Conversely, injection of parental NK cells, not directed against HER2/neu receptors, did not cause significant signal changes of the tumors. Histopathology confirmed an accumulation of the former, but not the latter cells in tumor tissue.

Conclusion: Human NK cells can be efficiently labelled with clinically applicable iron oxide contrast agents. The in vivo distribution and tumor accumulation of these labelled cells can be monitored in vivo with MR imaging.

Human progenitor cells migrate into squamous cell carcinoma (SCC) xenografts

F.M.A. Kiessling, J. Dittrich, T. Moehler, M. Le-Huu, M. Bock, R. Schulz, J. Peter, M. Mueller, W. Semmler; Heidelberg/DE

Purpose: Progenitor cells participate in various repair processes, however, their role in tumor formation remains unclear. Purpose of this study was to evaluate, whether these cells migrate into human squamous cell carcinomas (SCC) in relevant amounts.

Methods and Materials: SCC were grown in the upper thigh of nude mice. An > 80% pure preparation of AC133+ human stem-cells was obtained from peripheral blood of G-CSF stimulated humans. Stem cells were labeled with 111In-oxine and SPIOs. Intracellular iron-concentrations were determined by mass-spectroscopy. The labeled cells were injected intravenously or subcutaneously in the lower thigh at the tumor side and tracked over 5 days by scintigraphy and MR imaging.

Results: Only the sessile fraction of human stem cells/progenitor cells showed high uptake rates of SPIO (12 pg/cell after 5 h incubation with 3 mg Fe/ml). Related to the quadriceps muscle of the contralateral side 5.1/4.0 times higher cell concentrations were found in tumors after subcutaneous/intravenous injection as determined by gamma counting. Independent of the injection route highest stem cell fractions were found in liver, spleen and kidney. In the bone marrow stem cell concentrations were 2.6/6.9 (subcutaneous/intravenous) fold higher than in the muscle. Accumulation of labeled cells in tumors was successfully monitored using MR imaging and confirmed by histology, where Prussian blue positive cells were detected along stromal components including blood vessels.

Conclusion: Thus, human stem cells accumulate in human SCC are located in the stromal compartment in particular the tumor blood vessels. The pathophysiological role of these cells in tumor progression and the mechanisms of incorporation into the tumor tissue are currently under investigation.

C-0408

Receptor-PET/CT of neuroendocrine tumors using the gallium-68 labelled somatostatin analog DOTA-NOC: First clinical results

R.P. Baum¹, M. Schmücking¹, A. Niesen¹, K.P. Zhernosekov², F. Rösch²; ¹Bad Berka/DE, ²Mainz/DE

The octapeptide [DOTA]-1-Nal3-octreotide (DOTA-NOC) has 3-4 times higher binding affinity to sstr2 than DOTA-TOC (Wild, EJNM 2003;30:1338). These promising preclinical data prompted us to use this radiopeptide for somatostatin receptor PET imaging in patients with neuroendocrine tumours (NET) after labelling with Gallium-68, a short-lived positron emitter ($t_{1/2}$ 68 min). Ga-68 was eluted from a 30 mCi Ge-68/Ga radionuclide generator. Following chemical and radiochemical purifications, Ga-68 was eluted into the labeling vial containing 50 µg DOTA-NOC. Radiolabeling yields of < 80% were achieved within 15 min. Ga-68-DOTA-NOC was purified and finally eluted using 0.5 ml ethanol into 4.5 ml of isotonic saline. Overall, 370 MBq of Ga-68-DOTA-NOC were obtained within 20 min. 34 patients with histologically proven NET (mostly carcinoids) and progressive metastases were studied before peptide receptor radiotherapy (PRRT). A mean of 74 MBq (65-140 MBq) Ga-68 DOTA-NOC was injected. Acquisition was started 20-110 min p.i. using an LSO-based PET/CT (biograph DUO, Siemens). Standardized uptake values (SUV) were determined for all tumour lesions and normal tissues. SUV in liver metastases was as high 44.3 whereas normal tissue was in the range of 0.4 (lung) to 31.5 (spleen). Sandostatin given s.c. reduced the specific uptake by a factor of 4. Brilliant PET/CT images of all known tumour lesions and in addition small lymph node metastases of less than 5 mm were easily visualized as early as 20 min p.i. Receptor PET/CT using Ga-68 labelled DOTA-NOC advances as the new gold standard for imaging of neuroendocrine tumours possibly allowing also tumour dosimetry.

Combined MR- and NIR-targeting of macrophages using fluorochrome labelled magnetosomes *in vitro*

M.-R. Lisy¹, I. Hilger¹, R. Trost¹, J.R. Reichenbach¹, D. Schueler², W.A. Kaiser¹; ¹Jena/DE, ²Bremen/DE

Purpose: To label human cells with a bi-functional contrast medium for detection using near infrared optical imaging (NIR) as well as magnetic resonance tomography (MRT).

Methods and Materials: Fluorochrome Dy676 (Dyomics, Jena) has been covalently bound to bacterial magnetic nanoparticles (magnetosomes, particle diameter 42 nm). Cells from human macrophage cell line J774 were incubated with

the bi-functional contrast agent and examined by a whole body near infrared imaging system as well as by using a 1.5 T clinical MR system. T1 and T2 relaxation times were determined. Labelled cells were further characterized with fluorescence spectroscopy, fluorescence activated cell sorting (FACS) and confocal laser scanning microscopy (CLSM).

Results: Compared to non-labelled controls, macrophages that were incubated with our new contrast agent showed a significant fluorescence emission at 699nm using the whole body NIR imaging system, fluorescence spectroscopy, FACS and CLSM after excitation at 676nm. CLSM data showed highest fluorescence intensities within intracellular vesicles. The presence of magnetic nanoparticles caused a substantial signal decrease. Both T1 and T2 were shortened with increased labelling.

Conclusions: Human macrophages can be labelled by uptake of our new bi-functional contrast agent. The labelled cells can be detected by both 1.5 T MR scanner as well as by NIR fluorescence imaging.

Non-invasive imaging of alpha-v-beta-3-expression in patients with malignant tumors using [¹⁸F]GalactoRGD

A.J. Beer¹, R. Haubner¹, M. Goebel¹, S. Luderschmidt¹, A. Grosu¹, W.A. Weber², E.J. Rummeny¹, M. Schwaiger¹; ¹Munich/DE, ²Los Angeles, CA/US

Purpose: The integrin $\alpha v\beta 3$ is of importance in angiogenesis and tumor metastasis. We tested the performance of [¹⁸F]GalactoRGD for non-invasive imaging of $\alpha v\beta 3$ -expression in patients with malignant tumors.

Methods and Materials: 17 patients with malignant tumors (melanoma n = 7; sarcoma n = 7; head/neck cancer n = 3) were examined on an EcateExact PET-scanner or a Sensation 16 biograph-scanner after injection of 144-200 MBq [¹⁸F]Galacto RGD. Multiple scans from the thorax to the pelvis between 0-100 min p.i. and delayed images up to 140 min p.i. were acquired. Results were correlated with morphologic imaging (n = 17) and with the results of histopathology (n = 14) and immunohistochemistry against $\alpha v\beta 3$ (n = 6).

Results: Analysis of metabolites in blood samples (n = 4) using RP-HPLC showed > 95% intact tracer up to 120 min p.i. [¹⁸F]GalactoRGD showed predominantly renal and to a lesser extent hepatobiliary excretion with rapid blood clearance. SUV measurements in normal organs were as follows (5 min and 60 min p.i.): Blood 2.8 ± 0.5 / 1.2 ± 0.5 ; liver 2.7 ± 0.5 / 2.3 ± 0.5 ; kidney 9.1 ± 3.8 / 6.9 ± 4.3 ; intestines 3.2 ± 0.7 / 2.9 ± 0.6 . Two patients with multiple melanoma metastases and one patient with a liposarcoma showed no significant tracer uptake. The SUV in patients with visible uptake ranged from 1.2 to 10.0 (mean 4.2; 60 min p.i.) with continuously rising tumor/blood ratio over time (mean 3.3 ± 2.6 ; 60 min p.i.). Immunohistochemistry confirmed the expression of $\alpha v\beta 3$ on tumor cells (n = 2/6) and endothelium of blood vessels (n = 6/6).

Conclusion: [¹⁸F]GalactoRGD allows non-invasive imaging of $\alpha v\beta 3$ -expression in humans with good contrast. This method could be used for analysis of biological activity of tumors and for monitoring pharmacotherapy with $\alpha v\beta 3$ -selective agents.

C-0412

An automated image-guided robot arm control system for transgenic and drug delivery studies

Y.H. Huang, C.L. Chen, T.H. Wu, M.H. Lin, C.C. Yang, J.J.S. Lee; Taipei/TW

Purpose: Biological discovery and molecular genetic techniques has made great progress in recent years, especially for malignant tumors, trying to figure out the most effective ways of treatment. Hence, the aim of this study is to establish an integration of image-guide automatic robot arm system, for transgenic or drug delivery onto animal tumor models.

Methods and Materials: This system is composed of three main parts, including image fusion technique, stereotactic frame system, and automatic robot arm system. (1) The image fusion technique combines the PET imaging with MR imaging, providing direct image registration of both functional and anatomical information. (2) the small animal stereotactic frame immobilizes the experiment animals and then employs the fiducial marker to pinpoint the transformation relationships between the imaging and physical coordinates. (3) the image-guide automatic robot arm system is set up upon a stereotactic frame device that can be well directed to the target positions, and in accordance with predefined delivery routes for achieving high precision of gene or drug delivery.

Results: The system successfully guided the micro-injection from image planned

Scientific and Educational Exhibits

delivery routes into practice. Consequently, the mean of registration errors in our system is less than 1.5 mm, that apply to achieve the effective drug delivery rate up to 85% and reduce the normal tissue uptake.

Conclusion: The main advantage of the system is that it can accurately provide relative location sites of tumors from high resolution imaging and also provide highly precise micro-injection to increase the feasibility and safety for gene (drug) delivery.

Role of MR imaging and HSG in the evaluation of congenital uterine malformations

P. Nin Garaizabal, B. Ubeda Hernandez, A. Roma Dalfo, C. Traid Niella, R. Rotger Regi, A. Palacio Hermoso de Mendoza; *Barcelona/ES*

Learning Objectives: Describe the mean features of congenital uterine malformations with hysterosalpingography (HSG) and magnetic resonance (MR) imaging. Identify which imaging features at MR imaging are more specific for each entity for differential diagnosis.

Background: Congenital uterine malformations originate from nondevelopment or nonfusion of the Müllerian ducts, resulting in agenesis or doubling of the female reproductive organs, which are classified according to the American Society of Fertility. Anomalies of the urinary tract are frequently associated. Müllerian duct anomalies are often related to a broad variety of symptoms, including infertility and increased risk of miscarriages.

Imaging Findings: From January 2000 to December 2002, a total of 974 patients diagnosed of primary and secondary sterility underwent HSG at our institution, selecting those cases with congenital uterine malformations, according to the American Society of Fertility, correlating the findings with those found at MR imaging. The most frequent and illustrative cases of congenital uterine malformations are shown including unicornuate, septate, bicornuate and didelphys uterus, describing the HSG findings and making special emphasis in the role of MR imaging in the evaluation of the features that allow a differential diagnosis between the different entities.

Conclusions: HSG is the most commonly used technique in the diagnostic evaluation of infertility, often identifying Müllerian duct anomalies. MR is useful for documenting uterine morphology and is currently the most accurate technique for its diagnosis.

C-0414

Differential diagnosis of gynaecological solid masses on MR imaging-pattern approach and radiologic-pathologic correlation

S.P. Prabhu, T.V. Narayan, K. Prescod; *Bristol/UK*

Learning Objectives: 1. To define an algorithm for the differential diagnosis of gynaecological solid tumours on MR imaging. 2. To highlight features of gynaecological masses that suggest malignancy. 3. To illustrate the correlation of MR imaging appearances with histopathology. 4. Provide a desktop guide to the differential diagnosis of gynaecological tumours on MR imaging.

Background: There is a large variety of solid gynaecological tumors and this makes the diagnosis of these tumors challenging, even to experienced radiologists. Determining the organ of origin and then deciding if the mass could be malignant is the first step in the diagnostic algorithm.

Procedure Details: We reviewed MR imaging archives of two teaching hospitals in our area from Jan 2000 to Jun 2004 to identify cases of solid gynaecological tumours. We obtained clinical and histopathological data to compare with the radiology reports. Based on this data, we developed a desktop algorithm for the differential diagnosis of these tumours. We identified features of malignancy and invasive spread that are cornerstones of further management of these lesions. We also looked at and concurrent CT and ultrasound images in cases where these studies were useful. We elaborate findings of ovarian tumours and uterine tumours in this pictorial essay based on our research. In the final part of the essay, we present sample cases to show that our desktop algorithm is a practicable tool.

Conclusion: MR imaging is a useful investigation in the staging and differential diagnosis of solid gynaecological tumours, if clinical data is used in conjunction with radiological appearances.

C-0415

MR image characteristics during and after cryoablation of uterine fibroids

T. Shimizu, A. Sawada, Y. Kodama, Y. Watanabe, Y. Sakuhara, D. Abo, M. Funakubo, Y. Yoshida, K. Miyasaka; *Sapporo/JP*

Purpose: To demonstrate MR imaging characteristics of uterine fibroids during and after cryoablation.

Methods and Materials: Symptomatic uterine fibroids are cryoablated percutaneously using a MR compatible argon-based system under open MR imaging guidance. Follow up T1-weighted, T2-weighted and Gd-DTPA enhanced T1-weighted MR images are taken over at one day, two week, and six week intervals.

Scientific and Educational Exhibits

Results: Seven fibroids in 6 cases were treated. Five fibroids were intramural and two were submucosal. The maximum diameters of the fibroids ranged from 3.7 to 10 cm and the average was 7.4 cm. The maximum diameters of the frozen area ranged from 4.8 to 8.5 cm and the average was 6.5 cm. The average freezing time was 18.7 min. In four cases of intramural fibroids, the non-contrast enhanced areas in Gd-DTPA enhanced T1-weighted images at one day and 2-week intervals after cryoablation were larger than the frozen area. In two cases of submucosal fibroids, normal myometrium around the fibroids were frozen and the signal intensity of the MR images returned to normal in six weeks.

Conclusion: MR images after cryoablation indicate the necrotic area is larger than the frozen area in the uterine fibroid and we can expect spontaneous recovery of normal myometrium in the frozen area.

C-0416

Female genitalia on MR imaging: The comparison of premenopausal and postmenopausal women

D. Sung, K. Ahn, S. Cho, Y. Kim, K. Chung, J. Kim; Seoul/KR

Purpose: To describe normal anatomy and differences of the female genital organs on MR imaging between premenopausal and postmenopausal women.

Materials and Methods: A total of 19 premenopausal and 18 postmenopausal healthy women underwent 1.5 T MR imaging with a torso phased array coil. Axial T1, TSE T2 and fat suppressed Gd-enhanced axial T1-weighted images were obtained. Two radiologists measured the wall thickness of vagina, urethra and labium minora, the width of clitoral crura and vestibular bulb and the sectional dimensions of the clitoral glans.

Results: All genital structures were delineated more clearly on fat suppressed Gd-enhanced axial T1-weighted images than noncontrast axial T1 and TSE T2-weighted images. The separate three layers of vaginal wall were well visualized in premenopausal subjects but not clearly defined in postmenopausal subjects. The urethra had a target-like appearance with three layers in premenopausal and postmenopausal women. The clitoral crura were well delineated as a wishbone-shaped structure surrounding the urethra and vagina. The two vestibular bulbs were paramedian in location and lying just posterior to the clitoral crura as oval and elongated, enhanced structures. Postmenopausal subjects were observed to have smaller vaginal wall thickness (7.0 ± 0.9 mm versus 5.2 ± 0.7 , $p < 0.001$), urethral wall thickness (7.7 ± 0.8 versus 5.9 ± 0.9 , $p < 0.001$) and vestibular bulb width (5.6 ± 0.8 versus 4.9 ± 0.5 , $p < 0.05$) than premenopausal subjects.

Conclusions: The normal anatomy and differences of the female genital organs between premenopausal and postmenopausal women were well discernible on fat suppressed Gd-enhanced axial T1-weighted images. This study may provide valuable information for the future studies of female sexual function.

C-0417

Salpingitis isthmica nodosa (SIN) in female infertility

V.S. Gada, A. Hemingway, R. Williamson, G. Trew, S. Lavery, R. Margara; London/UK

Learning Objective: This study seeks to determine the incidence, distribution and clinical significance of salpingitis isthmica nodosa (SIN) diagnosed by hysterosalpingography (HSG) in women presenting with infertility.

Background: SIN, an uncommon disease of the fallopian tubes, is characterized microscopically by small diverticulae present in an irregularly hypertrophied myosalpinx.

Procedure Details: Between November 1996 and December 2003, 4464 women presenting to a tertiary referral centre with infertility were referred to two radiologists for an HSG. SIN was diagnosed in 100 examinations in 96 women, age range 21 to 47 years, (mean 35 years), accounting for 2.24% of the whole population studied and 10% of those with tubal pathology. Thirty two patients (33%) presented with primary and 64 patients (67%) with secondary infertility; 27 (28%) had one or more ectopic pregnancies. Other associated pathology included hydrosalpinges 23%, tubal occlusion 19%, tubal polyps 3%, uterine lesions (fibroids, adenomyosis, scar tissue) 20%. Fifteen patients had 46 previous IVF treatments elsewhere, 8 of which had been successful. Treatment options for SIN include resection of the diseased segment and tubal reanastomosis.

Conclusion: HSG is important not only in making the diagnosis of SIN but also in excluding other associated pathology which may dictate the success of the preferred management option. The strong association of SIN with ectopic pregnancy should also affect the early pregnancy management of women with this diagnosis.

C-0418

Patterns of recurrence in ovarian carcinoma

J.L. Hughes, A. Sadove, A. Rockall, R. Reznik; London/UK

Purpose: The aim of our study was to describe CT patterns of recurrent ovarian carcinoma after proven remission, to aid earlier recognition of recurrent disease which may facilitate successful treatment with second-line therapy.

Methods and Materials: We identified women with radiological relapse after complete remission, established by laparotomy and radiological assessment. CT imaging was retrospectively reviewed and site and patterns of recurrence were documented.

Results: Since 1985, 393 women were treated and 173 (44%) achieved complete remission. Of the 173, 79 (46%) had relapsed. Imaging was available in 60 patients. The most common site of relapse was in the pelvis (25 [42%]) which was seen alone in 12 (20%). 20 (33%) relapsed with enlarged lymph nodes, 13 (22%) had para-aortic or aorto-caval nodes. Five had para-cardiac nodes, and only three relapsed with pelvic or inguinal nodes. In 6 patients (10%) lymphadenopathy was the sole manifestation of recurrence. 15 (25%) presented had extra-peritoneal recurrence: 3 with splenic and 4 with hepatic metastasis and 2 with both; 3 with brain, 3 in skeletal muscles. 22 (36%) relapsed with peritoneal thickening. Median time to peritoneal relapse was 1.2 years (inter-quartile range 0.9-1.7) compared with 2.1 years (1.2-4.2) in those without radiological evidence of peritoneal relapse [$p < 0.001$].

Conclusion: Despite clinical complete remission, almost half relapse. The commonest mode of relapse is a recurrent pelvic mass or peritoneal disease. Extra-peritoneal disease may be the sole manifestation of recurrent disease in a significant number of women.

C-0419

Color Doppler and three dimensional ultrasound hystero-contrast-salpingography

B.M. Plavsic¹, S. Kupesic²; ¹New Orleans, LA/US, ²Zagreb/HR

Purpose: To demonstrate the efficacy of transvaginal color Doppler hystero-contrast-salpingography (Hy-Co-Sy) and 3D ultrasound Hy-Co-Sy in evaluation of patency of Fallopian tubes.

Methods and Materials: The findings of color Doppler Hy-Co-Sy in 152 patients and 3D ultrasound Hy-Co-Sy in 58 patients were compared to laparoscopic chromoperturbation. The contrast media used were isotonic saline or commercial echo contrast medium Echovist.

Results: Findings in 145 of 152 color Doppler Hy-Co-Sy were confirmed by chromoperturbation. Bilateral tubal patency was successfully detected by color Doppler Hy-Co-Sy in 64 of 67 patients (95%), while unilateral patency was shown in 36 out of 38 (95%). In 45 patients color Doppler Hy-Co-Sy showed bilateral tubal occlusion. Fifty six out of 58 (96%) 3D ultrasound Hy-Co-Sy findings were also confirmed by chromoperturbation. Transvaginal color Doppler Hy-Co-Sy had 98% sensitivity, 90% specificity, 95% positive predictive value and 96% negative predictive value respectively. Bilateral tubal patency was correctly detected by 3D ultrasound Hy-Co-Sy in each of 24 patients, while unilateral tubal patency was demonstrated in 17 out of 18 cases. In 15 patients 3D ultrasound Hy-Co-Sy indicated bilateral tubal occlusion. For 3D ultrasound Hy-Co-Sy the sensitivity was 97%, specificity 94%, positive predictive value 97% and negative predictive value 94%.

Conclusion: Transvaginal color Doppler Hy-Co-Sy is an efficacious and safe method to evaluate tubal patency without exposure to radiation and iodinated contrast media. Three dimensional ultrasound Hy-Co-Sy offers the possibility of simultaneous presentation of the uterine cavity and corresponding tube, shortening the procedure and discomfort.

C-0420

MR imaging of the urethral sphincter in incontinent women

K.J. Macura, R.R. Genadry, D.A. Bluemke; Baltimore, MD/US

Learning Objectives: 1. To review anatomic properties of the urethral sphincter, periurethral attachments, and pelvic floor that facilitate continence. 2. To discuss techniques for the evaluation of urethral morphology and function with MR imaging. 3. To review imaging findings in urinary incontinence, with a focus on dynamic pelvic floor evaluation and endocavitary MR imaging.

Background: Two generic conditions cause stress urinary incontinence in women: bladder abnormalities (detrusor overactivity and low bladder compliance) and sphincter abnormalities. Sphincteric incontinence is related to urethral hypermobility and intrinsic sphincter deficiency. MR imaging allows complete visualization of the urethral sphincter muscle and urethral support ligaments.

Scientific and Educational Exhibits

Imaging Findings: Dynamic MR imaging of the pelvic floor during straining allows evaluation of the urethral mobility, vesical neck insufficiency, and detection and grading of cystocele. Endocavitary MR imaging (intraurethral and endovaginal) provides higher spatial resolution imaging with smaller field of view, increased signal to noise, and improved depiction of the urethral sphincter morphology (striated and smooth muscles) and perirethral attachments (periurethral, paraurethral, and pubourethral ligaments).

Conclusions: MR imaging of the pelvic floor and urethral sphincter contributes to the evaluation of patients with urinary incontinence by allowing detailed assessment of the anterior pelvic floor compartment and urethral sphincter abnormalities related to urethral hypermobility and intrinsic sphincter deficiency.

C-0421

Three-dimensional power Doppler ultrasound in detection of early ovarian carcinoma

S. Kupesic¹, B.M. Plavsic²; ¹Zagreb/HR, ²New Orleans, LA/US

Purpose: To investigate the efficacy of different sonographic methods - 2D transvaginal grey scale ultrasound, 2D color Doppler ultrasound, 3D ultrasound, 3D power Doppler and contrast-enhanced 3D power Doppler ultrasound in preoperative evaluation of early ovarian carcinoma.

Methods and Materials: A five-year retrospective analysis of 43 patients with stage I ovarian carcinoma evaluated a week prior to surgery was performed. Sonographic assessment included examination of the ovarian volume, morphology and vascularity.

Results: Forty two of 43 early ovarian carcinomas were detected by combination of five complementary sonographic methods. 2D transvaginal ultrasound detected 28 (65%) cases of stage I ovarian carcinomas. By adding 2D transvaginal color Doppler ultrasound, 35 out of 43 early ovarian cancers (81%) were found. Morphological analysis by 3D ultrasound detected 31 of 43 ovarian carcinomas, reaching diagnostic sensitivity of 72%, yielding higher sensitivity than 2D transvaginal ultrasound alone. Qualitative analysis of the tumor neovascularity architecture by 3D power Doppler significantly improved the sensitivity to 93% and detected 40 cases of 43 stage I ovarian carcinomas. When morphological features obtained by 3D ultrasound were added to 3D power Doppler findings, diagnostic sensitivity of 95% has been achieved. Finally, the use of a contrast-enhanced 3D power Doppler sonography showed diagnostic sensitivity of 98% with only one false negative case.

Conclusion: Combined evaluations of morphology and neovascularity by 3D power Doppler ultrasound improve early detection of ovarian carcinoma. Contrast-enhanced 3D power Doppler imaging further contributes to the detection of the earliest features of ovarian carcinoma neovascularity.

C-0422

MR features of physiologic and benign conditions of the ovary

K. Tamai, T. Koyama, A. Kido, S. Umeoka, T. Fujiwara, T. Saga, S. Fujii, K. Togashi; Kyoto/JP

Learning Objectives: To review a spectrum of MR features in physiologic and benign conditions of the ovary.

Background: In reproductive women, various physiologic conditions can cause morphologic changes of the ovary, resembling pathologic conditions. Various benign diseases can also frequently simulate malignancies. In these conditions, MR imaging can play an important role in establishing accurate diagnosis and determining appropriate management. In this exhibit, MR and clinical features of various physiologic and benign conditions of the ovary are illustrated.

Imaging Findings: Various physiologic conditions cause ovarian cystic lesions. Corpus luteum cysts typically have a thick wall with increased intensity on T1WI. Endometrial cysts usually show specific pattern of signal intensity. In pregnant women, decidual change in endometrial cysts should not be confused with secondary malignancy. In peritoneal inclusion cysts, careful evaluation of the configuration may avoid confusion with neoplasms. Multi-cystic lesions simulating cystic neoplasms can be seen in hyperreactio luteinalis, ovarian hyperstimulation syndrome, and polycystic ovary syndrome. Recognition of clinical settings will help diagnose these conditions. Although ovarian torsion and massive ovarian edema may mimic solid malignant tumors, recognition of normal follicles and anatomic structures may help establish correct diagnosis. Many benign tumors, including teratoma, Brenner tumor, and sex-cord stromal tumor, frequently show characteristic MR findings. In inflammatory diseases, transfascial spread of the lesion should not be confused with invasive malignancy. Radiologic identification of abscess facilitates establishing diagnosis.

Conclusion: Knowledge of MR features in a variety of physiologic and benign conditions of the ovary facilitates establishing accurate diagnosis and determining treatment.

C-0423

Preoperative assessment of deep myometrial and cervical invasion in endometrial carcinoma: Comparison of magnetic resonance imaging and histopathologic evaluation

C. Vasconcelos, A. Félix, T.M. Cunha; Lisbon/PT

Purpose: This study aimed to evaluate the accuracy of magnetic resonance imaging (MRI) in the detection of deep myometrial invasion and cervical extension by endometrial carcinoma.

Methods and Materials: One hundred and one consecutive patients with histologically documented endometrial carcinoma were included in this prospective study, between July of 1998 and April of 2004. All patients underwent a preoperative pelvic MRI and the findings were compared with histologic diagnosis on surgical specimen. Axial T1, transverse and sagittal T2-weighted images and a dynamic study after the administration of 0.1 mmol gadolinium per kilogram of body weight in the sagittal plane were obtained with a 1-T superconducting magnet (model Gyroscan NT; Philips; Eindhoven, Netherlands), using a body coil.

Results: In the 101 cases studied by pelvic MRI, 43 were classified as deep myometrial invasion ($\geq 50\%$ of myometrium), 58 as superficial invasion ($< 50\%$). The pathologic evaluation confirmed those 43 cases as having deep myometrial invasion. Cervical extension in MRI study was found in 19 cases. Pathologic study found cervical extension and / or invasion in 31 cases, including all cases identified by MRI. The accuracy, sensitivity and specificity of MRI were 95%, 89%, and 100%, respectively, detecting deep myometrial invasion and 88%, 61%, and 100%, respectively, detecting cervical invasion.

Conclusion: MRI is an adequate method for determine the depth of myometrial invasion and cervical extension in endometrial carcinoma. The high accuracy achieved suggests that MRI is a reliable method for preoperative endometrial carcinoma "imaging staging".

C-0424

Posttreatment complications of gynecologic cancer

S. Vinhais, A. Félix, T.M. Cunha; Lisbon/PT

Learning Objectives: To review the imaging findings of complications related with the treatment of gynecologic cancer (GC).

Background: Curative procedures of GC can give rise to several complications, which can be separated into three categories: postsurgical, postirradiation and secondary to chemotherapy. Recognition of these complications is relevant, not only for their significant morbidity, and even mortality risk, as also because some may simulate tumoral disease, a critical situation for adequate clinical management.

Imaging Findings: Postsurgical complications of fluid nature comprise abscesses, hematomas, and more rarely, lymphoceles and urinomas, all these pathologic conditions being generally easy to diagnose. Difficulties arise in the identification of fistulas and unexpected entities such as gossypibomas.

The spectrum of postirradiation complications (fistulas, cystitis, stenosis of small bowel, thickening of uterosacral ligaments, hydro/hematometrocolpos, cases of hydrosalpinx, osteoradionecrosis and insufficiency fractures, among others) includes fibrotic changes and bone lesions, sometimes problematic of distinguishing from recurrent or metastatic disease. Imaging of chemotherapy complications is seldom depicted. Hepatic infarct is an example of a serious complication that may occur with specific drugs. Extensive knowledge of the possible effects of the chemotherapeutic agents is however crucial for a correct radiologic interpretation.

Conclusion: A careful clinical history comprising the previous therapeutics is essential for an appropriate radiological evaluation of patients with GC, allowing better orientation and interpretation of the exams. Computed tomography and magnetic resonance are the main imaging techniques to diagnose the posttreatment complications, but a multi-modality approach, including conventional radiographic studies, might be necessary.

C-0425

MR imaging spectrum of pelvic and extrapelvic endometriosis

A. Roma, P. Nin, B. Ubeda, J. Ares, C. Traid, A. Palacio; Barcelona/ES

Learning Objectives: - Describe the different manifestations of pelvic and extrapelvic endometriosis. - Outline MR imaging features of pelvic endometriosis. - Identify the MR imaging features that allow a differential diagnosis of endometriomas from other adnexal masses.

Background: Endometriosis is a gynaecologic disorder primarily affecting women during their reproductive years. Pathologically, it is the result of endometrium located outside the uterus and affects 5-10% of women. The most accepted etiologic theory is metastatic implantation from retrograde menstruation. Symptoms

Scientific and Educational Exhibits

do not necessarily correlate with severity of the disease. Patients may be asymptomatic or present with pelvic pain, infertility or adnexal masses. MR is a very useful and specific technique for the evaluation of endometriosis. Nevertheless, laparoscopy remains the mainstay for diagnosis, staging and treatment of the disease.

Imaging Findings: Pelvic endometriosis refers to lesions of the fallopian tubes, ovaries and local peritoneum. Extrapelvic endometriosis is defined as implants found elsewhere in the body, including the gastrointestinal tract, urinary tract and thoracic cavity. MR imaging is a very specific imaging technique for the diagnosis of endometriomas, more than the other non-invasive imaging techniques, due to the specific signal intensity of the lesions at the different sequences, depicting the presence of implants and adhesions and involvement of surrounding anatomic structures. Our protocol includes axial T1- and T2-weighted and T1 fat-suppressed, sagittal FSET2, and optional coronal FSET2 sequences.

Conclusion: This exhibit provides an overview of the pelvic and extrapelvic manifestations of endometriosis emphasizing the utility of MR imaging to diagnose and stage this entity.

C-0426

The effectiveness of MR hysterosalpingography in infertility

S. Karaköse, A. Karabacakoglu, E. Yalinkiliç, R. Haykir, H. Görkemli; Konya/TR

Purpose: In infertile patients the role of conventional hysterosalpingography (CHSG) and 3D MR hysterosalpingography (3D-MRHSG) were evaluated for detection of tubal, uterine, ovarian and paraovarian causes of infertility.

Material and Methods: 35 cases, their ages ranging between 19-39, clinically diagnosed as infertile (19 primary, 16 secondary) underwent CHSG and 3D-MRHSG. In examination, diluted paramagnetic and nonionic contrast material were injected into uterine cavity by 5F balloon catheter. Firstly 3D-MRHSG and then CHSG were performed in all cases. Also complementary MR images were taken during 3D-MRHSG.

Results: In 27 cases bilateral patent fallopian tubes were determined by CHSG, while bilateral tubal patency were determined in 25 of cases by 3D-MRHSG. Two tubal obstructions which has been demonstrated by 3D-MRHSG however were patent and patency was shown by CHSG. Congenital uterine anomalies were detected in 5 cases. Furthermore 4 cases with polycystic ovarian syndrome, 2 cases with ovarian cysts, a case of endometrioma, 5 cases with myoma were diagnosed by 3D-MRHSG but they were not shown by CHSG.

Conclusion: CHSG is used routinely in detection of uterine cavity pathologies and tubal patency, while CHSG remain insufficient in detection of myometrial pathologies, uterine congenital anomalies, ovarian and paraovarian pathologies. 3D-MRHSG is superior in the detection of internal and external borders of uterus, myometrial layers, ovarian and paraovarian pathologies. Also tubal patency and the uterine cavity can be examined by 3D-MRHSG. Due to these advantages of 3D-MRHSG it can be an effective alternative to CHSG.

C-0427

Imaging of endometriosis

G.C. Hargaden, M. Keogan; Dublin/IE

Learning Objectives: 1. To outline the classical appearances of endometriosis on ultrasound, barium enema and MR imaging. 2. To highlight the different imaging features of endometriomas and haemorrhagic ovarian cysts on ultrasound. 3. To show how the addition of fat saturation sequences on MR can improve diagnostic accuracy and help differentiate lipid-containing ovarian masses from endometriomas.

Background: Endometriosis is a common debilitating condition seen particularly in nulliparous women of child-bearing age in Europe and the USA. It is defined as the presence of functional endometrial tissue outside the endometrium and myometrium. Laparoscopy remains the gold-standard for diagnosis however many patients can be diagnosed on the basis of imaging findings in the correct clinical setting.

Procedure Details: Diagnosis of endometriosis remains a challenge to the radiologist although improvements in ultrasound and MR have led to improved diagnostic accuracy. We review the imaging findings of endometriosis on barium enema, the ultrasound appearances of endometriomas and highlight the differences between these and haemorrhagic cysts. We describe the optimal MR imaging sequences, illustrate how endometriomas can be confidently differentiated from lipid-containing dermoids and demonstrate the appearances of endometrial deposits in the bladder on MR imaging.

Conclusion: Although there are a wide range of imaging findings in endometriosis, familiarity with the more classical appearances as we describe in this educational exhibit can result in a high degree of diagnostic accuracy.

C-0428

Dynamic MR imaging in the assessment of female pelvic organ prolapse:

Baseline and post-surgical evaluation

A. Catalucci¹, L. Zugaro¹, M. Monina¹, A. Mancinotti¹, E. Di Cesare², C. Vicentini¹, C. Masciocchi²; ¹Teramo/IT, ²L'Aquila/IT

Purpose: To investigate the diagnostic role of MR imaging in the evaluation of female urinary incontinence and pelvic organ prolapse using dynamic MR imaging, in the baseline and after surgery using the "Patch and Plug" technique.

Material and Methods: 44 patients with a genuine stress urinary incontinence and genital prolapse were investigated by standard and dynamic MR imaging, using a 1.5 T unit. Patients were placed in a supine position with the legs slightly flexed and abducted; 250 ml of Gd-DTPA water solution were instilled into the bladder, 20 ml of Gd water-gel solution were injected into the vagina and 50 ml into the rectum. Dynamic images were obtained at rest and during Valsalva manoeuvre, using T1-FFE sequences on sagittal plane. Dynamic MR imaging was analyzed to determine the presence and extent of cystocele and vaginal vault prolapse.

Results: Dynamic MR imaging provided in all cases a good demonstration of genital prolapse during Valsalva manoeuvre; a good correlation with the clinical evaluation of both genital prolapse type and degree was found in the baseline and after surgery.

Conclusion: Dynamic MR imaging is a good aid in the evaluation of both kind and degree of the female pelvic organ prolapse. After surgery, it is useful to document both the disappear of the prolapse and the post-surgical evolution.

C-0429

Carcinosarcoma of the uterus: MR findings and the pattern of recurrence

S. Imai¹, T. Nakazono¹, Y. Matsuo², S. Kudo¹; ¹Saga/JP, ²Tokyo/JP

Purpose: To evaluate MR findings and the pattern of recurrence of uterine carcinosarcoma.

Material and Methods: We retrospectively reviewed clinical and radiologic findings of 10 women (ages 51-75, median age 65) with pathologically proven carcinosarcoma of the uterus. We evaluated preoperative MR findings, histopathological type, and surgical stage. We also evaluated the pattern of recurrence (rate, location, period after surgery), CT and MR findings of recurrence in 5 patients. The period of observation after the first diagnosis was 11-156 months (the mean 55.3 months).

Results: MR finding of primary uterine carcinosarcoma was a polyoid mass in the uterine cavity with inhomogeneous enhancement by contrast media. Five (50%) patients had recurrences within 12 months after the surgery. Locations of recurrences were at the stump of vagina, the pouch of Douglas, the retroperitoneum, and the pelvic wall. Extraabdominal recurrences were also seen in the lung and the thoracic vertebra. The majority of the abdominal and pelvic lesions were demonstrated as inhomogeneous solid masses similar to the primary lesions. All the patients with recurrence died within 10 months after the diagnosis of recurrence.

Conclusion: Uterine carcinosarcomas recurred in 50% of the patients within 12 months after the surgery, so they should be observed closely. In addition, uterine carcinosarcomas have no specific tumor marker, it is important to follow-up the patients radiologically.

C-0430

MR imaging features with pathologic correlation of uterine malignant mixed Mullerian tumors

E. Yamashita¹, T. Koyama², H. Kotani², A. Kido², S. Umeoka², T. Fujiwara², S. Fujii², Y. Imai¹, K. Togashi²; ¹Isehara-shi/JP, ²Kyoto/JP

Purpose: Malignant mixed Mullerian tumors (MMMTs) are rare but highly aggressive uterine tumor, though the role of MR imaging in this tumor have not been documented. The purpose of this study is to describe MR features of MMMTs in correlation with pathologic features, and to evaluate the accuracy of MR staging.

Methods and Materials: Preoperative MR images in 17 patients (age 50-82; mean 63.1) with pathologically confirmed MMMTs, including T1WI, T2WI and postcontrast-T1WI, were retrospectively reviewed for size, location, signal intensities and stage of the tumors. Pathologic specimens were reviewed for hemorrhage, necrosis, and the percentage of sarcomatous component. Pathologic stage was determined according to FIGO classification. Features and stages on MR imaging were compared with those in pathology.

Results: On MR, tumors were at least exophytic endometrial mass in all, with 10 lesions extending into the cervical canal. T1WI showed predominantly low intensity lesions in all, with focal high intensity (n=11). T2WI showed heterogeneous (n=13) or homogeneous high intensity lesion (n=4). Postcontrast-T1WI revealed

Scientific and Educational Exhibits

heterogeneous enhancement in all. Tumors with pathologic hemorrhage and necrosis corresponded to lesions with high intensity foci on T1WI. With increase of sarcomatous component, the size, the number of tumors with focal high on T1WI and heterogeneous appearance on T2WI increased. MR imaging provided correct staging in most of stage I lesions (8/10), but low accuracy for lesions over stage 2 (2/7).

Conclusion: MR features of MMMTs are variable according to pathological features. Although MR provides accurate staging in T1 disease, it frequently underestimates cervical involvement and extrauterine lesions.

C-0431

MR features of cervical adenocarcinoma with pathologic correlation

T. Koyama, S. Umeoka, A. Kido, K. Tamai, T. Saga, S. Fujii, K. Togashi; Kyoto/JP

Learning Objectives: To illustrate spectrum of MR features of cervical adenocarcinoma in correlation with pathologic findings, and to demonstrate problems and limitations in MR staging.

Background: In cervical cancer, the majority is squamous cell carcinoma (SqCC), while the incidence of adenocarcinoma is increasing. Histologically, cervical adenocarcinomas consist of several subtypes, which include mucinous carcinomas and carcinoma analogous to corpus cancer, such as endometrioid, serous, and clear cell carcinoma. The clinical and MR features differ according to histologic subtypes. Generally cervical adenocarcinomas are more resistant for chemotherapy and radiotherapy, and portends worse prognosis than SqCC. MR features in cervical adenocarcinoma have not been fully documented in radiologic literatures. In this exhibit, MR features in cervical adenocarcinoma are illustrated in correlation with pathologic findings. The problems in MR staging for adenocarcinoma are also discussed.

Imaging Findings: Cervical adenocarcinomas are typically demonstrated as infiltrative lesions of increased intensity on T2WI, arising from either cervical canal or lip. However, they can show variable appearance and signal intensity reflecting pathologic features. MR imaging occasionally fails in demonstrating invasive cancer confined within the cervical stroma. Although adenocarcinomas frequently infiltrate into the vaginal wall and parametrium, these extra-uterine extensions can be easily underestimated. As a result, the overall accuracy of MR staging in cervical adenocarcinomas is lower than that in SqCC.

Conclusion: The knowledge of MR features and clinical behavior of cervical adenocarcinomas helps accurate diagnosis and staging. The recognition of problems and limitations in MR staging encourages careful interpretation of MR findings.

C-0432

Ultrasound angiography in the assessment of cervical cancer treatment

E.A. Mikhailova, B.A. Minko, G.A. Ushakova, V.L. Vinokurov, K.V. Prozorovsky; St. Petersburg/RU

Purpose: To assess efficacy of 3D-ultrasound angiography (3D-UA) in the evaluation of cervical cancer (CC) treatment.

Materials and Methods: 25 patients (32-68 years old) with CC, stage II-III (FIGO classification) received combined radio- and chemotherapy including intra-arterial embolization (IAE) of internal iliac and uterine arteries. The treatment results were evaluated using 3D-UA. A digital color Doppler system SonoAce 8000 (Medison Co. Ltd., Korea) with transrectal transducers (3.5 and 7.5 MHz) was used at four different time points: before treatment; after chemotherapy with IAE; in the middle and after the completion of radiotherapy. Tumor characteristics, presence of metastasis, 3D image of tumor vascularisation were evaluated. The pulsatility, resistance index, and vascular index of tumor blood flow were measured.

Results: Out of the 25 patients, hypo- and hypervasculatized tumors were found in 3 and 15 patients, respectively. According to 3D-UA, in 16 patients, chemotherapy with IAE led to a 50% reduction in the tumor size and degree of vascularization. After completion of the radiotherapy, full deterioration of the tumor was found in 10 patients, substantial reduction (more than 50%) of tumor size and degree of vascularisation was found in 11 patients. Slight reduction (25%) of the tumor size was found in 4 patients, which can be explained by tumor resistance to the treatment. In these patients, changes in the treatment regimen were implemented.

Conclusions: 3D-UA provides accurate information during radiotherapy of CC by monitoring the tumor size and degree of vascularization and permits a more accurate selection of treatment options.

C-0433

Extrapelvic nodal metastases as the most frequent form of recurrence in uterine cervical carcinoma treated by radiation therapy

M. Castro Copete, J. Calbo Maiques, M. Carnero Ruiz, C. Crespo Martínez, M. Navarro Navarro, N. Picazo Escrivano, I. González Álvarez; Alicante/ES

Purpose: 1. To know the most frequent form of presentation and location of tumoral recurrences in patients with cervical cancer treated with radiation therapy. 2. To remember the importance of including an abdominopelvic CT in the following protocol of cervical carcinomas.

Materials and Methods: This is a retrospective evaluation of 121 patients with cervical carcinoma treated in our institution from 1994 to 2003. All patients had received radiation therapy, as unique or adjuvant therapy. We have reviewed CT images included in the follow-up protocol.

Results: Among 121 reviewed cases, we found tumoral recurrence in 21 patients: 5 local recurrences, 7 hematogenous metastases and 12 lymph node recurrence. In all lymph node recurrence cases, the nodal groups considered pathological at CT, were found above aortic bifurcation. There were no cases with pelvic lymph node recurrence.

Conclusion: Lymphatic involvement is the most frequent manifestation of recurrent disease in cervical carcinoma after treatment. There are three lymphatic pathways of spread of cervical carcinoma: external iliac nodes, internal iliac nodes and sacral nodes. All them converge at common iliac nodes and finally the tumor can arrive at paraaortic nodes. Pelvic radiation therapy includes only some of these nodal groups, and this results in a peculiar distribution of nodal recurrent that, definitively, "skip" radiated nodal levels. Radiologists and clinicians must become aware of the fact that the most frequent lymph node recurrence in patients with cervical cancer treated with pelvic radiation therapy occurs in extrapelvic lymph nodes and, as this way, far of primary tumor.

C-0434

Transvaginal sonography in postmenopausal bleeding. Sonographic findings in 200 cases. Endometrial carcinoma patterns

J. Morales Olaya, D. Dualde, T. Labrador, J. Cervera; Valencia/ES

Learning Objectives: To evaluate the utility of transvaginal ultrasound (TVS) in the diagnosis of postmenopausal bleeding.

Background: Prospective study of 200 women referred with abnormal vaginal bleeding. Mean age: 57.9 years. The period of amenorrhea surpassed one year in every case. The definitive diagnosis was established by means of hysteroscopy with or without biopsy. In cases of endometrial cancer TVS findings were compared with those obtained in the specimen after hysterectomy to evaluate the accuracy in determining the presence and the depth of myometrial invasion.

Imaging Findings: Endometrial atrophy: 98 patients (49%). Proliferative endometrium: 11 (5.5%). Endometrial hyperplasia: 37 (18.5%). Endometrial polyps: 32 (16%). Endometrial carcinoma: 22 (11%). 95.9% women with endometrial atrophy show an endometrial thickness less than 6 mm. Endometrial carcinoma pattern: endometrial thickness of over 6 mm (95.4%) (mean of 20.6 mm). Poorly defined margins (62.2%) heterogeneity (68.9%) and echogenicity (88.9%). 60% of cases presented myometrial invasion. The sensitivity of TVS in detecting deep invasion (more than 50% of the myometrial thickness) was 94.1%; specificity of 84.8%. Overall accuracy: 88%. Cervix was involved in 26.6%. The criteria to rule out a significant alteration was to consider 6 mm for normal endometrial thickness: Sensitivity: 95%. Specificity: 84%. Diagnostic safety: 90%.

Conclusion: We confirmed the value of TVS as the first test in postmenopausal vaginal bleeding, in ruling out significant disease when the endometrial thickness is less than 6 mm, avoiding more aggressive and costly tests.

C-0435

Prevalence of ovarian adrenal rest tumours and polycystic ovaries in females with congenital adrenal hyperplasia: Results of ultrasonography and MR imaging

H.M. Suliman¹, N.M.M.L. Stikkelbroeck², D.D.M. Braat², G.J. Jager², B.J. Otten²; ¹Amsterdam/NL, ²Nijmegen/NL

Purpose: The aim of the investigation was to assess the prevalence of ovarian adrenal rest tumours and polycystic ovaries in female patients with congenital adrenal hyperplasia (CAH).

Materials and Methods: Thirteen female CAH patients (median age 19.8 years, range 14.8-23.5 years) underwent transvaginal (n = 6) or transabdominal (n = 7) ultrasonography by a gynaecologist and MR imaging (n = 13) of the ovaries pre and post contrast-enhanced T1-and T2-weighted images.(Table.1). Ovarian adrenal rest tumours were defined as small hypoechoic and multifocal nodules on

Scientific and Educational Exhibits

ultrasound and iso-intense lesions on T1-and hypointense on T2-weighted MR images (derived from characteristics of testicular adrenal rest tumours). Polycystic ovaries were defined as the presence of > 10 follicles arranged peripherally around or scattered throughout increased stroma.

Results: No ovarian adrenal rest tumours were found either on ultrasound, or by MR imaging. Polycystic ovaries were found in 2 of the 13 patients (15.4%), both with ultrasound and MR (Fig.1). No ovarian adrenal rest tumours were detected in these female CAH patients, which suggests that ovarian adrenal rest tumours in CAH females are rare. The prevalence of polycystic ovaries corresponded to that in the general population.

Conclusion: From these results, we would suggest that routine ovarian imaging in CAH females is not indicated. However, when ovarian dysfunction is present, ovarian imaging is advised, first by ultrasonography, to detect ovarian adrenal rest tumours or polycystic ovaries.

C-0436

Pitfalls in MR imaging staging of carcinoma of the cervix

J.L. Hughes, A. Saddev, A. Rockall, R. Reznek; London/UK

Learning Objectives: 1.) To appreciate potential mistakes and pitfalls in the use and interpretation of MR imaging in the staging of cervical cancer. 2.) To learn strategies and techniques to avoid these potential errors.

Background: In patients with carcinoma of the cervix, accurate preoperative staging is key to determining management. MR imaging has gained wide acceptance for the staging of cervical cancer particularly in the detection of early parametrial invasion and nodal disease. Nevertheless the accuracy of the technique varies.

Procedure Details: We will present a range of pitfalls in the detection of the primary tumour and of parametrial spread including technical inadequacy, anatomical variants, confusion caused by co-existent disease and the effects of previous intervention. The limitations in sensitivity and specificity for detection of lymph node metastases are well known. We will however illustrate pitfalls in the identification of nodal metastases in the female pelvis such as confusion with physiological ovarian appearances.

Conclusion: Appreciation of pitfalls in the interpretation of MR imaging in cervical cancer can aid accurate diagnosis.

C-0437

MR imaging as an important tool in differentiating uterine adenomyosis from leiomyomas: A pictorial review

L. Chandratreya, S. Armstrong; Bristol/UK

Learning Objectives: MR imaging is an important imaging modality in the differentiation of adenomyosis and leiomyomas of the uterus, which are relatively common, but benign, myometrial conditions. We present a pictorial review of the MR imaging features distinguishing them.

Background: Adenomyosis is characterised by the invasion of the myometrium by endometrial tissue and hyperplasia of adjacent smooth muscle. Leiomyomas are well-circumscribed myometrial benign tumours containing mainly smooth muscle with some fibrous connective tissue. Adenomyosis is commonly a diffuse abnormality, or maybe focal as an adenomyoma. Presenting symptoms are similar.

Imaging Features: Sonographically adenomyosis may resemble leiomyoma, especially focal adenomyoma. MR imaging has a higher sensitivity and specificity in the differentiation of uterine adenomyosis from leiomyomas as compared to transvaginal ultrasound and this maybe due to better contrast and spatial resolution of MR imaging. The most pertinent feature of adenomyosis on T2 weighted MR imaging images is the widening of the junctional zone (JZ) and thickness of JZ over 12 mm is of high diagnostic accuracy. T2 weighted images also show areas of high intensity. Other features include myometrial nodules and cysts, linear striations and poor definition of the endomyometrial junction. Leiomyomas appear as well defined masses of low signal on T2 weighted images, which may enhance post Gadolinium. Appearances of degenerated leiomyomas vary.

Conclusion: The correct diagnosis is extremely important as the definitive treatment for adenomyosis is hysterectomy; whereas myomectomy can be performed for leiomyoma. MR imaging accurately detects leiomyomas and is useful in assessing the degree of myometrial penetration in adenomyosis.

C-0438

Magnetic resonance imaging in the characterization of ovarian masses

A.C. Tsili, C. Tsampoulas, F. Katzioti, E. Arkoumani, S. Tzioras, C. Mpougias, E. Paraskevaidis, S.C. Efremidis; Ioannina/GR

Learning Objectives: To describe the MR imaging features allowing differentiation between benign and malignant ovarian masses.

Background: Ovarian cancer accounts for nearly 4% of all cancer cases and it causes more deaths than any other cancer of the female reproductive system. The pretreatment characterization of ovarian masses is of outmost importance, since it can provide a basis for optimal preoperative planning, in cases of ovarian cancer. It can also reduce the number of unnecessary laparotomies in patients with benign disease. MR imaging has been shown to be useful in the characterization of ovarian masses.

Procedure Details: Sequences used were T1, T2 and fat-suppressed T1-weighted, before and after intravenous administration of gadolinium chelate. MR imaging due to its superb contrast resolution and its usefulness in tissue characterization, could accurately diagnose mature cystic teratomas, endometriomas or hemorrhagic cysts and tumors containing fibrosis or smooth muscle, in the majority of cases. The presence of entirely cystic lesions, with size less than 4 cm and wall or septal thickness less than 3 mm, were more suggestive of benignity. The presence of cystic lesions with wall or septal thickness more than 3 mm, with papillary projections, and the presence of solid components, with necrosis, all were suggestive of malignancy. The presence of lymphadenopathy, ascites and peritoneal metastasis were findings confirming malignancy.

Conclusion: MR imaging is a highly accurate technique in the differentiation between benign and malignant ovarian masses.

C-0439

Quantitative evaluation of ovarian tumors using Gd-dynamic contrast-enhanced MR imaging

K. Hayasaka, T. Saitoh, Y. Tanaka; Tokyo/JP

Objective: To conduct quantitative evaluation of ovarian tumors using Gd-dynamic contrast-enhanced MR imaging.

Materials and Methods: 78 ovarian tumors underwent Gd-enhanced dynamic MR imaging with a Siemens Magnetom Vision 1.5 T using 3D-FLASH (20 s) before and three times (30, 50, and 70 s) after a standardized bolus of Gd-DTPA. For quantitative MR imaging parameters, the following were examined by a consensus of two radiologists: ER (enhancement ratio) 1: (SI1-SI0)/SI0, ER2: (SI2-SI0)/SI0, ER3: (SI3-SI0)/SI0, ER2-1: ER2-ER1, and SAT: SI1/SI max. Analysis of variance was used to identify significant differences in quantitative parameters among ovarian tumors.

Results: The tumors were specified as benign [endometriosis (EM): 13, serous cystadenoma (SCA), fibrothecoma (FT): 2, mucinous cystadenoma (MCA), dermoid cyst (DC), cyst (CY): 7, other: 2], borderline: 2 and malignant group [serous cystadenocarcinoma (SCAC): 5, mucinous cystadenocarcinoma (MCAC): 12, clear cell carcinoma (CCC), endometrioid carcinoma (EMC): 7, immature teratoma (IMT): 2, other: 3]. In these ovarian tumors, there were statistically significant differences in various parameters between the following tumors ($p < 0.05$): benign vs malignancy (ER2, ER3, ER2-1, and ER3-1), CY vs. FT, FT vs. MCA, CY vs. EMC, EMC vs. FT, CCC vs. CY and MCA vs. SCAC (ER2-1, ER3-1), CCC vs. EM (ER1, ER2, ER3, ER2-1, ER3-1), CCC vs. MCA (ER3, ER2-1, ER3-1), DC vs. EMC, EM vs. SCAC and EMC vs. EM (ER2, ER3, ER2-1, ER3-1).

Conclusion: Analysis of various parameters using Gd-enhanced dynamic MR imaging with 3D FLASH technique was useful to determine the characteristics of ovarian tumors. Among various parameters analyzed, ER2-1 and ER3-1 were useful for differential diagnosis.

C-0440

Ancient schwannoma of the female pelvis: Radiologic-pathologic correlation

M. Takeuchi, K. Matsuzaki, H. Uehara, H. Nishitani; Tokushima/JP

Learning Objectives: To demonstrate characteristic imaging findings of ancient schwannoma in female pelvis with pathologic correlation based on ten patients. To describe the diagnostic clues of ancient schwannoma to differentiate from ovarian neoplasm.

Background: Schwannoma is a benign nerve sheath tumor which usually occur in the soft tissues of the head and neck and extremities. When the tumors are located in deep structures such as the mediastinum and the retroperitoneum, those tend to be larger masses with degenerative changes as ancient schwannoma. The majority of female pelvic masses arise from internal genital organs, but gastrointestinal, mesenteric, urinary, and primary extraperitoneal tumors also occur and may mimic gynecologic neoplasms. Especially masses with cystic nature may closely resemble ovarian neoplasm. Primary extraperitoneal neoplasms are rare and comprise various histologic origins. In the tumors, ancient schwannomas may tend to be mistaken for ovarian disease clinically, because the patients are usually asymptomatic and ultrasonography reveals as cystic masses.

Imaging Findings: On CT and MR imaging, centripetal displacement of the rec-

Scientific and Educational Exhibits

tum, the iliac vessels or the iliopsoas muscle are characteristic findings for its extraperitoneal origin and helpful to rule out ovarian disease. The characteristic location (presacral) is suggestive and detecting continuity to the nerve or neural foramen is diagnostic. Demonstration of formation of capsule, partial or total cystic degeneration and hemorrhagic change on MR imaging and calcification on CT reflected its pathologic features and suggestive of ancient schwannoma.

Conclusion: Diagnosis of ancient schwannoma mimicking ovarian neoplasm before surgical treatment is important for postoperative neurological difficulties often develop.

C-0441

The diverse ultrasonographic appearances of ectopic pregnancies: A pictorial review

S. Lam; Singapore/SG

Learning Objective: To review the ultrasonographic findings in ectopic pregnancies via illustrated examples.

Procedure Details: The ultrasonographic findings of ectopic gestations were retrospectively reviewed in a local women's hospital over a five year period.

Findings: The ultrasonographic findings depend largely on the different sites of implantations. An empty or near empty uterus with an intracavitory pseudosac or decidual cast is sometimes identified. Echogenic pelvic fluid suggests haemoperitoneum. A ring adnexal mass is considered the most predictive ultrasonographic finding. Associated risk factors (e.g. hydrosalpinx) may be detected adjacent to the ectopic gestation. A non specific adnexal mass due to haematoma surrounding the ectopic gestation and the ovary is sometimes seen. An adnexal mass containing a viable embryo is the only definitive diagnosis of an ectopic gestation. In interstitial ectopic pregnancy, the gestational sac bulges the cornua, thins the surrounding myometrium and disrupts the endometrium (interstitial line sign). In cervical pregnancy, the implantation causes cervical dilatation, giving an hourglass configuration. Peritrophoblastic blood flow can be identified on colour Doppler ultrasonography. Heterotopic pregnancies are very rare with both an intrauterine pregnancy and an ectopic gestation. This is seen in increasing frequency with assisted reproduction. A completely normal pelvic ultrasonogram may be present in up to 20% of patients.

Conclusion: Understanding that ectopic gestations can present in various forms can lead to an earlier diagnosis, reducing morbidity and mortality. Ultrasonography is widely available and remains the imaging modality of choice.

C-0442

Endometriosis or dermoid: Diagnostic dilemmas

S.A. Babar, E.K. Hughes, R. Willimason; London/UK

Purpose: To present the various diagnostic difficulties in MR imaging appearances of endometriomas versus dermoids and to determine the presence of associated pathology in these conditions.

Methods and Materials: We retrospectively reviewed 40 histopathologically confirmed cases of endometriomas and dermoids. MR scans were reviewed by two experienced radiologists to determine the cases with diagnostic difficulties. MR signal characteristics were identified in all cases and overlap in various imaging features determined. Our standard pelvic MR sequences include Coronal T1W, Sagittal and axial T2W and Coronal STIR. Fat saturation was used in some cases as a problem solving sequence.

Results: Of the total of 40 patients, we identified 16 (40%) cases with features resulting in some interpretative difficulty. This was seen in the form of signal loss on STIR sequence in endometriomas, various signal alterations of the blood products and the presence of various associated benign and malignant conditions. These associated conditions were seen in 5/16 (31.2%) cases of dermoids and 7/16 (43%) of endometriomas, which included adenomyosis, clear cell carcinoma, endometrial carcinoma and epithelioid angioma.

Conclusion: Although differentiation of endometriomas from dermoids should be straight forward this is not always the case. Use of fat saturation in addition to STIR can be used as extra sequence for problematic cases.

Genitourinary

Kidney

C-0443

An algorithm-based system to facilitate the sonographic diagnosis of renal disease: A DVD-Rom teaching file with US image and video database

P.S. Zoumpoulis, I. Theotokas, K. Pahou, D. Dalakostas, D. Schizas, V. Koratzinos, A. Filippidou, S. Kyriazi; Athens/GR

Learning Objectives: - To review the sonographic features of diffuse and focal renal diseases. - To provide a simple algorithm toward an accurate differential diagnosis. - To compare individual US images to image galleries of diagnostically confirmed cases.

Background: The purpose of this DVD-Rom is to promote accurate characterization of diffuse and focal renal lesions combining morphologic and hemodynamic criteria.

Procedure Details: The user can start using this teaching file by describing the US characteristics of a focal renal lesion that he has difficulty in diagnosing. The user designates the sonographic features of a specific renal lesion (echogenicity, border echogenicity, vascularity). The system guides him through a specific algorithm of all possible renal lesions that fit the characterization given. A large collection of classified US images and videos in each diagnostic category are available for comparison with the user's images. The user's image can also be linked to the contents of corresponding interesting cases, which are brief case reports with clinical, biochemical, imaging and pathological data. To outline the profile of each diagnostic category concise case reports are presented, correlating imaging findings with clinical, biochemical and histological data. This teaching file applies a dual approach to the differential diagnosis of renal disease, whereby a computer-based algorithm is complemented by the user's active and comparative assessment.

Conclusion: The user can be aided in the differential diagnosis of renal lesions by comparing his image to other "similar" sonographic images, which are available in galleries, videos and interesting cases.

C-0444

Renal perfusion abnormalities: Findings with multislice CT (MSCT)

A. Nunziata, O. Catalano, P. Mainenti, M. Salvatore, A. Siani; Naples/IT

Learning objective: To illustrate the MSCT findings in the wide spectrum of renal perfusion abnormalities. To show the practical value of MSCT findings in differential diagnosis of renal perfusion changes. To highlight the value of reformed, angiographic, and tridimensional MSCT images in this clinical setting.

Background: MSCT can recognise a wide spectrum of renal perfusion defects and abnormalities. In common clinical practice there is an overlap between different clinical scenarios capable of determining changes in the normal CT nephrogram.

Procedure Details: We illustrate several cases of renal perfusion defects, as seen on cortical, cortico-medullary, and/or excretory phase scans. These defects are segmental, multisegmental, total, or diffuse (non uniformly distributed) and can be unilateral or bilateral. Causes include dissection of abdominal aorta (so called malperfusion syndrome) hypovolemic/cardiogenic shock, avulsion or obstruction of arterial pedicle (blunt trauma, spontaneous thrombosis, aortic prosthesis placement or surgery, interventional renal procedures), severe stenosis of renal artery (atherosclerosis, neoplastic infiltration, or compression), acute urinary tract obstruction (ureterolithiasis).

Conclusion: MSCT transaxial and reformatted images have several applications in renal perfusion changes assessment. Knowledge of causes, related patterns, and clues to diagnosis allows proper categorization of these abnormalities.

C-0445

PCNL by numbers: A 7-year analysis of percutaneous nephrolithotomy in practice

C.P. Meehan, N. Gough, P.A. McCarthy; Galway/IE

Background: Percutaneous Nephrolithotomy is now an established string in the bow of the uroradiologist. In experienced hands and through careful patient selection, success rates above 90% can be achieved with minor complications. As this technique matures, innovative modifications promise to increase the variety of treatable calculi. We have reviewed our practice of PCNL.

Methods and Materials: We have undertaken a 7-year retrospective analysis of Percutaneous Nephrolithotomy practice at a university teaching hospital serving both rural and urban populations. A MS-Access database was compiled detailing

Scientific and Educational Exhibits

95 cases, performed between 1997 and 2004. Demographic data, clinical indications, indices of success, calculus characteristics and complications were compiled.

Results: 95 cases were documented involving 74 patients. Mean age was 49 years with slight female preponderance ($n = 55$). The majority of cases ($n = 56$) were idiopathic. Otherwise, PUJ obstruction ($n = 7$), ureteric stricture ($n = 3$) and patients post-urinary diversion surgery ($n = 3$) were predominant. The remainder ($n = 5$) comprised congenital structural malformation or metabolic derangements. 42 procedures were right sided. Of 112 calculi described, over half ($n = 60$) were located in either renal pelvis or lower pole. Successful retrieval, per initial objectives, was achieved in 80/95 cases, 67 being largely stone free or better post-PCNL. Complications were recorded in 14 cases, chiefly related to stone access, none proving serious.

Conclusions: PCNL is a well tolerated procedure with success rates up to and beyond 90% a realistic target. Lower pole calculi are especially amenable to retrieval. As experience continues to grow, further modifications will broaden the range of patients who may benefit.

C-0446

Renal tumours: Technical success and early clinical experience with radio-frequency ablation of 18 tumours

P. Vladica, R. Sabharwal; Sydney/AU

Purpose: To evaluate the safety and technical efficacy of image-guided radiofrequency ablation (RFA) for the treatment of small peripheral renal tumours and to report our early results with this treatment modality.

Materials and Methods: Thirteen RFA sessions for eighteen tumours were performed in eleven patients with renal tumours. Indications included coexistent morbidity, high surgical or anaesthetic risk, solitary kidney, and hereditary predisposition to renal cell carcinoma. Ten patients had CT-guided percutaneous RFA performed on an outpatient basis. One patient had open intra-operative ultrasound-guided RFA. Technical success was defined as elimination of areas that enhanced at imaging within the entire tumour. With the exception of one patient with renal insufficiency requiring a non-contrast enhanced CT, remaining patients underwent contrast enhanced CT for post treatment follow-up assessment. Follow up was performed after two to four weeks and then at three, six, twelve months, and every twelve months thereafter.

Results: Fourteen (78%) of eighteen tumours were successfully ablated with one treatment session. Three of the remaining four tumours required two treatment sessions for successful ablation. One tumour will require a third treatment session for areas of persistent enhancement. Mean patient age was 72.82 ± 10.43 years. Mean tumour size was 1.95 ± 0.79 cm. Mean follow-up time was 8.18 months. All procedures were performed without any major complications.

Conclusion: Percutaneous radiofrequency ablation of small renal tumours is well tolerated and minimally invasive. Our early experience with RFA demonstrates it to be a feasible, safe and effective treatment of small peripheral renal tumours.

C-0447

Cross-sectional imaging in the renal trauma: A trauma center experience

G. Regine, M. Atzori, V. Buffa, M. Galluzzo, V. Miele, L. Adami; Rome/IT

Purpose: To evaluate diagnostic accuracy of cross sectional imaging (ultrasound, ultrasound contrast agent, MDCT) in patients with renal trauma.

Material and Methods: Between September 2003 and August 2004, 265 patients, with abdominal blunt trauma, were evaluated. 25/265 showed renal lesions, the severity of renal injury was graded by the American Association for the Surgery of Trauma Organ Injury Severity Scale. All patients with hematuria (63) were evaluated with baseline ultrasound, after II generation (Sonovue) ultrasound contrast agent injection and multiphasic MDCT scan, integrated with vascular 3D reconstruction.

Results: 5/25 traumatic parenchymal lesions with perirenal fluid collection were identified at ultrasound baseline. 25/25 renal parenchymal lesions, with or without perirenal or retroperitoneal hematoma, were identified at contrast agent ultrasound. The MDCT multiphasic confirmed all positive cases at Ultrasound Contrast Agent, and moreover rated the lesions' grade, particularly the IV and V using 3D reconstruction in the vascular peduncle evaluation, the urinary excretory system lesion with urine leak was identified at delay phase scan integrated with MIP and V.R. reconstruction.

Conclusions: Our experience confirmed the diagnostic accuracy of the cross-sectional imaging both for correct diagnosis and for correct patient management. Specifically in our study we have noted the possibility of performing follow-up examination of renal lesions using ultrasound contrast agent which also reduces exposure to radiation (less MDCT examinations).

C-0448

Local staging in RCC: Is perinephric stranding and increased perirenal vascularity really helpful?

N. Kabakci, M. Secil, B. Tuna, A. Kefi, K. Yorukoglu, E. Igci, O. Dicle; Izmir/TR

Purpose: Preoperative staging of renal cell carcinoma has gained more importance after new techniques of nephron-sparing surgery. In this study, the aim was to investigate the accuracy of perinephric stranding and perirenal increased vascularity findings revealed by magnetic resonance imaging (MRI) in perinephric fat invasion.

Methods and Materials: The preoperative MR images of 40 patients who have received the diagnosis of RCC were retrospectively evaluated. MR examinations were performed by 1.5 T scanner (Gyroscan Intera, Philips, Netherlands) with fat-saturated TSE T2, WATS T1 and contrast-enhanced WATS T1 sequences. The patients who had renal vein thrombosis radiologically or pathologically were excluded from the study. Perinephric stranding and increased perirenal vascularity findings were investigated in the remaining 24 patients. The existence of this finding in any of the sequences was accepted to be positive for perirenal fat invasion. The RCCs were histopathologically staged according to the 1997 TNM classification. The results were compared with the pathological stages.

Results: Nineteen of 24 patients were pathologically stage 1; 3 were stage 2 and 2 were stage 3a. Perinephric stranding was seen in 14 of the 24 masses and perirenal increased vascularity was seen in 17 patients. These findings were not statistically consistent with stage 3a RCC.

Conclusion: Perinephric standing or perirenal increased vascularity findings do not reflect perirenal fat invasion in RCCs.

C-0450

Amyloid: Radiological manifestations from head to toe

S.P. Prabhu, K. Burney, A. Valencia; Bristol/UK

Learning Objectives: 1. To illustrate a few examples of biopsy-proven or post-mortem confirmed cases of amyloidosis seen on radiological investigations in our institutions over the last 10 years. 2. To demonstrate that radiological findings in amyloidosis are extremely variable and diverse

Background: Amyloidosis is a collective term for a group of diseases that are characterized by the widespread extracellular deposition of insoluble amyloid protein. The process is usually systemic, but localized forms are recognized.

Imaging Findings: We illustrate examples of biopsy-proven or post-mortem confirmed cases of amyloidosis seen on radiological investigations in our institutions over the last 10 years with radiologic-pathologic correlation. The usual sites of involvement in primary amyloidosis are kidneys, heart, lungs, gastrointestinal tract and skin, while the usual sites in secondary amyloidosis are kidneys, liver, spleen and adrenal glands. The focal form has been described in a number of entities including orbit, nasopharynx, larynx and tracheobronchial tree. Clinical manifestations are varied and are a result of organ dysfunction secondary to amyloid protein accumulation. Secondary causes include myeloma, solid malignancies, and chronic inflammatory conditions such as rheumatoid arthritis and tuberculosis.

Conclusion: Radiological findings in amyloidosis are extremely variable and diverse. It must be considered in the differential diagnosis in areas illustrated to enable appropriate patient management.

C-0451

Renal carcinoma: Therapeutic management with radiofrequency thermal ablation (RFA) under CT-guidance

L. Thanos, S. Mylona, M. Pomoni, A. Kokkinaki, E. Karahaliou, N. Batakis; Athens/GR

Purpose: To present the technique, the effectiveness and the possible complications of RFA in renal carcinoma.

Materials and Methods: In the last two years we applied RFA under CT-guidance on 49 patients with renal cancer. Thirty ablations were followed by surgical resection (24 nephrectomies and 6 tumor resections). Twelve patients were not candidates for surgery due to cardiorespiratory problems and seven patients had a recurrent tumor. We used RITA and MIRRAS generators with two different types of electrodes (hooked and spiral). The ablation lasted 15-18 minutes. The procedure was applied after analgesic treatment and local anaesthesia at the inlet. Follow-up with two-phase spiral CT after IV administration was made immediately after the procedure and 1, 6 and 12 months later.

Scientific and Educational Exhibits

Results: The histopathologic results in operated tumours were total necrosis in 28 and partial in 2. From the patients who underwent only RF ablation, we observed total necrosis in 13 tumours and partial necrosis in 6 (we proceeded to a second session). We had no complications. The 1- and 2-year survival was 100% and 91.83% respectively.

Conclusion: Radiofrequency thermal ablation is a safe and effective alternative method for the treatment of renal carcinoma.

C-0452

Comparison of tissue harmonic imaging with standard ultrasound mode, in the evaluation of the kidneys

M. Chalkia, I. Kirimlidis, A. Spanos, A. Papageorgiou, S. Spanidou, N. Vougiouklis; *Thessaloniki/GR*

Purpose: Our purpose is to compare tissue harmonic imaging (THI) with conventional ultrasonography (CU), regarding image quality and organ visualization during renal ultrasound examination.

Methods and Materials: 125 different kidneys were evaluated with both conventional ultrasonography and tissue harmonic imaging. Two experienced radiologists, blind the mode used and blind to each other, rated each image pair for resolution, detail and total image quality. The images were evaluated as: (1) insufficient, (2) good and (3) very good.

Results: Both the examiners considered the TH images very good in 34.4%, good in 45.6% and insufficient in 20% of the cases, while they considered the CU images very good in 15.6%, good in 49.2% and insufficient in 35.2% of them. More specifically, regarding imaging of renal cysts, the examiners considered the TH images very good in 38.39%, good in 45.53% and insufficient in 16.07% of the cases, while they considered the CU images, very good in 16.07%, good in 44.64% and insufficient in 39.28% of them. Regarding imaging of renal stones and nephroblastosis, THI shows superiority, since it was considered very good in 33.33% and good in 47.22% of the cases, while CU images were considered very good in only 5.5% and good in 38.88% of them. In imaging renal parenchyma THI shows a less distinct superiority, since it was considered very good in 29.76% and good in 45.23% of the cases.

Conclusion: THI proved to be superior than CU, regarding image quality and organ visualization in the evaluation of the kidneys.

C-0453

Laparoscopic cryoablation (LC) of small renal masses: Postoperative complications evaluation by magnetic resonance imaging (MRI)

G. Cardone, C. Iacobino, A. Cestari, L. Nava, P. Mangili, G. Balconi, G. Guazzoni; *Milan/IT*

Learning Objectives: To report the spectrum of post-operative complications in patients treated with laparoscopic renal cryoablation. To illustrate the MR findings of post-operative complications in patients treated with laparoscopic renal cryoablation.

Background: Laparoscopic renal cryoablation is a minimally invasive surgical technique for patients with small renal masses. MR is an effective tool for imaging follow-up of renal lesions treated with laparoscopic cryoablation.

Imaging Findings: 41 pts underwent LC of 43 renal masses. Patients were followed up clinically, biochemically and by MRI 24 hrs after surgery, and subsequently at 1, 3, 6, 12, 18, 24 and 36 months (mean 18). After surgery retroperitoneal and pleural effusions were found in all cases. Early post-procedure MR images showed incomplete ischemia of cryolesions in 10% of the cases, with small intraleisonal enhancement which afterwards disappeared in the following months. 21% of the cases showed a small intraleisonal haematoma which afterwards reabsorbed in the following months. In 11% of the cases a small perilesional haematoma was evident at 1 and 3 months after surgery, probably due to blood clot dissolution. No significant rise in creatinine was noted post-procedurally.

Conclusions: Our experience suggests that laparoscopic cryoablation is a safe, well tolerated and minimally invasive therapy for small renal masses, and MR is an effective imaging technique in the follow-up of renal lesions treated with laparoscopic cryoablation.

C-0454

Renal lesions treated with laparoscopic cryoablation (LC): Multi-detector row computed tomography (MDCT) imaging patterns

G. Cardone, D. Fiechi, A. Cestari, G. Guazzoni, P. Mangili, G. Balconi; *Milan/IT*

Learning Objectives: To report the spectrum of MDCT findings of renal lesions treated with LC. To show the evolution, as time passed, of the CT patterns of

renal lesions treated with LC. To illustrate the more significant MDCT criteria of absence of recurrence in the follow-up of renal masses treated with LC.

Background: Laparoscopic renal cryoablation is a minimally invasive surgical technique for patients with small renal masses. MR is an effective tool for imaging follow-up of renal lesions treated with LC, but in some cases CT can be a constrained choice.

Imaging Findings: 10 pts with 11 renal masses underwent renal LC. All patients underwent MDCT follow-up 24 hrs after surgery, and at 1, 3, 6 and 12 months. MDCT examinations were performed using unenhanced and post-contrast axial scans, associated to multiplanar reconstructions. Cryolesions were iso-dense on pre-contrast and hypo-dense on post-contrast images. 24 hrs after treatment all cryolesions were more than 1 cm larger than the original masses; cryolesions decreased in size of an average of 35%, 45%, 60% and 80% at 1, 3, 6 and 12 months respectively. Post-contrast MDCT images showed complete ischemia of cryolesions in all the cases. 50% of the cases showed a perinephric haematoma at 1, 3 and 6 months.

Conclusions: The more significant MDCT patterns in the follow-up of renal lesions treated with LC were the decrease in size as time passed and the complete ischemia of the cryolesions.

C-0455

Multislice CT (MSCT) features of renal and pelvic lesions: A pictorial review

P. Domínguez Echávarri, D. Cano Rafart, G. Bastarrica Aleman, J. Larrache Latasa, I. Vivas Perez, I. Gonzalez Crespo; *Pamplona/ES*

Learning Objectives: To review the MSCT appearance of renal and pelvic masses, benign and malignant. To illustrate MSCT features of local and advanced renal malignancy for staging purposes.

Background: Renal masses, cystic or solid represent a wide spectrum of diseases and constitute a common finding in radiological exams. MSCT is a valuable tool to characterise undetermined renal masses found after other diagnostic techniques, such as ultrasound. Furthermore, in many cases MSCT is the only imaging technique performed prior to surgery, and is the investigation of choice to stage renal carcinoma. MSCT renal imaging allows not only differentiation between benign and malignant lesions but also allows accurate delineation of the extent of the disease with multiphasic studies and high quality Multiplanar Reformations (MPR) and Maximum Intensity Projection (MIP).

Imaging Findings: We review and outline the most specific MSCT features of renal benign and malignant lesions including simple and complicated cysts, angiomyolipoma, adenoma, oncocytoma, cystic tumours, lymphoma, renal cell carcinoma, renal sarcoma, metastases and tumors of the renal pelvis.

Conclusion: MSCT is the technique of election to detect and characterise most renal masses, differentiating benign from malignant lesions. CT findings usually lead to an accurate diagnosis, allowing tumour staging in malignant tumours and adding precise anatomic information prior to surgery

C-0456

Angiogenesis assessment in renal cell carcinoma by echocontrast-enhanced power Doppler ultrasound

N. Kabakci, E. Igci, M. Seçil, U. Mungan, I. Celebi, Z. Kirkali, K. Yorukoglu, O. Dicle; *Izmir/TR*

Purpose: Tumoral growth is angiogenesis-dependent. Even if there are studies about the importance of histopathological angiogenesis in various malignancies, the assessment of the angiogenesis by radiological techniques, which is more practical to perform, is not well established. The aim in this study is to assess the efficiency of echocontrast-enhanced power Doppler ultrasound (PDUS) in determining the angiogenic status of RCC.

Materials and Methods: PDUS were performed before and after intravenous administration of the echocontrast agent, Levovist, in 43 renal lesions. The images were recorded in PACS. Twenty-one of these renal masses were diagnosed as RCC histopathologically. The images were analyzed by Photoshop 7.0 (Adobe Systems, San Jose, California), colored pixel ratios (CPR) of selected images were calculated using the ratio of the number of pixels showing power Doppler signals to the total number of pixels within the lesion. The results were compared with the histopathologic microvessel density (MVD), which is done by Chalkley method.

Results: A significant correlation was found between CPR and MVD values in both PDUS techniques. The use of echocontrast agent improved this correlation and p values (Spearman from $p = 0.436$ to 0.551 and from $p = 0.05$ to 0.01).

Conclusion: CPR values reflect the MVD in RCCs. Therefore, these results suggest that preoperative quantification of angiogenesis and therapy monitoring of antiangiogenetic agents could be possible by the help of PDUS in RCCs.

Scientific and Educational Exhibits

C-0457

Comparison of US and KUB for detecting renal calculi with nonenhanced multislice CT

K. Subramanian, A.K. Jain; Manchester/UK

Purpose: To compare the sensitivity and specificity of ultrasound (US) and plain radiograph abdomen (KUB) for detecting renal calculi with nonenhanced Multi-slice CT (NMSCT) as a reference standard. To compare their sensitivity in detection of calculi of different size.

Materials and Methods: US, KUB and NMSCT examinations of 42 consecutive patients presenting with renal colic and haematuria were compared retrospectively for detection of renal calculi. Their case notes, films and radiology reports were reviewed. Statistical analysis was performed using SPSS software.

Results: 21 male and 21 female patients with mean age of 51.8 years (range 21-78 years) were studied. US sensitivity was 68% with specificity of 50% (PPV 74%). However, the specificity for sonographers was 40% (62% for radiologists). KUBs sensitivity was 39% but specificity 100%. US sensitivity was 11% for calculi < 3 mm; 86% for 3-5 mm and 86% for > 5 mm. KUB sensitivity was 0% for < 5 mm and 68% for > 5 mm.

Conclusions: In comparison with previous studies, US sensitivity is comparable for calculi > 3 mm, but is low for < 3 mm. Furthermore, US specificity (50% vs. 90-95%) is poor. Commonest causes of false positive scans were misinterpretation of < 3 mm vascular, parenchymal calcification as intracalceal calculi. Focussed training in this regard could improve specificity. US is of limited value in assessing post-lithotripsy calculus burden (only 11% sensitivity for calculi < 3 mm). Such patients could be followed by NMSCT. With calculi > 5 mm, the specificity of KUB is very high, hence, KUB can be used to follow-up this group.

C-0458

Pictorial review of renal transplant imaging and complications

P. Rajiah, Y. Lim, N. Thomas; Manchester/UK

Learning Objectives: A. To illustrate the role and limitations of imaging in renal transplant recipients. B. To understand the normal ultrasound and Doppler appearances of renal transplant. C. To learn the imaging spectrum of pathological conditions affecting the renal transplant and the complications of immunosuppression. To demonstrate the role of interventional radiology in management of complications.

Background: The management of end stage renal disease has been revolutionized with the advent of renal transplantation, which offers good quality of life with low morbidity. The survival rates are very good due to excellent immunosuppressants. Imaging plays an important role in diagnosis and management of the complications arising in the renal transplant.

Imaging Findings: Ultrasound, Doppler and nuclear medicine are the main imaging modalities used in renal transplant recipients. CT scan, MR imaging and angiography are used in indeterminate cases. The various pathologies demonstrated in our pictorial review include rejection, ATN, Cyclosporine toxicity, infection, lymphocele, urinoma, haematoma, abscess, renal arterial stenosis, renal vein thrombosis, AV fistula and obstruction. Opportunistic infections and post transplant lymphoproliferative disorder are the complications of immunosuppression.

Conclusion: Ultrasound, Doppler, CT scan, nuclear medicine and MR imaging are vital investigations in diagnosing the complications of renal transplantation. Imaging guided interventional procedures are crucial in the management of complications such as collections, obstruction and vascular lesions.

C-0459

MR evaluation of renal cell carcinoma: Comprehensive protocol for determining venous extension

O. Mathieu, C. de Bazelaire, A.-M. Zagdanski, P. Bourrier, M. Albiter, J. Frija, E. de Kerviler; Paris/FR

Learning Objectives: To analyze renal and cava vena extension of renal cell carcinoma in MR imaging. A comprehensive protocol was performed using a black blood sequence (HASTE), a white blood sequence (TrueFISP), and a contrast-enhanced 3D T1-weighted sequence (VIBE).

Background: Preoperative staging of renal carcinoma relies on multi-slice CT. However, in patients in whom iodine injection is contraindicated, MR imaging becomes the method of choice for determining local tumour spread. Venous invasions represent one of main surgical concerns as it may lead to different surgical approaches. However, because of slowly flowing protons and numerous anatomical variants, MR examination of renal and cava veins could be tricky. The aim of this exhibit was to highlight specific advantages of 3 sequences based on dramatically different physics principles.

Procedure Details: MR imaging was performed on a 1.5 Tesla Siemens system, using three multiplanar breathold sequences: 1) Long TR/TE HASTE sequence i.e. black blood, 2) Short TR/TE steady state TrueFISP sequence i.e. white blood and 3) 3D contrast-enhanced VIBE sequence i.e. venography. Venous anatomy, normal signal and thrombus enhancement were evaluated.

Conclusion: Combining all three sequences took less than 10 minutes and lead to determine extension of renal tumour into the renal vein. HASTE was superior to other sequences in terms of contrast between thrombus and vascular lumen. Since TrueFISP uses a slice by slice acquisition, it was useful in uncooperative patients. The use of contrast enhancement with VIBE strengthens radiologist confidence in determining the nature of the thrombus.

C-0460

Imaging features of metastases and local recurrence in surgically treated kidney cancer

A. Guermazi¹, I. El-Hariry², Y. Miaux¹; ¹San Francisco, CA/US, ²Greenford/UK

Learning Objectives: To illustrate both typical and less typical ultrasound, CT and MR imaging appearances of metastases and local recurrence from renal cancers and to understand the mechanisms, risk factors, and clinical timing of recurrent disease in surgically treated renal cancer.

Background: Whole body spiral CT is currently the method of choice for evaluating the postsurgical nephrectomy site for the presence of recurrent lesions and for detecting the usual (common) anatomical sites of metastases. Administration of oral contrast material in CT is useful to differentiate these recurrent lesions from intestinal loops. In this study, we retrospectively review the radiological images of 120 patients with renal cancer who had been evaluated for the presence of recurrence or metastases.

Imaging Findings: Local recurrent lesions are usually detected as masses in the vacant renal fossa. Metastatic lesions are seen in the lung, pleura, pancreas, adrenal gland, liver, contralateral kidney, bone, lymph nodes, muscles, etc.

Conclusion: Knowledge of the mechanisms, risk factors, and clinical timing of recurrent disease in surgically treated renal cancer can assist the radiologist in understanding and detecting the patterns of recurrence observed on imaging. Ultrasound and MR imaging may be of interest when exploring particular organs such as liver, brain and spine.

C-0461

Imaging aspects of papillary renal cell carcinoma (RCC): Characterization and staging with pathological correlation

B. Sauer, S. El Ghali, X. Buy, H. Lang, C. Saussine, C. Roy; Strasbourg/FR

Learning Objectives: To recognize specific aspects of papillary type renal tumors. To define accurate criteria for local extension. To know and discuss main differential diagnoses.

Background: Papillary RCC is a subgroup (5-15%) of malignant renal epithelial neoplasms characterized by slower growth and a better prognosis. It represents a unique clinicopathologic entity which is morphologically and cytogenetically distinct from clear cell carcinoma. It is divided into basophilic type (I: most frequent, bilateral, multifocal) and eosinophilic type (II: unifocal, more aggressive with cystic aspect). It has been described as a hereditary tumor caused by a single gene mutation.

Procedure Details: MR imaging has been shown to be more accurate than CT in specific diagnosis and differential diagnosis for this tumoral type. On T2w, the specific aspect of papillary tumors is a low signal intensity, homogeneous pattern with delayed and low enhancement on dynamic Gd T1w compared to clear cell carcinoma. For local extension, identification of the pseudocapsule is an important and accurate feature to differentiate stage T1/T2 from T3a on MR, up to 95%. US is not pertinent enough. Multiple explanations are proposed to understand the hypointensity aspect. Several differential diagnoses of this pattern are discussed such as hemorrhagic cyst or tumor, lymphoma, fibroma.

Conclusion: Papillary renal tumors can be characterized on imaging findings, especially on MR, by an hypointense homogeneous pattern on T2w associated with low and late enhancement on Gd GET1w. Local extension is also sufficiently accurate on MR imaging to better select surgery type.

C-0462

Contrast-enhanced sonographic imaging of the kidney

A. Nunziata, O. Catalano, F. Sandomenico, M. Mattace Raso, A. Siani; Naples/IT

Learning objective: To illustrate the contrast-specific US findings in a wide spectrum of acute and nonacute disorders of the kidney. To show the practical value of

Scientific and Educational Exhibits

CE-US in renal differential diagnosis. To make radiologists aware of the typical and atypical appearance of renal disorders as shown with the novel, real-time, contrast-specific techniques.

Background: CE-US is used with increasing frequency in the evaluation of kidney. This is a highly vascularized organ, with a very rapid enhancement. These features make real-time, low mechanical-index US the ideal sonographic technique in imaging kidneys.

Procedure Details: A continuous-mode, low-mechanical index US technology is employed. A second-generation, sulfur-hexafluoride based contrast agent is used. The contrast agent, at a volume of 2.4 or 4.8 mL, is injected through a peripheral vein and a 20 G needle, using a three-way stopcock and 5-mL saline flushing. A wide spectrum of disorders are depicted: injury, infarction, abscess, acute pyelonephritis, small tumour (including differential diagnosis between angiomyolipoma and clear cell carcinoma), atypical cystic mass, and metastasis. Several potential pitfalls are also shown.

Conclusion: CE-US can recognise several findings useful in detection and characterisation of renal disease.

C-0463

Magnetic resonance imaging of pyelonephritis in renal transplantation

J. Maass, I. Tosetti, C.C. Bianchi, M. Stratta, C. De Feo, F. Barisone, M. Burdese, G. Gandini; Turin/IT

Learning Objectives: To illustrate the use of MR imaging in detecting acute pyelonephritis (APN) in patients with renal transplantation who have clinical signs of urinary tract infection.

Background: Urinary tract infections are common after renal transplant; APN is a critical disease which may cause permanent renal scar formation and sometimes result in allograft dysfunction and deteriorating renal function if prompt diagnosis and treatment are delayed. Between January 2003 and September 2004, 12 patients with clinical suspect of APN (fever, nausea, vomiting, pain in iliac fossa, leukocytosis) were evaluated with MR imaging; the procedure and its results are described and illustrated.

Imaging Findings: Ten out of 12 patients showed imaging signs of APN: among them, 5 had signs of focal APN in kidney poles, and other 5 showed diffuse APN signs. Three patients had also developed a renal abscess. Six patients came back for follow-up examination, where we were able to detect significant improvement or resolution of parenchymal lesions after antibiotic therapy; one patient developed a residual fibrotic scar following renal abscess. Two out of 12 patients had no signs of APN at all.

Conclusion: MR imaging is useful for detailed imaging of transplanted kidneys in order to diagnose APN and follow-up patients after treatment; it can also provide relevant information about evolution of parenchymal lesions.

C-0464

Focal hemorrhagic lesions of the kidney on MR imaging

A.E. Mahfouz, H. Sherif; Doha/QA

Objectives: To review the spectrum of focal hemorrhagic lesions of the kidney and to illustrate the MR imaging features of each of these lesions.

Background: Hemorrhagic lesions of the kidney are recognized on MR imaging by signal intensity of blood-degradation products. Signal intensity of hemorrhagic lesions differ widely according to age of the hemorrhagic process and the pulse sequence used. The most consistent of these signal intensity patterns is the high signal intensity on T1-weighted images which is not suppressed on fat saturation and the low signal intensity of the hemorrhagic lesion on T2-weighted images.

Procedure Details: Breathhold transverse, coronal, and sagittal half-Fourier fast spin-echo T2-weighted images (HASTE), transverse T1-weighted GRE images, and fat-saturated T1-weighted GRE images before and after intravenous injection of Gd-DTPA in the three orthogonal planes were performed for 100 patients with focal renal lesions. Among these, hemorrhagic lesions were selected to be presented in this educational exhibit. These lesions include traumatic injury, hemorrhagic cyst, hemorrhage in renal cell carcinoma, hemorrhage in angiomyolipoma, renal infarctions, and subcapsular hemorrhagic foci in cases of polyarteritis nodosa.

Conclusion: MR imaging is a useful imaging modality in detection of hemorrhagic focal lesions of the kidney and demonstration of certain imaging features which may help in reaching the diagnosis.

C-0465

Use of MR imaging for kidney evaluation after ESWL

P.V. Kuchuk, A.V. Arablinskiy, L.M. Rapoport, E.S. Belysheva, V.I. Rudenko, T.A. Uzhegov; Moscow/RU

Purpose: To use MR imaging for detection of possible renal complications after ESWL.

Materials and Methods: 15 patients with renal stones have been studied with MR imaging before lithotripsy, 1 and 9 days after ESWL. Renal perfusion was studied with fast spoiled gradient-recalled (FSPGR) sequences after Gd injection. Besides MR imaging, US Doppler and dynamic nephroscintigraphy with ^{99m}Tc-MAG₃ have been performed in all cases.

Results: After ESWL MR imaging detected some changes in kidneys in 14 of 15 patients. Perinephric oedema and perinephric fluid collection were revealed in 10 cases, subcapsular fluid collections in 4. Subcapsular haematoma was present in patient. Sites of intraparenchymal haemorrhage were detected in 3 patients and defects of cortico-medullary junction in 6. All changes, except for haematomas and intraparenchymal haemorrhage, regressed by 9 day after ESWL. Dynamic MR imaging found alterations of renal function in 9 patients, such as focal ($n = 2$) or total ($n = 3$) decrease of contrast enhancement and redistribution of renal blood flow ($n = 6$). US studies found morphological changes of kidneys in 3 patients.

Conclusion: MR imaging was more sensitive technique in revealing morphological changes of kidney impairment after ESWL, than US. At research of functional changes MR imaging has no important advantages over scintigraphy and ultrasound, except for an opportunity to reveal redistribution of blood flow between cortical and medullary substance. MR imaging should be used after ESWL in cases with high probability of complications.

C-0466

Evaluation of transplanted kidney function by the clearance of technetium-99m mercaptoacetyltriglycine: The comparison between two methods

S.L. Beatovic, E. Jaksic, R. Han; Belgrade/YU

Purpose: Our study aimed at evaluating the sensitivity of two methods for mercaptoacetyltriglycine (MAG3) clearance calculation in patients with transplanted kidney: single sample method and camera based method.

Methods and Materials: 62 patients were investigated. Group A consisted of 22 patients with well-functioning grafts, group B of 20 patients with suspected acute rejection and group C of 20 potential kidney donors. Single-sample method used the following formula: $CL = 512 \cdot e^{-0.00688 \cdot t} + 297 \cdot e^{-0.0135 \cdot t}$. In(dose/plasma counts). Camera-based method used counting rates from kidney region during the second minute of the study. The obtained value is expressed as clearance index (CI).

Results: Mean values of CL were: $187.8 \pm 39.2 \text{ ml} \cdot \text{min}^{-1}$ (group A), $64.3 \pm 22.6 \text{ ml} \cdot \text{min}^{-1}$ (group B) and $361.7 \pm 38.4 \text{ ml} \cdot \text{min}^{-1}$ (group C). The difference between groups A and B was statistically significant ($p < 0.05$). In groups A and B CL was significantly lower than in control group. Results of CI were: 50.9 ± 15.6 (group A), 27.9 ± 7.9 (group B) and 75.2 ± 9.5 (group C). Correlation between CL and CI was statistically significant. Results of CL correlated well with blood urea nitrogen (BUN), serum creatinine (Cr) and creatinine clearance (C_{Cr}): $BUN/CL r = -0.78$; $Cr/CL r = -0.69$; $C_{Cr}/CL r = 0.86$. Significant correlation between CI and kidney lab was not obtained.

Conclusion: CL is sensitive quantitative parameter of renal transplant function. CI could also reflect changes in kidney graft function, but is less sensitive than CL. Nevertheless, due to the simplicity of its calculation, CI merits further clinical evaluation as potential parameter of transplanted kidney function.

Imaging findings of extratesticular scrotal masses

C. Pozuelo Segura, O. Pozuelo, Y. Roca, L. Mones, C. Medrano, A. Torremilans, J. Quintero, D. Mulattieri; Barcelona/ES

Learning Objectives: The aim of this study is to illustrate the distinguishing features of extratesticular scrotal masses and to analyse the role of US in the diagnosis.

Background: Sonography is the imaging modality of choice in detecting and characterizing pathologic conditions affecting the extratesticular space. Although most abnormalities are benign, many may simulate or represent malignant processes. Accurate diagnosis is therefore essential and must be based not only on the sonographic findings but also on accurate clinical history and physical examination findings. We performed a retrospective study from the database between January 2000-September 2004 at our institution. All different sonographic features of extratesticular masses we reviewed. All patients were evaluated with Toshiba power vision 6000 with the highest frequency transducer (5-10 MHz).

Procedure Details: Most extratesticular masses are benign. We divided the pathologic findings depend the anatomical region: 1) tunica vaginalis: fluid collections (hydroceles, spermatoceles, pyoceles) and tumors. 2) epididymis: epididymitis (acute or chronic), cysts, granulomas and tumors. 3) Spermatic cord: varicocele and tumors 4) paratesticular masses: hernia, calculi, ...

Conclusion: US is a valuable tool for screening of scrotal lesions. If the lesion is extratesticular and shows a cystic appearance, a specific diagnosis can often be made and can be reassured that the mass is benign. Solid extratesticular masses can be somewhat more problematic to diagnose.

C-0468

MR imaging features of prostate carcinoma in local and nodal staging

J.J. Fütterer, S.W.T.P. Heijmink, R.A.M. Heesakkers, C.A. Hulsbergen van der Kaa, F.A. Witjes, J.O. Barentsz; Nijmegen/NL

Learning Objectives: To illustrate the spectrum of MR imaging features of prostate carcinoma in local and nodal staging.

Background: Prostate cancer is the second most frequent cause of cancer related death in men. To diagnose prostate cancer, digital rectal examination and the determination of the blood level of prostate-specific antigen (PSA) are the first tools. If these findings are suspicious of cancer, an investigation of transrectal ultrasound (TRUS) will follow. Subsequently, TRUS-guided multiple histological biopsies will be performed to obtain histopathologic confirmation. However, TRUS-guidance may fail to detect cancer in the prostate. Other techniques such as MR imaging can be used to allow visualization of the prostate. MR imaging is important to non-invasively show cancer localization, the extent of cancer and in possibly the near future also aggression of the cancer. Recently new MR techniques have been developed, which do not only show prostate morphology but also function. These techniques are contrast enhanced MR imaging, MR spectroscopy and MR with a specific lymph node contrast agent. This last technique may replace pelvic lymph node dissection.

Imaging Findings: This educational exhibit illustrates the MR appearances of local tumours, local stages, and nodal metastasis in prostate cancer. We demonstrate in this pictorial essay the current value of MR imaging in prostate cancer and will illustrate new developments.

Conclusion: MR imaging of the prostate provides important pre-therapeutic information about local- and nodal staging.

C-0469

Testicular masses in association with congenital adrenal hyperplasia: MR features compared with sonographic findings

H.M. Suliman¹, N.M.M.L. Stikkelbroeck², G.J. Jager², J. Blickman², B.J. Otten², A.R.M.M. Hermus²; ¹Amsterdam/NL, ²Nijmegen/NL

Purpose: To evaluate and describe the imaging findings of testicular "adrenal rest tumors" in male patients with congenital adrenal hyperplasia (CAH).

Materials and Methods: Seventeen patients with CAH due to 21-OH deficiency were evaluated. All patients underwent scrotal ultrasound (US), with color Doppler, and in 16 patients MR was performed. T2W and T1W images pre and post contrast were obtained.

Results: In 6 of the 17 patients the lesions were palpable. US revealed lesions in 16 of 17 patients (94%). The size varied from 2 mm to 40 mm. In 10 patients the

lesions were hypoechoic and in 6 they were hypoechoic with hyperechoic reflections. All lesions were located against the mediastinum. Acoustic shadowing and well-defined margins was present in 16 cases (Fig. 1). Hypervascularity was seen in 4 lesions (Fig. 2). MR revealed lesions in 15 of 16 patients. All lesions were isointense on T1W, and hypointense on T2W images. The lesions were clearly defined, homogeneous and located adjacent to the mediastinum testis. After iv of Gadolinium all lesions demonstrated strong enhancement (Fig. 4 and Fig. 5). None of the lesions showed a capsule or pseudocapsule.

Conclusion: Testicular lesions are common in CAH and have characteristic US and MR features. They are often multifocal, bilateral and are found around the mediastinum testis. US monitoring will be adequate for diagnostic evaluation.

C-0470

Transrectal ultrasound (TRUS) of prostate cancer (PRCA): A multimedia DVD Rom-based educational tool and database: Sonographic-pathologic correlation

D. Alexopoulos, S. Papavassiliou, I. Mastorakou, D. Leli, E. Tako, S. Faitaki, P. Karavitis, P.S. Zoumpoulis; Athens/GR

Learning Objectives: - To demonstrate the role of TRUS in diagnosing prostate lesions. - To present TRUS prostate echoanatomy, semiology and haemodynamics of PrCa. - To reach a sonographic diagnosis using algorithms. - To provide comparison of an US image with images of the database.

Background: Since TRUS is the most efficient way to detect Prostate Cancer (PrCa) the main purpose of this e-book is to teach the TRUS procedure in detection and staging of PrCa and correlate it with the histological findings emphasizing the use and effectiveness of USCA and local anesthesia prior to biopsy sampling.

Procedure Details: This medical e-book is a multimedia DVD-Rom based teaching file featuring 2500 US prostate images, 150 US video demonstrations, 400 video cases presenting clinical data and detailed description of TRUS techniques; chapters on prostate anatomy, TRUS technique for the detection and staging of PrCa (based on over 10,000 cases), Color Doppler, the technique of US-guided biopsies. The proper TRUS technique is demonstrated step by step. Its educational role is based upon Video Cases and double video presentations. The latter consist of a simultaneous presentation of the real time ultrasound exam and the examiner's technique. A database is included aiding the user to reach the correct diagnosis and to compare his sonographic image to histologically proven images of the database.

Conclusion: User-friendly DVD-Rom based teaching file on the Prostate with chapters on Anatomy, Pathology, Ultrasound Physics, Sonographic Appearance of the Normal Prostate, TRUS Morphology, Detection and Staging of PrCa, Local Anesthesia, USCA and Comparative Database.

C-0471

Diagnostic imaging in the staging and evaluation of prostatic carcinoma

A.M. Camenzuli¹, S. Lea², C. Romanuk³; ¹Liverpool/UK, ²Upton - Wirral/UK, ³Bebington - Wirral/UK

Learning Objectives: 1. Provide examples of the anatomy and staging of prostate carcinoma using MR imaging. 2. Staging pitfalls in MR imaging - the influence of haemorrhage, surgery and medication on local staging. 3. The use of Partin Tables in MR imaging staging and image interpretation. 4. Compare the role of isotope bone scintigraphy versus MR imaging in the assessment of bone metastases 5. Illustrate uncommon appearances that are prevalent in post graduate examinations: The superscan effect, the solitary sclerotic bone and dural metastases.

Background: The management of prostatic carcinoma (radical curative surgery or radiotherapy versus controlled disease with hormones or symptom relief) largely depends on the staging. This presentation will provide insight to the radiologists' perspective.

Imaging Findings: This presentation will graphically illustrate the patterns of spread of disease on MR imaging and nuclear medicine, with an outline of factors that influence the accuracy of staging such as tumour location, haemorrhage, infection, medication or previous surgery. It will also highlight the use of Partin's tables to predict the degree of invasion and likelihood of nodal metastases to improve the degree of confidence in reporting staging scans. The roles of nuclear medicine versus MR imaging to assess the metastatic burden to bone and its complications will be presented graphically. The final section illustrates presentations of post graduate exam interest.

Scientific and Educational Exhibits

C-0472

The importance of the transitional zone at repeat transrectal ultrasound-guided prostate biopsy

N. Gough, C.P. Meehan, P.A. McCarthy; Galway/IE

Background: A significant number of patients attending for Transrectal ultrasound guided prostate biopsy are having repeat biopsy as Prostatic Specific Antigen levels remain high and/or digital rectal examination remains suspicious. Some patients may undergo several biopsies with negative results. 24% of prostate carcinoma occurs in the transitional zone, an area not traditionally biopsied.

Materials and Methods: Group A: 756 Transrectal ultrasound guided prostate biopsies were performed between Jan 00 and Jan 03. Of these 99 were being repeated in 87 patients. (Range 1-5 per patient). From Jan 03 we proposed to take repeat biopsies from the transitional zone. Group B: 279 biopsies were performed between Jan 03 and Jan 04. Of these 56 were being repeated in 52 patients. (range 1-2 per patient).

Results: Of the 99 repeated biopsies taken from the peripheral zone 21 patients (21.2%) had positive results. Of the 56 repeated biopsies from the transitional zone 19 patients (34%) had positive results.

Conclusion: In our experience, routine targeting of the transitional zone at repeat biopsy significantly increases the detection of prostate carcinoma.

C-0473

Color-Doppler sonography (US): A pictorial atlas of scrotal disorders

F. Sandomenico, O. Catalano, A. Nunziata, P. De Feo, A. Siani; Naples/IT

Learning objective: To illustrate the colour-Doppler US findings in a wide spectrum of acute and nonacute disorders of the scrotum. To show the practical value of colour-Doppler in differential diagnosis of scrotal disease. To make the radiologist aware of all typical and atypical appearances of scrotal disorders as shown with colour- and power-Doppler US.

Background: Colour and power-Doppler imaging techniques are currently used in addition to grey-scale imaging in the assessment of a variety of scrotal disorders.

Procedure Details: Optimal imaging technique and equipment setting is shown. A wide spectrum of scrotal acute and nonacute disorders is depicted: injuries, ischemia secondary to funicle torsion or inguinoscrotal hematoma (post-herniorrhaphy), testicular infarction, scrotal abscess, orchitis and orchiepididymitis, testicular and extratesticular cysts and tumours, varicocele, Fournier gangrene, undescended testis. Several potential interpretative pitfalls are also illustrated.

Conclusion: High-resolution colour-Doppler US is used with increasing frequency in the evaluation of the scrotum and can demonstrate several findings relevant for patient management. Radiologist should be aware of all colour-Doppler features of scrotal disorders.

C-0474

Sentinel lymph node assessment by ^{99m}Tc-colloid orchifuniculoscintigraphy in patients with testicular tumors

M.D. Sterpu, V.Y. Soukhov, L.A. Tyutin; St. Petersburg/RU

Purpose: To evaluate direct orchifuniculoscintigraphy used as method of clarifying the routes of lymphatic cancer spread for optimization of radiation therapy.

Materials and Methods: Orchifuniculoscintigraphy was performed in 31 patients 17 - 47 y.o. with tumors of the testis by administration of 37-74 MBq of ^{99m}Tc-colloid beneath the tunica albuginea of the tumor-affected testis prior to its surgical resection or in the stump of spermatic cord, if the patient had earlier undergone orchiectomy. Examinations were performed 45-60 minutes p.i. on gamma-camera "E.cam Var" (Siemens) in four projections. Intact lymph nodes were seen on scintigrams as foci of intensive accumulation of the radiopharmaceutical. Reduction or absence of tracer uptake in the lymph nodes projections with simultaneous imaging of lymphatic vessels was considered as potential lymphatic cancer spread required local irradiation of these regions.

Results: Data of orchifuniculoscintigraphy helped to determine the direction of lymph outflow from tumor-affected testis or the stump of spermatic cord to sentinel lymph nodes by normal or changed lymph collectors. Thus, orchifuniculoscintigraphy led to exact determination of fields' size and configuration for local radiation therapy.

Conclusions: Finding of the lymph outflow routes with ^{99m}Tc-colloid increases the validity of early lymphatic cancer spread detection, including cases without lymph node enlargement. Determination of the lymph outflow routes gave an opportunity to configure the radiation fields within sites of ^{99m}Tc-colloid accumulation.

C-0475

Feasibility of quadrature body coil in prostate spectroscopic MR imaging

M.C. Martinez-Bisbal¹, B. Celda¹, B. Martinez-Granados¹, C. San Juan², L. Martí-Bonmatí²; ¹Burjassot/ES, ²Valencia/ES

Purpose: PSA measurements, transrectal ultrasonography, CT, and MR imaging often cannot reliably differentiate early prostate cancer from BPH and normal tissue. Proton spectroscopic imaging (¹H-MRSI) can evaluate the prostate with an appropriate matrix size and field homogenisation. In most centres spectroscopic images are obtained with an endorectal coil. We present our results with ¹H-MRSI obtained using the quadrature body coil, ensuring faster and reliable clinical application and lower patient disturbances.

Materials and Methods: 25 male patients were studied (1.5 T system) with a sagittal and transverse T2W images orthogonal to the prostate central gland axis. Transverse images were used to localize 2 ¹H-MRSI slices (TE 272 ms, thickness 20x22 mm, ROI 65x65 mm) including both the central and peripheral glands. When necessary, a single volume (TE 136 ms) was also acquired in regions with abnormal ¹H-MRSI findings. Spectra were analysed with jMRUI and SiView. Only subjects with pathological data (surgery or biopsy) were included.

Results: Higher Choline and lower Citrate were found in those patients with cancer in all pathological areas. ¹H-MRSI allowed the location of higher cellular regions in the central and peripheral portions. The spatial resolution was considered adequate by radiologists and urologic surgeons.

Conclusion: ¹H-MRSI and single voxel MRS with a 1.5 T unit using the quadrature body coil is an easily accepted technique useful in the diagnosis of prostate cancer. Patient conformance is high; it is non-invasive; and allows patient follow-up.

C-0476

Sonographic features of intratesticular pathology

C. Pozuelo Segura, O. Pozuelo, L. Mones, Y. Roca, C. Medrano, J. Quintero, A. Torremilans, D. Mulattieri; Barcelona/ES

Learning Objectives: The aim of this exhibit is to present the imaging findings of the intratesticular scrotal pathology and to analyse the role of US in the diagnosis

Background: High-resolution sonography is a very sensitive imaging modality for detecting intratesticular pathology and is an accurate means of distinguishing intratesticular lesions (usually malignant) from extratesticular ones (usually benign). We retrospectively reviewed the imaging findings of intratesticular scrotal masses diagnosed by US seen in our centers between January 2000-September 2004. All patients were evaluated with Toshiba power vision 6000 and Toshiba Nemio with the highest frequency transducer (5-10 MHz).

Procedure Details: We divided the pathologic findings depending on the clinical presentation: 1) acute scrotum (testicular torsion, epididymo-orchitis), 2) trauma 3) undescended testes (cryptorchidism) 4) benign masses (cysts, ectasia rete testis, microlithiasis, varicocele, ...) 5) malignant masses.

Conclusions: US is the primary modality for imaging scrotal lesions. It provides excellent spatial resolution and it has been shown to be nearly 100% sensitive in the identification of scrotal masses. However, sonography does have limitations in distinguishing benign from malignant neoplasms or from some inflammatory lesions. The combination of clinical and US findings facilitated the differentiation between non-neoplastic and neoplastic testicular cysts.

C-0477

Analysis of suprapubic and transrectal measurements in assessing prostate dimensions and volume: Is transrectal ultrasonography really necessary for prostate volume measurement?

E. Özden, Ç. Göğüs, Ö. Kılıç, Ö. Yaman, E. Özdiğer; Ankara/TR

Purpose: The objective of this study is to evaluate the reliability of suprapubic ultrasonography (SU) in prostate volume measurement and determine the correlation of SU and transrectal ultrasonography (TRUS) in according to different prostate volume ranges.

Methods and Materials: 100 consecutive patients with benign prostatic hyperplasia (BPH) were examined by SU and TRUS in the same session. Patients were further divided into 2 subgroups according to prostate volumes measured by SPUS: < 60 cc and > 60 cc. The three dimension (anteroposterior, transverse and craniocaudal) and volume measurements performed by SU were compared with corresponding measurements performed by TRUS in order to determine the correlation of the measurements. Volumes were calculated using the ellipsoid formula.

Results: The mean prostate volume of the 100 patients, measured by SU and TRUS were 65.9 ± 35.8 cc and 62.5 ± 32 cc respectively and strongly correlated ($r: 0.94, p < 0.001$). Craniocaudal diameters had the strongest correlation among

Scientific and Educational Exhibits

dimension measurements ($r: 0.89, p < 0.001$). Correlation coefficients for antero-posterior and transverse measurements were $r: 0.86$ and $r: 0.79$ respectively. In accordance to volume ranges the strongest correlation of two techniques were determined for prostates with volumes > 60 cc ($r: 0.90, p < 0.001$). The equation that converts the volume measured by SU to TRUS was determined as; TRUS = $7.116 + (0.84 \times SU)$.

Conclusion: There is a strong correlation between SU and TRUS measurements of prostate. SU as a more comfortable and better tolerated technique, may be used reliably in the measurement of prostate volume.

C-0478

Diagnostic value of TRUS in patients with PSA values ≥ 20 ng/ml: Can only lesion biopsies be adequate for diagnosis?

E. Özden, A.T. Turgut, Ç. Göğüs, C. Yagci, S. Küpel; Ankara/TR

Purpose: To investigate the value of transrectal ultrasonography (TRUS) in patients with prostate specific antigen (PSA) values ≥ 20 ng/ml, in order to determine if only lesion biopsies can be adequate for the diagnosis of prostate carcinoma in these PSA ranges.

Methods and Materials: 51 consecutive patients with PSA values ≥ 20 ng/ml who underwent TRUS and TRUS guided prostate biopsy were included in the study. TRUS guided sextant + lesion biopsies were taken and TRUS findings of each biopsy location were correlated with histopathology results of the same site.

Results: In the analysis of 408 biopsy foci, calculated sensitivity, specificity, positive and negative predictive values of TRUS were 63.5%, 90.4%, 83.7% and 76.2% respectively. There were 65 (15.9%) biopsy foci in which cancer were identified histopathologically although TRUS detected no lesion. Four of the (7.84%) patients with nonsuspicious TRUS findings had prostate cancer. There were nine (17.64%) patients with cancer foci detected at the contralateral side of the lesion detected by TRUS.

Conclusion: Diagnostic value of TRUS is not sufficiently high even in high PSA ranges and we suggest that in addition to the lesion biopsies, systematic biopsies should also be performed in patients with PSA ≥ 20 ng/ml.

C-0479

Comparision of lateral-medial peripheral zone prostate biopsies: Analysis of 12 core locations in 160 patients

E. Özden, Ç. Göğüs, A. Zümrütbas, S. Baltaci, Y. Bedük; Ankara/TR

Purpose: To investigate the value of lateral peripheral zone prostate biopsies.

Methods and Materials: The study included 160 consecutive patients who underwent 12 core transrectal ultrasonography (TRUS) guided prostate biopsy with total serum prostate specific antigen (PSA) values between 4.0 - 19.9 ng/ml. Sextant + 6 core lateral biopsies have been performed. Each biopsy specimen was labelled according to location and sent for pathologic evaluation in separate containers. Percent of cancer for each core location was assessed according to PSA ranges.

Results: Prostate cancer was diagnosed in 43 of the 160 (26.87%) patients. By analysis of the 1920 cores 226 cancer foci were detected of which 117 (51.77%) were detected at lateral and 109 (48.23%) at medial locations ($p: 0.571$). The detection rates for lateral locations were 54.08% and 50% in 4-9.9 and 10-19.9 ng/ml PSA ranges respectively. There were also no statistically significant difference for cancer detection rates between lateral and medial biopsy locations for basal-middle and apical regions. The highest detection rate was for bilateral basal lateral locations (15%) and the lowest was for right apicolateral location (7.5%).

Conclusion: Although cancer detection rate at lateral biopsies are higher than medial locations, there is no significant difference between them.

C-0480

Pitfalls in MR staging of prostate carcinoma: A pathological correlation (or prognostic pitfalls of prostatic proton pictures)

S. Punwani, D.J. Hopster, R. Chaudhuri, D. Murray; London/UK

Learning Objectives: To raise the awareness of the pathological correlate of MR appearances encountered in the pre-operative staging of prostatic carcinoma.

Background: Prostate cancer is the most commonly diagnosed non cutaneous cancer diagnosed in males. Primary staging helps to select patients that are suitable for potential curative radical surgery. MR is now routinely used in pre-operative staging of prostate cancer, but is known to have only moderate sensitivity and specificity in detecting extracapsular spread. An audit conducted at our institution over 18 months directly compared post prostatectomy pathological staging with MR pre-operative staging ($n = 18$). The results of the audit are presented with a pictorial correlation of the pathological findings.

Procedure Details: Normal imaging findings of the prostate and seminal vesicles and the corresponding pathological interpretation is demonstrated. MR appearances mimicking extra-capsular disease such as fibrosis, haemorrhage and inflammation are individually illustrated with corresponding images of pathological sections. Also, pathological correlation for the various MR appearances of the seminal vesicles is shown.

Conclusion: Awareness of the underlying pathological processes resulting in the MR appearances allows a more informed interpretation of MR prostate imaging. A multi-disciplinary (clinical, radiological and pathological) approach in the management of patients is of great educational value in the accurate staging of prostate cancer.

C-0481

An efficient way to reach the correct diagnosis on prostate lesions with transrectal ultrasound: DVD-Rom based teaching file with ultrasound images, real-time video display and comparative data

P.S. Zoumpoulis, D. Alexopoulos, S. Kyriazi, C. Beligiannis, D. Dalakostas, K. Pahou, L. Kaklamanis; Athens/GR

Learning Objectives: - To teach a trainee to describe the US characteristics of Focal Prostate Lesions. - To aid and guide the user in reaching a sonographic diagnosis through correct algorithms. - To compare US images of diagnostic difficulty to those of the database.

Background: The purpose of this DVD-Rom is to suggest *diagnostic algorithms* in order to characterize *focal prostate lesions* seen by TRUS, starting from an US image and its main morphologic and haemodynamic features.

Procedure Details: The user can start using this teaching file by submitting the US characteristics of a focal prostate lesion, which he has difficulty in diagnosing. He is asked to describe the echogenicity, anatomical position, border shape, acoustic impedance and the vascularity of the lesion. The system guides him through a specific algorithm to all possible diseases that coincide with criteria given. A large collection of classified US image galleries and video galleries are available in each diagnostic category giving the user the capability of comparing his own image(s) to those of the database. The user's image can also be linked to the contents of corresponding "interesting cases", which are brief case reports with clinical, biochemical, imaging and pathological data.

Conclusion: Assistance in deriving a diagnosis of a prostate lesion by viewing or comparing images of diagnostic difficulty to sonographic images of the database.

C-0482

Local anaesthesia before TRUS-guided prostate biopsy: Performance, technical results and side-effects on image quality. Indications and side effects on patients

A. Plagou, D. Alexopoulos, I. Theotokas, P.S. Zoumpoulis, S. Prapavesis, A. Fousteris, A. Filippidou; Athens/GR

Learning Objectives: 1. To discuss the indications for the use of local anaesthesia prior to TRUS. 2. To demonstrate the procedure of TRUS guided local anaesthesia before prostate biopsy. 3. To estimate the efficacy of TRUS guided local anaesthesia before prostate biopsy.

Background: Administration of local anaesthesia prior to TRUS-guided biopsy efficiently eliminates patient discomfort allowing for greater number of biopsies. 1600 TRUS-guided prostate biopsies have been performed following local periprostatic anaesthesia from 2000-2004.

Procedure Details: The procedure begins by injecting 8-15 cc of Xylocaine and 2% adrenaline through the biopsy needle. The technique, its effects on the US image, complications and side effects were compared to 8500 US-guided biopsies performed between the years 1994-2004, without local anaesthesia. There was no significant difference between the number and severity of complications in the group with local anaesthesia compared to the group without anaesthesia. There were no significant side effects caused by the infusion of the anaesthesia drug. However, degradation of image resolution is noted since air bubbles are sometimes infused with the drug causing a "fuzzy" image, which results in a degree of difficulty in guiding the needle. A thorough TRUS examination of the prostate prior to the anaesthesia helps the radiologist guide the needle to the appropriate area, even through a "fuzzy" image.

Conclusion: US-guided local anaesthesia, before TRUS biopsy, assures patient cooperation and is essential for a large (more than 10) number of biopsies.

Scientific and Educational Exhibits

C-0483

Transrectal prostate biopsy: Does a role for neurovascular bundle local anaesthesia exist?

D.G. Lohan, N. Gough, S.M. Walsh, C. Roche, P. McCarthy; Galway/IE

Purpose: To evaluate the efficacy of neurovascular bundle local anaesthesia (LA) infiltration in decreasing the discomfort experienced by patients undergoing transrectal ultrasound (TRUS)-guided biopsy of prostate.

Materials and Methods: In a six month interval, 150 patients underwent transrectal ultrasound-guided prostate biopsy (TRUS). All biopsies were performed by two Consultant Radiologists using a similar technique in each case. These patients were randomized to one of two groups, one of which received 5 mL 1% lignocaine to the neurovascular bundles bilaterally prior to traditional sextant biopsies, the other group receiving no local anaesthesia whatsoever. Patients then completed 10-point pain scoring, using a visual analogue scale, for each biopsy during, then immediately after and one week following the procedure.

Results: Pain scores in the local anaesthesia group correlated almost exactly with those experienced by the no local anaesthesia group immediately after, and one week following, TRUS-guided prostate biopsies. In addition, no significant difference existed between the two groups regarding adverse effects following the procedures.

Conclusions: Local anaesthesia for TRUS biopsy is a simple and well tolerated intervention. However, it fails to significantly reduce the pain associated with this often uncomfortable procedure. It is not associated with an increased incidence of adverse complications and increases the duration of the procedure - therefore its adoption as a routine part of TRUS-guided biopsy cannot be recommended.

C-0484

Imaging of common and uncommon scrotal diseases

N.J. Khoury, M.J. Mehanna, A.R. Karam, M.C. Haddad; Beirut/LB

Learning Objectives: To present our experience in imaging scrotal diseases, both testicular and extratesticular, including the common and the uncommon pathologies.

Background: Scrotal disease processes are commonly symptomatic, manifested mainly by scrotal pain and/or swelling. Other causes of presentation include infertility and empty scrotum. Patients with scrotal complaints are frequently referred for imaging in particular sonography, which has high diagnostic accuracy. MR imaging may be a helpful adjunct in few cases.

Imaging Findings: In this scientific exhibit we present our experience in imaging a wide variety of scrotal diseases using mainly ultrasound. MR imaging, CT scan and nuclear studies were used in few cases for further assessment of sonographic findings. The disease processes include testicular and extratesticular pathologies. Testicular pathology include: tumors (germ cell tumors, seminomatous and non seminomatous, stromal tumors, and metastases), infections (orchitis, abscess), and miscellaneous conditions (torsion, trauma, tubular ectasia of the rete testis, benign cysts, supernumerary testicle, undescended testis). Extratesticular diseases include epididymitis, epididymal cysts and masses, varicocele, hydrocele, hematocoele, pyocele and scrotolith.

Conclusion: Scrotal diseases include a wide spectrum of pathologies commonly encountered by radiologist. This review enables us to be familiar with the radiological manifestations of these diseases.

C-0485

MR imaging of penis and pelvic floor in patients after perineal blunt injury

M. Sharia, O. Belichenko, S. Gamidov, A. Denisov; Moscow/RU

Purpose: To study the diagnostic possibilities of MR imaging in lesion assessing after blunt perineal injury.

Material and methods. 32 patients with blunt perineal injury (mean age 44 years) have been studied with 1.0 T MR imaging system (Magnetom Harmony, Siemens). 14 of them suffered from erectile dysfunction (ED). All the patients underwent examination which consisted of the pharmacological dopplerography, electromyography of the penis with pharmacological loading and MR imaging of the perineum and the penis.

Results: MR imaging was useful in identification of anatomic structures of the penis and pelvic fundus, pathological tissue processes (hematomas, damaged tissues, fibrous scars) after blunt injury of the perineum responsible for ED. Results of pharmacological dopplerography, electromyography of the penis with pharmacological loading showed arterial (in 100% patients), venous (in 33.3% patients) and neurogenic (in 11.1% patients) lesions. Algorithm for diagnostics of ED in patients after perineal blunt injury has been developed based on the received results.

Conclusion: MR imaging of the penis and pelvic fundus is objective and highly informative method for identification of anatomic structures and assessing of penis lesions in patients with blunt perineal injury.

C-0486

Can longer tissue samples be extracted by pressing the prostate with the probe during TRUS guided biopsy?

E. Özden, Ç. Göğüs, E. Dasdemirov, A.T. Turgut, K. Türkölmez, Ö. Tulunay; Ankara/TR

Purpose: Several authors reported that biopsy needles sometimes sample a longer tissue than their suggested core lengths during prostate biopsy, but no explanation for this has been proposed yet. This is important because a significant trend was reported for increased detection of prostate cancer as longer prostate tissue samples are obtained. We investigated whether pressing the prostate by the probe during biopsy enables extraction of longer tissue samples.

Methods and Materials: The study included 23 patients who underwent transrectal ultrasonography (TRUS) guided prostate biopsy. Randomly, left or right side of the prostate of each patient have been sampled by pressing the prostate by the tip of the probe, whereas other side of the prostate have been sampled without any pressure. Difference between the length of the samples extracted by each method have been analysed statistically.

Results: Although mean length of samples extracted during pressing by the probe (16.17 mm) was 3.12% longer than samples taken without pressure (15.68 mm), the difference was not statistically significant ($p = 0.232$). Mean sample lengths also showed no significant difference when analysed according to base- mid and apical locations. Two patients (8.7%) had high fever after biopsy.

Conclusion: Pressing the prostate with the probe is of no use for taking longer tissue samples. In addition, high fever rate noted in this study was higher than reported in the literature. We suggest that pressure should not be applied to the prostate during TRUS guided biopsy.

C-0487

The effect of gleason scores on TRUS detection rates and sonographic appearances of prostatic carcinoma

E. Özden, Ç. Göğüs, Z. Tokatlı, Ö. Yaman, O. Göğüs; Ankara/TR

Purpose: To evaluate the transrectal ultrasonography (TRUS) features and detection rates of prostatic cancers in accordance to gleason scores.

Materials and Methods: Histopathologic results of 246 peripheral zone prostate cancer foci detected in 61 patients who have undergone TRUS guided sextant + lesion biopsy were compared with the TRUS findings of the same biopsy location. Cancer detection rates of TRUS and differences in TRUS features were analyzed in according to gleason scores.

Results: Detection rates of TRUS were 29.5% for cancers with gleason scores less than 7, and 56.3% for cancers with higher scores ($p < 0.001$). Whereas the TRUS features regional decreased echogenicity and hypoechoic nodule were respectively defined at 67.85% and 32.15% of the cancers with gleason scores less than 7, these rates were respectively 62.35% and 23.54% for the cancers with higher gleason scores.

Conclusion: The detection rate of TRUS for prostate cancers with gleason scores 7 or more are significantly higher than cancers with gleason scores less than 7. The sonographic features defined by TRUS are not affected by the gleason scores.

C-0488

The effect of rectal enema before TRUS guided prostate biopsy on patient comfort and biopsy related complications

E. Özden, Ç. Göğüs, M. Akand, Ö. Yaman, O. Göğüs; Ankara/TR

Purpose: To evaluate the effect of rectal enema before transrectal ultrasonography (TRUS)-guided prostate biopsy on patient comfort and biopsy related complications.

Methods and Materials: A total of 100 men, who underwent TRUS-guided prostate biopsy were equally randomized into two groups. Rectal enema (1 packet of Fleet enema) was administered 1 hour before the procedure in the first group, no bowel preparation was performed in the second group. All patients had 12 core prostate biopsy. In both groups, pain scores during needle insertion and total procedure discomfort (including pre and postbiopsy phases) was assessed separately by a 11-pointed visual-linear scale. One week after the biopsy patients were questioned about complications.

Results: There was not a statistically significant difference in mean age, PSA level and prostate volume between groups. Mean biopsy pain score was 1.72 ± 1.26 in the first and 1.34 ± 1.0 in the second group ($p = 0.099$). Mean total

Scientific and Educational Exhibits

procedure discomfort was 2.18 ± 1.27 in the first and 1.44 ± 0.97 in the second group ($p = 0.003$). Complication rates were as follows in the first and second groups respectively: hematuria: 65.9%, 63.6% ($p = 1.0$); hematospermia: 53.7%, 56.8% ($p = 0.941$); rectal bleeding: 61%, 52.3% ($p = 0.555$); high fever: 4.9%, 2.3% ($p = 0.607$).

Conclusion: Although biopsy pain scores between groups were not significantly different, in the group that didn't receive enema total procedure discomfort was significantly lower than the other. We think that use of rectal enema before biopsy increases patient discomfort because of rectal irritation, and should not be used as it also doesn't reduce complication rates.

C-0489

The ability of serum prostate specific antigen and Gleason score to predict radionuclide bone scan findings in patients with untreated prostate cancer

H. Aw Yeang, R. Hurst, V. Jackson, D. Scutt, S. Vinjamuri; Liverpool/UK

Learning Objectives: This study sets out to determine whether there is a critical level of serum PSA and Gleason score below which routine bone scans may prove to be of minimal value in the diagnosis of skeletal metastases.

Methods and Materials: 268 patients with histologically proven prostate cancer underwent radionuclide bone scans over the 19-month study period. A retrospective review was performed on the cohort and data was compiled on serum PSA levels, Gleason score, TNM classification, prostatic biopsy histology findings and bone scan result. Patients who had received prostate cancer treatment before evaluation of their serum PSA were excluded.

Results: A significant statistical difference was observed ($p < 0.001$) for mean serum PSA values between patients found to be bone scan positive and bone scan negative for skeletal metastases. Of the 21 bone scan positive patients, none had serum PSA within the normal range of 0 - 4.0 ng/ml. One patient had a positive bone scan with a serum PSA below 10 ng/ml. The negative predictive value of a serum PSA below 20 ng/ml with a negative bone scan was 98.9%. A significant difference was found between the Gleason scores of bone scan positive and negative patients ($p < 0.001$).

Conclusion: Radionuclide bone scans have minimal diagnostic value for prostate cancer patients with a serum PSA level below 20 ng/ml and a low Gleason score (2-4). This criteria could be used to select patients who will benefit from a bone scan and could result in cost-savings and a reduction in waiting times.

C-0490

Audit of the use of testicular ultrasound

J. Brittenden; Harrogate/UK

Purpose: There are no guidelines governing the use of scrotal ultrasound in the investigation of testicular pathology.

Methods and Materials: The aim of our audit was to assess the clinical indication for imaging, results and outcome in 400 patients who had a scrotal ultrasound in our institution over a one year period (1st April 2003 - 31st March 2004).

Results: 62% of referrals were to investigate a clinically detected testicular swelling with one third of requests not specifying the location as being intra or extra-testicular. 30% of scans were normal. There was good correlation between the clinical and ultrasound findings in patients referred with an extra-testicular swelling but conversely there was poor correlation in patients referred with intra-testicular swelling. More than half of the patients referred with pain but no palpable mass had normal imaging. Of the patients referred with infection only 6% had associated complications that required intervention. Only 14% of patients with an abnormal scan underwent intervention (e.g surgery, aspiration and embolisation).

Conclusions: The lack of guidelines has resulted in 54% of scrotal ultrasounds being requested for patients with extra-testicular swellings and with normal testes, who are likely to undergo subsequent intervention. Analysis of the results of the use of testicular ultrasound in our hospital has resulted in the proposal of guidelines which have been issued to all family doctors and hospital consultants. The audit loop will be completed in one year's time to assess the effect of this action on the referral practice.

C-0491

Prostatic carcinoma (PC) treated with cryosurgical ablation (CA): Magnetic resonance imaging (MRI) patterns

G. Cardone, L. Nava, A. Losa, G. Guazzoni, P. Mangili, G. Balconi; Milan/IT

Learning Objectives: To report the spectrum of MR findings of prostate gland treated with cryotherapy. To show the evolution, as time passed, of the signal intensities of prostatic lesions treated with cryotherapy. To illustrate the more significant MR criteria of appropriate treatment of prostatic neoplasms by cryotherapy.

Background: Cryoablation is a minimally invasive surgical technique for early-stage prostatic carcinoma and MR is an effective imaging technique in the follow-up of lesions treated with cryoablation.

Imaging Findings: 12 pts with PC underwent cryosurgical ablation. All patients underwent MRI before and 24 hrs, 3, 6 and 12 months after surgery. MR examinations were performed using TSE T1w, TSE T2w and ce-FS TSE T1w sequences; ce-T1w images were also evaluated before and after digital subtraction. On T1w images the gland was iso-hyperintense 24 hrs after treatment and hypointense at 3, 6 and 12 months. On T2w images the gland was hyperintense at 24 hrs and hypointense at 3, 6 and 12 months. 24 hrs after treatment the prostate was 59% larger than the original volume of the gland; the treated gland decreased in size of an average of 41%, 52% and 65% at 3, 6 and 12 months respectively. Ce-FS TSE T1w and subtracted MR images showed complete ischemia of the gland in all cases, with periurethral zone sparing to preserve the urethra.

Conclusions: The more significant MR patterns in the follow-up of PC treated with CA were the decrease in size of the gland as time passed and the complete ischemia of the prostate, with periurethral zone sparing.

C-0492

Trauma-related erectile dysfunction: Spectrum of penile Doppler US findings

S. Kim¹, S. Kim¹, D. Yang²; ¹Seoul/KR, ²Incheon/KR

Learning Objectives: To illustrate the spectrum of Doppler US findings in trauma-related erectile dysfunction, categorizing them according to types of injuries.

Background: Erectile dysfunction can happen as a traumatic sequela, particularly with pelvic, vertebral, or straddle injuries. Penile Doppler findings in these patients are various, from normal to serious arterial impairment, according to types of injuries.

Imaging Findings: With neurogenic causes (e.g. vertebral injury), Doppler finding is usually normal or shows exaggerated response to vasoactive agent. Relatively or absolutely decreased peak velocity in unilateral cavernosal artery with anatomical variation (e.g. distal branches from contralateral cavernosal or dorsal artery) is a common finding in the patients with previous trauma or after major surgery in the pelvic region (e.g. radical cystectomy or prostatectomy). With trauma in the penis or perineum in straddle injury, distortion or reconstruction of vascular anatomy may be encountered in the penis, and arteriovenous fistula may be found in the corpus cavernosum in posttraumatic high-flow priapism. Dorsal vein thrombosis can be another cause of priapism after trauma or pelvic surgery.

Conclusions: Knowing this spectrum will help understand Doppler US findings in the patients with erectile dysfunction after trauma.

Retroperitoneal anatomy: What could we learn from disease.

Part 1: Embryology

F.M. Danza¹, M. Scialpi², A. D'Amico¹, O. Pantalone¹, A. Bernardini¹, E. Bock¹; L. Bonomo¹, ¹Rome/IT, ²Taranto/IT

Learning Objectives: To review abdominal embryogenesis for a better understanding of anatomy of the retroperitoneum (RP) and pathway of spread of pathology.

Background: The classical RP anatomy doesn't explain diffusion of fluid collections, as displayed in CT/MR exams.

Procedure Details: We retrospectively reviewed CT of patients without (200) and with (100) retroperitoneal diseases. Abdominal embryogenesis, rotations and adhesions of primitive gut/mesia were used to understand origin of retroperitoneal spaces and fascial planes (FP). We distinguish a true RP (perirenal space [PS] and posterior pararenal space [PPRS]) from acquired RP (anterior pararenal space [APRS], divided in two different compartments: supra-mesocolic APRS [smc-APRS], and under-mesocolic APRS [umc-APRS]), each resulting from different gastric/colic mesia. Adhesions generate virtual, potentially dissectible FP: the retromesenteric one cross the midline to the fascial trifurcation, communicating with two other planes, the retrorenal and lateroconal spaces. A long FP formed by inferior blending of anterior renal, posterior renal, and lateroconal fascia, continues into pelvis anterolateral to psoas muscle.

Conclusion: RP is composed of four compartments (PS, PPRS [true RP], smc-APRS, umc-APRS [acquired RP]) and multiple, potentially expandable FP; fluid collections can spread in compartments and open new spaces dissecting FP. Mesenteric root is the central way of communication between true/acquired RP and peritoneum through which diseases and fluid collections can spread bidirectionally. True RP is symmetric; acquired RP is asymmetric either in smc-APRS (on left reaches pelvis, on right stops under caecum) either in umc-APRS (smaller on right). Superiorly right PS communicates with the bare area of the liver.

C-0494

Retroperitoneal anatomy: What could we learn from disease.

Part 2: Pathway of spread of pathology

M. Scialpi¹, A. Magistrelli², M. Scaglione³, L. Lupattelli⁴, A. Rotondo³, F.M. Danza², L. Bonomo²; ¹Taranto/IT, ²Rome/IT, ³Naples/IT, ⁴Perugia/IT

Learning Objectives: To discuss the CT assessment of major retroperitoneal emergencies resulting in involvement of compartments and fascial planes (FP) of retroperitoneum, with radiologic and clinical implications.

Background: Radiologists base their diagnoses on retroperitoneal anatomy and its interconnection with the peritoneal cavity, identifying different spreads of diseases. The real way of diffusion of fluid collections in retroperitoneum has not ever been completely understood. The new sight of the retroperitoneal anatomy, previously proposed, is used to better evaluate retroperitoneal emergencies: four retroperitoneal compartments (supra-mesocolic anterior pararenal space, under-mesocolic anterior pararenal space, perirenal space and posterior pararenal space) and FP (retromesenteric, retro-renal, lateroconal planes; fascial trifurcation and combined interfascial plane that continues into pelvis).

Procedure Details: Between July 2001 and March 2004 CT of 124 patients with leaking abdominal aortic aneurysm (35), acute pancreatitis (42), renal trauma (39), and miscellaneous lesions (8) were reviewed. In all cases diagnoses were confirmed by surgery or autopsy or clinical or imaging follow-up. We evidenced an heterogeneous distribution of fluid collections and haematomas in the four retroperitoneal compartments and FP. The number of involved FP is calculated for each disease. Interconnections between retroperitoneum and peritoneal cavity were defined.

Conclusion: Helical CT increases the ability to diagnose and stage the retroperitoneal emergencies. It accurately defines spread of retroperitoneal collections, blood, pus or gas, in retroperitoneal lodges and interfascial planes. Along the anatomical interconnections with the peritoneal cavity and organs the anterior extension of some retroperitoneal diseases is easily depicted. Similar considerations can be applied to neoplastic spread in the retroperitoneum.

C-0495

Complications of urogenital non-vascular interventional procedures

Z.I. Siric, M. Radovanovic, M. Mrvic; Nis/YU

Purpose: To show the complications resulting from percutaneous interventional procedures in our patients as well as the treatment options.

Materials and Methods: During the period of the last ten years, we performed 1836 interventional non-vascular uroradiological procedures in 1650 patients (age between 10 months and 78 years). There were 970 (58.78%) female and 680 (41.22%) male patients. The performed interventions include 1269 PCN, 128 PCNL, 146 sclerosation of cysts, 88 abscess/urinoma drainages, 58 anterograde double-J stent placement, 70 biopsies, 28 stent placements, 45 ureteral dilatations and 4 anterograde extractions of encrusted double-J stents.

Results: In total we recorded 97 (5.28%) complications including 3 (0.16%) lethal complications. The complications which resulted directly from percutaneous procedures are: hemorrhage in 47 patients, lesions of the renal pelvis in 21, urosepsis in 9, urinoma formation in 8, lesions of the large bowel in 5, A-V fistula in 4 and penetration of the sclerosants into the kidney pelvis in 3 patients. Most of the complications were treated by interventional methods (5 renal artery embolizations, 12 compressions with balloon catheter, 8 urinoma drainage and 12 prolonged urine diversion). Surgical intervention was performed in 10 patients (in 8 due massive hemorrhage and 2 due lesion of large bowel).

Conclusions: Percutaneous, non-vascular interventional treatment of urogenital disorders resulted in less morbidity, shorter hospitalization and lower procedure-related complication rate. It is important that procedure should be performed by well trained radiologists who are capable of recognizing the complication and treating it percutaneously whenever it is possible.

C-0496

Imaging of the ureter with multislice CT urography

A.F. Scarsbrook, N.C. Cowan, J. Willatt; Oxford/UK

Learning Objectives: To review the anatomy and pathology of the ureter using multislice CT urography with retrograde ureteropyelographic (RP) correlation.

Background: Significant advances in computed tomography of the genitourinary system have been made since the advent of multislice technology. Multislice CT offers rapid thin slice acquisition with improved spatial resolution and the opportunity to reformat isotropic voxels for 2D & 3D image processing. CT is recognised as a method of choice for investigation of urinary tract stones and for detection and staging of renal masses. There is not yet consensus on the ability and use of multislice CT for detection and diagnosis of urothelial lesions and also small benign lesions of the ureter.

Imaging Findings: A pictorial review of the normal and pathological appearances of the ureter as demonstrated by multislice CT and RP is presented. Images were obtained from a series of > 1000 cases performed at our institution over a 6-year period. Illustrations of normal, normal variants and congenital anomalies of the ureter are included. Benign lesions such as retroperitoneal fibrosis, infection, drug induced strictures, stone disease, trauma and iatrogenic injuries are shown. Malignant pathology of the ureter and of adjacent structures is also featured.

Conclusion: This review demonstrates the radiological features of normal, normal variants and benign and malignant pathologies of the ureter using multislice CT.

C-0497

Strategy for self-directed learning of female pelvic floor anatomy from cadaver cross-sections and magnetic resonance images

W.H. Umek, O. Preyer, M.C. Sora, A. Ba-ssalamah, V. Mlynarik, S. Trattning, K. Pinker; Vienna/AT

Learning Objectives: To develop a strategy for interactive, self-directed learning of female pelvic floor anatomy using side-to-side comparison of macroscopic cadaver cross-sections and magnetic resonance (MR) images.

Background: Female pelvic floor anatomy is still little understood. Although modern imaging techniques provide high soft-tissue resolution, scientific comparisons of macroscopic anatomy with female pelvic floor MR images are still scarce.

Procedure Details: We isolated two female pelvis from cadavers of the Vienna Anatomy Donation Program, cut to fit a standard MR head coil. High-field MR images were obtained using a 3 Tesla Bruker Medspec 30/80 Scanner with a head birdcage coil and an actively shielded gradient system (maximum gradient strength: 45 mT/m). A T2-RARE sequence (TR/TE: 10.100/39 ms; acquisition time: 16 min) and a T2-MSME sequence (TR/TE: 10.000/19 ms; acquisition time: 64 min) were used for axial high resolution images (matrix size: 512x384; FOV: 230x159). Slice thickness was 2 mm with 4 mm interslice gap. The pelvis were then plastic-

Scientific and Educational Exhibits

nated, cut in 3 mm axial slices, and all slices scanned. MR and cross-sectional anatomic images were electronically arranged side-by-side. We labelled overlays to MR and anatomic images using the FreeForm AutoShapes function (Microsoft Powerpoint 2002©). These overlays allowed 1.) feedback to the viewer about their observations and 2.) tracking individual pelvic floor structures in several cross sections.

Conclusion: The presented method of interactive, self-directed learning from side-to-side comparison of macroscopic cadaver cross-sections with MR images is feasible and improves the understanding of female pelvic floor anatomy.

C-0498

CT imaging findings in primary pigmented nodular adrenocortical disease (PPNAD) in patients with Carney complex (CNC) and Cushing's disease

N.A. Courcoutsakis¹, P. Prassopoulos¹, J.A. Carney², C.A. Stratakis³,
¹Alexandroupolis/GR, ²Minnesota, MN/US, ³Bethesda, MD/US

Learning Objectives: To illustrate CT imaging findings with pathologic correlation in primary pigmented nodular adrenocortical disease (PPNAD) as they were presented in 20 patients with Carney complex (CNC) and Cushing's disease.

Background: PPNAD is the cause of a non-ACTH dependent Cushing disease. CT studies of 20 consecutive patients with CNC and PPNAD (15 familiar and five sporadic cases, mean age: 14.5 y.o.) were analyzed and compared with findings at pathology. Nineteen patients underwent bilateral and one unilateral adrenalectomy.

Imaging Findings: Pigmented micronodules - less than 3 mm in diameter- were demonstrated in all left adrenals (100%) and in 14 right adrenals (73.6%) of 19 patients who were cured with bilateral adrenalectomy. Pigmented macronodules -4 to 11 mm in size- were also observed in nine right and 10 left adrenals, being bilateral in eight (42.1%) patients. All nodules were hypodense comparing with the normal adrenal parenchyma and presented no contrast enhancement. Black or brown cortical nodules were seen on gross pathology while histology disclosed increased lipofuscin concentration within the pigmented nodules and the characteristic internodular cortical atrophy. CT of the adrenal gland revealed all pigmented macronodules but failed to demonstrate nodules when lesions were smaller than 3 mm and located in the right side in two patients.

Conclusions: 1) Patients with PPNAD demonstrate at least three small hypodense nodules on CT studies with the left adrenal invariably involved. 2) Young patients with non-suppressed hypercortisolism and adrenal nodularity demonstrated on CT studies should be evaluated for PPNAD and CNC.

C-0499

Diagnosing metastatic lymph nodes in urogenital cancers: The clinical impact and the role of radiologic imaging

N. Morisawa, T. Koyama, S. Umeoka, K. Tamai, T. Fujiwara, T. Saga, T. Itoh, K. Togashi; Kyoto/JP

Learning Objectives: To illustrate the clinical significance and the role of radiologic imaging in diagnosing metastatic nodes in urogenital cancers, showing their way of spread and frequency.

Background: Radiologic identification of metastatic nodes is crucial, since it significantly alters management of the patients. The clinical significance of metastatic nodes greatly differs according to the primary. The presence of metastatic nodes alters surgical procedure in renal and ureteral cancers, and management in vesical and prostatic cancers, i.e. palliative therapy instead of radical surgery. US and CT are common modalities for evaluating nodes. FDG-PET is also useful, but the role of MR imaging is under discussion. In this exhibit, diagnostic criteria for metastatic nodes at each modality are also reviewed. Understanding the merit and limitation of these modalities is also beneficial for planning radiologic evaluation.

Imaging Findings: The lymphatic spread and frequency of metastases depend on primary tumors and their histologic subtypes. In renal cancers, metastatic nodes are usually seen in the renal hilum, along the renal and ureteral vessels. In urinary tract cancers, metastatic nodes are seen along the major vessels nearby, with variable frequency according to the local stage of the primary. In vesical and prostatic cancers, metastatic nodes can affect variable regions, reflecting multidirectional lymphatic pathways. In testicular cancers, metastases initially occur in paraaortic nodes, which can result in systemic spreads.

Conclusion: The precise knowledge about the preferential sites and frequency of metastatic nodes facilitate radiologic evaluation, and the recognition of the clinical significance is beneficial in determining appropriate management.

C-0500

Is fluid ingestion really necessary before ultrasonography performed for detecting ureteral stones? A prospective randomized study

E. Özden, Ç. Göğüs, K. Türkölmez, C. Yagci; Ankara/TR

Purpose: Evaluation of ureteral stones with ultrasonography (US) is performed after fluid ingestion for filling the bladder. We hypothesized that water ingestion may decrease imaging quality of US by formation of intestinal artefacts and evaluated the value of US for detecting ureteral stones performed with or without fluid intake.

Methods and Materials: 150 consecutive patients who underwent US with suspect of ureteral stone were randomized into 2 groups. In order to distend the bladder, group A patients ingested 500 ml of water and examined by US after manifesting feelings of desired micturition. Group B patients were examined without any fluid intake. Diagnostic value of US was analyzed for all ureteral stones and also according to location of stones.

Results: US detected 35 of 52 stones (67%) in group A and 68 of 73 stones (93%) in group B ($p < 0.001$). Sensitivity and specificity of US were 67%, 82% for group A, and 93%, 94% for group B respectively. Accuracy of US for detecting ureteral stones was 71% in group A and 93% in group B.

Conclusions: Water ingestion before US decreases the detection rate of ureteral stones because of formation of intestinal artefacts. Patients with suspicion of ureteral stones should be examined by US without any fluid ingestion.

C-0502

Urinary tract neoplasms: Conventional and pyelo-urographic magnetic resonance (MR) patterns

G. Cardone, P. Mangili, L. Nava, G. Guazzoni, G. Balconi; Milan/IT

Learning Objectives: To illustrate conventional and pyelo-urographic MR patterns in urinary tract neoplasia evaluation. To evaluate the effectiveness of urographic and pyelographic MR sequences in the diagnosis of urinary tract neoplasia. To compare pyelographic and urographic MR sequences in the evaluation of urinary tract neoplasia.

Background: For many years conventional excretory Urography and Computed Tomography (CT) were considered the standard techniques used to examine patients with urinary tract neoplasia. Recently, the employment of MR using heavily T2w TSE sequences (MR-pyelography) such as gadolinium-enhanced 3D-GRE sequences (MR-Urography), have been described in patients with urinary tract disease.

Imaging Findings: 30 pts with 32 transitional cell carcinomas were analysed. All patients underwent MR-pyelographic, MR-urographic and conventional morphologic GRE T1w, TSE T2w and ce dynamic GRE FS-T1w sequences. Neoplastic lesions were visualised as solid papillomas in 58% of the cases, as thickening of collecting system walls in 33% of the cases and as solid tissue in the renal sinus in 9% of the cases. Lesions appeared more evident on TSE T2w, ce FS-GRE T1w and MR-urographic images. Lesions appeared quite vascularized. Urinary tract dilatation was evaluated in 85% of the patients. Dilatation was better estimated on both the TSE T2w and the MR-urographic images in the case of normal renal excretory function and on both the TSE T2w and the MR-pyelographic images in the case of functionally excluded kidneys.

Conclusions: Conventional MR images combined with uro-pyelographic techniques allow an accurate evaluation of urinary tract neoplasia.

C-0503

Primitive and recurrent liposarcoma of abdomen: What should we have to know for a correct CT and MR diagnosis

F.M. Danza, V. Marino, A. Magistrelli, M. Cirillo, P. Ottaviani, A.L. Valentini; L.Bonomo, Rome/IT

Learning Objectives: CT and MR appearance of liposarcomas is variable due to different stages of differentiation of their nodules. This exhibit shows examples of this variability, to learn how recognize real extent of disease at diagnosis or during follow-up, to reduce post-op residual disease or late diagnosis of recurrences.

Background: Liposarcomas are huge, multinodular masses with various appearances in radiological exams, due to their different histological differentiation, often coexistent in the same patient; the fat content of more differentiated nodules can determine their difficult detection. During follow-up surgical fibrosis and changing of the histological pattern complicate the diagnosis. Failure to recognize a

Scientific and Educational Exhibits

nodule at diagnosis or during follow-up affect significantly the survival, reducing the surgical radicality, with re-operations required, or inducing a diagnostic delay of recurrences.

Procedure Details: CT and MR of 35 cases of liposarcomas, surgically treated in the last 6 years, were reviewed to define their morphological and topographic appearance. Radiological follow-up to June 2004 was reviewed. Recurrences were high (20/35). Most early re-operations were related to residual diseases not recognized during surgery, instead of recurrences (12/20). In 15 patients recurrence occurred twice or three times. 22 patients died during follow-up, 3 were lost to follow-up and 10 are now disease-free (8 after surgical removal of residual nodules detected on imaging).

Conclusion: Prognosis of liposarcomas is directly related to complete surgical resection. Knowledge of CT and MR appearance of liposarcomas is crucial to recognize their real extent, residual nodules not resected at surgery and recurrences.

C-0504

Decreasing the radiation dose for renal stone CT

E. Eikefjord, N. Ulvik, D. Jensen, J. Rørvik; Bergen/NO

Purpose: To compare image quality and effective dose (ED) of different multidetector CT (MDCT) protocols from phantom measurements in order to optimize a low dose CT protocol for suspected ureteral stone.

Methods and Materials: A number of human ureteral stones were implanted in two porcine kidneys, fixed in a plastic tank filled with water. The number, size and density of the smallest and largest stone in each kidney, together with subjective image quality (noise, sharpness, contrast and artefact) ranging from 1 (poor) to 5 (best), were evaluated at 7 different protocols. The protocols differed in ED from the standard protocol (7.5 mSv at 4 x 3.75 mm collimation, 120 kVp, 200 mA and pitch 1.5) in a range of 40% reduction to an increase of 34%. Parameters differed in collimation, pitch and mA. Doses were computer-simulated, based on NRPB SR 250.

Results: The measurements showed no statistically significant differences in the detection of number of stones (right kidney: mean 12.75 ± 0.27), size (right kidney: 16.92 ± 0.49) and density between the 7 protocols. The protocol of the highest ED (11.25 mSv) scored 3.87 in image quality compared to 3 at the lowest dose protocol (4.5 mSv).

Conclusion: Image quality and effective dose did not correspond in a linear fashion. There exists a potential to reduce MDCT radiation dose for suspected ureteral stones. A low-dose protocol should be evaluated on patients for image quality before establishing MDCT for ureteral colic.

C-0505

Bilateral adrenal masses: Algorithmic approach for diagnosis

J. Lim, H. Kim, D. Lee, Y. Ko; Seoul/KR

Learning Objectives: To identify the variety of diseases that cause bilateral adrenal masses. To describe the appropriate radiologic work-up of bilateral adrenal masses. To differentiate bilateral adrenal masses based on CT and MR imaging features.

Background: Bilateral adrenal masses are uncommon and various causes have been reported. The most common causes are adenoma and metastasis. The rest includes hemorrhage, lymphoma, granulomatous infection, and pheochromocytoma. In this exhibit we will describe the radiologic findings of bilateral adrenal masses and present the appropriate algorithmic approach for the diagnosis of bilateral adrenal masses.

Procedure Details: Of various imaging modalities, CT and MR imaging play a major role in the evaluation of adrenal masses. Unenhanced CT is often the key study in characterization of adrenal masses by identifying high fat component, hemorrhage, or calcification. When unenhanced CT is indeterminate in characterization, contrast-enhanced dynamic CT is helpful by identifying enhancement patterns; early washout in adenoma, significant enhancement in pheochromocytoma, homogeneous enhancement in lymphoma, and poor enhancement in granulomatous disease or hemorrhage. If there is uncertainty in the diagnosis on CT examination, MR imaging may act as a problem solving method. MR imaging can demonstrate more sensitively and definitely fat component, hemorrhage, and necrosis. High signal intensity on T2-weighted image is also helpful for the diagnosis of pheochromocytoma or metastasis.

Conclusion: Various diseases may affect the adrenal gland, bilaterally. Systemic algorithmic approach to bilateral adrenal masses may be helpful for correct diagnosis and may reduce the efforts of radiologists.

C-0506

Imaging of urethral disease: Pictorial review

A. Kawashima¹, C.M. Sandler², A.J. LeRoy¹, N.F. Wasserman³, B.F. King¹, S.M. Goldman²; ¹Rochester, MN/US, ²Houston, TX/US, ³Minneapolis, MN/US

Learning Objectives: To review the anatomy and diseases of the urethra in adults to define the current role of imaging of the urethra and periurethral structure.

Background: We reviewed our case series and the literature on this topic. While we focus on conventional urethrography, cross sectional imaging modalities are also discussed as appropriate. The scope of this exhibit is as follows: 1) normal anatomy of the urethra, 2) urethrography technique, 3) traumatic injuries, 4) inflammatory diseases, 5) strictures, 6) acquired urethral diverticula, 7) urethral calculi, and 8) primary and metastatic tumors. The key imaging features of the urethral diseases on conventional contrast urethrograms and cross-sectional imaging studies are illustrated with representative cases.

Imaging Findings: Retrograde urethrography and voiding cystourethrography are imaging modalities of choice for the urethra while cross-sectional imaging modalities including ultrasound, MR imaging, and CT are useful in evaluating periurethral structures. Retrograde urethrography is a primary imaging modality of the male urethra for the evaluation of traumatic injuries, inflammatory and stricture diseases. Sonourethrography has an important role in assessing thickness and length of bulbar urethral stricture disease. Although voiding cystourethrography is frequently used to evaluate women with urethral diverticula, MR imaging is highly sensitive in demonstrating urethral diverticula. MR imaging is accurate in local staging of urethral tumors.

Conclusion: Imaging of the urethra based on urethrography is an integral component of the evaluation of patients with suspected urethral disease. The incorporation of cross-sectional imaging techniques, particularly MR imaging, yields additional information essential to diagnosis and therapy planning.

C-0507

Retroperitoneal sarcomas

E. Alonso, E. de Lama, J.A. Narvaez, Y. Roca, E. Merino, S. Ruiz Osuna, J.L. Lopez-Moreno; Barcelona/ES

Learning Objectives: - To describe the CT and MR imaging features of retroperitoneal sarcomas, with special emphasis in those which suggest a specific diagnosis. - To illustrate the usefulness of CT and MR imaging in the treatment planning of these lesions. - To describe the more important prognostic factors in retroperitoneal sarcomas.

Background: Retroperitoneal sarcomas are rare mesenchymal neoplasms. These tumors typically originate as large masses. They usually present with pain and a palpable abdominal mass. Liposarcomas and leiomyosarcomas were the most common tumors. Some histologic subtypes have specific patterns of growth and extension that aid in narrowing the differential diagnosis. Moreover, some tumor contents (fat, myxoid stroma, calcification, and necrosis) can be clearly demonstrated at CT and MR imaging and may provide strong clues that help narrow the differential diagnosis.

Procedure Details: A retrospectively review of the clinical charts, and CT and MR imaging studies of all histologically proven retroperitoneal sarcomas seen in a universitary hospital during 10 years retrieved 40 cases. Epidemiological characteristics (age, localization, size, type and grade histological, treatment, surgery margins, treatment complementary, recurrence and survival) were reviewed. CT and MR imaging studies were also reviewed in order to determinate specifically these components than can delineate the specific diagnosis.

Conclusion: Familiarity with the specific features of various retroperitoneal tumors often allows accurate histologic diagnosis and helps suggest proper management. Complete resection and low grade continue to be the most important prognostic factors for this tumor. Anatomic restrictions to wide resection and local recurrence were the most important factors determining survival.

C-0508

Adrenal glands in beta-thalassemia major: MR imaging features and correlation with iron stores

E. Drakonaki¹, O. Papakonstantinou¹, T. Maris¹, C. Koulieraki¹, A. Vasiliadou², A. Papadakis¹, N. Gourtsoyiannis¹; ¹Iraklion/GR, ²Chania/GR

Purpose: To describe the MR imaging features of the adrenal glands in beta-thalassemia major and investigate the relation between adrenal signal intensity (SI) and liver iron overload, as expressed by the SI ratio of liver to the right paraspinous muscle (L/M). Adrenals in beta thalassemia have not been previously studied with MR imaging.

Materials and Methods: Abdominal MR imaging studies of 64 patients with beta-

Scientific and Educational Exhibits

thalassemia major (mean age 27 ± 5 years old) were retrospectively studied for determining adrenal size and SI on T1 (120/4/90), PD (120/4/20) and T2' (120/15/20) GRE sequences and compared to those of ten healthy controls. L/M ratios on all MR sequences were calculated. Adrenal SI was graded on a 3-point scale: grade 0 indicated normal SI on all sequences, grade 1 hypointensity on T2* only and grade 2 hypointensity on all sequences. Ferritin levels of the patients were also recorded. The data were statistically analysed using one-way ANOVA. Statistical significance was set at $p < 0.05$.

Results: The size of adrenals in all patients was within normal limits. Adrenal hypointensity (grade 1 and 2) was noted in 24/35 (68.5%) patients. Hepatic siderosis, expressed by L/M ratios, correlated with ferritin levels ($p < 0.001$) and adrenal SI ($p < 0.003$) in all three sequences. Patients with grade 1 and grade 2 adrenal SI had decreased L/M ratios compared to those with grade 0 ($p < 0.003$).

Conclusion: Adrenal hypointensity without size alteration is a common finding in MR imaging of beta-thalassemic patients and correlates with the degree of liver siderosis.

C-0509

Bladder imaging using multidetector row CT: Techniques, applications and findings

T.G. Mang¹, B. Happel¹, C. Mueller¹, M. Prokop², H.C. Klingler¹, M. Suasn¹, G. Heinz-Peer¹; ¹Vienna/AT, ²Utrecht/NL

Learning Objectives: 1. To describe the spectrum of multidetector CT (MDCT) findings of common and uncommon diseases of the urinary bladder. 2. To demonstrate the usefulness of virtual cystoscopy in the evaluation of bladder lesions. 3. To illustrate MDCT signs and criteria for staging of bladder cancer.

Background: Multidetector CT offers new possibilities for imaging of the urinary tract. Using thin collimation, near isotropic imaging of the urinary tract is possible and provides high quality multiplanar reformations and 3D reconstructions of the organ including virtual cystoscopic views. Thus, MDCT seems to be a valuable tool in the evaluation of hematuria. Proper distension of the urinary bladder and optimum intravenous contrast timing is required for detecting and staging of bladder lesions. Compared to conventional cystoscopy, MDCT provides information about the extravesical extent of disease.

Procedure Details: We describe optimized CT protocols and the CT appearance of various urinary bladder lesions. Additionally, staging criteria of bladder neoplasms are demonstrated.

Conclusion: MDCT is an accurate tool for detection and evaluation of bladder lesions. With the benefit of 3D imaging further increase of the diagnostic performance is possible.

C-0510

Comparison between 3D CT and MR protocols in the detection of bladder lesions

V. Panebianco, D. Tancredi, T. Celano, P.G. Nardis, L. Di Rezze, P. Paolantonio, R. Passariello; Rome/IT

Purpose: To evaluate the value of 3D-protocol based on MR and CT-datasets in detection and T-staging of bladder lesions.

Methods: Thirty five patients with known bladder lesion underwent CT and MR. CT included a non contrast enhanced scan. Each patient received air distension by Foley catheter. A pre-contrast CT scanning was performed (Kvp120, mAs80 slice, slice coll. thk3 mm, image-recon 1-2 mm). Images were used for 3D reconstructions. An additional scan was performed after contrast-agents administration (slice coll. thk 5 mm, image recon 5 mm). MR examinations were performed on 1.5 T magnet with phased array coil and included 2D FSE sequence on axial plane (TR: 4300 msec, TE eff.:132 msec, ETL: 33, Matrix: 420x512); 2D FLASH sequence on axial plane pre and post Gadolinium administration and 3D-FLASH sequence (TR: 4.6 msec, FA: 30°, TE: 1.8 msec, Slice thk:2 mm, Matrix: 195x512, TA: 23 sec.) for 3D reconstructions. Images were analyzed on Workstation (Vitrea "Vital Images"). We analyzed site, size, depth of invasion, perivesical fat tissue and lymph nodes. All images were compared with histology.

Results: Concerning site, size, morphology and lymph node involvement CT and MR allowed a precise detection of 33 bladder lesions, two polypoid lesions of 5 mm were missed only by MR. 10% of T1 lesions were overestimated by MR while 20% of T2 lesion with muscle invasion were underestimated by CT.

Conclusions: MR allowed a more precise local staging of bladder neoplasms compared to CT protocols. On the other hand CT protocols demonstrate a better identification of smaller lesions (5 mm size).

C-0511

MR-urography in the evaluation of urinary tract obstruction

L. Zugaro¹, A. Catalucci¹, M. Monina¹, E. Di Cesare², C. Vicentini¹, C. Masciocchi²; ¹Teramo/IT, ²L'Aquila/IT

Purpose: To evaluate the diagnostic capability of MRU in case of urinary tract obstruction.

Methods and Materials: 72 patients suffering by obstructive uropathy underwent MR examination (1.5 T units). Saline solution was administrated about 10 min before. Unenhanced-MRU (heavily T2-w fat-sat seq.) was followed by enhanced-MRU (coronal 3DT1FFE seq. after Gd-BOPTA); diuresis was induced by i.v. administration of low-dose furosemide; standard MR imaging was also performed. All patients underwent US examination, 55 excretory urography, 21 CT. MRU was evaluated to detect urinary tract dilatation, cause and level of the obstruction. Excretory urography and the final clinical diagnosis were used as reference.

Results: The obstruction site and cause were detected in all cases by MR imaging. Unenhanced-MRU was capable of demonstrating 68/72 dilated urinary tracts, including 5 cases of non functioning kidneys. Twenty-four patients had urinary tract obstruction by urinary stones, 32 by neoplasms, 9 by ureteral benign stricture, 6 congenital ureteral stricture, 1 by iatrogenic cause.

Conclusion: MRU, providing both morphological and functional information, may replace conventional urography to determine the level of obstruction in cases where iodinated contrast is contraindicated or ionizing radiation should be avoided; in combination with standard MR imaging, it can detect the cause of urinary tract obstruction.

C-0512

Multi-detector row CT urography: Comparison of fluid administration protocols for depicting the urinary collecting system

H. Shinjo, T. Gokan, N. Takeyama, J. Suyama; Tokyo/JP

Purpose: To compare four different fluid administration protocols for depiction of the urinary collecting system with multi-detector row CT urography (MDCTU).

Method and Materials: 172 patients with hematuria underwent MDCTU, during which thinly collimated (1-mm) excretory phase scanning was performed 8 minutes after contrast medium injection. Patients were examined one of four techniques: (A) (N = 46) intravenous infusion of 250 ml normal saline; (B) (N = 39) oral administration of 350 ml green tea about 15 minutes before the examination; (C) (N = 52) oral administration of 350 ml water about 15 minutes before the examination; (D) (N = 35) no administration of fluid and no intravenous infusion (control). Two reviewers measured urinary tract opacification on MIP (maximum intensity projection) images. Scoring system was used to evaluate the opacification of ureter. 0,unopacified; 1,less than 1/3 of segment opacified; 2,1/3 to 2/3 of segment opacified; 3, 2/3 to less than 100% opacified.

Results: Mean opacification scores of each group were as follows: group A:3.23, group B:3.30, group C:3.16, group D:2.84. Group B had the highest mean opacification score. Mean opacification of the ureter in A, B and C was significantly improved over that in group D ($P < 0.001$). But there was no significant difference among the scores in group A, B and C.

Conclusion: MDCTU with supplemental oral administration of green tea significantly improves display of the urinary collecting system and is easier than and as useful as supplemental infusion of normal saline.

C-0513

Imaging of lymphoproliferative diseases involving urogenital system

S. Hwang, S. Kim, S. Kim, S. Jung; Seoul/KR

Learning Objectives: To illustrate and review the wide spectrum of radiological findings of lymphoproliferative diseases such as lymphoma, leukemia, castleman disease and posttransplantation lymphoproliferative disease that involve urogenital systems including kidney, uterus, ovary, testis, adrenal gland. And describe clues for differential diagnosis of these diseases.

Background: Lymphoproliferative diseases are diseases characterized by proliferation of lymphoid tissue. Lymphoproliferative disease includes lymphoma, leukemia, postlymphoproliferative diseases, and castleman disease. Primary involvements of urogenital system from lymphoproliferative diseases are uncommon. But the manifestation of lymphoproliferative diseases shows wide variability with potential involvement of multi-organ systems.

Imaging Findings: Lymphoproliferative diseases in urogenital system shows variable imaging findings. Preservation of normal anatomy, homogenous solid mass, rarity of necrosis or hemorrhage, and associated lymphadenopathy will be sometimes clues in diagnosis.

Conclusion: The manifestation of lymphoproliferative diseases shows wide var-

Scientific and Educational Exhibits

ability with potential involvement of multi-organ systems. Both clinical and radiological findings often mimic other disease processes, so the radiologist should be aware of this entity.

withdrawn by authors

C-0515

Spectrum of imaging findings in genitourinary tuberculosis

F. Binokay, B. Soyupak, E. Akgul, S. Soyupak, M. Celiktas; Adana/TR

Background: The objective of this study is to describe the various diagnostic features of the genitourinary system as seen in our department.

Materials and Methods: A retrospective case review of all female and male cases of genitourinary tuberculosis imaged in our department over a six-year of period was done. A total of 16 cases of urogenital tuberculosis were reported during this time period. Only 21.4% of patients had a known history of tuberculosis. The age of the patients ranged from 26 to 54 years. The ratio of male to female patients was 1:1. Cystitis was the most frequent sign (74%), hematuria, nonspecific lumbar pain, genital signs and nephrologic signs are not rare.

Results: The series included three cases of renal, two adrenal, four bladder, two prostate, four endometrial and one tubo-ovarian tuberculosis. Patients were examined with intravenous pyelography (IVP), computed tomography (CT), ultrasonography (USG), color Doppler ultrasonography (RDUS) and hysterosalpingography (HSG). The radiological lesions most frequently encountered were renal calcifications (25.2%), destruction of calyces and pseudohydronephrosis (22.3%), atrophy and calcification in adrenal glands (9%), small-rigid tuberculous bladder (6.3%), tuberculous mass mimicking bladder carcinoma (4.2%), prostatic abscesses (3%), endometrial adhesions (6.5%), obliteration of the uterine cavity (2.1%), salpingitis isthmica nodosa and tubo-ovarian abscesses (8%).

Conclusions: Since tuberculous involvement in the genitourinary system may be confused with many other pathologies, both clinically and radiologically, radiologists should be aware of the different radiographic appearances of this protean but curable disease and should consider it in the differential diagnosis.

C-0516

Pheochromocytomas: Usual and unusual imaging findings

M.J. Pons, L. Diaz, A. Villanueva, P.D. Dominguez, M.A. Idoate, J.F. Boan, A. Benito; Pamplona/ES

Learning Objectives: To describe the different imaging findings in the study of adrenal pheochromocytomas.

Background: The great majority of adenomas, myelolipomas and adrenal gland cysts have typical radiological findings. The remaining pathological processes of the adrenals are a challenge for the radiologist. Adrenal pheochromocytomas are usually benign neuroendocrine tumors that very often show malignant behaviour on imaging studies.

Imaging Findings: 18 cases of pheochromocytomas diagnosed by a pathologist are illustrated. These cases were studied by intraoperative US, CT, PET and MR imaging. Pheochromocytomas appear as circumscribed round lesions, hyperintense in T2 weighted images, with early and prolonged contrast uptake. There are some aspects that still remain unclear about pheochromocytomas. In this study some of the most frequent and not so frequent findings of adrenal pheochromocytomas are shown. We included mixed pheochromocytomas, malignancy-associated pheochromocytomas and phaeochromocytoma involving the inferior cava vein and suprahepatic vein.

Conclusion: Even though their radiological appearance may be malignant, most cases of pheochromocytomas are benign lesions.

C-0517

Imaging of idiopathic retroperitoneal fibrosis

R. Cobelli, A. Vaglio, P. Greco, C. Buzio, M. Zompatori; Parma/IT

Learning Objectives: To illustrate the imaging with CT, MR of idiopathic retroperitoneal fibrosis and to described the differential diagnosis with other pathology of the retroperitoneum.

Background: Idiopathic retroperitoneal fibrosis is a rare pathology of the retroperitoneum. Its initial signs and symptoms are often nonspecific. For this reason it is important that the radiologist know the way of presentation, the differential diagnosis and the radiological criteria to establish the activity of this pathology.

Procedure Details: We retrospectively analysed 42 CT and 10 MR of 20 patient affected by idiopathic retroperitoneal fibrosis. We described the radiological pres-

entation, the natural history, the reactivation, the most frequent complication and the differential diagnosis through variegate and complete iconography.

Conclusion: Idiopathic retroperitoneal fibrosis is a rare pathology that can be manifested with different radiological pictures. The role of the radiologist is the detection, the evaluation of the effectiveness of the therapy and the identification of possible complications.

C-0518

Patient radiation dose at multidetector CT and conventional urography (IVU) for acute flank pain

E. Eikefjord, N. Ulvik, J. Rørvik; Bergen/NO

Purpose: To measure and compare patient effective doses (ED) from multidetector computed tomography (MDCT) and intravenous urography (IVU) for acute flank pain.

Methods and Materials: 117 patients with acute flank pain were included. Everyone underwent both MDCT (GE) with 4 x 3.75 mm collimation, 120 kVp, 200 mAs and pitch 1.5 and IVU with 70 kVp and automatic mA device (Canon DR) as standard parameters. The CT protocol included one volumetric acquisition of the abdomen and pelvis at standard parameters, mA varying due to patient size. The IVU protocol consisted of a standard acquisition of 3 AP images, total number varying. Effective doses were computer-simulated by using dosimetry programs for CT and conventional radiography, based on NRPB dose data sets from SR 250 and SR 262 respectively. Mean and SD of measured patient doses were calculated and compared.

Results: Mean patient ED for MDCT was $7.7 \text{ mSv} \pm 1.86$. The difference between men and women were 7.4 and 9.4 mSv respectively. Mean ED for IVU was $3.63 \text{ mSv} \pm 2.91$. Contrary to MDCT the ED was higher for men than for women, 3.93 mSv and 2.12 mSv respectively.

Conclusion: Standard protocol MDCT lead to approximately 50% higher ED than IVU. An optimized low-dose protocol should be considered before establishing MDCT for ureteral colic to minimize radiation induced cancer risk and secure adequate image quality. A low-dose MDCT protocol will be evaluated in a coming study.

C-0519

Dual time point [18F]-FDG PET for the differentiation between malignant and benign genitourinary lesions

D.V. Ryzhkova, L.A. Tyutin, N.A. Kostenikov, M.S. Tlostanova, S.V. Shatik, V.V. Zaytsev; St. Petersburg/RU

Purpose: The purpose of this study was to assess the advantage of dual time point [18F]-FDG PET imaging for the differentiation between malignant and benign genitourinary lesions.

Materials and Methods: We examined 31 patients (5 female, 26 male, aged 42 to 69 years) with genitourinary lesions proven by ultrasound, CT or MR imaging. Histological conformation of the diagnosis was performed in all patients. [18F]-FDG PET scans ("HR+", Siemens) were acquired in "Whole body" mode at 2 h and 4 h after injection of 370 MBq [18F]-FDG. During the time between injection and 2-h scans the patients were given 2 mg furosemide to remove excreted [18F]-FDG activity from the bladder. The patients were asked to void just before 2-h and 4-h scans. All images were evaluated visually and quantitatively calculating standard uptake value (SUV).

Results: We noted [18F]-FDG activity completely vanished from the bladder at 4-h, leading to good visualization of lower abdomen and pelvis areas. Benign lesions showed a low [18F]-FDG uptake (SUV < 2.5) at 2-h and had no significant [18F]-FDG uptake changes to 4-h. By contrast, malignant lesions showed more than 10-percent increase in [18F]-FDG uptake from 2-h to 4-h. Lesion-based diagnostic accuracy was improved from 71.4% to 95.2%, and patient-based diagnostic accuracy from 77.4% to 93.5%.

Conclusion: Dual time point [18F]-FDG PET imaging is a more reliable protocol for the differentiation of malignant from benign genitourinary lesions.

C-0520

The analytical value of the dynamic MR imaging semiquantitative parameters in detecting the stage and grade of bladder cancers

N. Tuncbilek, M. Kaplan, A. Semsi, O.O. Okten, I. Atakan, O. Inci; Edirne/TR

Purpose: So called "neoangiogenesis" is a new and an important prognostic sign that signifies the biological behaviour of solitary tumours. We investigated the role of semiquantitative contrast parameters of dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) on tumour grade, stage and indirectly on neoangiogenesis in patients with bladder cancer.

Scientific and Educational Exhibits

Materials and Methods: A total of 17 patients are taken with bladder cancer aged between 49 and 78 (mean: 64.1) to dynamic investigate with 1 T magnet turbo-FLASH sequence parameters with the formed time signal intensity curves in the end, first (E_1), second (E_2) and third (E_3) minute contrasting values and time SI curve slopes are calculated. The findings were correlated with DCE-MRI features and histopathological data by using statistical.

Results: The differential analysis to detect the difference between the superficial and deep tumours was successful in a 70.6% rate by using E_1 , E_2 , E_3 and time SI curve slopes. A significant correlation found between time SI curve slope and E_1 values and tumour grade ($p < 0.05$). In a multivariation differentiation analysis, tumour grade detected 58.8% correctly by using the DCE-MRI semiquantitative parameters in combination ($p < 0.05$).

Conclusion: DCE-MRI parameters are the indirect determinants of tumour microcirculation and perfusion. According to our findings, the relationship between the preoperative DCE-MRI semiquantitative parameters and the tumour stage and grade will indirectly show the biological behaviour of the tumour and will give the chance to estimate the metastasizing ability. By using the DCE-MRI findings, discriminating analysis can be used additionally to the known treatment methods.

C-0521

Urinary tract abnormalities on bone scintigrams: Boosting the diagnostic yield

S.P. Prabhu¹, D. Dunlop², K. Prescod¹; ¹Bristol/UK, ²Bath/UK

Learning Objectives: 1. To highlight the importance of looking at the renal outline on bone scans. 2. To illustrate cases where renal abnormalities on bone scans either added to or led to diagnosis of pathology. 3. To demonstrate variants of renal anatomy and physiology that may be seen on bone scans. 4. To show correlative cross-sectional or planar imaging to prove the diagnosis obtained from the bone scan.

Background: Renal tract abnormalities are detected as incidental findings in 10-15% of isotope bone scintigrams. We present a series of patterns seen on review of more than 7500 scintigrams in our institution.

Imaging Findings: Bilateral, diffuse increased renal uptake is seen in patients undergoing chemotherapy, hyperparathyroidism, hypercalcemia and sickle cell disease. Bilateral diffuse decreased renal uptake is seen in patients with end-stage renal disease, widespread skeletal metastases and hematologic disorders. Focal increased activity is associated with postsurgical and radiation changes. Focal decreased uptake is caused by space-occupying lesions such as abscesses, cysts, and neoplasms either arising from the kidney or adjacent structures. Renovascular disease, nephrectomy and congenital anomalies can cause decrease in renal size, shape and position. Bladder anomalies are also discernible on many bone scans. We correlate bone scan findings with appearances on other modalities.

Conclusions: Urinary tract abnormalities are seen on 20% of bone scintigrams and can enhance diagnostic yield in many cases. In some cases, diagnoses not related to the skeletal system but causing patient's symptoms are recognised like hydronephrosis or renal cell carcinoma. So, don't forget the kidneys and bladder on bone scans!!

Head

C-0522

The accessory oval foramen, so-called foramen of Vesalius: Anatomic CT study and clinical correlations

J. Renoux, K. Marsot-Dupuch, F. Benoudiba; *Le Kremlin-Bicêtre/FR*

Purpose: To define the prevalence and variants of the accessory oval foramen. We aimed to understand its significance and its correlation with clinical disorders.

Materials and Methods: We selected adult patients, without previous history of surgery. We examined prospectively one hundred ultra-high resolution CT studies of the skull-base performed in the same unit, with the same parameters, and read by the same team. Correlations with MR data were made when possible.

Results: The accessory oval foramen is an oblong hole with smooth walls, developed in the base of the pterygoid process. It has a tubular canal in sagittal and coronal views, coming from infra-temporal fossa to the temporal fossa. This canal is lateral to the pterygoid canal. Accessory oval foramen was depicted in 90%; in 70% it was well depicted and in 20% only multi-planar reconstruction could depict a very thin accessory oval foramen. It was bilateral in 70%, double in 2%. Presence of a bony dehiscence in the sphenoid sinus was found in 2%. In 4%, it was in continuity with a lateral canal, coming from the carotid canal, which contains the accessory meningeal artery. Accessory oval foramen was found to be larger than the foramen spinosum in 10%. This seems to be correlated with development factors, and not with pathological disorders.

Conclusion: Accessory oval foramen is a key route for dissemination of infections or tumors from the infra-temporal fossa to the cavernous sinus. Its anatomical characteristics can explain some sympathetic signs in sinus disorders.

C-0523

Greater occipital nerve infiltration under CT guidance: An anatomical and radiological study

B.A.C. Kastler, Z. Patay, Z. Boulahdour, E. Rodière, S. Aubry, J. Lerais, B. Fergane; *Besançon/FR*

Learning Objectives: To perform the infiltration one must first have a good understanding of the anatomical relationship of the greater occipital nerve (GON) and the surrounding structures, which determine the possible safe percutaneous pathways.

Background: Infiltration has been found helpful in the diagnosis and management of occipital neuralgia, particularly in patients resistant to specific medication. The purpose of this exhibit is firstly to depict the anatomy of the course of the GON. Anatomical studies suggest that there are two possible conflicting sites. The first site is at its origin (dorsal primary ramus of the second cervical nerve), located behind the C1 and C2 joint just medial to the vertebral artery. The second site is at its emergence where the GON pierces the fascia, just below the superior nuchal ridge along with the occipital artery.

Procedure Details: We will demonstrate step-by-step our technique of percutaneous infiltration of the nerve under CT-guidance.

Conclusion: CT-guidance allows safe needle progression and precise positioning particularly at the 1st target, which is not otherwise accessible. It allows reducing complications and optimizes procedure results.

C-0524

MR microimaging of human eye with a blinking-gated pulse sequence

T. Obata, H. Ikehira, M. Tamura, S. Tanada; *Chiba/JP*

Purpose: MR microimaging of the human eye is very difficult because of eye movement during the MR scan. To acquire high-resolution MR images, we developed a new blinking-gated pulse sequence with a surface coil specialized for microscopic imaging.

Methods and Materials: Four normal subjects were studied. Informed consent was obtained from all subjects prior to the experiment according to the guidelines of our institutional review board. To reduce eye movement, the eyes were kept open and fixated to a target in the MR gantry. To reduce motion artifact from blinking, images were obtained using the blinking-gated pulse sequences (T2 weighted fast spin echo, TR: 6 sec, TE: 100 ms, ET: 11, matrix: 256x128, FOV: 5 cm, slices: 1 mm x 30). Three scans (100 sec x 3) were obtained for each subject. They were added together after adjustment for location to make one high signal-to-noise-ratio (SNR) image set.

Results: T2 weighted MR images were acquired with high resolution and high SNR. Microscopic structures such as the iris and ciliary muscles were clearly

Scientific and Educational Exhibits

visualized. Since the whole eye can be covered by this method, 3D maps can easily be made from the obtained images.

Conclusion: The application of blinking-gated pulse sequences with surface coil for MR microimaging of the human eye might become a useful and widely adopted procedure.

C-0525

The role of radioimmunoscintigraphy in the diagnosis and follow-up of primary ocular melanoma

S.L. Beatovic, V. Obradovic, Z. Latkovic, E. Jaksic; Belgrade/YU

Purpose: Our study aimed at evaluating the role of immunoscintigraphy (IS) in the diagnosis and follow-up of patients with primary ocular melanoma.

Materials and Methods: IS was done in 17 patients: 9 patients with newly diagnosed choroidal melanoma (group A), 6 patients with choroidal melanoma treated by contact radiotherapy (group B) and 2 patients with melanoma conjunctivae (group C). F-(ab')-2 fragments of monoclonal antibody 225.28 S, directed against the high molecular weight-melanoma associated antigen (HMW-MAA) were used in our investigation. Planar scintigraphy was done 4 hours after injection of 270 MBq of labeled antibodies. 500000 counts static images were acquired in a 256x256 resolution matrix.

Results: All patients in group A showed positive finding of IS. The maximal diameter of these tumors, measured by ultrasound, was between 9 and 18 mm, with prominence between 5 and 10.5 mm. Both patients of group C showed negative IS finding, due to the small dimensions of the tumor (< 2.7 mm). In all 6 patients of group B, IS was negative, although the tumor dimensions were sufficiently visible by the scintigraphy (diameter between 8.3 and 17 mm and prominence between 5 and 10.3 mm).

Conclusion: IS is a useful diagnostic modality in detection of small intra-ocular tumors. Negative IS in patients with tumors treated by radiotherapy could be explained by the biological regression of tumor, that precedes regression in its volume. This finding indicates the potential usefulness of IS in the follow-up of conservatively or surgically treated patients with choroidal melanoma.

C-0526

Color Doppler US in the evaluation of Behcet's disease

B. Yagci, C. Isik, C. Yildirim, N. Sabir, S. Tatlipinar; Denizli/TR

Purpose: The purpose of the study was to detect prospectively the value of color Doppler US of orbital vasculature in the assessment of ocular involvement in patients with Behcet's disease without clinical ophthalmologic abnormalities.

Methods and Materials: Color Doppler US of the orbital vessels was performed on 26 eyes of 13 patients who were diagnosed as having Behcet's disease with ocular involvement (group1), 65 eyes of 33 patients who had Behcet's disease without ocular involvement (group2) and 40 eyes of 20 healthy volunteers (group3).

Results: The peak systolic (PSV) and end-diastolic (EDV) velocities of central retinal arteries (CRA) were significantly lower in both patient groups than in healthy control group ($p < 0.001$). When both patient and control groups were compared, slightly increase in the mean resistance indexes (RI) values of CRA in both patient groups were statistically significant (group1: $p = 0.027$, and group2: $p = 0.001$). In group2 a statistically significant decrease in the PSV and EDV, and a significant increase in the RI of the ophthalmic arteries (OA) were detected when compared with the control group ($p = 0.049$, $p < 0.001$, $p = 0.003$, respectively). In group1; the decrease in EDV of OA were statistically significant ($p = 0.041$). No significant differences between both patient groups were shown for the velocities and indexes of both arteries.

Conclusion: These results suggest that the detection of increased vascular resistance in the ophthalmic and central retinal arteries with color Doppler US analysis in patients with Behcet's disease without clinical ophthalmologic abnormalities might predict the pre-clinical diagnosis of ocular involvement in Behcet's disease.

C-0527

Role of radiology in the diagnosis and management of epiphora

K. Gopal, J. Tuck, R. Razzaq; Bolton/UK

Learning Objectives: Epiphora (watery eyes) is a common condition in ophthalmologic practice. In this pictorial review we present the common causes for the above and our role in the management of these patients.

Background: Epiphora is a common ophthalmologic problem, comprising 3% of clinical visits. It results most commonly from stenosis or obstruction of tear ducts in the majority of patients. Once over secretion of tear fluid has been ruled out, digital subtraction dacrocystography is performed to demonstrate obstruction of the lacrimal system. In stenosis or obstruction, interventional procedures such

as balloon dacrocystoplasty or stent implantation have become an alternative to surgical procedures in many cases.

Procedure Details: In this pictorial review we would like to highlight the anatomy of the lacrimal system, technique of dacrocystogram and balloon dacrocystoplasty. Both these procedures can ideally be performed in one sitting which obviates the need for a prior attendance for non-invasive imaging.

Conclusion: Dacrocystogram is a very quick and simple technique, which is able to demonstrate the cause of epiphora in most cases. In addition balloon dacrocystoplasty is a feasible non-surgical therapy in nasolacrimal duct obstructions with good clinical results that may be used as an alternative to surgical procedures.

C-0528

Imaging of head and neck vascular masses: A pictorial review

S.E.J. Connor, C.M. Flis; London/UK

Learning Objectives: To review the classification, radiological appearances and image guided treatment options of vascular masses of the head and neck.

Background: Vascular masses of the head and neck may be classified as congenital (vascular malformations and haemangiomas) or acquired (aneurysms and tumours). They may also be termed as low flow (venous, mixed and capillary malformations) or high flow (arteriovenous malformations, proliferating haemangiomas and aneurysms) and proliferative (haemangiomas or other tumours with secondary angiogenesis) or non proliferative (vascular malformations or aneurysms). Ultrasound or magnetic resonance imaging (MRI) are valuable in characterising these lesions on the basis of enhancement patterns, extent of parenchymal mass and flow characteristics. They can also delineate the deep extent and involvement of vital structures. Computed tomography (CT) may be reserved for the detection of bony involvement and the presence of phleboliths. Conventional angiography and percutaneous phlebography are performed as a precursor to radiological therapeutic procedures.

Imaging Findings: The ultrasound (including colour and duplex Doppler), CT, MRI and conventional angiographic appearances of venous and mixed low flow malformations, AVMs, aneurysms, haemangiomas (proliferating and involuting) and other vascular tumours (paragangliomas, juvenile angiobromas, haemangiopericytomas, vascular metastases) will be described and illustrated together with examples of radiological interventions. An approach to their radiological evaluation and the typical imaging features will be highlighted.

Conclusion: An understanding of the classification and imaging appearances of vascular masses of the head and neck is vital for the radiologist to propose an appropriate differential diagnosis and for the consideration of image guided therapy.

C-0529

Pictorial review of eye ultrasound with CT and MR correlation

D. Spitzer, J. Novák, M. Mrklovský, P. Jiricková, O. Spitzerová, V. Sloboda; Pardubice/CZ

Purpose: The objective of this exhibit is to review the normal and abnormal appearances of eye and orbit. Emphasis is placed on the use of state-of-the-art equipment and technique, including colour Doppler imaging.

Material and Methods: Over 30 different eye and/or orbit ultrasound (high definition high frequency linear probe) cases are demonstrated, including CT (double slice) and/or MR (1.5 T) imaging correlation.

Results: The cases include examples of normal anatomy, benign and malignant neoplasm, abscess, haematoma, simple and complex cyst, and both normal implants and implant complications, intraocular foreign bodies, cataract, vitreal pathology and ablation of the retina etc. We review the specific utility of ultrasound as it compares with other imaging modalities. We also demonstrate cases in which ultrasound was not useful.

Conclusion: Adequate knowledge of the anatomy of the eye and orbit is needed to correctly limit the differential diagnostic possibility of pathology of the eye and orbit. US is a readily available method for an accurate diagnosis within the eye, with CT and preferably MR, being reserved for cases which require additional information about deep structure, or those with which there is discrepancy between the sonographic and clinical diagnosis.

C-0531

Orbital MR imaging: A pictorial review

A.P. Dahir; Mumbai/IN

Purpose: To establish the importance of MR imaging in orbital imaging. To demonstrate MRI appearance of various orbital pathologies. To compare CT and MRI in diagnosis of orbital lesions.

Materials and Methods: 50 patients with orbital and visual complaints were studied on a 1.5 T MRI scanner. A comparative study between CT and MRI of 50 patients was performed. Contrast enhanced studies were performed to look for patterns and dynamics of enhancement.

Results: 20 out of 50 patients were identified as having neoplasms, 13 had inflammatory disease, and 8 had vascular abnormalities, 2 patient each had trauma, infection and congenital anomalies. In the comparative study between CT and MRI, MRI was found to be superior in 14 cases.

Conclusion: MRI is an excellent, non-invasive modality to diagnose and detect the extent of orbital pathologies and it is far superior to CT examination of the orbit.

C-0532

Post-radiation malignant tumors in head and neck: A review of the clinical and imaging features

S. Yamamoto, K. Motoori, T. Ueda; Chiba/JP

Purpose: The development of malignant tumors is a recognized complication of radiation therapy. Post-radiation malignant tumors are not rare but a long latency period, difficulty with long-term follow-up, and a failure to recognize and report cases of post-radiation tumors confound analysis of risk. We set out to retrospectively review the clinical and imaging features in patients with post-radiation sarcomas, especially in head and neck region.

Materials and Methods: 4 patients with post-radiation tumors in the head and neck were identified at a single institution. Computed tomography and/or magnetic resonance imaging were available for all patients. The medical records were reviewed for primary diagnosis, the radiation history, and the latency period prior to development of the malignant tumor.

Results: There were 2 male and 2 female with a mean age of 69 years. The mean latency period for the development of the malignant tumor was 10 years. The primary diagnoses were maxillary carcinoma, nasopharyngeal carcinoma, adenoid cystic carcinoma of oral floor and tonsillar tumor. The histopathologies were osteosarcoma of the jaw, spindle cell sarcoma, chondrosarcoma and malignant peripheral nerve sheath tumor. The common findings were an avidly-enhancing soft tissue mass and bone destruction.

Conclusions: Post-radiation malignant tumors, while uncommon, are not rare. The imaging findings are not pathognomonic, but an appreciation of the expected latency period may help to suggest the diagnosis. When radiotherapy is performed for a head neck neoplasm, even if the neoplasm is treated completely, periodical progress observation may be necessary at least for about ten years.

C-0533

Radiologic findings of variable diseases involving the orbital apex

I. Bae, S.-Y. Lee, K. Park, S. Kim, S. Cha, G. Han; Chungbuk/KR

Purpose: To illustrate the CT and MRI findings and to identify features that may differentiate between the benign and malignant diseases involving the orbital apex. **Materials and Methods:** We retrospectively reviewed the CT ($n = 3$) and MR ($n = 7$) findings in 7 patients with lesions involving orbital apex. The patients were 5 female and 2 male, aged between 33–63 years (mean: 52 years) who had visual disturbance, ptosis, CNIII palsy or eyeball pain. They underwent surgical mass excision, transphenoidal or endoscopic biopsy with pathological confirmation. We evaluated the lesions according to the location, gross appearance, signal intensity, contrast enhancement pattern, and associated bony change.

Results: Tumoral conditions included metastasis ($n = 2$), squamous cell carcinoma of the sphenoid sinus ($n = 1$), chondrosarcoma ($n = 1$), and meningioma ($n = 1$). Inflammatory conditions included mucocele of the pneumatized anterior clinoid process ($n = 1$) and aspergillosis of the posterior ethmoid air cell ($n = 1$). In metastasis, squamous cell carcinoma, chondrosarcoma, and aspergillosis, soft tissue mass formation with adjacent bony destruction were found. In mucocele and meningioma, soft tissue mass formation with bony remodelling were present. They could be differentiated by clinical history (metastasis), characteristic signal intensity (chondrosarcoma and mucocele), enhancement pattern (aspergillosis), and location (meningioma).

Conclusion: Awareness and knowledge of lesions of the orbital apex is important because there may be much confusion both clinically and radiologically. Familiarity with imaging findings of lesions of the orbital apex will facilitate accurate diagnosis and can help to avoid unnecessary radical surgery.

Neck

C-0534

Utility of contrast-enhanced MR imaging with three-dimensional volumetric interpolated breath-hold examination (3D-VIBE) in preoperative staging of hypopharyngeal cancer

K. Tamai, T. Koyama, S. Tanaka, R. Asato, S. Umeoka, A. Kido, T. Saga, K. Togashi; Kyoto/JP

Purpose: To evaluate the value of contrast-enhanced (CE) MR imaging with 3D-VIBE in staging hypopharyngeal cancer (HPC), in comparison with T2-weighted images (T2WI).

Methods and Materials: 22 patients (18 male, 4 female) with histologically proven HPC underwent preoperative MR imaging. Following T2WI, CE 3D-VIBE images were obtained at 20 (1st-early-phase) and 60 seconds (2nd-early-phase) after injection of Gd-DTPA at a rate of 3 ml/sec. Two radiologists evaluated both T2WI and CE images independently, regarding T- and N-stage. Radiologic criteria for T-stage were as follows; T1: Limited to one subsite and < 2 cm; T2: More than one subsite or 2–4 cm without deviation of hemilarynx; T3: > 4 cm or with deviation of hemilarynx; T4: Invasion into the adjacent structures. The results were compared with pathologic findings. On CE images, SNR and CNR between the tumor and muscles were calculated for both phases and statistically compared.

Results: On CE images, 21 tumors were correctly staged (96%), while one was understaged (T3). On T2WI, 18 (82%) were correctly staged, while one was over-staged (T3), 2 understaged (T3 and 4), and one missed (T2). In 2 T2 tumors, involvement of posterocord region was missed on T2WI, whereas it was clearly demonstrated on CE images. N-staging was same on both T2WI and CE images ($n = 11$). SNR of 1st- and 2nd-early-phase was 45 ± 15 and 43 ± 12 , respectively ($P = 0.226$). CNR was 27 ± 13 and 21 ± 10 , respectively ($P = 0.002$).

Conclusion: CE 3D-VIBE is highly accurate in staging of HPC and superior to T2WI in delineating tumor extent. In 3D-VIBE images, 1st-early-phase can provide better conspicuity.

C-0535

CT-MR image fusion vs. CT and MR in the pre-surgical evaluation of laryngeal cartilage neoplastic invasion: Reliability in correlation with histopathology

F. Bruculeri, S. Santocino, A. Stecco, M. Dominietto, M. Brambilla, A. Carriero, G. Valente; Novara/IT

Purpose: To evaluate the diagnostic reliability of fusion image vs. CT and MR, on the identification of laryngeal cartilage neoplastic invasion, using the histological test as gold standard.

Methods and Materials: 5 patients with laryngeal carcinoma were submitted to contrast-enhanced CT and unenhanced MR scans. After surgical treatment, a pathologist evaluated the specimens. Image fusion was accomplished by mean of Syntegra Pinnacle software (version 1.2 B), fusion of MR SET1 images on MR SET2 and MR SET1 images on CT data set. Sensitivity, specificity and diagnostic accuracy were calculated, together with software elaboration time and feasibility.

Results: Image fusion was feasible in 100% of cases. Average fusion time for any patient was 10 minutes. Compared to histological test, fusion of MR SET1 images on MR SET2s showed a 100% sensitivity, 100% specificity, 100% diagnostic accuracy; whereas fusion of MR SET1 images on CTs has shown 67% sensitivity, 100% specificity, 80% diagnostic accuracy. MR alone had 100% sensitivity, 50% specificity and 80% diagnostic accuracy, while CT alone 67% sensitivity, 100% specificity and 80% diagnostic accuracy.

Conclusion: The assessment of laryngeal cartilage neoplastic invasion with MR on CT fused images and CT only gives similar results. The evaluation by mean of MR SET1 on MR SET2 fused images shows the same sensitivity of MR alone, but with improved the specificity.

C-0536

Image findings of idiopathic carotidynia in multiple modalities

N. Kosaka, H. Uematsu, T. Sagoh, S. Miyayama, M. Noguchi, H. Itoh; Fukui/JP

Learning Objectives: To familiarize participants with the clinical entity of idiopathic carotidynia. To teach participants to recognize the radiological features of idiopathic carotidynia in multiple modalities.

Background: Idiopathic carotidynia is a self-limited neck pain syndrome associated with tenderness over the carotid bifurcation. This entity is well known by otolaryngologists and neurologists, but not by radiologists. In this presentation,

Scientific and Educational Exhibits

we discuss five patients who met the clinical criteria established for the diagnosis of carotidynia by the International Headache Society Classification Committee. We also review the image findings of idiopathic carotidynia, including ultrasonography ($n = 5$), computed tomography ($n = 4$), and magnetic resonance imaging ($n = 4$).

Imaging Findings: Abnormally enhanced tissue surrounding the symptomatic carotid artery localized at the level of the distal common carotid and carotid bifurcation is supportive of the diagnosis. No associated narrowing of the vessel lumen was present in these patients. The lack of any other findings to suggest alternative diagnoses strongly supports the existence of carotidynia as a distinct clinical entity. In addition, follow-up imaging studies ($n = 3$) after resolution of symptoms demonstrated disappearance or improvement of the abnormal enhancing tissue.

Conclusion: These radiological findings may be helpful in the evaluation of patients with suspected carotidynia. To avoid unnecessary invasive examinations, the radiologist should be familiar with the clinical entity and radiological features of idiopathic carotidynia.

C-0537

Dental CT in the detection of periodontal lesions

P.M. Carrascosa, F. Sanchez, C. Capuñay, E. Martín López, M. Ulla, J. Carrascosa; Buenos Aires/AR

Purpose: To describe the CT characteristics of the periodontal lesions.

Methods: 72 patients with pre-implant studies were evaluated by CT. Their diagnoses were confirmed by clinical evaluation, plain films findings and in one case by histology. Studies were performed with slices of 1 mm width, 1 mm reconstruction interval. After acquisition, images were post-processed in a workstation with Dental CT software. Panoramic, axial, parasagittal and 3D images were obtained.

Results: There were 41 (24.1%) periapical lesions, 78 (45.8%) periodontal lesions, 1 (0.5%) condensant osteitis, 1 (0.5%) osteomyelitis, 37 (21.7%) diffuse atrophy, 1 (0.5) complicated odontogenic cyst and 11 (6.4%) maxillary sinusitis.

Conclusions: The high prevalence of periodontal and periapical lesions in patients who have a Dental CT carried out as a pre-implant study makes tomographic recognition of these lesions necessary, in order to allow the dentist to perform the right treatment and to prevent future complications.

C-0538

Basal cell adenoma of the parotid gland: MR imaging findings with pathologic correlation

M. Okahara, H. Kiyosue, S. Matsumoto, Y. Hori, S. Tanoue, D. Uchida, H. Mori, Y. Kondo; Oita/JP

Purpose: Basal cell adenomas (BAC) are rare parotid gland tumors. Few case reports describing MR imaging features of BAC have been published. The aim of this study is to describe and characterize the MR findings of BAC of the parotid gland.

Methods and Materials: We retrospectively reviewed MR images of BAC with pathologic correlation in 7 cases (2 men, 5 women; age range, 52-82 years) collected between January 1992 and August 2004 from our pathological database. All MR images were retrospectively evaluated with respect to the marginal morphology, signal intensity, and enhancement behavior by two experienced radiologists.

Results: Pathologically, 4 tumors were solid type, 2 tumors were trabecular type and one was membranous type. All the tumors were well-circumscribed with a smooth contour. Cystic changes were seen in 3 cases. On T1-weighted images, 6 tumors showed homogeneously low signal intensity (SI) equal to muscle and one showed inhomogeneously low SI. On T2-weighted image, all of them showed slightly lower SI than that of surrounding parotid tissue. On Gd-enhanced T1-weighted images, six tumors demonstrated moderate enhancement and one demonstrated avid enhancement (membranous type). Dynamic studies were performed in 4 cases. All showed rapid and prolonged enhancement.

Conclusion: MR imaging findings of basal cell adenoma were well-defined and smooth marginal morphology, contrary to lobulated contours seen in pleomorphic adenoma; relatively low SI on both T1 and T2-weighted images and rapid and prolonged enhancement on dynamic studies. Although BACs are rarity, BAC should be suspected when the tumor shows all of these characteristics.

C-0539

Development of the method of kinetic analysis for the temporomandibular joint using flat panel detector system: Verification by magnetic resonance imaging

Y. Ohtani, S. Sanada, K. Ueki, T. Miyati, T. Matsui, Y. Matsuura; Kanazawa/JP

Purpose: To verify the accuracy of the result of the kinetic analysis of the temporomandibular joint (TMJ) using flat panel detector (FPD) system by pseudo-dynamic MR imaging.

Methods and Materials: Axially positioned radiographs were obtained sequentially from opening to closing of the mouth by a modified dynamic FPD system. Pseudo-dynamic MR imaging of the TMJ was performed. The images were taken at seven mouth opening steps that started from a closed position to fully-opened mouth position. The images were taken for mouth closing steps with the same manner as mouth opening. The subjects were five symptomatic and asymptomatic volunteers. We analyzed the movement of the condyle. We also checked the movement and displacement of the temporomandibular articular disc by MR imaging. We compared both results of the TMJ kinetics by dynamic FPD and pseudo-dynamic MR imaging.

Results: Using an FPD system, we found that anteroposterior condylar movement ranged over a distance from 18.8 mm to 20.3 mm (average = 19.6 mm). There were deviations in the incisal path of the symptomatic volunteers, and the temporal changes in the maximum velocity of their condyles were asymmetric, unlike in those of healthy volunteers. These results were consistent with the diagnosis of an experienced maxillofacial surgeon by visual inspection and palpation. However, there are no asymmetric movements between right and left condyles and disc displacement with mild symptomatic volunteers by pseudo-dynamic MR imaging.

Conclusion: The kinetic analysis using FPD system is capable of analyzing the real entire motion of the TMJ in normal and pathologic stages, especially in those with mild pathology.

C-0540

Ultrasound assessment of superficial lymph nodes (three-dimensional imaging, tissue harmonic imaging and panoramic imaging) intended for diagnostic excision

E.J. Bialek, W. Jakubowski, A.B. Szczepanik, R.K. Maryniak, M. Prochorec-Sobieszek, R. Bilski, M. Serafin-Krol; Warsaw/PL

Purpose: To assess the usefulness of three-dimensional (3D), tissue harmonic (THI) and panoramic imaging in the ultrasound assessment of superficial lymph nodes intended for diagnostic excision.

Methods and Materials: Fifty-two lymph nodes (35 cervical, 16 axillary, 1 inguinal), scheduled for resection (clinical suspicion of lymphoma), in 52 patients were examined by ultrasound using 3D, THI and panoramic modes. Final histopathologic diagnoses included 36 lymphomas, 11 reactive lymph nodes, 3 metastases and 2 plasmacytoma infiltrations.

Results: THI improved visualization of borders and internal structure of lymph nodes in 96% and of surrounding tissue architecture in 92%. Intra-nodal artifacts were reduced after application of THI in 85% of lymph nodes. The appearance of hilum and lymph nodes as a whole changed in C-plane of 3D mode (as compared with 2D presentation) respectively in 28% and 36%. Panoramic imaging allowed for measurement of large lymph nodes, presentation of relations between the examined lymph node and surrounding tissues or other lymph nodes on one image, and demonstration of the arrangement and spatial relationships between lymph nodes within a group.

Conclusion: Application of THI, 3D and panoramic imaging may improve general quality of ultrasound images of examined lymph nodes, supply the examiner with new information in comparison to standard 2-D ultrasound, and allow for presentation of location, arrangement and spatial relationships between the examined node and other lymph nodes or tissues on one image. *The work was financially supported by a grant from the State Committee for Scientific Research.*

C-0542

Comparison of ultrasonography (US)-guided fine needle aspiration biopsy (FNAB) with histopathologic finding after thyroidectomy for thyroid nodules and the usefulness of follow-up US-guided FNAB

D.H. Kim, H.W. Oh, J.Y. Choi, J.N. Byun, Y.C. Kim, Y.S. Kim, J.H. Oh; Gwang-Ju/KR

Purpose: The purpose of this study was to compare of US-guided FNAB result with histopathologic finding after thyroidectomy for thyroid nodules and to assess the usefulness of follow-up US-guided FNAB.

Material and Method: US-guided FNAB was performed in 926 patients from 2002 to 2004. Thyroidectomies were performed in 96 of these patients. We compared the results for US-guided FNAB with post-operative histopathologic finding in these patients. All aspirations were performed with 21-gauge needles attached to a 10-mL syringe with a syringe holder. A high-frequency linear-array transducer was used for biopsies performed under ultrasound guidance.

Results: A comparison of US-guided FNAB results with histopathologic findings after thyroidectomies was interpreted as 2 (5%) false-positive and 7 (12%) false-negative results. 2 patients with non-diagnostic US-guided FNAB results were proven to be benign nodules on histopathologic findings after thyroidectomies. Cause of false negative results was mainly inadequate sampling due to very small size (infracentimetric). On follow-up FNAB or histopathologic findings after thyroidectomies, these nodular lesions were proven to be malignant nodules.

Conclusion: The main cause of false negative US-guided FNAB results was inadequate sampling due to very small nodule size. To improve the detection rate of malignant nodule, follow-up US-guided FNAB is necessary.

C-0543

The relationship between clinical outcome and detailed nodal features on initial and follow-up CT for cervical tuberculous lymphadenitis

B.-K. Je¹, S.-B. Kim², D. Park², T.-K. Kim¹, M. Kim², N. Lee²; ¹Kyungido Ansancy/KR, ²Seoul/KR

Purpose: The purpose of this study is to correlate the relationship between initial and follow-up CT features of cervical tuberculous lymphadenitis with clinical outcome.

Materials and Methods: Reviewing the medical records from March 2000 to March 2004, we selected 69 patients with cervical tuberculous lymphadenitis who underwent both initial and follow-up CT during scheduled chemotherapy. The outcomes of the patients were divided into favorable (n=41) and unfavorable groups (n=28) by clinical responses. On both initial and follow-up CT, we evaluated the features of the nodes in terms of calcification (no/punctuate/large), necrosis (no/eccentric/central), perinodal infiltration (no/localized/extensive), and enhancement pattern (no/peripheral/homogeneous).

Results: No detailed nodal feature on initial CT had a statistically significant relation with the clinical outcomes. However, some of detailed nodal features on follow-up CT showed statistical significance; the favorable group had more "no calcification" ($p=0.001$), but "punctuate calcification" was more frequent in unfavorable group ($p = 0.036$). There was more "no necrosis" with the favorable group ($p \leq 0.001$), but more "central necrosis" with the unfavorable group ($p \leq 0.036$). With regards to infiltration, "no infiltration" was more frequent in the favorable group ($p \leq 0.001$), but "localized infiltration" in the unfavorable group ($p = 0.002$). Enhancing pattern showed that "normal (no or homogeneous) enhancement" was related to the favorable group ($p = 0.005$), and peripheral enhancement to the unfavorable group ($p \leq 0.001$).

Conclusion: Cervical tuberculous lymphadenitis which showed punctuate calcification, central necrosis, localized infiltration, and peripheral enhancement on follow-up CT after scheduled medication is more likely to have an unfavorable outcome.

C-0544

Application of dynamic temporomandibular MRT in evaluating the effectiveness of orthodontal treatment

T.V. Bulanova, A.Y. Vasilyev, M.M. Antonik, N.S. Drobysheva; Moscow/RU

Purpose: To assess the dynamics of the TMJ condition in patients with occlusion disorders.

Material and Methods: MRT was performed on 270 occlusion disorder patients wearing brackets and occlusal splints. All patients (Age: 10-34; 178 female, 92 male), regardless of subjective and clinical manifestation, underwent bilateral TMJ examinations prior to treatment. The TMJ dynamics was examined in 56 patients (observation period 7-12 months). The MR-protocol included the following: in occlusion - T1 and T2WI in oblique sagittal projection, T1WI - in oblique

coronal projection; in mouth-open-position - T1WI in oblique sagittal projection; 5-phase imaging (from the mouth-closed to the maximal mouth-open position).

Results: The original asymmetric changes of TMJ were found in 251 patients (92.5%). The group for dynamic observation comprised of 56 patients with a complete or partial ventral dislocations of the disc. The dynamics did not reveal a full normalization of disc position, whereby in 44 patients the initial position of the disk remained unchanged, in 12 cases only the grade of dislocation became less distinctive. The appearance of fibrous changes in the bilaminar zone and the superior belly of the lateral pterygoid muscle during treatment was observed in 13 patients with a complete ventral disc dislocation. In patients with condyle hypermobility wearing occlusal splints, a normalization of the condylar motion despite the remaining disc dislocation was observed in 84% of cases.

Conclusion: The orthodontic occlusion treatment allows one to achieve a reduction of the condyle hypermobility, however, it barely corrects the ventral disc dislocation.

C-0545

Dynamic phono-articulation tract assessment by gated MR imaging

J.C. Vilanova, J. Barceló, J. Pujol, M. Villalón; Girona/ES

Learning Objectives: To illustrate the phono-articulation tract during repetitive speech using gated MR imaging, displaying 2D movies and outlining its applications in different fields.

Background: Current methods to evaluate the phono-articulation tract are video-nasendoscopy and video-fluoroscopy. Both methods are difficult to perform and non-objective. MR imaging is capable of producing images with excellent contrast and spatial resolution. However conventional MR imaging is limited to static structures as moving structures produce blurred images. New techniques could attempt to overcome these limitations.

Procedure Details: The phono-articulatory tract was imaged using a 1.5 T MR unit with a gated SPGR sequence. An external 1 Hz trigger was fed to the cardiac gate. Each acquisition of 16 phases/s was performed. All the vowels, selected consonants and several consonant-vowel syllables were acquired. Single slice FSE T1 was acquired as an anatomical image for each vowel and consonant. Single-slice data was displayed static and dynamically as a cine-loop. The relationship between the tongue, palate, lips, pharynx and epiglottis was depicted either from the single image as from the cine loop images, and from the gated images.

Conclusion: Dynamic gated MR imaging of the phono-articulation tract allows one to visualize the movement of all its anatomical structures. This method provides a very useful tool in the phonetic field from every speaking language in various aspects of logopedics such as diagnosis and rehabilitation regarding the speech pathology and in evaluating defects in the velum and palate; but also in other fields like teaching phonetics and other languages, physiologic speech, research or design synthesized voices.

C-0546

The role of computed tomography with aerial manoeuvres in the diagnosis of aerodigestive tract tumors

C. Gonzalez Gordaliza, J. Martinez San Millan, A. Vicente Bartulos, O. Sanz de Leon; Madrid/ES

Purpose: The aim of this study is to show the accuracy of helical multislice CT with aerial manoeuvres (inhalation, phonation and Valsalva) for detection, localization and exact extension of tumoral pathology in oral cavity, hypopharynx and larynx.

Material and Methods: Prospective study between May 2003 and August 2004 involving 42 patients (40 male and 2 female), mean age 61 years, with clinical suspicion of larynx (n = 21), pyriform sinus (n = 6), faucial tonsil (n = 5), buccal mucosa (n = 5), gingival mucosa (n = 1), tongue (n = 3) or lip (n = 1) tumors. All patients were examined using helical CT with neutral (inhalation), phonation and double Valsalva manoeuvres. The protocol was: matrix 512 x 512, thickness 3.2 mm, interval reconstruction 2.5 mm, pitch 1, 40 seconds after 80 cc intravenous iodinated contrast media.

Results: In our experience, morphologic assessment of the laryngeal, hypopharyngeal and oral cavity lesions was easier in CT with manoeuvres. In comparison with a baseline study (neutral CT), the use of manoeuvres better identified tumoral lesions in 15% cases (n = 6) and dismissed this pathology in 23% patients. In addition, in 26 patients (62%) we proved with manoeuvres more extension than without them.

Conclusion: CT with aerial manoeuvres showed more exactly presence and extension of tumoral lesions in aerodigestive tract.

Scientific and Educational Exhibits

C-0547

CT evaluation of neck masses: A pictorial review

A.P. Datar; Mumbai/IN

Purpose: (1) To assess the role of spiral CT in pre-operative characterization of neck masses and to evaluate the role of 3D reconstruction techniques in delineating the anatomical extent of neck masses. (2) To evaluate the imaging criteria in correlation with histopathological diagnosis.

Materials and Methods: 110 patients with palpable neck masses were studied by Multislice spiral CT Siemens Somatom volume access. 3D reconstruction techniques were performed to demonstrate the anatomical extent, and pre-operative findings were compared with FNAC/HP diagnosis.

Results: Review in the study group of 110 cases revealed specified age of presentation, anatomical location and CT imaging features of the pathological diagnostic categories. Metastatic lymphadenopathy (35%) predominated amongst the cases followed by malignant thyroid masses (20%). Inflammatory features were confirmed in 8%. Miscellaneous group included vascular masses, cystic masses, soft tissue tumors, etc (37%). The presence of fat, calcification, extension into extra-glandular spaces, hemorrhage, necrosis and cystic changes proved beneficial in CT characterization of neck masses and subsequent treatment planning.

Conclusions: Multislice spiral CT is an invaluable tool in the pre-operative evaluation of neck masses. The superior soft tissue discrimination and precise spatial resolution with respect to critical structures in the neck were beautifully depicted by various 3D reconstruction techniques. Although exact tissue diagnosis was not possible, careful analysis of imaging features in combination with clinical correlation provided a reasonably short differential diagnosis in nearly every case.

C-0548

Role of multidetector CT in the evaluation of primary and secondary hyperparathyroidism

F. Ricci, S. Campagnano, A. Casale, M. De Vargas Macchiucca, F. De Cristofaro, G. Panzironi; Rome/IT

Purpose: In primary and secondary hyperparathyroidism, accurate localisation of abnormal glands is essential in order to perform a minimally invasive surgery. The aim of this study is to evaluate the role of multidetector CT in primary, recurrent or persistent, and secondary hyperparathyroidism.

Methods and Materials: 25 consecutive patients with secondary hyperparathyroidism, due to chronic renal failure, and primary hyperparathyroidism, recurrent or persistent, or primary hyperparathyroidism with inconclusive scintigraphy and ultrasonographic examinations underwent multidetector CT (Somatom Volume Plus 4 Siemens). At surgery the location, number, size and histopathologic results of all identified parathyroid tissue was recorded and compared with CT results.

Results: At surgery, 11 adenomas and 35 hyperplastic parathyroid glands were detected in 12 cases of primary hyperparathyroidism, 1 primary, persistent and 2 primary, recurrent cases of hyperparathyroidism, 7 secondary and 3 secondary, recurrent cases of hyperparathyroidism. CT sensitivity was 57% because it does not detect small hyperplastic glands; most of them smaller than 1 cm (16/35 nodules). CT demonstrates a good accuracy in the localization of adenomas (91%) and of the 5 cases of ectopic glands (100%), all of them larger than 1 cm.

Conclusion: Multidetector CT is able to correct localize adenomas and ectopic parathyroid glands while it does not correctly detect hyperplastic multi-glandular involvement which is usually smaller in size. However CT is surgically useful in the selection of patients for minimally invasive procedures.

C-0549

Usefulness of the apparent diffusion coefficient in line scan diffusion-weighted Imaging for distinguishing between squamous cell carcinoma and malignant lymphoma of the head and neck

M. Maeda, H. Sakuma, K. Takeda; Tsu/JP

Purpose: Squamous cell carcinoma (SCC) and malignant lymphoma are common malignant tumors of the head and neck. The purpose of this study was to determine whether the apparent diffusion coefficient (ADC) in line scan diffusion-weighted imaging (LSDWI) is useful for distinguishing between SCC and malignant lymphoma of the head and neck.

Methods and Materials: LSDWI was prospectively performed for 39 patients with SCC and 14 patients with malignant lymphoma. Images were obtained with a diffusion-weighted factor (b factor) of 5 and 1000 sec/mm², and ADC maps were generated. ADC values were measured for the two types of tumors.

Results: The mean ADC values were $0.96 \pm 0.11 \times 10^{-3}$ mm²/sec for SCC and $0.65 \pm 0.09 \times 10^{-3}$ mm²/sec for malignant lymphoma, showing a statistically significant difference ($p < 0.001$). All but one of the patients with malignant lymphoma showed lower ADC values than the lowest ADC value (0.76×10^{-3} mm²/sec)

observed in SCC. When an ADC value of 0.76×10^{-3} mm²/sec was used for distinguishing between SCC and malignant lymphoma, an accuracy rate of 98% (52/53) was achieved.

Conclusion: The ADC value may be useful for distinguishing between SCC and malignant lymphoma in the head and neck.

Color Doppler ultrasonography findings in hypothyroidism

A.T. Turgut, E. Cakal, P. Birincioglu, U. Kosar, B. Demirbas, Y. Aral; Ankara/TR

Purpose: To define the color Doppler ultrasonography (CDUS) characteristics of the thyroid gland and inferior thyroidal artery (ITA) in patients with hypothyroidism.

Materials and Methods: We investigated 42 patients with hypothyroidism clinically, by thyroid function laboratory tests and by CDUS concerning the estimation of the parenchymal color flow pattern (PCFP) of the thyroid and the measurement of the maximum systolic velocity (MSV) in the ITA.

Results: 8 of the 42 hypothyroid patients had PCFP 0, MSV of 23.4 cm/sec, TSH of 21.6 µIU/ml. In 34 patients different degrees of increased parenchymal vascularisation and MSV were detected (22 patients with PCFP I, MSV: 35.8 cm/sec, TSH: 21.8 µIU/ml, 9 patients with PCFP II, MSV: 44.9 cm/sec, TSH: 20.0 µIU/ml, 3 patients with PCFP III, MSV: 37.7 cm/sec, TSH: 82.5 µIU/ml). In regard to the PCFP, significant differences for TSH, glandular volume and MSV were detected ($p = 0.047$, $p = 0.007$ and $p < 0.001$ for each). Significant differences were detected by the comparison of each of the subgroups with PCFP 1, 2 and 3 and that with CFP 0 for mean MSV ($p < 0.001$, $p < 0.001$ and $p = 0.014$ for each) and of the subgroups with PCFP 0, 1 and 2 and that with PCFP 4 for mean TSH ($p = 0.024$, $p = 0.015$, $p = 0.012$ for each).

Conclusion: We conclude that MSV of the ITA, as well as PCFP, can be accepted as a reliable measure of increased vascularity in hypothyroidism, a state formerly attributed only to hyperthyroidism. Our findings suggest that thyroid stimulation mainly by TSH is responsible for the increased flow.

C-0552

A new parameter for the evaluation of the efficacy of medical treatment in hypothyroidism: Color Doppler measurement of blood flow in the inferior thyroidal artery

A.T. Turgut, E. Cakal, U. Kosar, P. Birincioglu, B. Demirbas; Ankara/TR

Purpose: To determine whether color Doppler ultrasonography (CDUS) of the thyroid gland and the inferior thyroidal artery (ITA) can be a reliable measure for the efficacy of the medical treatment for hypothyroidism.

Methods and Materials: 42 patients with hypothyroidism were evaluated clinically, by laboratory tests regarding the thyroid function and by CDUS concerning the estimation of the parenchymal color flow pattern (PCFP) of the thyroid and the measurement of the maximum systolic velocity (MSV) in the ITA both before and after medical treatment for 6 months.

Results: The number of patients with PCFP 0, I, II and III before and therapy were 8, 22, 9, 3 and 10, 23, 9, 0 respectively. Mean TSH and MSV values of the ITA which were noted before and after therapy as 25.7 ± 26.7 µIU/ml, 35.5 ± 10.1 cm/sec and 1.6 ± 0.8 µIU/ml, 31.0 ± 10.2 cm/sec respectively were significantly different from each other ($p = 0.02$, $p < 0.001$, for each). The PCFP did not change in 29 patients whereas in 14 patients it decreased and in 3 patients it became higher. By comparison of the patients without any change in PCFP and those with a change to lower grade, a significant decrease for TSH and MSV of the ITA was noted in the latter ($p = 0.026$ and $p = 0.017$, for each).

Conclusion: The decrease in the MSV of the ITA closely reflects the efficacy of the medical treatment in hypothyroidism and can be utilized for the follow-up as an alternative to laboratory tests.

C-0553

MR imaging of parotid gland tumours with radiologic-pathologic correlation

S.P. Prabhu, R. Davies, J. Luker, J. Kabala; Bristol/UK

Learning Objectives: To illustrate the role of magnetic resonance imaging in the diagnostic work-up of parotid tumours. To illustrate MR imaging findings of parotid tumours and demonstrate how these correlate with pathologic findings.

Background: Benign and malignant tumours of the parotid gland are being increasingly imaged on MR imaging before surgery. We elaborate our imaging protocols and algorithms to differentiate benign tumours, low-grade malignant tumours and high grade malignant tumours on MR imaging.

Scientific and Educational Exhibits

Procedure Details: We reviewed the MR imaging archives in our teaching hospital to identify cases of parotid tumours imaged preoperatively with MR imaging. We obtained the pathology reports of these cases and details of any follow-up imaging. We elaborate on the appearances of various types of parotid masses with radiologic-pathologic correlation. Difficulties faced in distinguishing various tumour types are highlighted and suggestions for overcoming these problems are elaborated. The various tumours illustrated include pleomorphic adenomas, adenolymphomas, monomorphic adenomas, mucoepidermoid carcinomas, adenoid cystic carcinomas, lymphomas, squamous cell carcinomas and acinic cell carcinomas.

Conclusion: MR imaging is often useful in differentiating benign and malignant tumours of the parotid gland, and can provide important clues in the diagnosis of their histology.

C-0554

Neck lumps and bumps: Ultrasound is the way forward

K. Satchithananda, H. Purushothaman, P.S. Sidhu; London/UK

Learning Objectives: 1. To understand the diverse disease processes that affect the soft tissues of the neck in both children and adults. 2. To learn how to use all aspects of ultrasound imaging (grey scale, colour Doppler and fine needle aspiration) to evaluate lesions. 3. To recognise the pattern of ultrasound features of the different pathological processes.

Background: The soft tissues of the neck lie in a superficial position, thus making them ideal for ultrasound examination. High frequency linear probes with new colour Doppler facilities make imaging of this region by ultrasound the optimal modality.

Procedural Details: Diseases of the thyroid, parathyroid, major salivary glands and lymph nodes are well characterised by ultrasound and a definitive diagnosis can often be made without needing to use CT or MR imaging. Ultrasound is also advantageous in imaging children with its use of non-ionising radiation and its ability to make the diagnosis with both congenital and acquired lesions. Image-guided tissue sampling with ultrasound allows accurate, real time aspiration of cells for immediate histological diagnosis.

Conclusion: This exhibit will illustrate the use of ultrasound in evaluating masses in the neck and demonstrate the vital role ultrasound plays in this clinical setting.

C-0555

Cancer of the posterior tongue: Contribution of MR imaging in staging and in therapeutic workup

A. Kalai, Brot, Y.K. Maratos, P. Halimi; Paris/FR

Purpose: We compared MR imaging findings to the initial staging after clinical examination of posterior tongue cancer. We evaluated the impact of MR imaging and the modification of the therapeutic workup.

Materials and Methods: 40 patients with cancer of the posterior tongue were examined by MR imaging. The following anatomic structures were analyzed by MR imaging, endoscopy and surgery: extension to the midline, lateral oropharyngeal wall, soft palate, posterior pillar, pterygo-mandibular area, anterior tongue, vallecula and pre-epiglottic space. Results of MR imaging were compared to the results of biopsy, surgery and follow-up of patients.

Results: MR imaging showed often that lesions were much larger than they were expected after clinical examination, particularly in relation to midline extension, the pterygo-mandibular area, the posterior pillar and deep extension. Evaluation with MR imaging prevented more than 30% of the operations that were planned after initial clinical evaluation.

Conclusion: MR imaging is better correlated to histological and surgical data than clinical findings. MR imaging evaluation is mandatory prior every curative surgical procedure.

C-0556

Nodal involvement of peripheral T-cell lymphoma in the neck: Two-phase CT findings

J. Choi¹, S. Kim², E. Kim¹, D. Na¹, J. Ryoo³, H.-J. Kim¹; ¹Seoul/KR,
²Chunchon/KR, ³Jinju-Si/KR

Purpose: To describe two-phase CT findings of nodal involvement of PTCL in the neck.

Methods and Materials: Enrolled were 27 patients (M:F = 20:7; mean age, 57.5 years) who had pathologically proven PTCL with nodal involvement in the neck. Patients consist of those with PTCL, not otherwise specified (NOS) (n = 20), natural killer (NK)/T-cell lymphoma (NKT) (n = 5), and angioimmunoblastic T-cell lymphoma (AITL) (n = 2). Early- and late-phase axial CT scans were obtained with

scanning delays of 30 and 180 seconds respectively, following administration of contrast medium in all patients. We retrospectively evaluated lymph nodes on CT images with special attention to central necrosis, extra-nodal extension, and enhancement patterns.

Results: Extra-nodal extension and central necrosis were seen in 19 of 27 patients (70.4%) and 11 of 27 patients (40.7%), respectively. Nineteen of 27 patients (70.4%) demonstrated heterogeneous enhancement of the enlarged lymph nodes on early phase, of whom heterogeneous enhancement on late phase is noted in 11 patients (57.9%). In 6 of 27 patients (22.2%) including 5 patients with PTCL NOS and one with NKT, homogeneous enhancement was seen on both early and late phases without extra-nodal extension or central necrosis. Heterogeneous enhancement on early phase, extra-nodal extension, and central necrosis were seen in 13, 13, and 6 patients with PTCL NOS, respectively; 4, 4, and 3 patients with NKT; and in all patients with AITL.

Conclusion: Heterogeneous enhancement on early phase, extra-nodal extension, and central necrosis of the lymph nodes are relatively common findings of PTCL.

C-0557

Differentiation of benign from malignant salivary gland tumors using color Doppler sonography

S.S. Petrovic; Nis/YU

Purpose: The aim of this study was to determine the color Doppler features of benign and malignant salivary gland tumors and their possible differentiation using color Doppler sonography.

Materials and Methods: This prospective study included 76 patients with salivary gland tumors examined using color Doppler sonography before surgery. Examinations were made by 7.5 MHz linear probe with Doppler imaging. The intratumor vascularity was graded on a four step analogue scale and the patterns of vascular distribution were characterized as peripheral (basketlike) or hilar (branching).

Results: Post surgical and histo-pathological verification revealed that 58 patients (76.32%) had benign and 18 patients (23.68%) had malignant salivary gland tumors. Of the benign tumors, 10 (17.24%) showed no color Doppler signal, 29 (50%) had first, 17 (29.31%) second, and 2 (3.44%) third grade of vascularization. Of the malignant tumors 1 (5.55%) had first, 5 (27.77%) second, and 12 (66.66%) third grade of vascularization. The peripheral pattern of vascularization was found in 34 (58.62%) and hilar in 14 (24.13%) benign tumors. On the contrary, only 2 (11.11%) malignant tumors had peripheral, and 16 (88.89%) hilar pattern of vascularization. A statistically significant difference was found in grade ($p < 0.001$) and pattern ($p > 0.05$) of vascularization between benign and malignant salivary gland tumors.

Conclusion: Our experience showed that color Doppler sonography is a sensitive method for the diagnosis of salivary gland tumors. On the basis of the grade and pattern of vascularity it is possible to distinguish benign from malignant salivary gland tumors with great certainty.

C-0558

The importance of cervical fascial planes and compartments in treatment and prognosis in life threatening deep neck infections

N. Erdogan, E. Inci, B. Dirim Vidinli, E. Uluç, A. Roditi, M. Dirik; Izmir/TR

Learning Objective: We aimed to emphasize the importance of radiological evaluation in cervical fascial planes and compartments in deep neck infections, which have a high morbidity and mortality.

Background: 15 patients who were thought to have deep neck infection were evaluated. The patients went through contrast-enhanced axial CT scan with routine neck protocol including the upper mediastinum.

Imaging Findings: In our study 15 patients (Age: 3-90, mean age 40.4; 4 Male; 11 Female) underwent enhanced axial neck CT scan. The location of infection (compartment), mediastinal infiltration, the characteristics (abscess, cellulitis), accompanying lymph nodes and primary cause which could not be diagnosed clinically were evaluated by radiologists. In 5 patients the primary cause could not be diagnosed. 6 patients had gingivitis and related illness. The rest had peritonsillar abscess, meningitis, burns in the neck and rheumatoid arthritis (amyloidosis and renal insufficiency).

Conclusion: The cervical region has a complex anatomical structure subdivided by fascial planes. Deep neck infections infiltrate by these routes into anatomical spaces and most often these infections require surgical procedure. Some invade the mediastinum which has a poor prognosis. Even though it is relatively easy to diagnose a deep neck infection clinically, it is very important to evaluate the fascial planes and compartments accurately for the treatment choice, for surgical planning and patient follow-up.

Endolymphatic sac tumors: A major criteria of Von Hippel-Lindau disease

K. Marsot-Dupuch, S. Richard, S. Bobin; *Le Kremlin-Bicêtre/FR*

Purpose: To analyze the characteristic findings of endolymphatic sac tumors (ELST) in VHL disease.

Materials and Methods: A consecutive series of 250 patients presented with VHL disease controlled by the same team of geneticist (S. Richard). All patients had an imaging survey consisting of a brain and spine MR imaging with focused images on the temporal bone if deafness, vertigo, tinnitus or facial palsy was present.

Results: 8% (20) of VHL patients had an endolymphatic sac tumor. In one case out of 250, the lesion was very suspicious but not proven as it was not operated upon. The lesion was always unilateral except in one case. In 20% ELST was the onset of the disease. In one case, the delay between the ELST and the disease was of 30 years. Deafness was always present except in one case. Hormonal impact on the tumor growth was evident in one patient. A cerebellar location of a metastasis of a kidney neoplasm mimicked an ELST.

Conclusions: The work depicts all aspects of the ELST, their spread and the follow-up to perform. Sporadic ELST should raise the suspicion of VHL disease and the patient should have a genetic screening.

C-0560

Imaging technique for obtaining optimal sections of the ossicular chain by high-resolution multiplanar reformation based on measurements of normal auditory ossicular angles

N. Fujii, K. Katada, S. Yoshioka, K. Takeuchi, A. Takasu, K. Naito; *Toyoake/JP*

Purpose: The angles of the ossicles relative to a reference plane were measured, and optimal sections for high-resolution multiplanar reformation (HR-MPR) of the ossicular chain were reconstructed.

Methods and Materials: The reference plane included the lower margin of the orbit and the external auditory canal. Using 3D-CT, the angles of the stapedial crus in the sagittal plane and the incudal long process and stapes in the coronal plane and rotation of the stapes relative to the incudal long process in the axial plane were measured in HR-MPR images of 50 normal ears with a 0.5 mm, 4-row multislice CT scanner (Toshiba).

Results: The section including the malleal head and manubrium was parallel to the incudal long process, vertical in the reference plane. The angle of the stapedial crus to the reference plane was similar (mean 6°). The incudal long process was approximately 90° to the stapes (mean 89°), and the stapes was approximately 45° to the reference plane (mean 44°). The stapes extended straight from the incudal long process in 80% of ears. The malleal head and incudal short process were easily seen in the axial plane. The malleus image including the malleal manubrium was reconstructed in the coronal plane. The incudal long process was seen immediately behind the malleus. The stapes image was reconstructed from the incudal long process image. These four sections are considered optimal for visualizing the ossicular chain.

Conclusion: This imaging technique for the ossicular chain is useful due to its reproducibility and ease of operation.

C-0561

Labyrinthitis ossificans: CT scan and MR imaging findings

C. Gonzalez Gordaliza, J. Martinez San Millan, A. Vicente Bartulos, O. Sanz de Leon; *Madrid/ES*

Purpose: Labyrinthitis ossificans (LO) is a pathologic ossification in the cochlea and labyrinth. It is usually caused by an infection that reaches inner ear via tympanogenic, meningeal or hematogenous route. Inflammatory injury results in fibrosis (fibrous stage), which is followed by formation of new bone (ossification stage). The aim of this study is to describe the CT and MR findings of LO, and to show their role in diagnosing each stage.

Material and Methods: Prospective study involving 26 ears (13 patients) with sensori-neural hearing loss. All patients were examined using helical CT and MR. CT imaging was performed with a high resolution protocol: contiguous 0.6 mm thick images obtained through the petrous bones with posterior reconstruction in axial, coronal and sagittal planes. MR imaging was performed on a Philips 1.5 T scanner, with fast spin echo T2-weighted study of temporal bones, 3D-CIIS acquisition and spin echo T1-weighted pre/post-gadolinium scans.

Results: We studied 26 ears, 15 with LO. 2 patients were bilaterally affected. In 13 ears, CT showed sclerosis, irregularity or obliteration of labyrinth (ossification stage). In 4 ears, MR could correctly demonstrate high signal of normal labyrinth replaced by low signal intensity (sclerosing tissue: Fibrous stage). However, in these 4 ears, CT failed to visualize sclerosing tissue. In 2 cases, there was a simultaneous stage: Endoluminal calcifications demonstrated in CT and sclerosing tissue showed in MR.

Conclusion: CT scan can precisely demonstrate ossification stage of LO, but MR better demonstrates the fibrous stage and the real extent of the disease.

C-0562

Embryological correlation of congenital labyrinthine abnormalities

S. Avula, A. Thimmarayappa, C. Yeong; *Warrington/UK*

Learning Objectives: This poster aims to illustrate the development of the inner ear and demonstrate the appearances of congenital labyrinthine abnormalities that occur as a result of arrests during the various stages of embryogenesis.

Background: The inner ear development starts at the 4th week and its ossification is complete by the 24th week of gestation. The basic structure of the bony labyrinth is formed by the 8th week. Genetic and non-genetic insults occurring during this period can arrest or cause aberration in the development, resulting in labyrinthine anomalies whose appearance resemble that of the inner ear at the corresponding stage of embryogenesis. These anomalies can be identified on CT or MR scans and are accountable for approximately 20% of patients with congenital sensorineural hearing loss.

Procedure Details: Labyrinthine anomalies noted in high resolution CT scans of the temporal bone in patients investigated for sensorineural hearing loss have been demonstrated with comparative images of the developing labyrinth between 4 and 8 weeks of gestation.

Conclusion: A clear understanding and application of labyrinthine embryogenesis will be helpful in the interpretation of CT or MR studies performed for the investigation of congenital sensorineural hearing loss.

C-0563

Magnetic resonance imaging in temporo-mandibular joint internal derangements

J. Kleinrok, T.K. Rozylo, M. Janczarek; *Lublin/PL*

Learning Objectives: To present the spectrum of imaging findings in internal derangements of the temporomandibular joint (TMJ) obtained by means of magnetic resonance imaging (MRI).

Background: An internal derangement is an abnormality in the position and sometimes the morphology of the TMJ disk that may interfere with normal function. MRI is a gold standard in TMJ disk imaging and therefore it is essential to know the range of possible findings.

Procedure Details: MRI examinations were performed in 216 patients aged 13-57. The examinations were performed by means of a 1.5 T machine. T1- and T2-weighted images were obtained in sagittal and coronal views. The examinations were performed in different positions of the mandible: maximum occlusion (closed mouth), maximum mouth opening, mandibular protrusion, mandibular retro position in occlusion as well as in therapeutic position with an individual silicone splint. This was presented as a pictorial review of the range of MRI findings and the impact of different mandibular positions on disk images was underlined.

Conclusion: Internal derangement is a common problem and therefore confident radiological diagnosis is essential. It is important to perform MRI studies in different positions of the mandible as this may enhance the sensitivity and specificity of diagnosis of causes of TMJ internal derangement.

C-0564

Three-dimensional reconstruction of spiral, multidetector images from computer tomography in diagnosing innate and acquired anomalies of facial skeleton

S. Trzeszkowska-Rotkegel, S. Skrzelewski, J. Glowacki, M. Tarnawski, A. Pisulska-Otremba, H. Borowiak, T. Legaszewski; *Zabrze/PL*

Purpose: Recognition of the type of anomaly, its size and character and the degree of deformation of the visible anatomic elements is vital in making the right decision about further clinical procedures. The usefulness of three-dimensional reconstruction of spiral computer tomography images in constructing virtual, three-dimensional models of the facial skeleton to show the deformations and to make planimetric measurements before a planned, surgical correction of the anomaly was evaluated.

Methods and Materials: A group of 35 patients with a clinical diagnosis of hemi-

Scientific and Educational Exhibits

hypoplasia of a face (22 persons) and with temporomandibular joint ankylosis (13 patients) was examined. The group consisted of 23 males (aged 7-23) and 12 females (aged 4-21). CT examinations were performed with a spiral, four-row apparatus. The data from this was then used for multiplanar and three-dimensional reconstructions. The obtained models were presented as bone (skeleton) and soft-tissue images. Our own modification of planimetric measurements was used for comparing chosen anatomic and topographic parameters of the right and left side of the face. In each case an image of the cervical part of the spine was evaluated.

Results: The performed examinations in all 35 patients allowed us to define the type of anomaly, its size and the degree of facial skeleton deformations.

Conclusion: A spatial visualization of the examined structures allows a better and more complex understanding of the anatomic anomalies present in a patient, as well as defining possibilities and tactics of further treatment pre-operatively and prognostically evaluating the operative treatment effectiveness.

Interventional Radiology

Vascular

Virtual stenting (VS): A new modality for choosing a stent or a stent-graft by three-dimensional rotational angiography (3DRA)

F. Pozzi-Mucelli¹, D. Babic², A. Calgaro¹, R. Pozzi-Mucelli¹; ¹Trieste/IT, ²Best/NL

Purpose: VS is a new dedicated technique, recently implemented in the 3D rotational angio workstation and intended for virtual placement of stents on pathological vessel portions. The technique enables 3D assessment of stents and stent graft geometry on stenotic, obstructive or aneurysmatic vessel lesion to be treated.

Methods and Materials: 28 patients underwent 3DRA for stenotic or aneurysmatic lesions of thoracic or abdominal aorta (5 patients) and/or iliac arteries (23 patients: 30 lesions) and 3D vessel elaborations and VS was performed. The geometrical properties of the virtual stents (length, proximal/distal diameter) were compared with the geometry of the stents implanted in the patients or with CT scanner measurements (in cases of AAA not treated by endovascular approach).

Results: Iliac artery stenting was performed in 28/30 lesions; only 2 elongated iliac aneurysms were considered unsuitable for endovascular treatment. In treated cases a corresponding correlation between VS and real stenting was observed with a mean diameter of real stent of 8.72 mm compared to 8.61 mm of the virtual stent. Aneurysmatic aortic lesion underwent endovascular treatment in 2/5 cases with a good correlation to VS data while the 3/5 cases not endovascular treated VS showed a good agreement to CT scanner measurements.

Conclusions: The "virtual stenting" technique appeared effective, fast and objective in almost all cases. The technique provides the required geometrical information on the minimum stent diameter and optimal length. In cases of extreme vessel tortuosity associated with aneurysmatic disease a manual intervention is required in order to optimize the lumen path.

C-0566

Catheter fragmentation of acute massive pulmonary thromboembolism: Relationship between distal embolization and pulmonary arterial pressure elevation

K. Nakazawa, H. Tajima, S. Murata, T. Kumazaki, K. Ichikawa, T. Fukunaga, S. Onozawa, T. Yamamoto, T. Takano; Tokyo/JP

Purpose: To clarify the relationship between pulmonary arterial pressure and distal embolization due to catheter fragmentation for lifethreatening acute massive pulmonary thromboembolism.

Methods and Materials: 33 patients with hemodynamic impairment (10 men and 23 women; aged 27-82 years) were treated by mechanical thrombus fragmentation with a modified rotating pigtail catheter. After thrombus fragmentation, all patients received thrombolytic therapy, followed by manual clot aspiration using a large-lumen PTCA guide catheter. Serial pulmonary angiography was performed for the evaluation of the extent of thrombus formation. Pulmonary arterial pressure was also continuously recorded during the procedure.

Results: Distal embolization was confirmed by angiography in 13 out of 33 patients. A significant elevation in mean pulmonary arterial pressure occurred after thrombus fragmentation (pre 30 ± 8.3 mmHg, post fragmentation 33 ± 9.8 mmHg, $p < 0.005$), and a statistical decrease in mean pulmonary arterial pressure was found after thrombolytic therapy and thrombus aspiration in this group (post aspiration 22 ± 5.6 mmHg, $p < 0.001$). No distal embolization was seen in 20 of 33 patients, and a significant decrease in mean pulmonary arterial pressure was confirmed after thrombus fragmentation (pre 32 ± 6.2 mmHg, post fragmentation 27 ± 8.8 mmHg, $p < 0.001$), and after thrombolysis and thrombus aspiration (post aspiration 22 ± 4.6 mmHg, $p < 0.001$).

Conclusion: Distal embolization and a elevation in pulmonary arterial pressure might occur during mechanical fragmentation using a rotating pigtail catheter for the treatment of acute massive pulmonary thromboembolism. Thrombolysis and thrombus aspiration provided for a hemodynamic stabilization and partial recanalization.

C-0567

A new ischemic model using radiofrequency wire electrode in rabbit hind limb

H. Baik, B. Kwak, H. Shim, Y. Kim, J. Lee, I. Song, K. Kim; Seoul/KR

Purpose: To establish an ischemic limb model endovascularly made by radiofrequency (RF) wire electrode for the investigation of new treatment modality of limb-threatening ischemia.

Scientific and Educational Exhibits

Methods and Materials: Polytetrafluoroethylene coated 0.035 inch wire with 2 cm-exposed tip was inserted through left carotid artery into left femoral artery in 7 New Zealand white rabbits. RF ablation at 20 watt with RF generator (RF3000) was performed for 145 ± 7.97 seconds pulling it from distal superficial femoral artery up to proximal external iliac artery. We observed clinical changes and performed angiography. Blood pressure and tissue perfusion and permeability measured by the laser tissue blood flowmeter and CT were assessed up to 6 weeks and left to right (L/R) ratio were calculated. The degree of collateral formation and vascular reconstitution in angiography was graded from 0 to 6 as an angiogenic score.

Results: In all rabbits, the angiography demonstrated complete obstruction from proximal external iliac artery to distal superficial femoral artery. The angiogenic score gradually increased to a plateau at the sixth postoperative week ($R = 0.86$, $p < 0.05$). Blood pressure at left calf was too weak to be measurable before the fourth postoperative week. The L/R ratio of blood pressure at the fourth week was 0.68 ± 0.100 and increased to 0.71 ± 0.074 at the sixth week. The L/R ratio of the tissue perfusion and permeability was significantly reduced at the first and second week ($p < 0.05$), and gradually increased until the sixth week.

Conclusion: Endovascular RF ablation with wire electrode is a reproducible and measurable model of ischemic limb disease.

C-0568

The endovascular treatment of deep vein thrombosis

S.-H. Suh, J. Won, D. Lee; Seoul/KR

Purpose: To evaluate the effectiveness of endovascular treatment of deep vein thrombosis.

Materials and Methods: 80 patients (M:F = 35:45, mean 55 years) with deep vein thrombosis (DVT) were analyzed since Jan 1999. All patients had acute ($n = 56$) or chronic ($n = 24$) pain, swelling and color changes on lower extremity. Various methods of thrombus removal had been performed until patency of external iliac vein was restored. All patients underwent consecutive angioplasty and stent insertion. Placement of IVC filter before stenting was combined in 12 patients with risk factor of thromboembolism. Patients were followed up by ultrasound or venography.

Results: Procedures were successful in all but one patient in whom passage of the guide wire through the common iliac vein failed (technical success rate = 98%). There were complications of minor bleedings (gum, nasal bleeding and woozing at puncture site) in 4 patients. Immediately after treatment, complete or partial resolution of symptoms was achieved in all patients with technical success. 4 patient received secondary thrombolysis and angioplasty due to the rethrombosis of iliac vein and stent on venography taken 1 month after the initial treatment and patency of iliac vein and stent was restored. On the follow-up ($n = 45$, mean 18 months), all stents were proved patent, however, partial stenosis (< 50%) was noted due to the intimal hyperplasia on venography. The overall patency rate at 1, 2, 3 year was 100, 98, 95%. (2 - 43 months, mean = 14 month).

Conclusion: Endovascular treatment of DVT is effective and safe.

C-0569

Contrast harmonic imaging with power mode and coded harmonic angiography using Optison for assessing vascularization during chemoembolization in HCC. First experiences

D.-A. Clevert¹, E. Jung², M.F. Reiser¹, N. Rupp²; ¹Munich/DE, ²Passau/DE

Problem: To what extent does contrast enhanced ultrasound using Optison enable recording of intratumoral vessels in hepatocellular carcinoma as compared to selective DSA?

Materials/Methods: In 30 patients with 39 lesions caused by hepatocellular carcinoma, a perfusion assessment using vascular ultrasound (Logiq 700, Logiq 9, GE) was carried out immediately before and during a selective chemoembolization. Using multifrequency transducer, it was possible to assess blood flow using color duplex sonography (CDS), power mode (PM) and after a contrast agent injection intermittently using coded harmonic angiography mode (CHA) and contrast harmonic imaging with power mode (CHI+PM). An evaluation was performed comparative to selective intra-arterial DSA with probing of the segmental vessels perfusing the tumor.

Results: Using CDS it was only possible to record intratumoral perfusion in 15/39 HCC tumor lesions. Using power mode it was possible in 20/39 lesions, primarily at the tumor margins. A one-time injection of Optison via a peripheral indwelling cannula permitted recording of intratumoral vessels in 30/39 lesions using CHA mode and in all 39 cases using CHI + power mode. An assessment of capillary perfusion only succeeded in CHA mode, which permitted subtraction of the surrounding tissue. Using CHI+PM, it was possible in all cases to sonograph-

ically record the segmental vessels perfusing the tumor for performing the chemoembolization after contrast agent enhancement.

Conclusion: A one-time injection of Optison in small doses in CHA mode and in CHI with power mode enables a recording of intratumoral vessels in HCC with high diagnostic certainty before and during chemoembolization.

C-0570

Percutaneous treatment of pulmonary arterio-venous malformations (PAVM)

F. Volpini, D. Ghirardo, A. Scarrone, I. Mondino, M. Grosso; Cuneo/IT

Purpose: Rendu-Osler-Weber's disease is a rare autosomic dominant pathology; the main symptoms are epistaxis, teleangiectasia and visceral lesions. The prevalence in Europe in 1991 was 1-2 cases on 100,000; the incidence of Pulmonary Arterio Venous Malformations (PAVM) is 15-33%. Right to left shunt causes complications such as cyanosis with dyspnea on efforts, paradoxal embolization with TIA, stroke and cerebral abscess due to septic emboli. We report our experience about treating PAVM in Rendu-Osler-Weber disease, to show the benefits of percutaneous treatment of high flow lesions by embolization, saving the parenchyma.

Materials and Methods: Since 2001 until May 2004, in our hospital 11 patients (4 male and 7 female, from 20 to 74 years) suffering from Rendu-Osler-Weber disease were treated for an amount of 18 PAVM embolized. All our patients have been treated using non-magnetic coils.

Results: Clinical and radiographic involution of PAVM was immediately complete in all patients, with a meanful increasing of PAO₂. No early or late migration of the devices occurred; no significant complications were noted, except for a case of transitorial ischaemic brain attack solved in 72 hours.

Conclusions: Percutaneous embolization is an optimal treatment of PAVM in Rendu-Osler-Weber disease, allowing a selective occlusion saving pulmonary parenchyma. Indications are all fistulas with the afferent artery > 3 mm diam. Non-magnetic coils, particulary spiral shaped coils (VortX, Boston Scientific), are the best material because of their biocompatibility and the security of a definitive occlusion, preserving pulmonary parenchyma.

C-0571

Partial splenic embolization using microsphere

J. Koizumi; Isehara-city/JP

Purpose: To assess the effect of embolization of the splenic artery by various size of microspheres.

Materials and Methods: Four different size (100-300, 300-500, 500-700, 700-900 microns) of microspheres were infused into the main splenic artery of swines (about 40 kg) via 4 Fr. catheter under general anesthesia. Microspheres were infused incrementally under duplex ultrasound measurement until the splenic arterial flow ceased. Splenic arteriography was performed before and after embolization. Five hours later the swine was sacrificed and the spleen was harvested from the swine after the final duplex measurement and angiography.

Results: Total amount of microspheres to obtain an initial cease of the splenic arterial flow was 0.65, 0.30, 0.75, 1.0 mL, while the flow recovery ratio (final blood flow volume before sacrifice/initial blood flow volume before embolization) was to 41.6, 42.2, 61.2, 54.5% by 100-300, 300-500, 500-700, 700-900 microns correspondingly. The specimen showed mostly patchy distribution of ischemic changes in any size variation but the size of each ischemic focus was the smallest using 100-300 microns of microspheres.

Conclusions: The most effective size of microspheres for partial splenic embolization seems to be 300-500 microns although flow recovery was the least at 100-300 microns of microspheres.

C-0572

Endovascular treatment of cerebral arteriovenous malformation

K. Kordecki¹, J.R. Janica¹, A. Lewszuk¹, J. Kochanowicz¹, B. Kadzolek², M. Zabek², J. Walecki¹; ¹Bialystok/PL, ²Warsaw/PL

Purpose: We present our results of treatment of cerebral arteriovenous malformations by implementing percutaneous embolization.

Material and Methods: Between 2001-2003 34 patients had undergone endovascular embolization of cerebral arteriovenous malformation. Ten female and 24 male patients, aged 15 to 78 years. Angiographic DSA examination was performed to assess possibility of percutaneous embolization. Microcatheters 1.2f, 15f or 1.8f were used in accordance with the malformation dimensions. The tip of catheter was placed close to nidus of malformation.

Results: Cerebral arteriovenous malformations were localized mainly in temple

Scientific and Educational Exhibits

region - 38% or in parietal region - 27%. The primary embolization resulted in total occlusion in 41% of AVMs fed by up to three vessels. Repeated interventions led to occlusion of the additional hemangiomas up to 70.5% of all lesions. In case of AVMs fed by more than 4 vessels, the second embolization have not resulted in total occlusion of hemangiomas. The curative results have been obtained only in 12 patients (35%). Total or partial occlusion have resulted in the partial reduction in malformation diameter by 30 to 80%.

Conclusions: The best results of embolization were achieved in cases of small and medium malformations fed by 1-3 vessels - 70.5% cases. In our opinion, percutaneous embolization could be applied as independent curative method in adult patients with small and medium arteriovenous malformation, grade I or III in Spetzler-Martine score.

C-0573

Advantages of virtual 3D Digital Subtraction Angiography option and "cut" function for imaging of the neck of aneurysm of the Willis' circle with complicated morphology

W. Wawrzynek¹, J. Baron², S. Kasprowska¹, A. Siemianowicz¹, B. Koczy¹, H. Boldys²; ¹Piekary Śląskie/PL, ²Katowice/PL

Purpose: Purpose of the work is to show the usefulness of the new technique of 3D DSA and a simple "cut" function for: - Evaluation and imaging of the aneurysmal neck with complicated structure before planned endovascular embolization procedure. - Qualification to endovascular or clipping procedures.

Materials and Method: 21 patients with aneurysms with complicated morphology. Phillips DSA Allura apparatus with 3D station and virtual angi option (AVA) and "cut" function.

Results: For 9 out of 21 patients with aneurysms with complicated morphology virtual 3D option and "cut" function occurred to be the only methods to precise analysis of the aneurysmal neck and it was possible to image additional vessel from aneurysmal neck and its sac. Based on images acquired in virtual option there were six aneurysms rejected, qualified earlier after DSA and 3D DSA for endovascular embolization procedure. Two aneurysms were disqualified for any medical procedure and one was provided with endovascular GDC embolization coils.

Conclusions: Virtual 3D DSA (AVA) option and "cut" function of 3D DSA may be very helpful in some percent of diagnostically difficult aneurysms. For some cases these techniques are the only possible tools to describe morphology of the aneurysmal neck and its sac.

C-0574

Transcatheter arterial chemoembolization through left inferior phrenic artery in hepatocellular carcinoma

S.-H. Suh, J. Won, D. Lee, K.-M. Paik; Seoul/KR

Purpose: To evaluate radiological findings of Hepatocellular Carcinoma (HCC) supplied by extrahepatic collateral supply of left inferior phrenic artery (LIPA) and the efficacy of transcatheter arterial chemoembolization (TACE) through LIPA.

Materials and Methods: Among 1,508 patients who underwent hepatic angiography for the treatment of HCC from February 2003 to January 2004, we found 13 patients with HCC supplied by LIPA collateral (10 males and 3 females, mean age 52 years). TACE of all the LIPA collaterals was performed. We evaluated the radiologic findings of HCC with LIPA collaterals. The clinical outcome, complication and development of another collateral supplies were also evaluated.

Results: The radiological findings of HCC with LIPA were: multinodular HCC (82%), located in left lateral segment (56%), and defect in iodized oil retention or progression of HCC at right dome and left anterolateral segment (68%). The angiographic findings had shown history of TACE more than 4 sessions (60%), hypertrophied LIPA (56%) and isolated origin of LIPA above celiac trunk (73%). The follow-up angiogram showed persistent occlusion in 8 patients and development of other collateral supplies in 7 patients. Three patients complained of left shoulder pain and no other specific complications.

Conclusion: TACE through LIPA was safe and effective. LIPA collaterals developed in 0.8% of patients with HCC. The search for LIPA collaterals should be performed in treatment of such a HCC.

C-0575

Treatment of malfunctioning radial native haemodialysis fistulas:

Comparison between cutting-balloon PTA and standard PTA

J. García-Medina¹, C. Serrano-García¹, A. León-Hernández¹, A. Basile², V. García-Medina¹, R. Leal-Adán¹; ¹Murcia/ES, ²Catania/IT

Purpose: To compare the results of cutting-balloon (CB) angioplasty versus and

high pressure balloon (HPB) angioplasty in the treatment of radial native haemodialysis fistulas.

Methods and Materials: We prospectively evaluate 20 randomized patients (16 men and 4 women, with average age of 66 years), with post-anastomotic stenoses in 20 radial autogenous malfunctioning arterio-venous fistulas treated either with CB (n = 10) or with HPB (n = 10). Inclusion criteria was fistulas without any previous treatment either radiological or surgical. The follow-up finished at 12 months, and the last case at 6 months of the end of the surveillance.

Results: We treated 24 post-anastomotic venous stenoses with an average length of 4 cm (range: 1-8 cm). The average number of inflations was 3 for CB and 4 for HPB. The average inflation pressure was 8 atmospheres for CB (range = 5-10) and 17 for HPB (range = 10-20). Five patients treated with CB had no pain feeling during the inflation, versus only one patient treated with HPB. The Technical success was of 100% in both group. A burst cutting-balloon occurred at the inflation pressure of 5 atmospheres without any consequences. The patency rate at 6 and 12 months were 75% and 8% with the CB and 58% and 16% with the HPB.

Conclusion: In our experience the use of cutting-balloon angioplasty is not justified in the treatment of radial native fistulas with first dysfunction, due to its greater price. The only advantage is related to the less pain feeling experienced by patients during the inflation.

C-0576

Vascular complications in orthotopic liver transplantation (OLT): A pictorial essay

A. Alonso, J.J. Noguera, L. Díaz, P. Domínguez, A. Martínez-Cuesta, J.I. Bilbao; Pamplona/ES

Learning objectives: To review and illustrate the different findings and the role of the percutaneous interventional procedures in the treatment of vascular complications after orthotopic liver transplantation (OLT) in living and cadaveric donors. In this report, special attention to the interventional techniques and diagnostic procedures, as well as the results obtained, is given.

Background: Vascular complications occur in approximately 7% to 14% of liver transplant recipients and they are responsible for 10% of graft losses. The clinical relevance will be determined by the extent of the graft vascular compromise and these complications are associated with a higher risk of graft's dysfunction. The most representative cases in each type of vascular complication following OLT, since the beginning of the OLT program in our centre in 1990, as well as the diagnosis and percutaneous interventional treatment are illustrated and described.

Imaging Findings: Imaging findings from fluoroscopy, angiography (including 3D-angiography), multislice-CT and ultrasound obtained at the time of diagnosis, treatment and follow-up in different cases are illustrated and shown.

Conclusion: Percutaneous interventional procedures, including angioplasty, local thrombolysis and embolization, have gained worldwide acceptance for treatment of these complications, due to their minimal invasiveness as well as low complication and high success rates. A reduced blood loss and a low incidence of procedural complications allow for rapid recovery and to diminish the rate of retransplantation, however, an early diagnosis and correct patient selection are essential factors in order to obtain the best results.

C-0577

Head and neck paragangliomas: Imaging and embolization

A.M. Crespo, G. Hernandez, R. Barrena, A.B. Garcia, B. Izquierdo, E. Angulo; Zaragoza/ES

Purpose: 1. To determinate imaging features of head and neck paragangliomas and to study their value in the differential diagnosis and surgical planning. 2. To determinate the usefulness of pre-operative embolization.

Methods and Materials: From January 1994 to March 2004, 28 patients were found to have paraganglioma in our institution. They were imaged by US, CT, MR imaging and angiography and histopathologically confirmed. 19 patients underwent selective embolization.

Results: Jugulo-tympanicum tumors represented the most common paraganglioma, 15 patients (54%). 12 patients (43%) had carotid body tumors. One patient suffered from a vagal paraganglioma. One patient had bilateral carotid glomus, another one had family history and another patient had multicentric paraganglioma. Presentation was typically late in the course of the disease, with a pain-less slow-growing mass. 22 paragangliomas (79%) were surgically removed. 5 glomus (18%) were only surgically treated and 2 paragangliomas underwent embolization without surgery. 17 tumors (61%) underwent combined endovascular and surgical treatment. 2 patients were treated with pre-operative embolization, surgery and radiation therapy as palliative adjunct. Surgical complications were nerve paralysis in 6 patients (21%) and cerebrovascular accident in one case. A patient

Scientific and Educational Exhibits

had an inguinal hematoma, another one a facial paralysis and another one stroke due to pre-operative embolization.

Conclusions: 1. Imaging studies are essential to differentiate paragangliomas from other masses of the head and neck. 2. Imaging procedures depict location and extent of the paraganglioma, helping determinate the surgical approach and help predict post-operative morbidity. 3. Pre-operative embolization decrease intra-operative bleeding.

C-0578

Endovascular treatment of aortoiliac occlusive lesions using a bifurcated endoprosthesis

T. Zander¹, R. Llorens¹, R. Rostagno¹, I. Zerolo¹, V. Prieto¹, Z. Qian², M. Maynar¹; ¹Santa Cruz de Tenerife/ES, ²New Orleans, LA/US

Purpose: To report initial experience with bifurcated endoprostheses in the management of aortoiliac occlusion.

Patients and Methods: Five patients with diffuse aortoiliac occlusions were treated by the endovascular placement of bifurcated endoprostheses. Indications for treatment were severe claudication (n=3), rest pain (n=1) tissue loss (n=1). All these patients were considered as non-surgical candidates because of their high-risk factors, such as cardiac disease, hostile abdomen, or obesity. After the occlusive lesions were successfully recanalized by fibrinolysis and/or balloon angioplasty, bifurcated aortic endoprosthesis (Excluder®, W.L. Gore, Flagstaff, AZ) was placed to reconstruct the aortoiliac bifurcation. The patients were followed up clinically and ultrasonographically every 3 months during the first year and semiannually afterwards.

Results: Technical success was achieved in all patients. Endovascular aortoiliac bifurcation reconstruction restored iliac artery flow immediately in all cases. The mean post-grafting ABI was significantly improved from 0.66 ± 0.04 before the procedure to 0.94 ± 0.06 immediately after procedure ($P < 0.01$). The ABI remained stable during the follow-up period. There was no mortality nor amputation required in this series during the follow-up period. All patients have remained free of ischemic symptoms up to the last follow-up.

Conclusion: Endovascular placement of bifurcated endoprostheses is technically feasible, effective, and safe in the management of aortoiliac occlusive disease.

C-0579

Indications, diagnostic methods and radiologist's role in acute interventional stroke therapy

B. Schmitz, R. Huber, A.J. Aschoff; Ulm/DE

Learning Objectives: To learn about the role of the radiologist in acute interventional stroke therapy. To review the appropriate diagnostic strategies to identify tissue at risk. To illustrate educational cases in which (based on MR imaging criteria) local thrombolysis has been successfully performed beyond the 6 hour time window.

Background: Intravenous and local intraarterial thrombolysis is the only acute stroke therapy with evidence based improved outcome. However, time windows of 3 hours for intravenous and 6 hours for intraarterial therapy are still small. The rationale of thrombolysis is based on the penumbra concept that is reflected in a diffusion - perfusion (DWI/PWI) mismatch in MR imaging studies. MR imaging may justify even later local thrombolysis in selected cases based on thorough image interpretation.

Imaging Findings: To rapidly identify tissue at risk an immediate DWI/PWI MR imaging is desirable. The only other crucial task is the reliable exclusion of intracerebral hemorrhage as the major differential diagnosis. This can be done with MR imaging as well and a CT scan can be omitted even in the acute stage if a MR imaging scanner is available.

Conclusion: In this exhibit we describe the indications and possibilities for interventions in acute stroke. Radiologist's role, interventional methods and strategies are reviewed in detail. MR imaging is pointed out as the method of choice for the identification of tissue at risk. Additionally, educational cases with successful interventional treatment beyond the 6 hour time window based on MR imaging diagnosis are presented.

C-0580

Transplant renal artery stenosis (TRAS): Long-term impact on kidney function and blood pressure control of percutaneous transluminal angioplasty and stenting

R. Corso, R. Vercelli, A. Rampoldi, E. Minetti, D. Leni, A. Vanzulli; Milan/IT

Purpose: We assessed long-term effect on blood pressure control and renal graft function in the treatment of TRAS with PTA and/or stenting.

Materials and Methods: From 1996, 884 kidney transplants have been performed in our Institution. 12 of these were referred to angiographic suite for TRAS associated to refractory hypertension (6), renal function impairment (4), or both conditions (2). Four patients had end-to-end anastomosis while eight had end-to-side anastomosis. All cases underwent PTA and/or stent placement. Immediate outcome and follow-up data have been reviewed and analysed. Mean blood pressure, load in antihypertensive drugs and serum creatinine levels were considered before PTA and in the follow-up (1, 3 month and every 6 months after the procedure). The average follow-up was 42.8 months (range 21-102).

Results: The mean age of transplant at intervention was 11.7 months. Technical success was achieved in all patients, with no major complications. In 7 patients PTA alone was performed while 5 patients underwent stent placement after PTA (3 recurrence, 1 recoil and 1 for dissection). In the follow-up the mean blood pressure fell from 116.6 ± 8.4 to 100.9 ± 9.44 mmHg ($p < 0.01$) and in 7 patients (87.5%) we registered persistent normal blood pressure with reduction or suspension of load in antihypertensive drugs. Similarly, the serum creatinine levels fell from 1.78 ± 0.8 to 1.20 ± 0.6 ($p < 0.05$), being still stable in the follow-up for 5 patients (83.3%).

Conclusion: PTA and/or stent placement is effective and safe in the treatment of TRAS and it warrants a long-term benefit over blood pressure control and graft function.

C-0581

Coil embolization therapy of pulmonary arteriovenous malformations: Combination of 16-detector CT angiography and interlocking detachable coils

N. Hirai, N. Toyota, H. Kakizawa, M. Hieda, T. Tachikake, K. Ito; Hiroshima/JP

Purpose: Our goal was to establish the utility of CT pulmonary angiography (CTPA) and interlocking detachable coils (IDCs) for coil embolization therapy of pulmonary arteriovenous malformations (PAVMs).

Materials and Methods: Seven consecutive patients with PAVMs were performed both CTPA and coil embolization therapy using IDCs. CTPA were performed as pre-embolization survey using sixteen-detector CT scanner. CT scanning started at twenty seconds after starting injection of non-ionic contrast material via antecubital vein at the rate of 2.5 ml/sec. Acquired scanning data was reconstructed into 1.25-mm-thick axial images at every 1.25-mm interval. Volume rendering images were constructed using segmentation threshold at 130 HU. After the careful selection of pulmonary vessel trees, color coding were performed as feeding arteries into red, nidus into yellow, and drainage veins into blue to distinguish these structures easily. Using these volume rendering images, we considered the location and shape of PAVMs, and we shaped five-french sized strait catheter to fit to feeding arteries. We also studied about the best angle for fluoroscopy to select feeding arteries. Coil embolization of feeding arteries were performed using IDCs. Conventional microcoils were also used as additional embolization, if required.

Results: Eighteen PAVMs of seven patients were treated using these methods. In all eighteen PAVMs were completely embolized without coil migration and incidental pulmonary infarction. Using preparation CTPA and shaped catheters, fluoroscopic time and contrast material dose were reduced compared with our conventional methods.

Conclusion: CTPA and IDCs combination therapy is useful to treat PAVMs with lower invasion.

C-0582

Percutaneous transhepatic portal vein embolization using newly altered four-lumen balloon catheter: Preliminary clinical experience

M. Gibo, S. Murayama, T. Nakayama, T. Morita, S. Gibo; Okinawa/JP

Purpose: Percutaneous transhepatic portal vein embolization (PTPE) is effective to expand the residual liver volume and to avoid postoperative hepatic failure. The purpose of the present study was to assess the safety and technical success rate of PTPE using improved four-lumen balloon catheter by ipsilateral approach.

Methods and Material: To make better ipsilateral approach method, we used an improved four-lumen balloon catheter which has one lumen connected to the catheter tip for guide wire, one lumen connected to the balloon, and two other lumina connected to the side-hole open just proximal to the balloon. The right branch of portal vein was embolized in 6 patients, the left branch in one patient. We used fibrin glue with iodized oil as the embolic material and injected simultaneously through the separate side-hole lumina.

Result: Technical success was achieved in all cases. Complications related to the procedures did not occur. We could inject a large amount of fibrin glue with iodized oil (6.0-15.4 ml; mean 10.8 ml) and perform effective embolization.

Scientific and Educational Exhibits

Conclusion: Ipsilateral approach using triple-lumen balloon catheter without guide wire lumen previously reported. Our method is considered to be more easy and safe than that traditional ipsilateral approach because a guide wire is available for accessing targeted portal vein. In addition, use of our new catheter makes it possible to measure the portal vein pressure elevation following PTPE through guide wire lumen of the catheter tip.

Giant liver hemangiomas: Results of transcatheter embolization

K. Malagari, D. Antonopoulos, J. Mitromaras, E. Alexopoulou, K. Hatzimichail, A. Nikita, A. Kelekis, M. Kampanarou, D. Kelekis; *Athens/GR*

Purpose: To evaluate the efficacy of transcatheter embolization in the management of giant liver hemangiomas.

Material and Methods: Twenty two patients with giant liver hemangiomas (mean diameter 8.9cm; range 5-18) were included in the study. Mean age was 43.6 yrs (32-67). Of them, 16 were symptomatic (consumption coagulopathy: n=2; abdominal pain: n=9, discomfort and abdominal fullness: n=5). Color Doppler evaluation with contrast enhancement and CT evaluation was available before and after embolization (one week and 6 months post procedure). Embolization was performed after selective arteriography in 21 cases with spherical embolic agents (Embospheres; Biosphere, Rockland, MA) alone or in 17 patients combined with Gelatin sponge particles in 4 cases (Gelfoam; Upjohn, Kalamazoo, MI). One patient was excluded because of extensive arteriovenous shunting.

Results: Embolization was successful in obliterating the vasculature of the lesions in all cases immediately post procedure. In the patients with Kasabach Merritt the coagulopathy reversed immediately and 24 h post embolisation platelet counts were above 150.000/mm³ and fibrinogen 244 µg/dl and 280 µg/dl respectively. Vascularity was significantly decreased on Doppler studies in all cases. Follow up showed relief of symptoms in 19 patients (90.47%). On six month follow-up, 17 patients showed revascularization on Doppler evaluation (80.95%). Nine patients underwent repeat embolization and angiography showed increased vascularity before embolization within the lesion. Six month follow-up in these cases also showed revascularization.

Conclusion: Embolization of giant liver hemangiomas is useful for relief of symptoms, however, in the long run the lesions are revascularized and may present a similar to preembolization clinical pattern.

C-0585

Carotid stenting with protection device (CASPD) and brain diffusion-weighted MR imaging (DWI-MRI): Control within 6 and 24 hours after stenting

I. Sansoni, A. Laghi, C. Miglio, M. Celestre, M. Rengo, L. Coletta, M. Di Martino, R. Passariello; *Rome/IT*

Purpose: The aim of this study was to assess if brain diffusion-weighted MRI monitorization should be performed within 6 or 24 hours from carotid angioplasty and stent placement with protection device (CASPD).

Methods and Materials: Thirty-four age range: 66-95 Ys, mean 75 ± 5.7 consecutive patients referred for CASPD procedure (inclusion criteria: asymptomatic stenosis > 80% in 30 cases or symptomatic stenosis > 50% in 4 cases) underwent neurologic examination before, within 6 hours and 1 day after CASPD. MR protocol (FLAIR and DWI images) were performed 1-3 hours before, within 6 and 24 hours after CASPD, in order to verify the number of new ischemies (symptomatic or silent). Total examination time was 5 minutes. The three set of images were examined by two independent blinded reviewers for new high-signal areas suggestive for acute ischaemic lesions. We correlated positive results with risk factors, technical difficulties and plaque characteristics.

Results: Within 6 hours DW-MRI images showed one new high signal intensity lesions (2.9%) on the opposite side of stent placement; 24 hour DWI detected three more cases of acute ischemic lesions in 8.82% of patients, two symptomatic and one asymptomatic; all four patients had two or more risk factors and a fibrocalcified plaque.

Conclusion: Embolic events may occur after CASPD, even if the use of early (within 6 hours) DW-MRI confirmed CASPD as a safe procedure, with few strictly procedure-related ischemic complications. On the other hand, late (24 hours) DW-MRI monitorization showed the possibility of later embolization.

C-0586

The effectiveness of magnetic resonance (MR) in diagnostic pattern prediction and follow-up of uterine fibroids embolization

R. Marcello, F. Anglana, P. Signorile, G. Assegnati, A. Di Blasi, M. Castrucci; *Rome/IT*

Purpose: To assess the value of MR imaging pattern in the planning and follow-up of uterine fibroids treated with percutaneous catheter embolization.

Methods and Materials: 29 patients (31-46 Y, mean 38), were evaluated with MR of the pelvis before uterine fibroid embolization and after 10 days, 6 months and 12 months the interventional procedure. MR examination was based upon FFE T1W, FFE T1W post Gad and TSE T2W sequences in coronal, sagittal and axial planes. The volume, location, number, vascularity appearance and the association with any other gynecologic abnormalities were evaluated. Volume decrease rate of fibroids and the possible symptoms persistence after embolization were assessed at follow-up.

Results: MR was useful in assessing the correct imaging pattern predicting the better clinical results of fibroid embolization. MR follow-up showed a volume decrease rate of uterine fibroids ranging from 50% to 65%. Any patient was retreated.

Conclusions: MR is to be considered the leading imaging modality in the assessment of uterine fibroids before embolization and in the follow-up. The early (10 days) post procedure MR examination is predictable of the further response to embolization treatment.

C-0588

Selective arterial emolisation in the management of massive obstetrics hemorrhagic complications

A. Álvarez Luque, I. Acitores, F. Ybáñez, G. Garzón, B. Marín, A. Bravo, M. Parrón; *Madrid/ES*

Learning Objectives: To describe the selective percutaneous arterial embolisation technique in the treatment of hemorrhagic obstetrics complications, outlining the advantages and limitations of the procedure.

Background: Massive obstetric hemorrhagic bleeding is a life-threatening complication of pregnancy and postpartum. Classically hemorrhage was treated conservatively with external compressive massage, internal packing and drugs. Hysterectomy and major vascular procedures were used to preserve life. Percutaneous vascular technique allows localising and selectively embolising the bleeding point. This challenging technique helps decreasing further complications and preserve the uterus.

Procedure Details: A serial of 41 ASE was carried out. Distal aortography including external iliac, femoral and hypogastric arteries with its pelvic branches was performed to localise any bleeding point. Hypogastric arteries were selectively catheterised by conventional diagnostic catheters as 4F or 5F renal catheters or 3F co-axial catheters. Bleeding points were embolised with polyvinyl alcohol or microspheric particles (700µ) and sealed with coils. An arteriography was then performed to rule out extravasation. After the procedure, arterial inducers were always kept to allow urgent intervention if any complication. None of the patients died although four were reembolised because of rebleeding. Endovascular procedures were performed at the internal pudendal artery in 12 patients, at the uterine artery in 9, hypogastric branches in 7, vaginal artery in 5, obturator artery in 4, and pelvic muscular branches in 3 patients.

Conclusion: Endovascular treatment of massive obstetrics bleeding should be considered as an effective alternative to surgery. This procedure allows preserving the uterus and the reproductive function, avoiding the surgical morbility.

C-0589

Endoluminal treatment of liver transplantation complications. Sixteen-year experience in 570 patients

R. Lopez-Benitez¹, H.M. Barragan-Campos², G.M. Richter¹, G. Kauffmann¹, T. Marinelli¹, P.J. Hallscheidt¹; ¹Heidelberg/DE, ²Paris/FR

Purpose: To retrospectively evaluate most frequent complications related to liver transplantation and how interventional radiology has contributed to improve survivals and outcomes in these patients.

Materials/Methods: From a total of 570 patients who had undergone partial or total liver transplantation in a 16-year period (1987-2003) those in whom one or several minimally invasive procedures were performed in our institution where included.

Scientific and Educational Exhibits

Results: Several variables were evaluated, including number of interventions, type of complication (vascular, portal, biliary or miscellaneous), morbidity and mortality, improvement of survival in every specific complication and outcomes. Seven percent of all transplanted patients underwent interventional procedures. Biliary and arterial interventions were most frequent and included stent insertions and biliary drainages.

Conclusion: There was an increase in the number of interventional procedures in the last years due to the improvement of materials and new devices. The survival of the transplanted patient has significantly improved.

C-0590

A 4-year experience in trans arterial chemo embolization of primary and metastatic liver tumors

A. Scarrone, F. Pedrazzini, G. Lingua, F. Testa, M. Grossi,
F. Groppo Marchisio; Cuneo/IT

Purpose: To report our experience using biocompatible hydrophilic microspheres (Embosphere, Biosphere medical), in hepatic Trans Arterial Chemo Embolization (TACE).

Materials and Methods: Since February 2000 until August 2004, 52 patients (50 HCC, 2 liver metastases; 38 male, 14 female) underwent a selective segmentary chemoembolization. We used a mixture of chemotherapeutic drug (Adriblastin or Doxorubicin 30-40 mg), Lipiodol (10 ml) and Embospheres (100-300 microns, 1-2 ml), opportunely emulsified. At the end of the infusion, if blood support remains, embolization is completed by using microspheres of larger diameter (300-500 microns), according to residual vascularization.

Results: Twenty-five patients had only 1 lesion, 14 had a maximum of 3 lesions, 13 had multifocal lesions. CT follow-up at 1, 6 and 12 months showed in most of cases good results with no contrast enhancement in treated lesions; any new lesions were furtherly treated with the same technique. No problems occurred versus the cases treated by TACE with Spongostan. Death rate at 30 days was about 8%, with survival rate at 6 months of 81%.

Conclusions: Our preliminary experience shows that the treatment with Embospheres is optimal in hepatic TACEs, because they can be emulsified with Lipiodol and a chemotherapeutic drug. It is possible to get a distal embolization and exclude the lesion from any blood support. Complication rate is lower than TACEs traditionally made. TACE with Embospheres does not exclude further chemoembolizations.

C-0591

Percutaneous revascularization of popliteal and infrapopliteal arteries

S. Tettoni, A. Scarrone, F. Pedrazzini, R. Priotto, G. Gallarato, M. Grossi;
Cuneo/IT

Purpose: To present 3-years experience results in percutaneous treatment of distal occlusions of lower limb arteries in patients with AOCP.

Material and Methods: Since May 2002 to September 2004, we treated 48 patients (20 female, 28 male, mean age 70 years), suffering from claudication and/or trophic lesions due to critical atheromasic stenosis of distal vessels of lower limb. 71 angioplasties were performed (30 in popliteal artery, 14 in posterior tibial artery, 9 in anterior tibial artery, 12 in interosseous artery, 5 in tibio-peroneal trunk, 1 in pedal artery). Technique consists of a wire-made recanalization followed by balloon dilatation, trough a percutaneous proximal access. Forty-six patients were treated by traditional technique, 2 by subintimal technique.

Results: Six months mean follow-up showed lower limb saving in 82.9%. Three patients underwent a minor amputation, 6 a major amputation; 4 patients died before radiologic follow-up for other causes not related to the procedure.

Conclusions: Percutaneous treatment of lower limb popliteal and infrapopliteal arteries critical stenosis is a safe technique which allows to preserve limb from amputation in most cases. Vessels treated develop compensatory collateral blood-streams, which remain even if mean artery re-occludes.

C-0592

Preoperative selective transarterial embolization therapy for diffuse plexiform neurofibroma of the skin: Our initial experiences

J. Tanaka, A. Kuramochi, N. Nishi, M. Yuasa; Iruma-gun/JP

Purpose: To evaluate the usefulness of transarterial embolization as a preoperative therapy to cutaneous diffuse plexiform neurofibroma of neurofibromatosis type 1 (NF-1). This disease of the skin sometimes grows to an enormous size and occasionally becomes malignant. Surgical reduction is desirable as far as possible but is usually very difficult to stop bleeding during surgery due to the abundance of vulnerable abnormal vessels within the tumor. Preoperative em-

bolization therapy has never been applied to this disease so far as we know, however.

Methods and Materials: Selective angiography and embolization have been carried out without any technical difficulties for four cases of NF-1 cutaneous diffuse neurofibromas up to 16 cm in maximum diameter, using gelatin sponge particles few days prior to reduction surgery. Amount of bleeding was recorded accurately at surgery.

Results: In all of the four cases, subtotal removal of the tumors have been done with less than 10 ml of total bleeding. Results of reduction surgeries were satisfactory in all of the cases.

Conclusion: Preoperative selective transarterial embolisation may be a preferable option for patients with cutaneous plexiform neurofibroma when surgical resection is planned.

C-0593

Development of collateral channels after successful transcatheter gastric variceal embolization: Assessment by CT and endoscopic examinations

Y. Watanabe¹, H. Sugimoto²; ¹Sapporo/JP, ²Yakushiji/JP

Learning Objectives: To describe how often and when new collaterals such as esophageal varices or splenorenal shunt develop or gastric varices recur after successful transcatheter gastric variceal embolization based on a series of 15 patients.

Background: Gastric varices due to portal hypertension are treated by endoscopic, surgical or interventional radiological procedures. Since its introduction in the mid-1990s, balloon-occluded retrograde transvenous obliteration (BRTO) has become a widely accepted transcatheter gastric variceal embolization method in Japan. This method is minimally invasive and highly effective. However, even after successful variceal treatment, development of collaterals or recurrences of gastric varices do occur due to the remaining portal hypertension. In this exhibits, we will describe the long term result after successful BRTO, especially regarding collateral development and gastric variceal recurrence.

Procedure Details: We retrospectively reviewed follow-up CT and endoscopic examinations of 15 patients with gastric varices due to portal hypertension. Gastric variceal embolization was successfully performed by balloon-occluded retrograde transcatheter obliteration (BRTO) method. The follow-up periods ranged from 12 to 66 months (average 33 months). We evaluated collateral vessels after BRTO using serial CT and endoscopic examinations.

Conclusion: Recurrence of gastric varices was rare and did not require any additional treatment. Esophageal varices occurred in 9 patients. The period of occurrence showed a bimodal peak for 4 months and 20 months in average after successful BRTO and they required additional treatment. Two developed spleno-renal shunt with no recurrence of gastric varices or esophageal variceal development.

C-0594

Interventional procedures of acute retroperitoneal hemorrhage, especially renal and pancreatic hemorrhage

Y. Watanabe¹, Y. Kodama¹, A. Sawada¹, Y. Sakuhara¹, D. Abo¹, M. Funakubo¹, H. Sugimoto², K. Miyasaka¹; ¹Sapporo/JP, ²Tochigi/JP

Learning Objectives: To illustrate the spectrum of acute retroperitoneal hemorrhage, especially renal and pancreatic hemorrhage, that could be treated by transcatheter embolization.

Background: Retroperitoneal hemorrhage is a clinical setting in which transcatheter embolization may prove useful. Transcatheter embolization for active bleeding is less invasive treatment than surgical intervention, and in certain clinical settings, such as postsurgical fields, it can become only alternative treatment because of the difficulty of surgery.

Procedure Details: We reviewed 18 cases of acute renal and pancreatic hemorrhage that underwent angiography between January 2000 and August 2004. Six renal cases included blunt renal trauma, rupture of renal angiomyolipoma, rupture of renal pseudoaneurysm due to polyarteritis nodosa, and rupture of aneurysmal type of renal AVM. Twelve pancreatic cases included aneurysm of the splenic artery, pseudoaneurysm of the celiac artery, postoperative psuedoaneurysm of the gastroduodenal artery stump after pancreatectoduodenectomy. Embolized materials were steel coils, microcoils, gelatin sponge particle, and absolute ethanol.

Conclusion: Transcatheter embolization is useful treatment for acute retroperitoneal hemorrhage.

Scientific and Educational Exhibits

C-0595

Is transcatheter therapy of renal artery stenosis choice in treatment of renal hypertension? Diagnostic value to detect restenosis in long-term follow-up
J. Saponjski, M. Ostojic, D. Masulovic, B. Beleslin, Z. Markovic; Belgrade/YU

Purpose: The aim of the study was to analyze in eight-year follow-up period the value of PTA (percutaneous angioplasty) in the treatment of renovascular hypertension.

Methods: In eight-year period (1996-04) selective arteriography of the renal arteries was performed in 93 patients (female 60, male 32; mean age 41 ± 7 years). Significant renal stenosis, defined as diameter stenosis $> 50\%$ was found in 43 (46%) patients (mean diameter stenosis $78 \pm 12\%$).

Results: PTA was done in all 43 patients, reaching successful result in 38 patients, while in 5 patients procedure was completed with stent implantation. Mean systolic and diastolic blood pressure before intervention was 180 ± 25 mmHg and 120 ± 15 mmHg, respectively. Immediately after the intervention, systolic and diastolic blood pressures were reduced to 130 ± 7 mmHg and 90 ± 5 mmHg, respectively ($p < 0.001$). In the follow-up period, control arteriography was performed in all patients disclosing restenosis of the renal artery in 12 patients (31%), and all of them had increased blood pressure (defined as higher than 140/90 mmHg). In 13/43 patients with normal blood pressure in the follow-up period, none of the patients had significant renal restenosis (sensitivity 100%). However, increased blood pressure was found in 30/43 patients, of whom in 13 patients elevated blood pressure was not accompanied by renal restenosis (specificity 46%).

Conclusion: Increased blood pressure in the follow-up period after PTA is not associated with renal restenosis, indirectly supporting the concept of reevaluation of the indications for PTA of the renal arteries.

C-0596

Communications between carotid and vertebrobasilar system via persistent primitive arteries

D. Mihajloski, G. Damjanoski; Skopje/MK

Learning Objectives: To present a very rare cases of persistent primitive arterial communications between carotid and vertebrobasilar system. To outline the necessity of detailed angiographic evaluation of cerebral arterial supply in such cases.

Background: Communication between carotid and vertebrobasilar system via persistent primitive arteries is very rare condition. Such primitive persistent arteries are: persistent primitive proatlantal intersegmental artery (PPPIA), primitive trigeminal artery, hypoglossal artery and otic artery. We present three cases with this type of primitive persistent communication. Two of them with primitive trigeminal artery and one with PPPIA and saccular aneurysm originating from PPPIA.

Imaging Findings: In all cases a detailed angiographic evaluation of cerebral arterial supply was performed. In two cases angiography revealed a primitive trigeminal artery originating from internal carotid artery. In one case 42-year old female patient was admitted for MR imaging study of the brain because of persistent headache. On MR imaging study basilar artery aneurysm was suspected. A detailed angiographic study of carotid and vertebrobasilar system was performed. A PPPIA was revealed originating from left internal carotid artery on the level of C1-C2. The vessel coursed dorsally and entered skull via the foramen magnum. A saccular aneurysm was also revealed originating from PPPIA. The basilar artery was originating exclusively from this vessel. Both vertebral arteries were hypoplastic.

Conclusion: Communications between carotid and vertebrobasilar system via persistent primitive arteries is very rare. In such cases a detailed evaluation of cerebral arterial supply is necessary.

C-0597

Stent placement in symptomatic middle cerebral artery stenosis

K. Karaman, L. Onat, C. Duran, M. Sirvanci; Istanbul/TR

Purpose: To report our experience with the stent placement for symptomatic middle cerebral artery stenosis in three patients.

Materials and Methods: We treated 3 patients with middle cerebral artery stenosis with primary stent dilatation ($n = 2$) and in combination with stent placement due to impaired balloon dilatation ($n = 1$). Two of the lesions were located in MCA M1 segment and the other in M2 segment. According to the NASCET criteria, all patients had high grade stenoses (70-90%). The indication for stent placement was acute ischemic stroke in all patients.

Results: Transient procedural complication was not detected. During clinical follow-up, no one had further ischemic symptoms. In one patient, balloon angioplasty was done at first. 1 month later, restenosis was seen and finally stent

placement was applied. The treatment was technically successful in all patients.

Conclusion: Endovascular revascularization of middle cerebral artery stenosis by stent placement is technically feasible, effective and safe. But for the best treatment modality, more clinical trials and much research are needed.

C-0598

Lipiodol flowing into portal vein after arterial embolization: The influential factors and clinical significance

H. Wu, G. Feng, H. Liang; Wuhan/CN

Purpose: To find out the factors correlated with lipiodol flowing into portal vein (LFPV) after arterial embolization and its clinical significance.

Methods and Materials: Total 274 times of LP-TACE procedures were performed to 147 cases of HCC (247 times) and 26 cases of hepatic hemangioma (27 times), who had no evidence of hepatic arterioportal shunt in conventional DSA. The sign of LFPV was observed and the relationship between it and multivariate factors (sex, age, tumor type, size, blood vessel abundant degree, procedure times, catheter location, lipiodol type, lipiodol dosage /tumor size) were analyzed by multivariate logistic regression model.

Results: The signs of LFPV were seen 78 times in 274 procedures (28.5%), 62/247 in HCC group and 16/23 in hemangioma group. In HCC group, single-variate analysis showed that LFPV was related to tumor type, size, catheter location, lipiodol type and lipiodol dosage/tumor size, and multivariate logistic regression analysis showed that it was related with lipiodol type, catheter location and tumor type. In hemangioma group, LFPV was only related with lipiodol type. The lipiodol in portal veins disappeared gradually within 1-3 days after TACE. The liver function changes were no different between LFPV positive and negative groups. Lipiodol accumulated better in LFPV positive group than in the negative groups.

Conclusion: It is suggested that the sign of LFPV was one of the markers of full dosage of lipiodol in TACE procedures. The LFPV sign easily appeared in hepatic hemangioma, using ultrafluid lipiodol, super-selective embolization and small-size tumor.

C-0599

Standard-protocol moving-bed MR angiography for planning of interventional procedures in patients with peripheral vascular occlusive disease

R. Drescher, T. von Rothenburg, O. Köster; Bochum/DE

Purpose: The aim of this study was to evaluate the usefulness of standard-protocol MR angiography for the planning of interventional procedures in the lower extremity vascular territory.

Methods and Materials: In this prospective study, patients with known or suspected peripheral vascular occlusive disease of the lower extremities underwent MR angiography for planning of interventional treatment. Contrast-enhanced MR angiography was performed using a three-step moving-bed technique on a 1.5 T scanner with a dedicated flex array. Digital subtraction angiography (DSA) was done in patients scheduled for interventional treatment and served as the standard of reference.

Results: 100 MR and digital subtraction angiographies of 83 patients (63 men, 20 women, mean age 65 years) were evaluated. MR angiography showed slight overestimation of stenoses compared to DSA (stenosis 55-99%, mean 81.1% versus 60-93%, mean 76.9%). 4 vessel occlusions were shown. 34 balloon angioplasties, 58 stent implantations and 3 recanalizations were performed. 92 interventions (92%) were correctly planned. One low-grade in-stent restenosis was not treated. In 4 cases balloon angioplasty was planned, but stent implantation was performed. In 3 cases endovascular treatment was not possible. In one patient a highly stenotic artery occluded before DSA could be performed. No complications occurred during MR angiography or DSA.

Conclusion: MR angiography of the lower extremities is a safe, noninvasive tool for preinterventional assessment of peripheral vascular occlusive disease. It allows exact planning of endovascular interventions despite a slight overestimation of stenoses on MR imaging compared with DSA. Artifacts due to stents can make evaluation more difficult.

C-0600

Estimating the maximum radiation skin dose during percutaneous coronary intervention using the fluoroscopic time, dose-area product, and body mass index

K. Chida, H. Saito, M. Zuguchi, H. Otani, H. Shimura, D. Ito, M. Nakada, S. Takahashi, K. Shirato; Sendai/JP

Learning Objectives: To understand that the skin dose of percutaneous coronary intervention (PCI) may occasionally exceed the dose causing erythema. To

Scientific and Educational Exhibits

understand the methods to obtain useful information for estimating the maximum radiation skin dose (MSD) in patients who underwent PCI.

Background: PCI can potentially result in high patient radiation doses. Since high doses cause potentially harmful radiation skin injuries, the MSDs should be recorded. However, real-time maximum dose monitoring of the skin is unavailable on many of the X-ray machines. Therefore in this exhibit, the correlations between the MSD and body mass index (BMI), fluoroscopic time, and dose-area product (DAP) were investigated to examine whether these factors could prove useful in estimating the MSDs during PCI.

Procedure Details: We measured the skin dose, fluoroscopic time, DAP, and BMI for 172 consecutive patients who underwent PCI. The patient skin dose and DAP were measured using Caregraph (Siemens) with skin dose mapping software. We found a poor correlation between the MSD and total fluoroscopic time ($r^2 = 0.395$, $p < 0.0001$). There was a significant correlation between the MSD and total DAP in PCI ($r^2 = 0.524$, $p < 0.0001$). We found reasonable correlations between the MSD and BFP (BMI \times fluoroscopic time, $r^2 = 0.494$, $p < 0.0001$) and BDAP (BMI \times DAP, $r^2 = 0.565$, $p < 0.0001$).

Conclusion: BDAP may be good predictor of skin injury risk in PCI. When DAP cannot be monitored, BFP may be reasonable predictors of skin injury risk. This study provides potentially useful information for estimating MSDs; this information could be used to help prevent patient skin injuries during PCI.

C-0601

Repeated transarterial chemoembolization for the treatment of advanced pancreatic cancer with superselective catheterization of the pancreas

S. Kawamura, T. Okuno, F. Ganaha, K. Hayakawa; Kanagawa/JP

Learning Objectives: To present the advantages and limitations of the transarterial chemoembolization for advanced pancreatic cancer. To describe the angiographic findings and the result of the treatment for a series of 25 patients.

Background: Pancreatic carcinomas still present poor prognosis because many of the cases are found at an advanced stages and are therefore non-resectable. When conventional chemotherapy is discontinued because of its ineffectiveness or its side effects, alternative therapies have been few. From January 1998 to June 2004, 25 patients with advanced pancreatic cancer received transarterial chemoembolization with superselective catheterization of the pancreas.

Procedure Details: Patients with stage III (n = 3) or IV (n = 22) pancreatic cancer were treated on an outpatient basis once a month. We superselected into dorsal pancreatic arteries (DPA) or inferior pancreaticoduodenal arteries (IPDA) to sufficiently supply chemotherapeutic reagent accompanied with molecules of hundreds-nanometer in diameter to the primary tumors. Metastatic lesions were treated in the same way.

Conclusion: Superselective catheterization was attained in 64% (16 patients). The mean survival period was 188 days. The seemingly short survival may be associated with the long latency period (137 days, Mean) before the initiation of the therapy. The procedure takes 65 minutes in average, so far has presented little complication and therefore may result in make better quality of life of the patients than chemotherapy or surgery. The superselective chemoembolization may make an alternative treatment for advanced pancreatic cancer when conventional therapy is discontinued or no longer indicated.

C-0602

Endovascular embolization of multiple arteriovenous fistulas of extremities

Y.A. Akhmetov, D.D. Potseluyev, V.A. Jakupov, D.T. Mussagalev, O.V. Gorgots; Almaty/KZ

Purpose: To improve the results of treatment of patients with multiple AVF of extremities through improvement of the tactics and methods of radio-endovascular surgical interventions.

Materials and Methods: 33 patients with AVF of extremities at the age from 7 to 31 had examination and treatment at SSC for the period from 1994 to 2004, which is 42.64% of the total number of patients with AVF of different localization. Lesion of 2 and more anatomic regions of extremities were reported in 27 cases (81.81%). Duplex scanning of main arteries, veins, and the zone of AVFs, CT, MRT of extremities, were used to assess the patients. The principal method of AVF diagnostic was selective, super-selective digital subtraction angiography, which was combined with the cure stage - endovascular embolization of AVF arteries. The number of stages of inpatient treatment of the patients was 2 to 7 and depended on the vessels involvement.

Results: Satisfactory results of treatment of multiple AVF of extremities (disappearance or reduction of pain intensity, volume of extremities, and pathological arteriovenous fistula) were received in 30 (90.91%) of patients. In 3 cases (9.09%), there was no any improvement in regional hemodynamic after RES.

Conclusion: Thus, multi-phased super-selective catheterization and emboliza-

tion of multiple AVF of extremities permit to receive satisfactory clinical results in majority of patients.

C-0603

Stent-assisted coil embolization of wide-necked aneurysms

M. Jaworski, O. Rowinski, R. Maciąg, M. Januszewicz; Warsaw/PL

Purpose: To present our initial experience in using stent to treat patients with broad-neck cerebral aneurysms.

Methods and Material: Material consists of 10 patients (F: 6, M: 4), age range: 28 - 54 years with intracranial aneurysms. Aneurysms location: Carotid cavernous n = 2, carotid ophthalmic n = 3, MCA n = 1, basilar tip with extension to P1 n = 4. Aneurysms architecture: neck length from 5 till 11 mm, aneurysms size from 4 till 31 mm. Qualification to procedure was done after angio CT by a neuro-radiologist and neurosurgeon. After appropriate anticoagulation was performed (Clopidogrel and Aspirin), microstent was delivered across the neck of the aneurysm via femoral route. Subsequent filling of the aneurysmal sac was done with GDC or/and Matrix coils through the stent interstices.

Results: Microstents were deployed in correct position in whole cases. After stent placement, total coil embolization was achieved in eight cases, subtotal in one case. One aneurysm was stented only; disappeared during the procedure. One patient experienced thromboembolic event, resolved after Abciximab (ReoPro) with no neurological deficit.

Conclusion: Intracranial stent is an important new tool in endovascular therapy, improving the occlusion of wide-neck aneurysms while protecting the proper lumen of the patent parent artery.

C-0604

Recovery of non-developed vascular accesses for hemodialysis

D. Coll, R. Vidal, M. Perez-Lafuente, M. Moreiras, A. Romero-Jaramillo, A. Segarra; Barcelona/ES

Objectives: To demonstrate the effectiveness of interventional techniques for the repair and recovery of non-developed arterio-venous dialysis fistulas as an alternative to surgery.

Methods and Materials: 62 patients were reviewed (42 men, 20 women), ranging in age from 37 to 81 years (mean age 60). The type of vascular access was native fistulas in 59 (43 radiocephalic, 11 brachiocephalic, 5 brachiobasilic) and synthetic grafts in 3. The clinical findings were: fistulas did not develop (45 patients), scant arterial flow (15 patients), elevated venous pressure during dialysis (8 patients), prolonged compression time (1 patient) and access occlusion (2 patients). All patients underwent fistulography of the vascular region before treatment. Therapy consisted of PCTA, PCTA + mechanical thrombectomy, PCTA + fibrinolysis or stent placement.

Results: Initial technical success was obtained in 58 accesses (93%). There were 15 relapses (12 patients); 9 of these responded to repeat percutaneous treatment. The complications were: 3 venous tears (with loss of the access in 1), 1 thrombosis that resolved with fibrinolytic treatment, 1 transient arterial spasm and 1 hematoma at the puncture site.

Conclusion: With the increased life expectancy of patients undergoing dialysis, viability of the vascular access and the quality of dialysis are of prime importance. In contrast to surgery, interventional techniques preserve the vein in its entire length and can be repeated as often as necessary during the life of the fistula. Percutaneous repair is the technique of choice for non-developed accesses, with surgical treatment being reserved for fistulas that cannot be recovered percutaneously.

C-0605

Life-threatening rectus sheath hematomas in patients undergoing anticoagulation. Management with selective arterial embolization

J. Rimola, J. Perendreu, J. Falcó, J.R. Fortuño, J. Branera, A. Massuet; Sabadell/ES

Learning Objectives: Rectus sheath hematomas due to inferior epigastric artery pseudoaneurysm are a recognized complication of anticoagulation therapy with a potential risk of hemodynamic collapse. The aim of this study is to review the vascular anatomy of the abdominal wall and evaluate the utility of embolization of the inferior epigastric artery in rectus sheath hematoma with hemodynamic collapse.

Background: We performed a retrospective review of ten patients with rectus sheath hematoma that caused hemodynamic collapse diagnosed with US and/or CT between January 2001 and April 2004. All patients were undergoing anticoagulation therapy when bleeding occurred.

Scientific and Educational Exhibits

Procedure Details: Selective angiography demonstrated active bleeding of the inferior epigastric artery in all cases and, in 2 cases, also from the deep iliac circumflex artery. In all patients, hemodynamic parameters (blood pressure and heart rate) stabilized shortly after embolization. Eight of the ten patients had good evolution, though two died a few days after the procedure due to multiple organ failure.

Conclusions: Embolization of active bleeding from the inferior epigastric artery using coils and gelfoam in patients is an effective and safe technique for restoring hemodynamic stability in anticoagulated patients. Knowledge of the vascular anatomy of the abdominal wall and the vessels that supply it is essential to ensure the success of embolization.

C-0606

Isolated iliac artery aneurysms: An infrequent pathology with effective endovascular treatment

M.I. Alegre, A. Talens, S. Ferrer, R. García, I. Artigues, A. Batista; Valencia/ES

Learning Objectives: Isolated iliac artery aneurysms are infrequent but entail a dangerous high risk of rupture and have been associated with high operative mortality rates. We describe our experience with the percutaneous placement of stentgrafts for endovascular repair of iliac artery aneurysms.

Background: Between January 1998 and October 2003 eight iliac artery aneurysms in seven patients (all males, mean age 75.5 years) were treated with 12 covered stentgrafts. CT preoperative and arteriography were performed to define the exact diameter and length.

Procedure Details: All the patients underwent initially successful treatment with immediate aneurysm exclusion. In three cases iliac aneurysm involve both common and hypogastric arteries, in two cases the common iliac artery and only the hypogastric artery in three. Eleven different types of stentgrafts were positioned in the external and/or common iliac artery using over-the-wire techniques under local anaesthesia in six cases; coil embolization of the hypogastric artery was performed in two patients. One iliac aneurysm was treated using a bifurcated prosthesis under epidural anaesthesia and femoral exposition. No procedural complications, acute or late graft thrombosis or further leakage occurred. The median follow-up period was 42 months.

Conclusion: Endovascular repair of iliac artery aneurysms is a safe and effective technique with satisfactory results in patients at standard and high operative risk.

Interventional Radiology

Non-vascular

C-0607

Covered, retrievable, expandable prostatic stent: Feasibility study in dogs

C. Yoon¹, H.-Y. Song², J. Shin²; ¹Seong Nam/KR, ²Seoul/KR

Purpose: To evaluate the feasibility of a covered, retrievable prostatic stent and to determine whether persistent dilation of the prostatic urethra can be achieved even after stent removal.

Materials and Methods : PTFE-covered retrievable nitinol stents were placed in the prostatic urethras of 13 dogs. The stents were removed with retrieval hook wires 8 weeks after placement. Five dogs were sacrificed just after stent removal, and the other eight dogs were sacrificed 4 weeks (n = 3) and 8 weeks (n=5) after stent removal. Retrograde urethrograms were obtained at 2-weeks interval after stent placement until sacrifice. The explanted prostate specimens were histologically examined.

Results: Stent placement was technically successful in all dogs. In two dogs, a second stent was placed because of complete migration of the first stent into the urinary bladder. Stent removal was successful in all dogs without complication. Follow up urethrograms showed persistent dilation of prostatic urethra until sacrifice, while filling defect due to granulation tissue gradually decrease after stent removal. Histologic examination revealed periurethral glandular atrophy and fibrosis, which were persistent until sacrifice. The papillary projection of the epithelium and inflammatory cell infiltration gradually decreased after stent removal. **Conclusion:** The covered, retrievable nitinol stent seems feasible for use in the prostatic urethra. The urethrographic findings and histologic changes obtained after stent removal suggest persistent dilation of the prostatic urethra can be induced.

C-0608

Complications of living donor liver transplantation: Image findings and interventional treatment strategies

N. Muraoka¹, H. Uematsu¹, K. Kinoshita², T. Takeda², H. Matsunami², E. Yamanouchi³, H. Itoh¹; ¹Fukui/JP, ²Gifu/JP, ³Tokyo/JP

Learning Objectives: To present representative image findings of fatal complications in living donor liver transplantation (LDLT) based on 24 recipients and to describe interventional treatment strategies for these complications.

Background: Liver transplantation is an accepted therapy for patients with end-stage liver disease. In Japan, LDLT is mainly performed instead of the orthotopic liver transplantation due to legal issues. Retransplantation is difficult after transplantation because of post-operative adhesion; in some cases, an interventional procedure may be useful for various vascular and biliary complications. In this exhibit, we present the representative image findings of fatal vascular and biliary complications based on 24 recipients in LDLT, and demonstrate the advantages of interventional treatment for the various complications.

Procedure Details: We demonstrate the successful percutaneous transluminal angioplasty (PTA) of various vascular types, including hepatic artery, portal vein, hepatic vein and inferior vena cava at the anastomosis. We also demonstrate successful stent placement in portal venous elastic stenosis at the anastomosis and covered stent graft placement for hepatic artery pseudo-aneurysm. Biliary stricture or occlusion at the anastomosis is one of the most common complications in LDLT; however, conventional percutaneous biliary treatment sometimes fails to re-canalize at the occlusion. Recently, our group has proposed a new therapy called "magnetic compression anastomosis development method," for biliary-enteric anastomotic stricture. We discuss the advantages and limitations of this method in this presentation.

Conclusion: Appropriate interventional procedures are invaluable in the management of LDLT complications.

C-0609

PTFE covered metallic stent in the treatment of nasolacrimal duct obstruction: Long-term results

M.D. Monedero, J.R. Olalla, J.J. Martinez-Rodrigo, A. Ruiz, E. Lonjedo, J. Vilar; Valencia/ES

Purpose: To evaluate the long-term efficacy of PTFE covered metallic stent placement as treatment in patients with nasolacrimal duct obstruction.

Methods and Materials: PTFE covered metallic stents (JOSTENT®) were placed under fluoroscopic guidance in 128 eyes of 110 patients (20 men and 90 women) with nasolacrimal duct obstruction (age range: 40-75 years; mean age: 58 years).

Scientific and Educational Exhibits

Patients with obstruction at the nasolacrimal duct and the junction between the lacrimal sac with the nasolacrimal duct were selected. All of them had severe epiphora according to Munk's scale (69.5% grade V and 30.5% grade IV). Slit-lamp exam, lacrimal irrigation and anterior rhinoscopy were performed in order to exclude lacrimal sac and endonasal tumors. Dacryocystography was performed in all patients before stent placement and in patients with recurrence of epiphora after the stenting. Follow-up examinations were scheduled for 1 week, 1, 3 and 6 months, 1, 2 and 3 years after stent placement. The clinical follow-up consisted on lacrimal irrigation and Munk's test to evaluate stent patency and clinical success.

Results: Stent placement was technically successful in all patients. Primary and secondary patency were 74.2% and 81.3% respectively. The overall clinical success rate was 78.1%. Stent patency was higher in women ($p < 0.05$) but it was not related to age.

Conclusion: PTFE covered metallic stents are an effective therapeutic option for treating epiphora.

C-0610

Radiofrequency in the treatment of hepatocellular carcinoma. Multicenter study in Spain

M. Squarcia, R. Vilana, L. Bianchi, C. Nicolau, M. Sala, J.M. Llovet, J. Bruix, C. Bru; Barcelona/ES

Purpose: To assess the therapeutic efficacy, survival rates and complications of Radiofrequency (RF) in the treatment of hepatocellular carcinoma (HCC) in a multicenter study in Spain.

Methods and Materials: Data of 10 Spanish hospitals were retrospectively (1998-2002) collected and reviewed. The study includes 249 patients (167 male/82 female), mean age 68 ± 8 years, with HCC, (uninodular = 203/multinodular = 46, mean tumor size = 29 ± 2 mm) that were treated with RF.

Results: Evaluation of tumoral necrosis was possible only in 233 patients. Initial Complete Response (CR) = 83% (single tumors < 2 cm, CR = 97.2%). Intratumoral recurrence was seen in 58 patients (25%) and distant recurrence was seen in 39 patients (17%). One, 2 / 3 and 4 years survival rates were 87%, 74%, 61% and 47% (mean follow-up = 19.5 months). Preserved liver function (Child-Pugh), and achievement of CR were observed to be predictors factors of longer survival. Tumor seeding was observed in 7 cases of subcapsular tumors treated in the initial period during which RF was performed. Others major complications accounted for 5%.

Conclusion: RF is an effective procedure for the treatment of HCC. Higher rates of CR and survival are obtained in patients with small tumors and preserved liver function. RF is a safe technique, however precautions should be taken while performing this procedure.

C-0611

Radiofrequency ablation may activate the immune system and induce specific anti-tumoral immune responses in cancer patients

S. Haen¹, C. Gouttefangeas¹, A. Boss¹, S. Clasen¹, D. Schmidt¹, M. Kuczyk¹, A. Stenzl¹, H. Schild², P.L. Pereira¹, H.-G. Rammensee¹; ¹Tübingen/DE, ²Mainz/DE

Purpose: Percutaneous radiofrequency (RF) ablation causes local coagulation necrosis of tumoral tissues. This could lead to the release of heat shock proteins (HSPs) and to the subsequent activation of an anti-tumoral immune response. Our purpose was to determine if an increased level of HSP70 was measurable in the blood of patients after RF ablation and if CD8⁺ T cells specific for tumor-associated antigens could then be detected.

Methods and Materials: 20 patients treated with RF ablation for liver metastasis (colorectal or breast carcinomas) or for primary carcinomas of the liver or the kidney were prospectively included in the study. Peripheral blood mononuclear cells (PBMCs) and serum were isolated from blood samples obtained at predefined time-points before and after RF ablation. We measured serum levels of HSP70 by specific ELISA. PBMCs of HLA-A2⁺ patients were stimulated with HLA class I-binding peptides derived from tumor antigens known to be expressed by most of the tumors. Specific IFN γ production was subsequently measured by real time RT-PCR.

Results: Preliminary results show a transient increase in HSP70 serum levels in several patients one day after RF ablation. Moreover, induction of tumor-antigen specific CD8⁺ T lymphocytes was detected at the earliest 3 months after treatment.

Conclusion: Production of HSP70 and increase in the activity of antigen-specific CD8⁺ T lymphocytes was observed in some patients after RF ablation. Thus, activation of the immune system might represent another beneficial effect of RF-ablation in addition to the local destruction of metastasis or primary carcinomas.

C-0612

Presurgical transcutaneous MR imaging-guided marking of intramedullary tumors

J. Fritz, C.W. König, P. Böhm, F. Maurer, A. Badke, M. Müller-Schimpffle, C.D. Claussen, P.L. Pereira; Tübingen/DE

Purpose: The extent of intramedullary tumor is intraoperatively difficult to assess. A new stereotactic method for presurgical transcutaneous coil-marking of intramedullary tumor using interventional magnetic resonance imaging (MRI) guidance is introduced.

Material and Methods: In 5 patients intramedullary tumor extent was preoperatively marked. Imaging and puncture guidance were performed using an open low-field MR-Scanner with horizontal access (Magnetom Open Viva®, Siemens, Erlangen, Germany). After imaging the extent of the tumor, MR imaging guidance was used to place MR-compatible titanium coils (MReye®, Cook, Bjaevskov, Denmark) parasagittally at the level of the upper and lower pole of the lesion. Postinterventional X-ray imaging of the puncture side documented coil position in all patients. Intraoperative X-ray fluoroscopy was used to confirm congruence of coil position. Coil placement was performed up to 58 hours prior to surgery. The inclusion of the tumor borders was examined by cross sectional pathology of surgical specimens.

Results: All lesions could be precisely evaluated by using MRI only. Intervention was successfully performed in all patients using MRI guidance only. Ten coils were used to preoperatively mark 5 lesions. Intraoperative X-ray fluoroscopy demonstrated no evidence of coil migration. Histological examination of the resection borders proved no residual tumor cells were present. No complications were observed. With a mean follow-up of 12 months, no recurrence occurred.

Conclusion: Presurgical MRI-guided coil-marking for exact delineation of the extent of intramedullary lesions is technically feasible and can readily demonstrate the full extent of tumors. It contributes to sufficient surgical exploration and total resection.

C-0613

Ureteral implantation of Paclitaxel-eluting balloon-expandable metallic stents: An experimental study in the pig model

D. Siablis, N. Christeas, D. Karnabatidis, K. Katsanos, E.N. Liatsikos, N. Flaris, G.C. Kagadis; Patras/GR

Purpose: Ureteral implantation of metallic stents suffers from low patency rates owing to urothelium hyperplasia and stent encrustation. Paclitaxel-eluting stents have portrayed auspicious results in inhibiting neointimal hyperplasia in the coronary vascular bed. The goal of our study was to evaluate the paclitaxel-eluting versus the conventional metallic stents in the pig ureter model.

Methods and Materials: The metallic stents under investigation were randomly balloon-expanded near the ureteropelvic junction of either the right or left ureter of 10 female pigs (weight 25-30 kgs), for a total of 20 stented ureters. Ten ureters received a 4x32 mm Paclitaxel-Eluting Coronary stent (Boston Scientific, USA), while the contralateral ureters were stented with a 4x18 mm R-Stent (Orbus Medical Technologies, Netherlands) serving as the control. Ureteral patency was assessed with nephrostomography 24 hours and 21 days following stent insertion. Subsequently, animals were sacrificed and the ureters were pathologically inspected.

Results: Uncomplicated stent delivery was accomplished in all ureters (20/20). Unobstructed urine flow was depicted 24 hours after implantation in all stented ureters. The 21-day nephrostogram revealed complete blockage of 5 ureters from the R-Stent group (5/10), whereas no obstructed ureter was detected in the Paclitaxel group (0/10). Pathologic inspection documented severe inflammation and urothelium metaplasia in the obstructed R-Stents, a polypoid reaction in the still patent R-Stents and only a mild ureteral inflammatory response in the Paclitaxel group.

Conclusion: Ureteral stenting with Paclitaxel-eluting stents inhibits tissue inflammation and urothelium hyperplastic response and improves ureteral patency. Long-term human trials are required in order to verify our results.

C-0614

Malignant biliary obstruction: Treatment with interventional radiology

F. Amodio, A. Pinto, R. Niola, G. Taliercio, M. Maglione; Naples/IT

Purpose: The authors report their experience in the palliative percutaneous treatment of malignant biliary obstruction.

Methods e Materials: 729 patients underwent transhepatic placement of metallic stents and/or plastic tubes. Obstruction predominantly involved both the right and left hepatic ducts in 324 and in 405 common bile duct or choledochus. All

Scientific and Educational Exhibits

stents were self-expanding flexible tubes made from woven stainless steel or nitinol wires. In its constrained state the stent has an outer diameter of 7-10 Fr. After deployment, it expands to a maximal lumen of 8-10 mm.

Results: In hilar obstructions we implanted Kissing stents in 51, 81 were treated with one stent and external drainage on the other side, 138 underwent catheter placement for two sided drainage and 54 required single-sided external drainage. For common bile duct or choledochus obstructions, 264 underwent stent placement and 141 catheter placement (8 external drainage). In 74 (10.1%) jaundice was not adequately reduced. Major complications occurred in 21 (2.9%) (9 severe septic events, 3 subcutaneous abscesses, 3 hepatic abscesses and 6 subcapsular hematoma). Minor complications involved 45 (6.1%) with self-limited bleeding into the drainage tube and 57 (7.8%) with fever less than 39° C. Average patency of stents was 7.5 months and average survival was 9 months.

Conclusions: Percutaneous transhepatic bile drainage as a palliative procedure is well tolerated by patients. Major complications are rare. Treatment (metallic stent or plastic tube) is based on the site of obstruction, nature of malignancy, life expectancy and ability to pass the stenosis.

C-0615

Early experiences of percutaneous radio-frequency ablation for unresectable small lung malignancies

T. Matsuoka¹, M. Toyoshima², A. Yamamoto¹, Y. Oyama¹, T. Okuma¹, K. Nakamura¹, R. Yamada¹, Y. Inoue¹; ¹Osaka/JP, ²Kobe/JP

Purpose: To assess technical and clinical success of RFA for unresectable lung metastases of less than 3 cm.

Materials and Methods: Fifty-nine secondary nodules (5-29 mm, mean 16.0 mm, from lung 18, others 41) in 31 patients were treated by RFA under CT guidance using LeVeen Needle from June 2000. The procedure was started at 10-30 watt by gradually increasing output until roll off (sudden rise of impedance meaning tissue coagulation) being achieved or 15 minutes. CT was performed every 2 or 3 months after the procedure and the largest diameter (LD) of ablated area consisting of the lesion and surrounding lung tissue was measured. It was judged as a recurrence when LD which had reduced with time turned in increase. Clinical success was assessed among nodules observed more than six months.

Results: All procedures were technically successful. In 40 nodules ablation was repeated to cover the whole lesion. Average ablation time per a nodule was approximately 40 minutes. Pain needing treatment was observed in 57%. Minor pneumothorax occurred in 30% except one case, which required a chest tube. Of 37 nodules which were observed during 6-43 months (mean 14.6 months), 9 were judged as a recurrence and an effective rate was 75.7% (28/37). The group in which roll off was achieved in the whole lesion had a significantly higher effective rate of 86.7% (26/30) than non roll off group of 28.6% (2/7).

Conclusion: Percutaneous RFA has the potential to become an effective and minimally invasive option for small lung metastases.

C-0616

Malignant duodenal obstructions: Palliative treatment using self-expandable nitinol stents

C. Yoon¹, H.-Y. Song², J. Shin²; ¹Seong Nam/KR, ²Seoul/KR

Purpose: To assess the efficacy and complications of self-expandable nitinol stents in the palliative treatment of malignant duodenal obstructions.

Materials and Methods: Under fluoroscopic guidance, 66 patients (44 male and 22 female, mean 63.0 years) with malignant duodenal obstructions were treated with per-oral placement of four types of self-expandable nitinol stents. All patients presented with severe nausea and recurrent vomiting, and their obstructions were inoperable.

Results: Technical success was achieved in 62 of 66 patients (93.9%). After stent placement, food intake capacity improved in 59 of 62 patients (95.2%). Stent migration occurred in one patient 4 days after stent placement. A covered stent was placed over ampulla of Vater in eight patients without external biliary drainage, of whom three patients (37.5%) became jaundiced. During the mean follow-up of 73.6 days (9-370 days), seven patients developed recurrent obstructive symptoms caused by tumor ingrowth (n = 2) and tumor overgrowth (n = 5), which were successfully treated with additional stent placement. The primary stent patency rates were 96.1%, 81.0%, and 37.8% at 1-, 3-, and 6-months, respectively.

Conclusions: Fluoroscopic peroral placement of self-expandable nitinol stents is an effective palliative treatment for malignant duodenal obstructions.

C-0617

Percutaneous vertebroplasty: Correlation between cement leakage into the disk and new fractures of adjacent vertebral bodies

M. Romero, A. Tomasello, J. Blasco, J. Pomés, J. Macho, M. Burrel, X. Tomàs; *Barcelona/ES*

Purpose: Patients successfully treated with vertebroplasty may return with pain caused by a new vertebral fracture that often affects vertebral bodies adjacent to the ones initially treated. We have analyzed the risk of subsequent fractures of adjacent vertebral bodies in relationship to cement leakage into the disk during initial vertebroplasty in a group of osteoporotic patients.

Methods and Materials: We have analyzed 44 patients treated with vertebroplasty between April 2002 and March 2004. Postprocedural CT scans were obtained in all cases to evaluate cement leakage. Patients who developed new pain after initial successful vertebroplasty were evaluated by repeat MR imaging. We documented the incidence of new fractures of adjacent vertebral bodies in relationship to cement leakage into the disk occurred during the initial vertebroplasty.

Results: Thirteen cases of cement leakage into the disk were detected. Five patients developed new fractures affecting adjacent vertebral bodies during the follow-up period, but only in 1 case this new fracture was associated with cement leakage into the adjacent disk. A secondary analysis showed that 7.7% of vertebral bodies adjacent to a disk with cement leakage fractured during the follow-up period, compared with 3.8% of the vertebral bodies adjacent to disks without cement leakage.

Conclusion: In our series, probably due to our low percentage of new fractures associated with adjacent disk cement leakage - only 1 case, there is not enough evidence to confirm or exclude this association.

C-0618

Ultrasound guided interventional procedures. A simple way of self-training

A.N. Chalazonitis, J. Tzovara, E. Protopapa, S. Giannou; *Athens/GR*

Learning Objectives: 1. To learn the general principles and advantages of ultrasonographic-guided interventions. 2. To learn the techniques and applications employed with ultrasonographic guidance. 3. To acquire the skill to direct a needle to a target with ultrasonographic guidance. 4. To anticipate common pitfalls to be avoided.

Background: Ultrasound-guided intervention offers the unique ability of real time imaging of both needle and the target. Low cost, speed and portability are further advantages of the method.

Procedure Details: This exhibit is a comprehensive and user-friendly educational tool for freehand ultrasonographic techniques of aspiration, core biopsy, cyst drainage and positioning of localization needles. Our presentation provides practical advice on current techniques mainly to residents and physicians with minimal or no experience on interventional procedures. Techniques and procedures are presented using versatile animal tissue models modified with a variety of implants to simulate solid or cystic lesions, as described above. Indications and contraindications, patient's preparation, possible complications and pitfalls are also analyzed.

Conclusion: Our tutorial, that consists of real time ultrasonography, live practical demonstrations, images and graphics presented audiovisual can be used to explore the general principles and advantages of ultrasonographic-guided interventions and to acquire the skills to perform a successful procedure.

C-0619

Non-liver metastases in patients with primary gastrointestinal carcinoma.

Treatment with radiofrequency thermal ablation

L. Thanos, S. Mylona, E. Karahaliou, M. Pomoni, A. Kokkinaki, N. Batakis; *Athens/GR*

Purpose: To evaluate the results of RFA on non-liver metastatic tumors from gastrointestinal carcinoma.

Materials and Methods: In a thirty-month period we performed 83 RFA sessions under CT-guidance on 61 metastatic lesions (10 from gastric and 51 from colorectal carcinoma) in 42 patients. The RFA was performed in 25 pulmonary, 23 osseous, 2 retrosternal and 3 painful perineal lesions, as well as in 4 supradiaphragmatic lymph nodes and in 4 local recurrences from rectal carcinoma. Each session lasted 13-17 min. We began the procedure after analgesic therapy and local anesthesia at the point of puncture. The follow-up with dual-phase spiral CT took place immediately after the ablation and at 1-, 3-, 6- and 12-month intervals.

Results: We succeeded total necrosis in 48 (78.68%) lesions and partial necrosis in 13 (21.32%). A new session was performed on all tumors with partial necrosis. Nine (14.7%) lesions that relapsed were treated with RFA. All patients with

Scientific and Educational Exhibits

osseous metastatic disease and perineal lesions had elimination of their pain symptoms. The one- and two-year survival was 100% and 78% respectively. We had no complications.

Conclusion: In our experience RFA provides a new alternative treatment in metastatic disease.

C-0620

Vascular complications of biliary interventional radiology

M. Acquafresca, E. Mazza, F. Toccafondi, M. Zini, L. Sali, C. Vannini, M. Falchini; Florence/IT

Purpose: To assess the incidence of vascular complications that occur during biliary interventional procedures and validate the effectiveness of the embolization treatment.

Methods and Materials: From January 1991 to February 2004, 2322 biliary interventional procedures were performed at our Interventional Radiology Unit of A.O. Careggi, in Florence, Italy. Nine cases of severe hemobilia represented the most relevant vascular complication. An angiographic examination was carried in all cases and demonstrated the presence of a pseudoaneurysm of the right hepatic artery in six cases; a pseudoaneurysm of the left hepatic artery in one case, an artero-portal fistula in one case and extravascular spread of contrast medium at the site of the right hepatic artery in one last case. All patients were treated by means of transcatheter embolization. Gianturco's coils were employed in four cases whereas gelatin sponge pledges (Gelfoam) were applied in five patients.

Results: In all cases, complete remission of the hemobilia was achieved after percutaneous embolization treatment. A limited hepatic septic ischemia occurred in one case in which Gianturco's coils had been used and we resolved it through percutaneous treatment.

Conclusion: Percutaneous interventional procedures represent a well established method to treat several cases of biliary disorders. They are rarely burdened with complications, mostly represented by hemobilia, which can be effectively treated and resolved through percutaneous procedures, without resort to the surgical intervention.

C-0621

The efficacy of "mini-perc" technique for the treatment of renal complete staghorn calculi, especially results in the upper pole

S.Y. Jeong, S.W. Choo, Y.M. Sung, S.S. Jeon; Seoul/KR

Purpose: To evaluate the effectiveness of "mini-perc" technique of the percutaneous nephrolithotomy in complete staghorn stones, especially those in the upper pole.

Materials and Methods: We retrospectively reviewed the records of 39 patients (10 males and 29 females, mean age 49) with complete staghorns, who had been treated with "mini-perc" technique between July 1999 and June 2004. Percutaneous tract formation was done via single lower-pole access with exception of two patients who had two tracts. A 14 Fr peel away sheath was then utilized for percutaneous access at the operating room. Lithotripsy was achieved using a Holmium: YAG laser by an experienced urologist. Initial stone free rate and final stone free rate after additional treatment were evaluated. Procedure-related complications also were evaluated. And postoperative intravenous urography was performed when intraoperative urinary tract injuries were suspected.

Results: Initial stone free rate and final stone free rate after additional treatment such as ESWL was 13% and 64% overall, and 41% and 90% respectively in the upper pole. Intravenous urography was done in 16 renal units postoperatively and revealed good function in all the units. Bleeding requiring transfusion occurred in 3 patients (7.6%), and one of them had an arterial embolization.

Conclusions: "Mini-perc" monotherapy for complete staghorn calculi resulted in a lower stone free rate, but when combined with additional treatment such as ESWL, it achieved better results. The stones located in the upper pole could be removed effectively via only single lower-pole access.

C-0622

MR imaging of radiofrequency (RF) induced coagulation in liver ex vivo: Histopathological correlation of different MR sequences between a low and a high field MR scanner

D. Schmidt, S. Clasen, A. Boss, J. Truebenbach, P. Pereira, F. Schick, C.D. Claussen; Tübingen/DE

Purpose: To compare MR sequences for the visualization and the determination of short axis diameter of coagulation following RF ablation between low and high field MR scanner.

Method and Materials: RF ablations ($n = 10$) were performed in bovine liver

tissue ex-vivo by using an internally-cooled cluster electrode. MR imaging of the coagulation were obtained by using two different spin echo sequences for the open low (0.2 T) and closed high (1.0 T) field MR scanner with following parameters: T1 weighted (TR 400 ms/TE 12 ms; matrix 256x256, 4 acquisitions) and T2 weighted (TR 4000 ms/TE 85 ms; matrix 256x256, 4 acquisitions). Both MR scans were evaluated by two observers for assessment of the zone of white coagulation with a score ranging between 1-5. The zone of white coagulation was determined histopathologically. Short axis diameters of the zone of white coagulation were measured and correlated with MR imaging.

Results: The white zone of coagulation necrosis was significantly better visualized in T2 weighted sequences using high field (1.0 T) MR imaging ($p < 0.001$). The short axis diameters of histopathologically determined white coagulation had the best correlation to with high field MR imaging ($r^2 = 0.97$). The differentiation of normal liver tissue and white coagulation was possible for both MR sequences and MR scanners.

Conclusion: T2w sequences are superior to T1w sequences for the visualisation of RF induced white coagulation in liver tissue ex-vivo. The short axis diameters measured with T2w sequences in high field MR scanner had the best correlation to histopathologically findings.

C-0623

MR-fluoroscopy-guided corticosteroid-infiltration of the sacroiliac joints:

Pain therapy of sacroiliitis in patients with spondylarthropathy

J. Fritz, C.W. König, S. Clasen, I. Günaydin, G. Tepe, I. Köller, C.D. Claussen, P.L. Pereira; Tübingen/DE

Purpose: To evaluate the efficacy and specific properties of MR-fluoroscopy-guided corticosteroid-infiltration of the sacroiliac joints (SIJ) in patients with therapy refractory sacroiliitis due to spondylarthropathy.

Material and Methods: In 20 patients MR-fluoroscopy-guided SIJ-Infiltration was performed using a fast imaging with steady precession (FISP) sequence. The entire intervention was performed by using a C-shaped open 0.2-T-MR-Scanner (Magnetom Open Viva®, Siemens, Erlangen, Germany). Puncture side evaluation and needle placement was performed with free-hand technique and continuous action control via in-room monitor. After needle placement two perpendicular MR images ensured successful articular needle placement and 40 mg triamcinolonacetone (Volon A, Bristol-Myers Squibb, München, Germany) were instilled. Inflammatory back pain was documented on a visual analog scale (VAS). Wilcoxon test was used to assess significant differences between VAS-Scores.

Results: MR-fluoroscopy-guided SIJ-Infiltration was feasible and technically successful in all patients. There was statistically significant ($p < 0.001$) improvement (-62.5%) of the VAS-Score from 8 (10-5) to 3 (0-6). FISP sequence was characterized by decreased resolution and decreased tissue contrast but did provide fast imaging of sufficient quality for save and exact needle placement. The average procedure time for puncture site evaluation was 2 (1-3) min and 4 (2-7) min for needle placement. The mean remission time was 11 (5-14) months.

Conclusion: MR-fluoroscopy-guided corticosteroid infiltration of the SIJ proved to be an effective therapy of inflammatory back pain with a long lasting effect in patients with therapy refractory sacroiliitis. MR-Fluoroscopy guidance proved to be a feasible modality that enabled exact and fast device placement with continuous action control.

C-0624

Percutaneous CT-guided drainage of abdominal and pelvic abscesses

L. Thanos, A. Nikita, G. Papaioannou, K. Malagari, D. Loggitsi, D. Kelekis; Athens/GR

Purpose: To assess the efficacy of percutaneous drainage of abdominal and pelvic abscesses under CT-guidance.

Materials and Methods: During a 6-years period, 641 patients with abdominal and pelvic abscesses underwent percutaneous CT-guided drainage using pigtail catheters 8-16F. Two hundred sixty-eight of them were liver abscesses, 21 splenic, 72 pancreatic or peripancreatic, 134 retroperitoneal (37 renal and perinephric and 97 iliopsoas abscesses) and 146 pelvic abscesses. In all the cases, for the insertion of the catheter we used the trocar technique. Aspiration of the lesions was performed in order to obtain material for culture and susceptibility testing.

Results: The length of time that catheters remained in place ranged from 6 to 25 days. Abscesses were successfully drained in 545 (85%) of 641 patients. In the remaining 96 (15%) cases, residual collection was noted indicating incomplete drainage of the abscess and an open surgical drainage was performed. No major complications were observed related to the procedure.

Conclusion: CT-guided percutaneous catheter drainage of abdominal and pelvic abscesses is an effective and safe treatment procedure and it may replace surgery in the majority of the cases.

Scientific and Educational Exhibits

C-0625

Radiofrequency ablation of liver tumors developed after hepatectomy

L. Thanos, A. Nikita, G. Papaioannou, D. Danassi-Afentaki, S. Kampanarou, D. Kelekis; *Athens/GR*

Purpose: To assess the effectiveness of radiofrequency ablation (RF) in the treatment of recurrent or new liver tumors developed after hepatectomy.

Materials and Methods: Twenty-six patients with liver tumors developed after hepatectomy (17 with hepatocellular carcinomas and 9 with metastatic lesions) underwent percutaneous RF ablation instead of repeated hepatectomy. Fourteen of them represented new lesions and the remaining 12 of them represented recurrent tumors. The mean diameter of treated tumors was 3.3 cm (range 1-5 cm). Electrodes of 7 or 9 active tips were advanced under CT guidance. Contrast enhanced CT was used to assess the therapeutic response immediately after the procedure and for the follow-up.

Results: In the CT scan immediately after the procedure 23 (88.4%) of 26 lesions presented complete necrosis. Incomplete local RF treatment was observed in the remaining 3 (11.6%) patients and a second RF session was performed resulting to complete necrosis of the tumors. The 1-year, 2-year and 3-year survival rates are 100%, 96% and 76% respectively. No deaths or major complications were observed related to RF ablation.

Conclusion: Percutaneous RF ablation is an effective method for treating liver tumors developed after hepatectomy, with satisfying survival rates.

C-0626

Radiofrequency thermal ablation coupled with hepatic arterial occlusion in treating large-size HCC

L.F. Frigerio, F. Garbagnati, G. Di Tolla, S. Rossi; *Milan/IT*

Purpose: To assess whether the RTFA coupled with the mechanical occlusion of the hepatic artery achieves necrosis 2 to 4 cm larger than RTFA alone (loose blood flow) in lesions with diameter up to 8.5 cm.

Methods: A single-session RTFA was performed together with i.a. hepatic embolization with Gelfoam in 132 patients with single HCC lesions ranging from 3.5 to 8.5 cm in maximum diameter, rejected to surgery.

Results: 100% of the lesions showed a partial reduction in size ranging from 40 to 80%. 22% of the patients had local recurrence at the site of the lesion, 43% had satellite nodules during follow-up from 3 months to 2 years after the initial treatment, the actual follow-up is 28 months.

Conclusion: The reduced thermal dispersion by convection and the modified tumoral tissue conductivity related to occlusion of the HCC blood supply as well as the single pass of the neoplastic capsule by the RTFA needle result in larger areas of coagulative necrosis while preserving the critical amount of residual liver intact

C-0627

Role of contrast-enhanced ultrasound in the radiofrequency thermal ablation treatment of malignant hepatic tumors

A. Orlacchio, S. Fabiano, A. Rotili, M. Stefanini, R. Pasquarelli, G. Simonetti; *Rome/IT*

Learning Objectives: To evaluate the role of contrast-enhanced ultrasound in the management of malignant neoplasms of liver treated by means of radiofrequency (RF) thermal ablation. To illustrate the patterns of contrast enhanced ultrasound in the recognizing of residual tumor or neoplastic recurrence. To show the method to guide a further ablative treatment to residual viable tumor.

Background: The traditional therapeutic option to treat primitive focal liver tumors is surgery. Liver resection is not always possible. The improvements in imaging technologies have permitted to guide better the percutaneous treatment of liver neoplasms.

Procedures Details: Many thousands of RF thermal ablation treatments have been performed during the last years. Usually RF thermal ablation treatment was performed by means of ultrasound guide. The immediate result of RF thermal ablation treatment is not detectable with conventional ultrasound because of intense sonolucency.

Conclusion: The recent introduction of contrast enhanced ultrasonography is a very promising tool to cross this limit of US and it shortened the length of treatment.

C-0628

Usefulness of three-dimensional rotational angiography following percutaneous vertebroplasty; with special interest on detectability of cement leakage

Y. Arisaka¹, M. Matsusako¹, A. Uemura¹, N. Kobayashi¹, M. Takase¹, M. Terada¹, R. Nakagawa², H. Komatsu², Y. Numaguchi¹; ¹Chuo-ku, Tokyo/JP, ²Shinagawa-ku, Tokyo/JP

Purpose: Imaging evaluation of cement leakage around vertebral bodies is crucial because it affects the postprocedural patient care. The goal of this study is to evaluate the usefulness of three-dimensional rotation angiography (3D-RA) following percutaneous vertebroplasty (PVP) in terms of detectability of cement leakage.

Methods and Materials: Thirty-eight patients (84 vertebral bodies) who underwent 3D-RA and multidetector CT (MDCT) were included in this study. 3D-RA was performed by using a rotational angiographic unit. Multiplanar reconstruction (MPR), maximum intensity projection (MIP) and gradient rendering images were created by using workstation. 3D-RA images and MDCT images were evaluated by two radiologists. The existence and location of cement leakage around the vertebral bodies was evaluated. 3D-RA findings were correlated with MDCT as a golden standard.

Results: MDCT revealed 52 leakages among 38 vertebral bodies. On 3D-RA, 53 sites among 39 vertebral bodies were diagnosed as cement leakage. Sensitivity, specificity, positive predictive value and accuracy of 3D-RA were 86.5%, 98.4%, 84.9% and 97.0% respectively.

Conclusion: 3D-RA is useful tool for evaluation of cement leakage during PVP and may replace postprocedural CT.

C-0629

MR imaging findings following radiofrequency ablation (RFA) of lung tumors

J. Yoshigi, J. Ishida, T. Nakamura, K. Izaki, S. Ando, T. Kajitani, T. Yoshizako, H. Kitagaki; *Izumo/JP*

Learning Objectives: 1. To describe MR findings within treated tumor and to recognize features of residual disease. 2. To review peritumoral findings following RFA on MR imaging.

Background: Therapy effect judgment by imaging for RFA of lung tumor is not established, because contrast enhancement of lung tumor is generally low and evaluation by ultrasound is difficult. On CT, visual evaluation of contrast enhancement and ablated area is difficult. Therefore we reviewed MR imaging findings following RFA of lung tumor to investigate potential of therapy effect judgment by MR imaging.

Procedure Details: MR imaging was performed before, 1 week and 1 month after RFA. MR imaging was performed with a 1.5 T system with torso phased array coil. T1 and T2-weighted image (WI) and 3D dynamic images were obtained. Subtracted images were also obtained by subtracting ordinary T1-WI from the enhanced T1-WI. The effectiveness of RFA was evaluated on the basis of the area of the enhanced components in the tumor on initial and follow-up images. Subtracted image was excellent to detect enhanced component. After 1 week, the diameter of tumor increased in size. Signal change of a tumor was unsettled on T1 and T2-WI. Peritumoral enhancement and slightly high signal intensity on T2-WI were also seen. Residual tumor was detected by only the subtracted image. After 1 month necrotic lesion decreased in size. Peritumoral enhancement and high signal intensity on T2-weighted image decreased in size.

Conclusion: MR imaging findings following RFA of Lung tumors has an impression to be useful in a therapy effect judgment.

C-0630

Development of animal model for solitary hepatic tumor: Operative intrahepatic transneedle inoculation of VX2 particles

J.H. Cho, B.H. Park, T.B. Shin, J.Y. Oh, J.H. Lee, S.K. Yoon, J.C. Choi, K.N. Lee, K.J. Nam; *Busan/KR*

Purpose: To develop a large animal model which has a proper solitary intrahepatic tumor and to evaluate tumor progression after intrahepatic inoculation of VX2 cells to New Zealand white rabbits

Materials and Methods: 21 NZ white rabbits were selected. We made a 1 mm³ VX2 tumor fragment and minced it to be mountable in a tuberculin syringe with normal saline. We injected the minced VX2 tumor onto the left hepatic lobe through 21 G needle. To prevent hemorrhage or leakage of VX2 tumor cells from the injected site, we tied around the suture site using black silk and covered the injection site with Surgicel® patch. Intrahepatic inoculated VX2 tumors were then

Scientific and Educational Exhibits

imaged with 16 channelled MDCT at every week interval. We sacrificed from 3 weeks bi-weekly, and correlated with CT and pathologic findings.

Results: Intrahepatic inoculated VX2 tumor was invisible on first week, and detectable on 2nd week by 66.7% (6/9). After 3rd week after inoculation, all tumors are detectable on CT scan. Tumor metastasis to extrahepatic organ increased according to time and size increase. In 3 cases (15%), early peritoneal seeding was detected within 3 weeks after inoculation. The other rabbits (85%) show successful inoculation to make a solitary hepatic tumor models without complication. **Conclusion:** Tumor metastasis to extrahepatic organs were detected from 4th week in period or more than 35 mm in diameter, after inoculation of tumors. Operative intrahepatic VX2 tumor particles injection method seems to be good for development of animal model with intrahepatic solitary tumor.

C-0631

Percutaneous treatment of hydatid cysts of the liver: Our experience

D.M. Masulovic, M. Milicevic, D. Saranovic, A. Djuric, A. Ivanovic, B. Dobriserevic; Belgrade/YU

Objective: The purpose of our study was to present our experiences in percutaneous treatment of liver hydatid cysts.

Materials and Methods: 21 male and 36 female patients, ranging in age between 17 and 67 years with 84 liver hydatid cysts underwent percutaneous treatment with albendazole prophylaxis. In 61 cases, PAIR were used for hydatid cysts smaller than 6 cm. Larger cysts (23) were treated by catheterization. CT and/or ultrasound guidance with or without fluoroscopy was used. Ultrasound was used in follow-up that has been performed every third month of the first year, every sixth month of the second year, and once a year thereafter.

Results: The mean reduction in volume at the time of the first follow-up was 82.0% in catheterization and 70% in PAIR patients. The immediate US changes after treatment were detachment of the endocyst and disappearance of the regular endocyst, with a decrease in the fluid component. Fifty three of fifty seven patients were cured, with four recurrences. No mortality, abdominal dissemination, or tract seeding occurred. Minor complications were urticaria and fever in three patients. Major complications were infection of the cyst cavity in (3) and development of biliary fistula (2). Average hospitalization time was 20 days for cases with complications and 2 days in uncomplicated cases.

Conclusion: Our experience shows that long-term results of percutaneous liver hydatid cyst treatment are in line with short-term results, indicating that the procedure is efficient and safe and offers complete cure in selected patients with a short hospitalization.

C-0632

CT guided therapeutic spine interventions

H. Brat¹, T. Bouziane², O. Cappeliez³; ¹Mons/BE, ²Tournai/BE, ³La Louvière/BE

Learning Objective: Teaching file for CT guided minimally invasive therapeutic spine interventions.

Background: CT fluoroscopic needle guidance has allowed decreasing risk and maximizing patient comfort in peri-spinal minimal invasive interventions. These techniques may represent alternative treatments to surgery in many cases.

Imaging Findings and Procedure Details: Indications, target, procedure details, potential hazards and complications are detailed and illustrated with images and CT fluoroscopy films for each type of intervention. Interventions are listed in green and red light procedures according to degree of difficulty. Perispinal infiltrations and neurolysis, treatment of disc herniation, vertebral metastasis and fractures are reviewed using a step by step teaching file.

Conclusion: CT fluoroscopic guidance for interventional procedures allows fast, safe and precise interventions with minimal risk and X-ray exposure to the patient.

C-0633

Changes in disc herniations after CT guided percutaneous laser disc decompression (PLDD): MR findings

H. Brat¹, T. Bouziane², O. Cappeliez³, L. Divano¹; ¹Mons/BE, ²Tournai/BE, ³La Louvière/BE

Purpose: To assess changes in disc herniations on MR imaging after PLDD.

Materiel and Methods: Follow-up MR imaging were obtained in 27 consecutive patients (M:F = 19:8, mean age: 43 years) who had been successfully treated by CT guided PLDD for persistent radiculopathy due to a lumbar disc herniation after 6 weeks of conservative treatment. Mean duration of symptoms before treatment was 39 weeks (6-200). Mean follow-up with MR imaging was 7.5 months (3-15). Size and signal of diseased disc and hernia has been assessed before and after treatment on MR examinations.

Results: Follow-up MR imaging showed no change in the decreased disc signal in T1 & T2WI. Conversely, the disc hernia, initially always of low signal on T1WI and T2WI, presented a high signal on T2WI in 59% (16/27 patients) and a low signal in 41%. Shrinking of the hernia with raise of nerve root compression has been observed in 18/27 patients (66%) on MR imaging. Height of discs remained stable in all patients.

Conclusion: MR imaging of disc hernia after PLDD shows appearance of a high signal on T2WI in the hernia in 59% and a shrinking of the hernia in 66%.

C-0634

Ultrasound of the liver to follow-up ablative therapy of liver malignancies: Detection of residual and recurrent tumor compared to CT and MR imaging

W. Kröger, V. Nauck, C. Rosenberg, N. Hosten; Greifswald/DE

Purpose: To evaluate the efficacy and potential of ultrasound as an alternative to CT and MR imaging, the gold standard in controlling hepatic tumor ablative therapy. Description of sonographic criteria to determine tumor tissue activity.

Materials and Methods: 25 liver lesions in 18 patients with non-resectable primary or secondary hepatic malignancies (1 gastric, 10 colorectal, 4 hepatocellular, 3 renal cell carcinomas) were examined before and after thermoablative therapy (laser or radiofrequency-induced) at days -1, +4, +120. Lesion size and perfusion were measured to determine tumor tissue activity (HDI 5000, Philips). Tumor perfusion was visualized using color Doppler, pulsed Doppler and contrast-enhanced (SonoVue, Altana Pharma) ultrasound. CT, MR imaging or histologic findings, if performed, were correlated with ultrasound.

Results: US visualized 19 out of 25 lesions before and after ablative therapy. On follow-up, in 17/19 patients the US diagnosis "no residual tumor" or "residual tumor" was correct when compared to CT/MR imaging/histology. 10 out of 17 hepatic tumors were found to be treated sufficiently. 7 lesions showed residual or recurrent tumor activity. Sufficient ablative therapy of liver malignancies resulted in missing tumor perfusion and a decreased or stable lesion size, whereas detectable perfusion on US and /or enhanced tumor size defined residual or recurrent tumor. In one case ultrasound led to a false-negative result; residual tumor was not detected. One residual tumor in ultrasound was shown as complete ablation in CT.

Conclusion: Contrast-enhanced ultrasound to follow-up thermoablative therapy of liver malignancies represents an alternative method to CT/MR imaging.

C-0635

Stenting of the tracheobronchial tree

D.G. Lohan, S.M. Walsh, G.J. O'Sullivan; Galway/IE

Learning Objectives: According to patient requirements, temporary or permanent endoluminal stents of various types are now available for use throughout the central tracheobronchial tree.

Background: Insertion of a cylindrical structure into the trachea to maintain its patency was first performed by Trendelenburg, in 1872. However, it was not until the 1980s that both flexible silicone rubber and rigid metallic endoluminal stents became commercially available for use in the management of subglottic tracheobronchial stenoses. Central airway stenosis, with resultant severe morbidity, patient distress and potential mortality, may occur secondary to a myriad of both benign and malignant endoluminal and extrinsic tracheobronchial conditions. Until recent times, existing therapeutic options were often quite limited, with poor patient general condition and multiple comorbidities often precluding open reconstructive surgery. By providing a non-invasive alternative to surgical techniques, endoluminal tracheobronchial stenting has revolutionized the management of airway stenoses of many aetiologies.

Imaging Findings: By way of a pictorial review, we explore the realm of tracheobronchial stenting including pre- and post-insertion studies of patients treated in our institute. In addition, we illustrate the complications of this procedure including a discussion on methods of prevention and management of these adverse outcomes.

Conclusion: Often surgical options may be limited due to underlying co-morbidities in patients with tracheobronchial pathology. In this instance endobronchial stenting may offer a rapid, relatively inexpensive, well-tolerated method of symptomatic relief suitable for physically poor patients.

Scientific and Educational Exhibits

C-0636

Transgastric drainage technique in pancreatic fluid collections and in traumatic lesions

E. Mazza, L. Sali, C. Vannini, D. Beccani, M. Falchini, M. Zini, M. Acquafresca; Florence/IT

Purpose: To evaluate modified transgastric drainage technique of acute fluid collections secondary to biliary or pancreatic surgery or to pancreatic trauma.

Methods and Materials: From January 1998 to February 2004, 11 patients with retrogastric fluid collections (post surgical fluid collections in 6 cases; infected collections from acute pancreatitis in 2 cases, post traumatic fluid collections in 3 cases) were treated with modified transgastric technique. Lesions were single in 7 cases and multiple in 4. In all patients multiple drainages (from 2 to 6) were positioned under CT guidance and left in place for a period of 10 to 30 days. Subsequently they were replaced under fluoroscopic and endoscopic guidance with cysto-gastrostomic double-mushroom prostheses, left in place for 4 to 6 months. Finally all endoprostheses were endoscopically removed, after remission of collections was ascertained on CT images.

Results: Resolution of fluid collections was achieved in all lesions. In post-traumatic lesions the procedure was repeated up to 3 times due to the development of new collections days to months after the first procedure. Due to isolation of a Vancomycin- and Fluconazol-resistant strain, in one case drainages were left in place for a prolonged time till the resolution was finally obtained.

Conclusion: Transgastric drainage technique, already validated for the treatment of pancreatic pseudocysts, may be successfully employed with a few adaptations to the treatment of acute, infected collections secondary to biliary or pancreatic surgery or to pancreatic trauma.

C-0637

Radiographic and clinical results of balloon kyphoplasty in the treatment of osteoporotic vertebral compression fractures

C. Doria, G.B. Meloni, P. Lisai, S. Profili, F. Meloni; Sassari/IT

Purpose: Aim of this study was to measure sagittal alignment of the spine in patients with osteoporotic vertebral compression fractures (VCFs), before and after treatment with balloon kyphoplasty.

Materials and Methods: 29 osteoporotic VCFs were treated during 21 balloon kyphoplasty procedures in 17 patients. The fractures, which occurred between T8 and L4, were sustained within a mean of 3.2 months of the procedure. The fracture was confirmed as the likely pain generator by correlating physical findings with the identification of edema in the fractured vertebra with Short Tau Inversion Recovery Magnetic Resonance Imaging. Under general anesthesia and biplanar fluoroscopy an 11-gauge Jamshidi needle was placed percutaneously into the posterior vertebral body through either a trans-pedicular approach. KyphX® Inflatable Bone Tamps (IBTs) were placed bilaterally into the vertebral body through a working cannula. The IBTs were inflated using visual fluoroscopic and manometric parameters. Once maximum fracture reduction and height restoration were achieved, both balloons were deflated and removed, leaving behind a cavity, which was then manually filled under low pressure with viscous, radioopaque polymethylmethacrylate cement. Standing radiographs centered on the treated level/s obtained prekyphoplasty and postkyphoplasty were analysed for improvement in sagittal alignment using the Cobb technique. Statistical analyses were done using paired simple t test and Wilcoxon signed-rank-test.

Results: Mean improvement in local sagittal alignment was 11.4° toward lordosis (range 0°-32°). Patients surveys revealed significant pain reduction within the first week after kyphoplasty.

Conclusion: Kyphoplasty improves physical function, reduces pain and may correct kyphotic deformity associated with vertebral compression fractures.

C-0638

Sacral cementoplasty using combination CT and fluoroscopic guidance: Technical approach

P.C. Young; Cleveland, OH/US

Learning Objectives: The radiologist will understand the indications for percutaneous sacral cementoplasty and become familiar with the technique of utilizing a combination of fluoroscopy and computed tomography for needle placement and cement injection.

Background: Vertebroplasty with injection of PMMA (bone cement) has become common in the treatment of osteoporotic compression fractures of vertebral bodies. Recently a similar procedure for treatment of sacral insufficiency fractures has been described. A few preliminary results have been published with favorable results in relieving pain from these fractures. Here, we describe a different technique for sacroplasty using CT and fluoroscopy.

Procedure Details: Patients are prone in the CT/fluoroscopy suite. The fluoroscopic tube is placed in an oblique orientation in a manner that profiles the sacroiliac joints. The needle is then placed in a location at the mid sacrum on the side of the sacral insufficiency fracture 1-2 cm medial to the SI joint. This approach allows a safe placement of the needle avoiding sacral nerve roots. Radioopaque PMMA is then injected and intermittent fluoroscopic and CT images are obtained allowing confirmation of appropriate location of the cement and prompt visualization of any extravasation. The procedure is otherwise similar to the technique of percutaneous vertebroplasty.

Conclusion: Percutaneous cementoplasty (sacroplasty) is a promising new therapy for the treatment of sacral insufficiency fractures. Using a combination of CT and fluoroscopy during needle placement and injection of PMMA improves visualization of the sacral neuroforamina thus decreasing the risk of extravasation and sacral nerve injury.

C-0639

Percutaneous tumor ablation in liver tumors causes a transient immunosuppression

C. Schmuckenschlager, M. Ploder, B. Wessner, F. Längle, E. Roth, J. Lammer, J. Kettenbach, A. Spittler; Vienna/AT

Purpose: Radio frequency ablation or ethanol instillation in patients with liver tumors are possibly accompanied by an activation of Kupffer cells which then produce a variety of inflammatory cytokines and cause an imbalance of the redox status. The aim of the present work was to determine the patients' immunological and oxidative status before and after percutaneous tumor ablation.

Methods: 0.5 h before, 0.5 h, 24 h and 5d after intervention human leucocyte antigen-DR (HLA-DR) expression on monocytes, ex-vivo LPS induced tumor necrosis factor-alpha (TNF-alpha) production, plasma interleukin (IL)-6, procalcitonin (PCT), peroxide levels and antioxidative capacity were measured.

Results: In this prospective study 25 patients (mean age 67.0 ± 10.6) were included. In all patients HLA-DR expression (24 h $p < 0.01$; 5d $p < 0.05$) and TNF-alpha production (1 h $p < 0.001$) were significantly diminished, IL-6 (24 h and 5d $p < 0.01$) and PCT levels (24 h $p < 0.05$) were significantly enhanced compared with pretreatment values. Interestingly, 5d after intervention peroxide levels were significantly higher ($p < 0.01$), whereas antioxidative capacity did not change. Significant differences between the two treatment groups were found in IL-6 (24 h $p < 0.05$), PCT (1 h $p < 0.05$, 24 h $p < 0.05$, 5d $p < 0.05$) and peroxide levels (1 h $p < 0.05$).

Conclusion: Although in all patients interventions were minimal invasive treatments, we assume that Kupffer cells were activated triggering a transient immunosuppression. In addition altered peroxide levels indicate the occurrence of oxidative stress.

C-0640

Computed tomography guided automated cutting needle biopsy of pulmonary lesions. Self assessment test

A. Grgic¹, M. Heinrich¹, M. Girmann¹, B. Kramann¹, M. Uder²;

¹Homburg a.d. Saar/DE, ²Erlangen/DE

Purpose: We evaluated the diagnostic accuracy and incidence of complications of transthoracic needle biopsy with an automated cutting 16-gauge core biopsy needle and gun using computed tomography guidance.

Patients and Methods: In a retrospective analysis diagnostic yield and complications of the needle biopsy with a 16 gauge needle in 44 patients (33m, 11f, 61 years, range 29 to 80 years) between May 2000 and August 2004 were analysed. Hard copy images, pathology reports and clinical reports were reviewed for the histopathological diagnoses and complications of the biopsy. The size of the lesions ranged from 1.8 cm to 8 cm in diameter.

Results: An adequate sample for histological diagnosis was obtained in all cases. There were 40 of 44 (90.9%) true positive biopsies for malignant lesions and a specific histopathological diagnosis was obtained in all benign and malignant lesions. Complications occurred in 11 patients (25%) and included 8 cases with a small pneumothorax, one case with a pneumothorax requiring drainage and 6 cases of local parenchymal hemorrhage with minor hemoptysis.

Conclusion: The transthoracic biopsy with an automated 16-gauge core biopsy needle and gun system provides a high level of diagnostic accuracy that effectively distinguishes benign from malignant diseases and allows an accurate distinction of malignant cell types with low complication rate.

Scientific and Educational Exhibits

C-0641

Management of pancreatic fluid collections with percutaneous drainage under CT guidance

G. Papaioannou, L. Thanos, A. Nikita, A. Sissopoulos, D. Antonopoulos, D. Kelekis; *Athens/GR*

Purpose: To assess the efficacy of percutaneous drainage of pancreatic fluid collections under CT-guidance.

Materials and Methods: During a 5-years period, 148 patients with pancreatic fluid collections (noninfected fluid collections, pseudocysts and abscesses) underwent percutaneous CT-guided drainage using pigtail catheters 12-16F. Indications for drainage were pain, sepsis and gastrointestinal or biliary obstruction. Forty-five cases required the use of multiple catheters.

Results: Percutaneous drainage was successful in 128 of 148 (86.4%) patients. Recurrence occurred in 20 of 148 (13.6%). Fifteen of them underwent repetition of the procedure. Overall, failure of the technique occurred in 18 out of 148 (12.1%) patients, requiring subsequent surgical drainage. No procedural complications were noted.

Conclusion: Percutaneous CT-guided drainage of pancreatic fluid collections is a safe and effective procedure and it may replace surgery in the majority of the cases.

C-0642

Percutaneous radiological gastrostomy: New modifications

M.C. Hurley, M. Given, S. Lyon, M. Lee; *Dublin/IE*

Learning Objectives: 1. To describe Percutaneous Radiological Gastrostomy (PRG). 2. To detail new developments in gastrostomy tube placement.

Background: Preshaw first described the fluoroscopic technique of PRG in 1981. The procedure was initially limited to standard foley or pigtail catheters. Because of difficulties with catheter clogging and displacement, recent trends include placing pull-type PEG tubes radiologically or placing gastrostomy button catheters de novo. Advantages of PEG-type tubes include their robust nature and good retention. Button advantages include lack of clogging and patient preference. PRG has advantages in patients with neurodegenerative disorders, due to poor respiratory function, aspiration risk, and high riding stomachs.

Procedure Details: To safely introduce a button tube de-novo, T-fastener gastropexy is routinely performed. Track length is measured to ensure a good fit. The button tube has a flush exterior, reducing the rate of dislodgement. To introduce a PEG-type tube, the stomach is punctured percutaneously, a guidewire is passed retrogradely up the esophagus and retrieved from the oropharynx. A snare catheter is then used to draw suture material along the same path. This is attached to the outer portion of the PEG tube which is pulled antegradely and into position. These robust tubes are ideal for long-term use.

Conclusion: Technical success rate is close to 100%, though a significant number require replacement. Complications include peritonitis, due to leakage or intraperitoneal siting of the tube, and puncture of colon or liver. These new techniques place the interventional radiologist at the forefront of enteral nutrition provision.

C-0643

Bleeding after US-guided percutaneous liver biopsy: Role of Doppler US examination immediately after the biopsy procedure

K. Kim, T. Kim, S. Park, M.-J. Kim, A. Kim, H. Ha; *Seoul/KR*

Learning Objectives: To illustrate predictive findings or evidences of bleeding after the percutaneous liver biopsy at Doppler US examination immediately after the biopsy procedure.

Background: The role of US-guided percutaneous needle biopsy has been well established in the diagnosis of both diffuse and focal hepatic diseases. Whereas it is considered a relatively safe procedure in patients with normal coagulation, the risk of bleeding after the procedure increases in patients with coagulopathy. Although Doppler US examination has been known to be a sensitive method in detection of post-biopsy complications such as arterial pseudoaneurysm and arteriovenous fistula, the efficacy of Doppler US in the detection of the bleeding immediately after the biopsy procedure has not been determined yet.

Procedure Details: We recently performed Doppler US examinations immediately after percutaneous liver biopsy in 114 patients and found several predictive findings of post-biopsy bleeding including flow signals along the needle tract. In this exhibit, we present a pictorial review of predictive findings or evidences of post-biopsy bleeding at Doppler US examination immediately after percutaneous liver biopsy.

Conclusion: Doppler US examination after percutaneous liver biopsy provides excellent screening for detection of post-biopsy bleeding. A patent tract sign,

which persists for five minutes after the biopsy, strongly predicts the possibility of subsequent occurrence of clinically significant post-biopsy bleeding.

C-0644

Percutaneous vertebroplasty in the treatment of metastatic spinal disease

S. Ristic, P. Bosnjakovic, M. Mrvic, A. Bojanovic, D. Ilic, D. Stojanov, M. Ilic; *Nis/YU*

Purpose: The objective of this study was to determine the efficacy and durability of percutaneous vertebroplasty for the treatment of back pain associated with metastatic vertebral body lesions.

Methods and Materials: Over the last 30-months period sixty four vertebrae (48 lumbar, 16 thoracic) were treated in 40 patients with spinal metastases. There were 36 female and 4 male patients (32 ambulatory, 8 hospitalized) in our group, mean age 52 years All patients suffered intractable spinal pain refractory to analgesic therapy. Pain intensity before and after the procedure was evaluated using a visual analog scale (VAS). Vertebroplasty was done under continuous fluoroscopy guidance, after pre-medication and under local anesthesia. Percutaneous puncture of the involved vertebral bodies was performed via transpedicular or intercostovertebral approach.

Results: All procedures were technically successful and resulted in significant pain relief and clinical improvement in all patients immediately after. Preoperative VAS score ranged 6.6-9.4 (mean 7.8) decreased to 0-3.8 (mean 2.3) postoperative. No major complications were noted. Paraspinal soft tissue leakages, that occurred in nine levels, eight epidural, five intradiskal and three venous leaks of methyl methacrylate had no clinical importance. Two patients experienced mild transient radiculopathy, which resolved after NSAID therapy. Beneficial effects were persisted in all of cases at follow-up, with mean duration 13.6 months (range 2-27 months).

Conclusion: Vertebroplasty is a minimally invasive outpatient procedure that provides immediate pain relief, spinal stabilization and mobility improvement in cancer patients. It is safe and highly efficacious therapy, and promising to have long lasting benefit.

C-0645

Vertebroplasty using transoral approach in vertebral fractures due to metastatic lesions at C2 level

M. Romero, A. Tomasello, J. Blasco, J. Macho, J. Pomes, M. Burrel, X. Tomas; *Barcelona/ES*

Learning Objectives: To illustrate our experience in vertebroplasty using the transoral approach in vertebral fractures due to metastatic lesions at C2 level.

Background: Percutaneous vertebroplasty is becoming the standard treatment of painful vertebral fractures associated with metastasis and osteoporosis. The Transoral approach allows a safe and effective access for the upper cervical spine.

Procedure Details: CT scan and MR imaging were used to confirm the diagnosis and the absence of any anatomical vascular variants around the oropharynx. The procedure was done under general anaesthesia and with the aid of a mouth retractor. Under fluoroscopy an appropriate access to C2 vertebral body was achieved. After placement of a 15 cm/15 G needle at the center of the vertebral body, the cement was injected by using a screw syringe. Feasibility of the technique as well as immediate and mid-term follow-up were analyzed. Cement distribution was optimal in both cases, without any vein or disk cement leakage. No medical or radiological complications appeared related with the procedure. Both patients experienced important pain relief within 24 hours after the procedure. One of the patients died during follow-up due to his primitive disease. Pain relief persisted 6 months after the procedure in the other patient.

Conclusion: Transoral approach is an effective and safe access for upper cervical spine vertebroplasty.

C-0646

Radiofrequency ablation in the management of colorectal liver metastases

A. Afag; *London/UK*

Learning Objectives: Essentials of technical considerations in Radiofrequency Ablation (RFA) of hepatic metastases. Current concepts in the role of RFA from a review of the literature. Suggestions for further research for optimizing management of colorectal liver metastases.

Background: Surgical resection is known as the gold standard of treatment, but most patients present with unresectable disease. RFA has been shown to be a safe and feasible alternative in unresectable tumours. This involves image guided placement of a needle electrode into the metastases allowing alternating current to cause localized thermal coagulative necrosis.

Scientific and Educational Exhibits

Imaging Findings: Follow up imaging of successful RFA should demonstrate an area of necrosis with no residual tumour. Of the few published studies, there is a greater proportion including reports from London, (5 year survival 30%), Bordeaux, (1 year survival 85%), and Busto Arsizio, (3 year survival 46%) promoting the role of RFA. However results from the largest study from Texas, were less favourable.

Conclusion: Most studies favour the use of RFA in unresectable disease and it has the advantage of being more easily repeatable so new tumours can be treated as they are detected. Unfortunately outcomes of studies can be difficult to interpret, with problems of variation of tumour biology likely to influence which metastases are unresectable, small cohorts and short follow-up. Although evidence for the role of RFA in combination with resection is growing, controversy remains and comprehensive clinical trials with comparable designs would help determine whether studies on potentially resectable metastases is the way forward.

C-0647

Vertebroplasty with volumetric CT guidance: Speed, precision and clinical efficiency

H. Brat¹, T. Bouziane², J. Lambert¹, O. Cappeliez³, L. Divano¹; ¹Mons/BE,
²Tournai/BE, ³La Louvière/BE

Learning Objective: Teaching file for volumetric CT guided vertebroplasty.

Background: Usually, vertebroplasty is performed under general anaesthesia and with a conventional C-arm fluoroscopy. Triple slice CT fluoroscopy allows a volumetric approach of the collapsed vertebra and highest precision in needle tip placement. Local anaesthesia alone allows one day stay in hospital.

Imaging findings and procedure details: Indications, technical aspects, advantages, procedure details, hazards and complications for volumetric CT guided vertebroplasty compared to conventional fluoroscopy and combined (conventional and CT) fluoroscopy are detailed and illustrated. Advantages in terms of speed of procedure, increase in security and precision, decrease in hospital stay are emphasized. Case reports are used for additional illustration.

Conclusion: Volumetric CT guidance makes percutaneous vertebroplasty under local anaesthesia an easy to perform procedure with maximum patient security and comfort.

C-0648

Benefits of triple slice CT fluoroscopic needle guidance in percutaneous laser disc decompression (PLDD)

H. Brat¹, T. Bouziane², O. Cappeliez³; ¹Mons/BE, ²Tournai/BE, ³La Louvière/BE

Purpose: To evaluate benefits of triple slice CT fluoroscopic needle guidance in PLDD.

Material and Methods: 40 consecutive patients (M:F = 21:9, mean age: 43 years) presenting a contained disc hernia (2 L3/L4, 15 L4/L5, 23 L5/S1) and corresponding radicular pain of more than 6 weeks have been treated with multislice CT guided PLDD. Mean duration of symptoms before treatment: 39 weeks (6-200). Patients were treated under local anaesthesia on a one-day treatment unit. All procedures have been achieved with a 2/4/2 mm collimation and at low dose (10-25 mAs). Evaluated criteria: mean duration of fluoroscopy, percentage of needle repositioning, confidence interval for needle placement and technical success rate of the procedure.

Results: Mean duration of fluoroscopy: 23 seconds (11-43). Percentage of needle repositioning: 5%. Confidence interval for needle placement: 3/3. Technical success rate of the procedure: 100%. Benefits of multislice fluoro-CT needle guidance: low X-ray exposure time, management of patient z-axis, central intradiscal needle placement, absence of technical failure and absence of radicular lesion.

Conclusion: Triple slice CT fluoroscopy allows a volumetric approach for fast, precise and efficient needle positioning, increasing patient's comfort and security. Main benefit seems to be due to management of patient Z-axis.

C-0649

Percutaneous image-guided lymph node biopsy in lymphoma: Tips and tricks

A. Guermazi¹, S. Guth², A. Gangi²; ¹San Francisco, CA/US, ²Strasbourg/FR

Learning Objectives: Our objectives are to describe thoracic and abdominal percutaneous image-guided lymph node biopsy in patients with lymphoma and to describe some alternatives, tips and tricks for when the procedure tends to be difficult.

Background: Open surgical biopsy has long been the gold standard for obtaining lymph node samples in patients with lymphoma. However, the procedure can

have significant complications. With advances in cytopathologic diagnostic techniques, percutaneous image-guided biopsy with its high overall accuracy has become the procedure of choice, and is taking a prominent place in the management of lymphoma. It is now considered a safe, low cost, and valuable tool for patients with suspected or recurrent lymphomas. Between January 1998 and December 2003, we performed 198 percutaneous image-guided lymph node biopsies in patients with non-Hodgkin lymphoma.

Procedure Details: We will describe the technique of abdominal and thoracic percutaneous image-guided lymph node biopsy and give some suggestions and tips and tricks for when the procedure tends to be difficult, especially in posterior and/or deep-seated lymph nodes.

Conclusion: A well-planned and executed biopsy provides an accurate diagnosis and facilitates treatment. CT, which is widely available, allows image-guided biopsy in a large majority of patients. US-guided biopsy is an alternative, and is the guidance technique of choice at some institutions.

C-0650

A survey of radiation dose and image optimisation for cardiac

interventional procedures

C.S. D'Helft¹, A.M. Mc Gee¹, L.A. Rainford¹, S.L. Mc Fadden², C.M. Hughes², J.R. Winder¹, P.C. Brennan¹; ¹Dublin/IE, ²Belfast/UK

Purpose: Interventional radiological procedures are increasingly common because of their cost-effectiveness compared with surgical procedures. Prolonged fluoroscopic exposures, particularly those associated with cardiovascular studies are responsible for some of the highest patient and staff radiation doses. Such exposures increase the risk of stochastic effects and regularly cross the threshold dose above which, deterministic effects such as erythema, epilation and ulceration are experienced.

Method and Materials: Radiation levels using dose area product and fluoroscopy time are currently being determined and compared for coronary angiograms (CA), percutaneous coronary intervention (PCI) and permanent pacemaker insertion procedures (PPI) across 15 hospitals. Other factors such as operator grade, technique and equipment used are also recorded, and their potential effect on patient dose investigated.

Results: To date, the results demonstrate a mean dose for CA procedures of 74.26 Gy cm², for PCI procedures 107.44 Gy cm², for PPI procedures 37.05 Gy cm². However, large intra- and inter-hospital variations were noted. The screening time varied by a procedure-specific extent, and shows a strong relationship with radiation dose delivered. Other causal will be discussed.

Conclusions: Due to the risks associated with X-ray exposure, radiation doses should be kept as low as reasonably achievable, consistent with good image quality. However, significant variations in radiation dose and image quality for coronary interventional procedures have been shown within and between hospitals in Ireland for the first time. Possible areas of standardisation and potential Diagnostic Reference Levels will be proposed.

IVR techniques for bone tumor: A comprehensive review

T. Inaoka¹, K. Takahashi², T. Yamada¹, M. Mineta¹, W. Yamamoto¹, K. Nagasawa¹, H. Hirota¹, T. Yamaki¹, T. Aburano¹; ¹Asahikawa City/JP, ²Iowa City, IA/US

Learning Objectives: To review a variety of interventional radiologic (IVR) techniques of primary and secondary bone tumors. To describe indications, contraindications, efficacy and complications.

Background: A variety of interventional radiologic (IVR) techniques of primary and secondary bone tumors have been described. It is important for general radiologists to know a variety of IVR techniques of bone tumors for establishing an optimal patient management. The purpose of this exhibit is to demonstrate various IVR techniques with indications, contraindications, efficacy and complications.

Procedure Details: Topics are primarily divided into two categories by approaches, 1) transcatheter approach including transcatheter arterial embolization (TAE), trans-catheter arterial infusion (TAI), arterial infusion chemotherapy via arterial port-catheter system; and 2) percutaneous approach including US-guided or CT-guided bone biopsy, percutaneous vertebroplasty and percutaneous ablation therapy.

Conclusion: Essential knowledge of a variety of IVR techniques of primary and secondary bone tumors could make it possible to perform more effectively and safely, and to improve patient's quality of life.

C-0652

The role of in-phase and out-of-phase magnetic resonance imaging and in vivo ¹H single-voxel magnetic resonance spectroscopy in the differential diagnosis of monoclonal gammopathies

G. Bajzik, M. Egyed, E. Karadi, B. Kollar, G. Rumi, P. Rajnics; Kaposvar/HU

Purpose: In many cases it is difficult to separate multiple myeloma and monoclonal gammopathy of unknown significance (MGUS) by routine clinical and pathological examination and the appropriate therapy can be delayed. We investigated the potential role of in-phase and out-of-phase magnetic resonance imaging and in vivo ¹H single-voxel magnetic resonance spectroscopy in characterization of bone marrow tissue in patients with multiple myeloma and MGUS.

Methods and Materials: Twenty patients with clinically and pathologically confirmed monoclonal gammopathy were examined. We acquired in-phase and out-of-phase gradient-echo sagittal images of the lumbar spine using a 1.5 T magnet. Identical region of interests were placed on the body of the first to fourth lumbar vertebra and the difference in mean signal intensities were calculated. The voxel of the ¹H magnetic resonance spectroscopy (PRESS) sequence was placed on the body of the third or fourth lumbar vertebra. We calculated the ratio of the areas under the water and lipid peaks followed by logarithmic transformation. The Mann-Whitney test was used for statistical analysis.

Results: The signal intensity difference values for in-phase and out-of-phase images were significantly higher ($p = 0.0002$) in the MGUS group (Mean: 152.3, SD: 13.1), than in the myeloma group (Mean: 24.9, SD: 13.1). Values of logarithmic transformation of water/lipid ratios were significantly different ($p < 0.0001$) between the MGUS group (Mean:-0.29, SD:0.32) and the myeloma group (Mean:0.93, SD:0.51).

Conclusion: Our findings suggest that chemical shift imaging and magnetic resonance spectroscopy could be useful in differentiation myeloma from MGUS, therefore can help to decide the initiation of therapy.

C-0653

Investigation of trabecular bone structure by means of DTI techniques

S. Capuani, C. Rossi, F. Fasano, B. Maraviglia; Rome/IT

Purpose: An application of DTI techniques to trabecular bone marrow analysis to obtain structural information on spongy bone tissue was presented.

Methods and Materials: In trabecular bone tissue, molecular diffusion shows different properties along the different observation directions. In such anisotropic media it is necessary to introduce a diffusion tensor, D, that describes the mobility of Brownian particles. The set of all MR imaging techniques that enables us to determine the elements of such a tensor is known as Diffusion Tensor Imaging (DTI). In our study a PGSTE sequence was used to obtain a series of MR images from a bovine bone sample. The intensity of the gradient was varied for each of the seven directions of the diffusion sensitive-gradients and therefore, the experimental b-value varied as well. Starting from these images it was possible to

Scientific and Educational Exhibits

calculate the fractional anisotropy (FA) map, which measures the degree of anisotropy of the sample, and the mean diffusivity (MD) map, which allows monitoring of the general diffusion properties of the sample.

Results: The MD and FA images show different contrast with respect to conventional T2-weighted image, especially in trabecular bone region. In particular, the FA map appears more sensitive to orientated sample structures while MD provides information on mean pore size.

Conclusion: Our preliminary results show that MD and FA maps are more sensitive than conventional NMR imaging techniques to bone trabecular network microstructure. DTI maps might provide a powerful tool to improve diagnosis of bone diseases at an early stage.

Effectiveness of ESWT (extracorporeal shock wave therapy) in treating pseudoarthrosis and delayed union

D. Rozzati, F. Cravero, A. Meni, G. Sessa, A. Stecco, A. Carrieri; Novara/IT

Purpose: To investigate the effectiveness of ESWT in the treatment of non-healed fractures of long bones or pseudoarthrosis, and which of these categories is more eligible to perform ESWT with a clinical success.

Methods and Materials: From March 2003 to March 2004, 10 female and 20 male (range 15-68 years) were treated. 15 patients had pseudoarthrosis and 15 delayed union of long bones. The fractures included diaphyseal fractures of femur, tibia, humerus, radius, ulna, scaphoid and metatarsus. Inclusion criteria were well assessed non-union of long bones fractures, defined as a failure to show bony union 6 months after initial closed or open treatment. Exclusion criteria were pregnancy, heart disease, neoplastic disease, coagulopathy, epiphyseal plate within the shock wave field, brain or spine within the shock wave field. The study was done with an HMT (High Medical Technologies) "Reflectron" ESWT system. An evaluation form to define the outcome of bony union was done for every patient. We applied the Mann Whitney U Test to evaluate statistically significant differences in percentage of success between the two groups.

Results: The treatment was successful in 8/30 patients (26%), 2/15 (13%) of the patients with pseudoarthrosis and 6/15 (40%) of patients treated for delayed healing of long bones fractures. We found a statistical significant difference between the percentages of success in ESWT in the two groups.

Conclusion: Results in our study show that ESWT can be considered a complementary therapy in the treatment of delayed union of long bones and pseudoarthrosis.

C-0656

Os trigonum syndrome: MR imaging findings in young athletes

A. Iovane, M. Galia, T. Bartolotta, F. Sorrentino, M. Midiri; Palermo/IT

Learning Objectives: To illustrate Magnetic Resonance (MR) imaging findings of the os trigonum syndrome.

Background: The os trigonum is an accessory bone of the foot, localized posterolateral to the lateral tubercle of talus. Even in the presence of os trigonum it is usually an asymptomatic condition; particular activities, such as ballet, running, soccer, football and volleyball may cause repeated stress and chronic micro-traumas to the hindfoot, resulting in the os trigonum syndrome, also called posterior ankle impingement syndrome (PAIS).

Procedure Details: Twenty-eight patients with a clinical diagnosis of PAIS, were submitted to MR, which was performed by using a 0.5 T superconductive MR unit with a dedicated extremities transmitter/receiver coil, and a 0.3 T dedicated MR unit. SE T1-w, GE T2*-w and STIR images were obtained in the axial, sagittal and coronal plane. Two experienced radiologists evaluated all MR studies in consensus. MR evaluation showed the following pathological changes: a) osteochondrosis changes of the os trigonum and neighboring bones, talus, calcaneus and tibia; b) soft tissue changes, represented by impingement between the os trigonum and the flexor hallucis longus tendon with distension of its sheath and distension of the posterior capsular recess consistent with presence of fluid or synovitis.

Conclusions: MR imaging allowed the correct identification of the os trigonum and characterization of the structural changes (osseous, cartilaginous, tendinous and capsular) taking place or associated with PAIS. Moreover MR may provide some important information concerning the biomechanics underlying disease development.

C-0657

Percutaneous radiofrequency ablation: Relationship between probe type, time of procedure and the extent of the osteonecrosis in a long bone dog model.

J. Martel¹, Á. Bueno¹, P. Domínguez¹, M. Nevado¹, P. Llorens², J. Quirós², C. Delgado²; ¹Alcorcón/ES, ²Madrid/ES

Purpose: We have been using radiofrequency ablation (RFA) for the percutaneous treatment of osteoid osteomas since 2001. Frequently, lesions are located near the joint surface, involve the vertebral body or are close to major nerves. We seek to determine whether RFA can be used safely in these cases.

Material and Methods: A total of 65 lesions were induced in 4 dogs. Each dog underwent RFA on the diaphysis of long bones, as well as femoral and humeral heads. Four different sessions were carried out by using 1 cm and 2 cm probes with or without a cool-tip system and varying the time procedure. Plain film, CT, and MR imaging were obtained. All bone samples were examined histologically.

Results: The activity of dogs after the procedure was normal. No complications were found. Cortical bone was respected. There was no damage to joint cartilage. Plain radiographs obtained *in vivo* demonstrated only the drill holes. CT showed a spherical lytic lesion with a sclerotic rim around the electrode tract. With MR imaging, the thermal lesions displayed low signal intensity with a sharp rim of high signal intensity and showed a good correlation with the pathologic measurement. There were no significant differences between lesion size, probe type and the duration of the procedure. The mean lesion diameter perpendicular to the electrode was 18.5 mm.

Conclusions: Our study confirms the insulative effect of cortical bone. RFA can be safely performed close to the joint surface without damaging the cartilage.

C-0658

Protocol optimization for analysis of trabecular bone structure with multislice spiral CT at the calcaneus for the assessment of osteoporosis

J.S. Bauer¹, P.V. Patel², S. Prevrhal¹, C. Phan¹, F. Eckstein³, E.-M. Lochmueller⁴, S. Majumdar¹, T.M. Link¹; ¹San Francisco, CA/US, ²North Chicago, IL/US, ³Salzburg/AT, ⁴Munich/DE

Purpose: With the spatial resolution of Multislice Spiral CT (MSCT) coming close to trabecular dimensions, visualization and analysis of trabecular bone structure becomes more feasible. The aim of this study was to optimize MSCT protocols for analysis of trabecular bone structure of the calcaneus and to compare these measures with bone mineral density (BMD) in their ability to differentiate donors with and without osteoporotic fractures of the spine.

Material and Methods: Forty-two formalin-fixed calcaneus specimens (mean age of donors: 81.2 ± 10 years) were imaged with a 16-detector MSCT system using four different scan protocols with varying spatial resolution ($400\mu\text{m}$ to $210\mu\text{m}$ in-plane) and radiation dose levels (90-120 kV and 150-300 mAs). Structure parameters of trabecular bone were derived from these images, and BMD of the calcanei was determined using dual energy X-ray absorptiometry (DXA). Fracture status of the spine was classified on conventional lateral post-mortem radiographs. Receiver-operator-characteristics (ROC) - analysis was performed to determine the diagnostic performance of BMD and structure parameters.

Results: Significant differences between both donor groups were found for structure parameters and BMD ($p < 0.05$). The highest ROC-values were found for the protocol with the highest spatial resolution and highest exposure dose. Apparent trabecular thickness was the structure parameter that obtained best results and stayed significant when corrected for BMD.

Conclusion: A high-resolution, high-dose MSCT protocol is required to sufficiently assess trabecular bone structure. Using such a protocol, structural parameters of trabecular bone of the calcaneus can be used to differentiate donors with and without osteoporotic vertebral fractures.

C-0659

MR imaging of bone tumors: A pictorial review

G.K. Schneider, R.M. Seidel, K. Remberger, D. Kohn, P. Fries; Homburg a.d. Saar/DE

Learning Objectives: To present MR imaging features of both benign and malignant tumors as well as tumor-like lesions. To demonstrate characteristics of benign and malignant tumors in MR imaging. To demonstrate important findings for staging and therapy planning.

Background: The therapy of bone tumors generally depends on the extent of the tumor, its growth behavior as well as its exact histological diagnosis. Although conventional X-ray is the basis of diagnosis, MR imaging today is the method of choice for evaluating the soft tissue components and extent of the tumor. Unlike

Scientific and Educational Exhibits

most of other imaging modalities MR imaging allows exact tumor staging, which generally is essential for treatment.

Imaging Findings: The aim of our exhibit is to show typical MR imaging patterns of malignant bone tumors such as osteosarcoma, Ewing sarcoma and metastases as well as benign tumors and tumor-like lesions (e.g. histiocytosis, aneurysmal bone cyst, chondroblastoma and others) and to explain important imaging findings for staging and therapy planning. Emphasis is laid on typical cases and special differential diagnosis by age specific algorithms. Additionally, the appropriate imaging technique is presented.

Conclusion: Adequate characterisation and staging is crucial for an optimal therapeutic approach to bone tumors. MR imaging reveals an excellent technique for the characterisation of bone tumors in addition to radiography.

C-0660

Comparison of DEXA, QCT and trabecular structure in beta-thalassaemia

M.D. Mylona, M. Leotsinidis, P. Andrikakos, A. Christopoulos, P.A. Dimopoulos; Patras/GR

Purpose: The assessment of β-thalassaemic spinal disease with DEXA and QCT, with emphasis on lumbar trabecular and cortical properties, assessed by HRCT.

Materials/Methods: Bone Mineral Densities (BMD) of 48 patients were expressed as Z scores, using values of sex- and age-matched controls and the results were correlated. The presence of hypogonadism, hypothyroidism, hypoparathyroidism, diabetes, backaches and fractures was recorded. The effect of age, sex, type of thalassaemia and hormonal factors on BMD was assessed. HRCT was performed in each vertebra with the lowest BMD, in order to estimate the cortex integrity and the number of trabeculae; the latter were classified to a three-grade scale.

Results: The overall prevalence of osteoporosis was 43.8% with DEXA and 6.3% with QCT. Both techniques revealed an inverse correlation between age and BMD and no difference between Thalassaemia Major and Intermedia (TM, TI) patients. Hormonal factors demonstrated associations with QCT and DEXA measurements. Patient's classification into normal, osteopenic and osteoporotic, using the number of trabeculae, was in better agreement with that of QCT's Z ($K = 0.209$, $p = 0.053$), than classification according DEXA's Z ($K = 0.145$, $p = 0.120$). Cortex evaluation by HRCT showed discontinuity in 15 patients (10 of 15 were TI).

Conclusion: Hormonal deficiency is associated with thalassaemic osteoporosis. Both methods indicate a progression of osteoporosis with age whereas the visual estimation of cortex indicates that TI could be more affected than TM. Regarding the number of trabeculae, as an indicator of osteoporosis, it seems that QCT may reflect osteopathy more accurately than DEXA.

C-0661

Computed tomography (CT) in monitoring of remineralization of bone metastases in patients treated with radiotherapy and ibandronate: Work in progress

C. Kalogeropoulou, V. Vassiliou, I. Tsota, D. Kardamakis, P. Sakellaropoulos, C. Katsarou, T. Petsas, I. Dimopoulos; Patras/GR

Purpose: To quantitatively evaluate the effect of external radiotherapy in conjunction with ibandronate on osteolytic bone metastases using CT and to correlate our results with the patient's clinical outcome.

Method: Eighteen patients with osteolytic bone metastases (11 males, 7 females; age range: 52 - 77) received radiotherapy with a 6-MV linear accelerator combined with a monthly infusion of 4 mg ibandronate. The total dose received was 30-40 Gy (1.8-2.0 Gy /fraction). CT scans were performed at the irradiated site before and 3 months after the treatment. Two radiologists contoured the osteolytic irradiated areas on the most representative CT slices (3-5 mm thickness). The same anatomical area was defined on the post treatment images. The delineated areas were analyzed as to density and the pre- and post-treatment values compared in ratios. The patient's clinical outcome was monitored by pain response, re-treatment rate, pathological fracture rate, spinal cord compression rate and quality of life.

Preliminary Results: The three months follow-up results were favorable since there was complete pain response in 15/18 patients. The re-treatment rate was 0/18, the pathological fracture rate was 1/18, and the spinal cord compression rate was 0/18. Quality of life was found to improve by an average of 3.94 out of 10 points (EORTC-QOL). CT density measurement changes in the region of bone metastases seemed to correlate with patient's clinical status.

Conclusion: CT-based bone density measurements could offer an objective method to assess the effect of treatment in patients with osteolytic bone metastases.

C-0662

Surface lesions of bone: A pictorial review

S. Takaø, M. Uetani, T. Yamaguchi, Y. Kawahara; Nagasaki/JP

Learning Objectives: To present an overview of imaging features of surface lesions of the bone with an emphasis on the plain radiographic findings. To describe the utility of other imaging modalities that assist in lesion characterization.

Background: A variety of tumor and tumor-like conditions originate from the surface of bone. They can arise within the cortex, between the cortex and the periosteum, within the periosteum, or in the tissues adjacent to the periosteum. Whilst some lesions have classical imaging features, many are nonspecific, and correlation with clinical information is often the key to the proper diagnosis.

Imaging Findings: Radiographic features are characterized by patterns of calcification, appearance of cortex and patterns of periosteal reaction. CT can assist in characterizing the origin, location and extent of the lesion. MR imaging is best for demonstrating soft tissue mass and bone marrow involvement and is therefore useful for pre-operative planning once a diagnosis is established.

Conclusion: Careful radiographic analysis with appropriate use of other imaging modalities is important to reach the proper diagnosis of surface lesions of the bone.

C-0663

Osteoid osteoma treated with percutaneous radiofrequency ablation: MR imaging follow-up

M. Lee¹, J. Ahn², J. Suh¹, H. Lim¹, E. Chung¹, N. Jung¹; ¹Seoul/KR, ²Iowa City, IA/US

Purpose: To assess the usefulness of MR imaging in follow-up evaluation of osteoid osteoma treated with CT-guided percutaneous radiofrequency (RF) ablation.

Materials and Methods: Fifteen patients with osteoid osteoma treated with RF ablation underwent MR imaging. The protocol required T1w, T2w and contrast-enhanced (CE) T1-weighted images with fat saturation at each visit, from immediately to 15 months after treatment (mean, 2.5 times; range of time interval, 1-7 months). MR images were evaluated by consensus of two reviewers, with regard to the appearance of treated areas including nidus, presence of abnormal findings such as fluid collection, and the best sequence for visualization of signal intensity (SI) changes. The therapeutic response was evaluated to be a clinical success with relief of pain.

Results: The treated areas had a characteristic "target" appearance at MR imaging: inner band (Z2), peripheral outer zone (Z3) surrounding central core (Z1). Z2 was hyperintense on T2WI with strong enhancement. Z3 was less hyperintense and less enhanced. Z1 was non-enhancing central zone with low SI on T2WI. All nidus were within Z1, showing low to intermediate SI on T1, T2WI. Target appearance became evident on MR images after 1 week following treatment. On follow-up, Z2 became thicker with fill-in enhancement into Z1, whereas Z1 was gradually decreased in size. Z3 showed diminishing enhancement and extent. No complications were found. CE-T1WI was best for visualizing SI changes. Clinical success was achieved in all patients.

Conclusion: MR imaging allowed accurate monitoring of treated areas for osteoid osteoma following RF ablation.

C-0664

Bone stiffness indices in patients having type I and type II diabetes mellitus based upon ultrasound osteometry of the calcaneum

V.D. Zavadovskaja, O.S. Shoulga, O.Y. Kilina, O.S. Tonkikh, E.S. Nigmatova; Tomsk/RU

Purpose: To assess bone stiffness in patients with diabetes mellitus of the 1st and 2nd type (DM 1-2) using ultrasound osteometry (UO) on the setting of peripheral flow disturbance.

Material and Methods: We studied 72 DM patients (18 males and 28 females aged 41.1 ± 6.7 years, 24 patients with DM-1 and 48 patients with DM-2). Angiopathy was revealed in 58% of DM-1 patients and in 36% of DM-2 patients. UO was performed using "Achilles Express" (Lunar, USA).

Results: Mean indices of SOS, BUA and STI (stiffness index) did not differ significantly in DM-1 and DM-2 patients. DM-1 patients revealed significantly higher osteoporosis frequency than DM-2 patients ($31 \pm 5\%$ versus $20 \pm 6\%$ respectively, $P = 0.001$). Frequency of osteopenia and osteometry normal indices did not differ in M-1 and DM-2 patients. STI indices of DM-1 patients with distal angiopathy were significantly lower than those of DM-1 patients without angiopathy ($P = 0.004$). Osteoporosis was revealed in 50% of DM-1 patients with distal angiopathy and was not revealed in those without angiopathy. Osteometry indices

Scientific and Educational Exhibits

and osteoporosis frequency did not depend on peripheral flow disturbances in DM-2 patients.

Conclusion: Based upon ultrasound osteometry, DM-1 patients reveal a higher frequency of osteoporosis compared to DM-2 patients. Bone metabolism disturbance is aggravated by distal angiopathy in DM-1 patients.

C-0665

Radiologic and magnetic resonance patterns of myeloma and differential diagnosis

J.J. Noguera, A. Alonso, E. De Luis, P.D. Domínguez, J.D. Aquerreta, O. Cosín; Pamplona/ES

Learning Objectives: To describe the four classical radiological patterns of myeloma on plain films. To correlate these four patterns with magnetic resonance imaging (MRI). To expose the main differential diagnosis of each pattern.

Background: Myeloma is a plasma-cell neoplasm with bone marrow affection, usually detected in the elderly population. The knowledge of MRI appearance of myeloma is needed due to the widespread use of MRI in the diagnosis and staging of myeloma.

Imaging Findings: Apart from the normal findings, four radiological patterns of myeloma have been typically described in plain films: a) Unique lytic lesion or plasmocytoma. b) Multiple lytic lesions or myelomatosis. c) Diffuse osteopenia and multiple vertebral fractures. d) Osteosclerotic myeloma, typically related with POEMS syndrome (very rare, 1%). Sensitivity of MRI is higher than plain film to detect osseous involvement by myeloma. In MRI myelomatous lesions appear as hypointense in T1 sequences and hyperintense in T2, in a poorly specific manner. Three MRI patterns are observed, with prognostic significance: a) Focal lesion, the most frequent appearance. b) Diffuse pattern. c) Variegated pattern, with multiple tiny foci of marrow affection and the best prognosis. These patterns in plain films and MRI are compared and illustrated.

Conclusion: MRI bone marrow surveys in patients with myeloma show a broad spectrum of involvement, with important prognostic significance. These patterns should be widely known by radiologists, as MRI will very probably be the diagnostic and staging tool of choice for myeloma instead of the plain film survey.

C-0666

Chondroblastoma: Radiographic and MR features

C. Blancas, J. Llauger, J. Palmer, E. Granell, N. Cañete; Barcelona/ES

Learning Objectives: To review and present the various imaging manifestations of chondroblastoma at different locations, emphasizing the role of MR imaging in its diagnosis.

Background: Chondroblastoma is an uncommon benign chondral tumor, which typically involves the epiphysis of long bones. 16 patients with histologically confirmed chondroblastoma were investigated with routine radiographs, MR imaging ($n = 13$), and CT ($n = 9$). The age and sex of the patient, location and size of the lesion, matrix calcifications, periosteal reaction, and signal characteristics were recorded.

Imaging Findings: Of the 16 patients with chondroblastoma, 12 were found in the epiphysis of the long bones, 3 around the hip, and one in the patella. Epiphyseal lesions were found in distal femur ($n = 6$), proximal humerus ($n = 4$), femoral head ($n = 1$), and proximal tibia ($n = 1$). The average size of the tumor was 3 cm in maximum diameter. Average age was 18.6 years. All lesions were well circumscribed. Mineralization was seen in 35% of lesions on radiographs or CT. On MR imaging, surrounding marrow edema was a prominent feature, as seen in 80% of the cases. Signal intensity on T2-weighted images was predominantly low to intermediate.

Conclusion: Chondroblastomas commonly manifest as well-defined epiphyseal lesions in young patients. MR imaging features of low to intermediate signal intensity on T2-W images and prominent surrounding edema are characteristic of this tumor.

C-0667

Added value of helical CT multiplanar reconstructions on the conventional transverse CT examination of the degenerative spine

S. Costa, L. Martí-Bonmatí, E. Arana, J. Forner, E. Mollá; Valencia/ES

Purpose: To analyse the diagnostic value of multiplanar sagittal and coronal reconstructions (MPR) in the CT evaluation of degenerative spine diseases, compared with CT axial slices.

Methods and Materials: A total of 170 patients were studied with helical CT (Phillips CT Aura). There were 50 cervical, 20 dorsal, and 100 lumbar spine examinations. Images were prospectively reconstructed in the transversal, sagittal

and coronal planes. The following variables were recorded: more affected disc abnormality, spondylolisthesis, spinal stenosis, degeneration of posterior articular facet joints, lateral foramina, and osteophytes. A global subjective comparison was established: axial better than MPRs, MPRs better than axial, or both of equal value. Statistical comparisons were obtained.

Results: Of the 170 patients, 125 showed discal pathology, with the transverse plane better analysing discal pathology with statistical significance. Conversely, all spondylolisthesis and most spondylolysis were undetected in the transverse images. Lateral foramina and osteophytes were better seen in the MPR images (which detected 29 foraminal stenosis and 32 osteophytes misdiagnosed in the axial plane) with statistical significance. On the contrary, there was good concordance in the evaluation of spinal canal stenosis and posterior facet joints. There were no differences between the different spinal segments.

Conclusion: Sagittal and coronal helical CT reconstructed images are quite useful in evaluating degenerative spinal diseases. The main additional valuable information is related to spondylolysis and spondylolisthesis, lateral foramina and osteophytes. A volumetric helical CT acquisition of the spine with posterior multiplanar reconstructions, at least in transversal and sagittal planes, is advocated.

C-0668

Standardization of BMD measurements in different DXA devices

M. Ucar, A. Özdemir; Ankara/TR

Purpose: To compare BMD values of AP lumbar and hip regions measured in two different DXA devices in one laboratory, and to investigate the efficiency of a standardization formula.

Materials and Methods: AP lumbar (L2-L4) and right hip BMD values were obtained in 100 women, consecutively in Lunar DPX-NT and Hologic QDR 4500 C DXA devices. Standardization of BMD values was done according to the method developed by ICSBM, using the European Spine phantom to obtain the specific constant value. Mean calculated sBMD values in two devices were compared with each other and with mean reported sBMD values, respectively.

Results: Mean lumbar BMD values were $0.950 \pm 0.117 \text{ g/cm}^2$ for Hologic and $1.068 \pm 0.135 \text{ g/cm}^2$ for Lunar ($p < 0.05$); mean sBMD values were $1.035 \pm 0.128 \text{ g/cm}^2$ for Hologic and $1.035 \pm 0.131 \text{ g/cm}^2$ for Lunar ($p > 0.05$). Mean hip BMD values were $0.798 \pm 0.114 \text{ g/cm}^2$ for Hologic and $0.895 \pm 0.111 \text{ g/cm}^2$ for Lunar ($p < 0.05$); mean sBMD values were $0.869 \pm 0.124 \text{ g/cm}^2$ for Hologic and $0.867 \pm 0.108 \text{ g/cm}^2$ for Lunar ($p > 0.05$). The difference between the mean values of BMD and sBMD were statistically important in each device ($p < 0.05$). Mean values of calculated and reported sBMD were also significantly different in each device ($p < 0.05$), which is probably related to manufacturers' references of ICSBM calculations based on models different from ours.

Conclusion: sBMD values should be used instead of BMD, whenever quantitative values are needed. However, reported sBMD values by DXA devices may not represent the model-specific sBMD values.

C-0669

Solitary bone lesions: Imaging approach and differential diagnosis

C. Mueller, T.G. Mang, W. Huber, H. Imhof, F. Kainberger; Vienna/AT

Learning Objectives: To demonstrate the imaging features of lytic and sclerotic solitary bone lesions. To recognize characteristic benign and malignant bone lesions on radiographs. To illustrate the optimal imaging work-up of indeterminate and malignant bone lesions.

Background: Radiographs are usually the first imaging modality in patients with bone pain. Therefore they play an important role in differentiating benign, so called "leave me alone" lesions from indeterminate or malignant bone lesions. To prevent unnecessary investigations or biopsies it is important to recognize the imaging criteria of benign bone lesions. Additionally it is essential to identify signs of malignancy on radiographs.

Procedure Details: We present the broad spectrum of benign and malignant solitary bone lesions on base of radiographs, CT and MR images. The imaging criteria that are helpful for differential diagnosis for these diseases will be discussed.

Conclusion: Radiographs are a useful diagnostic tool to identify characteristic benign bone lesions that need no further follow-up. If malignancy is suspected additional imaging studies with CT and MR imaging are needed for the subsequent diagnostic and therapeutic approach.

Scientific and Educational Exhibits

C-0670

3D structure analysis of the calcaneus using the scaling vector method in the prediction of osteoporotic spine fractures

D. Mueller¹, R. Monetti², S. Majumdar³, C. Raeth², E.J. Rummeny¹, T.M. Link³,
¹Munich/DE, ²Garching/DE, ³San Francisco, CA/US

Purpose: To investigate the trabecular bone structure of the calcaneus applying the new scaling vector method (SVM) on high resolution magnetic resonance (HR-MR) images. Using the SVM a 3D non-linear texture measure which takes into account the anisotropic nature of the trabeculae was extracted and compared with BMD in its diagnostic performance to differentiate post-menopausal patients with and without osteoporotic spine fractures.

Methods and Materials: Axial HR-MR images of the calcaneus were obtained in 76 women (40 postmenopausal women with osteoporotic spine fractures and 36 postmenopausal controls) at 1.5 T. A 3D-GE sequence was used with a slice thickness of 500 µm and in-plane spatial resolution of 195x195 µm². Structure analysis was performed using algorithms based on the anisotropic SVM, which respects the orientation of the trabeculae of the analyzed bone. In addition BMD measurements of the spine, calcaneus and proximal femur using dual energy X-ray absorptiometry (DXA) were obtained in all patients.

Results: Receiver operating characteristics (ROC) analyses were used to determine the diagnostic performance in differentiating both groups. In the comparison with BMD of the spine (AUC = 0.75), BMD of the calcaneus (AUC = 0.71) and BMD of the proximal femur (AUC = 0.84) the best results were found for the 3D SVM (AUC = 0.88).

Conclusion: The results of this study show that the new anisotropic algorithm based on a local 3D SVM which respects the orientation of the trabeculae may improve the diagnostic performance in differentiating postmenopausal women with and without osteoporotic spine fractures.

C-0671

Bone marrow invasion in patients with Hodgkin's disease: Prognostic value of scintigraphic data

S. Kanaev, S. Novikov, M. Gershovich; E. Shelkoplias, St. Petersburg/RU

Purpose: It has been demonstrated that in patients with Hodgkin's disease (HD) bone marrow (BM) scintigraphy (BMS) is significantly more sensitive and accurate than iliac crest biopsy. Prognostic value of scintigraphic data remains undetermined.

Materials and Methods: Since 1992 BMS was performed in 319 primary patients with HD. Whole body BM visualisation started 45-90 min after i/v injection of 8-10 MBq/kg of 99mTc-colloids. Scintigraphic signs of BM invasion (BMI) were classified as follows: localised lesions manifested by 1-2 focal defects, generalised involvement - by multifocal (3 and more) defects or diffusely diminished tracer uptake. BMI was confirmed by additional examinations (biopsy, MR imaging, bone scanning, X-ray). Patients with localised BMI underwent combined modality treatment: 6 cycles of chemotherapy and involved-field irradiation. Patients with generalised BMI received 6-8 cycles of chemotherapy without irradiation.

Results: From 1992 to 1998 BMS was performed in 319 primary patients with HD. BMI by HD was diagnosed in 56 (17.5%) cases: localised - in 39, generalised - in another 17 patients. For all 56 patients with BMI 5 year disease free survival was equal to 27% (15/56). Only 2 of 17 patients with generalised HD survived 5 years without HD: DFS - 11%. 5 year disease-free survival for patients with localised BMI by HD was equal to 33% ($p < 0.05$).

Conclusions: Scintigraphic pattern of BMI by HD has significant prognostic value: for localised BMI 5 year disease free survival it is 33%; for generalised BMI only 11%.

C-0672

Osteoid osteoma: A pictorial review

L.F. Foo, N. Raby, M. Sambrook; Glasgow/UK

Learning Objectives: To present the spectrum of imaging findings of osteoid osteoma.

Background: Osteoid osteoma is a painful benign bone-forming tumour, most frequently affecting children and young adults. Although typically a small lesion, rarely achieving a size greater than 1.5 cm, it has a tendency to incite marked peritumoural local tissue reaction. This may result in a wide spectrum of symptoms and imaging appearances, depending on the site of the lesion.

Imaging Findings: A pictorial review of imaging findings are presented, with an emphasis on the plain radiograph, isotope bone scan, CT and MR imaging appearances.

Conclusion: Osteoid osteomas display a wide spectrum of presentations. Most

lesions have characteristic imaging features. Those in unusual sites often present as diagnostic challenges, with atypical manifestations which may mimic and confuse.

C-0673

Imaging of spinal primary bone tumors in adults

M. Rodallec, L. Rillardon, M. Kalamardes, A. Feydy; Clichy/FR

Learning Objectives: To have an overview on the imaging findings of the most common primary bone tumors of the spine in adults. To be able to recognize the specific imaging features of some of these tumors.

Background: Primary bone tumors of the spine are relatively infrequent lesions compared with metastatic disease, multiple myeloma, and lymphoma. An accurate diagnosis is warranted, as the therapeutic approach differs between these two groups of tumoral lesions. A wide variety of benign bone neoplasms can involve the spine, including hemangioma, osteoid osteoma, osteoblastoma, aneurysmal bone cyst, giant cell tumor, enostosis, and osteochondroma. Common primary non-lymphoproliferative malignant neoplasms of the spine include chordoma and chondrosarcoma. The imaging features of these lesions of the spine are often characteristic and suggestive of the diagnosis.

Procedure Details: In this educational exhibit, we discuss and illustrate the most common benign and malignant primary bone tumors of the spine with radiographs, CT and MR imaging.

Conclusion: This educational exhibit provides a comprehensive review of the imaging findings of primary bone tumors of the spine. Radiologists should be aware of the typical imaging features of the most common of these tumors.

C-0674

Evaluation of the phenotype of an insertional mutation affecting the osteopontin (opt) gene in mice: A comparative pilot study using micro CT, radiography and histology

F.W. Roemer¹, M.L. Sohaskey², A. Mohr³, W.C. Skarnes², H.K. Genant⁴,
¹Augsburg/DE, ²Berkeley, CA/US, ³Kiel/DE, ⁴San Francisco, CA/US

Purpose: The *osteopontin (opt)* gene is a novel gene of undefined biochemical function. The aim of this study was the evaluation of micro CT and radiography for the morphologic assessment of the phenotype of *osteopontin (opt)* mutant mice in comparison to histology.

Material and Methods: 8 mice with insertional mutations in the *opt* gene and 4 wild-type controls (age 20 days) were evaluated radiographically, by micro CT and histologically. For the micro CT evaluation multiplanar reconstructions and 3D surface reconstructions were applied. The three modalities were compared regarding the detectability of bone pathologies.

Results: The *opt* -/- mice exhibited severe growth retardation in comparison to the *opt* +/- and +/+ mice. The radiographic examinations showed osteopenia and fractures with hypertrophic callus formation and pseudarthroses of the forelimbs and ribs. The radiographically detected fractures were verified by micro CT. Additional fractures not seen by radiography were detected by micro CT (radius and ulna n = 2, scapula n = 2, phalanges n = 11 artificial fractures n = 8, ribs n = 23). Histological analysis verified several of the micro CT-detected pathologies. Additionally, a disorganized non-columnar appearance of proliferating chondrocytes within the growth plates was observed histologically, as was reduced ossification in the -/- mice.

Conclusion: Micro CT is able to screen *opt* mutant mice for osseous pathologies and furthermore identify and classify these anomalies. The modality is superior to conventional radiography but is not able to identify cellular pathology or organization as could be shown by histology. However, histology is invasive and more time and material consuming than micro CT.

C-0675

The role of computed tomography examination with multiplanar and three-dimensional reconstructions in evaluation of cervical spine fractures

A. Siemianowicz¹, W. Wawrzynek¹, J. Baron², B. Koczy¹, S. Kasprowska¹,
¹Piekary Slaskie/PL, ²Katowice/PL

Purpose: To evaluate the role of CT examination including multiplanar and 3D reconstructions in the diagnosis of cervical spine fractures, especially in patients with false negative X-ray films and in patients whose X-ray films did not show all existing pathology.

Material and Methods: 71 patients aged 11-75 were admitted to hospital because of trauma, with suspicion of cervical spine injury. In all cases the CT examination was performed in the Radiology Department of Trauma Surgery Hospital in Piekary Slaskie. Helical CT scanner - Hi Speed CT^e GE Medical System was

Scientific and Educational Exhibits

used. The following examination conditions were applied: slice thickness 2 or 3 mm; reconstruction 2 mm; pitch 1.3; with automatic mAs selection. Multiplanar and three-dimensional reconstructions were performed. In some cases X-ray films were previously done in other hospitals.

Results: We often observed multi-level fractures and fractures of different parts of one vertebra. Fractures of C1 vertebra were observed in 10 patients, fractures of C2 in 21 patients, fractures of C3 in 12 patients, fractures of C4 in 15 patients, fractures of C5 in 27 patients, fractures of C6 in 17 patients, fractures of C7 in 8 patients. At levels C3-C7 in 20 cases we observed dislocation of bone parts into the vertebral canal with compression of the spinal cord. In some cases not all fractures were visible on X-ray films.

Conclusions: Application of CT examination technique with multiplanar and 3D reconstructions extends the possibilities of precise radiological diagnosis of cervical spine fractures ensuring the optimal choice of therapeutic method.

C-0676

The role of bone mineral density and risk factors with gonarthritis patients

J. Vasic-Vilic¹, N. Prodanovic¹, O. Jovanovic-Nikolic², S. Radovinovic-Tasic¹, B. Vukomancic¹, ¹Belgrade/YU, ²Podgorica/YU

Purpose: Recent findings showed connection of lower level of bone mineral density (BMD) and osteoarthritis stages. Obesity, general weakness, weakness of leg muscles, genetic factors and hormonal status influence the disease progress. The aim was to determinate BMD and compare them to gonarthritis radiographic stages, in female and to determinate percent of known risk factors.

Methods and Materials: Since October 2002 to April 2003 we carried out measurements, which included 86 women with gonarthritis, with average age of 66 with the 2nd, 3rd and 4th radiographic stages. We determined body mass index (BMI), physical activity. We established the percents of hormonal imbalance and investigated living environment. The BMD was measured on the femur with LumarDEXA2000.

Results: Knee joints radiographs confirmed osteoarthritis of the 2nd stage in 37 female patients (groupA), of the 3rd stage in 43 patients (groupB), and of the 4th stage in 16 (groupC). GroupA: 22 patients had a normal BMD, osteopenia BMD level, with an average Tscore-1.57SD was detected in 14 patients,osteoporosis was found in 1 patient,with an average Tscore-2.55SD. GroupB: 13 patients had a normal BMD, BMD at the osteopenia level, with an average Tscore-1.72SD was found in 22 patients, and osteoporosis was found in 8 patients,with an average Tscore-1.68SD. GroupC: normal BMD was detected in 5 patients,BMD at the level of osteopenia with an average Tscore-1.57SD was detected in 7 patients,while a lower BMD at the osteoporosis level, with average Tscore-2.74 was found in 4 patients. 22(A), 33(B) and 11(C) patients had lower muscles power, 20(A), 24(B), and 9(C) had the high BMI. In 9 (A), 12(B) and 7 patients (C) was detected hormonal imbalance. Planned physical activity was carried out by 7 patients (A), 12(B) and 8(C). 8 patients (A), 14(B) and 12(C) lived in villages. 18 patients (A), 21(B) and 10(C) had the positive genetic.

Conclusion: Research showed strong correlation between more severe radiographic stages of gonarthritis (3rd and 4th) and decreasing of BMD. This conclusion indicates the necessity for BMD measurement with gonarthritis patients. Muscle power, BMI and the physical activity are important for developing osteoarthritis; it is necessary to apply adequate physical therapy.

C-0677

Imaging of calcaneal tumours: Radiologic-pathologic correlation

B. Rodriguez-Vigil, D. Bernabeu, C. Martín Hervas, F. Lopez Barea, E. Fernandez Canabal, N. Gomez León; Madrid/ES

Learning Objectives: To analyse and illustrate a wide spectrum of bone neoplasms involving the calcaneus in infancy and adulthood. To understand the radiologic features on the basis of pathologic correlation.

Background: The incidence of calcaneal tumours is low. Bone tumours involving the calcaneus as the sole site constitute an uncommon finding, with few cases reported. Both benign and malignant neoplasms can be found. Since early diagnosis is crucial for prompt therapy, imaging plays an essential role. Plain radiograph is the primary modality in the diagnostic approach. Computed tomography (CT), magnetic resonance imaging (MRI) and bone scan may also help establish the diagnosis.

Imaging Findings: We retrospectively reviewed the imaging findings of all the bone tumours of the calcaneus from our musculoskeletal pathology database. Fourteen bone tumours affecting the calcaneus were found. Plain X-rays were performed in all the patients, CT in 9 cases, MRI in 8 cases, and bone scan in 4 patients to assess for metastasis. Findings were correlated with pathology (biopsy or surgery) in all the cases. Specific neoplasms addressed include benign

(intraosseous lipoma, chondromyxoid fibroma, benign fibrous histiocytoma, solitary bone cyst, benign schwannoma) and malignant tumours (Ewing's sarcoma, osteogenic sarcoma, malignant hemangioendothelioma, solitary calcaneal metastasis). Imaging and pathologic features are discussed. Diagnostic difficulties, as well as pitfalls and differential diagnoses are emphasised.

Conclusions: Bone tumours of the calcaneus are rare. Since we will show different types of neoplasms affecting the calcaneus, this exhibit will help the radiologist to better understand and recognise them.

High field magnetic resonance imaging of reconstituted articular cartilage: Evaluation of cartilage maturation for determination of optimal transplantation time

M.H. Fuchsjäger, V. Mlynarik, S. Marlovits, M.O. Philipp, S. Trattnig; Vienna/AT

Purpose: To assess growth and maturation in reconstituted articular cartilage in-vitro and to compare it with histology findings.

Materials and Methods: Six specimens, consisting of collagen matrix with autologous chondrocytes transferred on its surface, were examined on a 3 T-whole-body scanner using a micro-imaging gradient system. Specimens were cultivated in standard and simulated conditions. T1-weighted inversion recovery spin-echo and T2-weighted multiple spin-echo images of specimens were acquired with in-phase resolution of 0.27 mm. Diffusion maps were measured using the pulse gradient spin echo experiment. In-vitro cultivation for all specimens started the same day, measurements were obtained after 14, 28, 42, 56 and 70 days. Afterwards cell constructs were analyzed histologically and with molecular biology.

Results: Cultivated specimens demonstrated a slight increase of T1 and T2-relaxation times and apparent diffusion constants, followed by a drop in values after 70 days. Histological evaluation revealed a continuous increase of glycosaminoglycan until day 42. Total number of chondrocytes was constant under simulated conditions and showed a slight drop under standard conditions beginning after day 28. Apoptosis index showed a peak for both types of cultivation at day 56. The primary architecture of collagen membranes gradually dissolved over the study period. Decrease of relaxation times corresponded to degradation of specimens in histology.

Conclusion: MR-imaging of cartilage implants in vitro may help to determine optimal transplantation time.

C-0679

Pitfalls in MR arthrography of shoulder

F. Cravero, M. Barini, A. Puppi, M. Lovisolo, A. Stecco, A. Carriero; Novara/IT

Learning Objectives: The evaluation of MR arthrograms is complicated by several procedural, technical and anatomic pitfalls that can be confused with pathologic abnormalities; our objective is to review, illustrate, classify and eventually find solutions to avoid the most important of these.

Background: Shoulder MR arthrography is mandatory in evaluation of the glenoid labrum, glenoid cartilage, gleno-humeral-ligaments, rotator cuff lesions, and capsular and periosteal lesions that can be found in shoulder instability, traumatic injuries, overhead athletes and also in the evaluation of the postoperative shoulder.

Imaging Findings: Analyzing our electronic archives we grouped these findings into three classes: (1) "iatrogenic" artifacts; (2) technical artifacts and (3) anatomic variants. "Iatrogenic" artifacts include extra-articular injection of contrast media, presence of intra-articular gas and degradation of contrast material solution. The most important technical artifacts are the magic angle effect and the transitional zone that can be mistaken respectively for tendinosis or SLAP lesions. Anatomic variations include the three categories of capsular insertion, the variable morphology of the anterior and posterior parts of glenoid labrum, the sublabral recess, or sulcus; sublabral foramen, or hole; and Buford complex. For each type we have analyzed the main elements of differential diagnosis with similar pathological findings and we have tried to find the technical and methodological solutions.

Conclusion: Knowledge of the typical location and MR appearance of pitfalls aids the radiologist to avoid technical errors and in evaluating MR arthrography images of the shoulder.

C-0681

MR imaging of traumatic elbow injuries with arthrographic, sonographic, clinical and surgical correlation

J.S. Weaver, J.A. Jacobson, M. De Maeseneer, M. Kalume Brigido, Y. Morag, D.A. Jamadar; Ann Arbor, MI/US

Learning Objectives: The learning objectives are to describe the spectrum of MR imaging findings of common traumatic elbow injuries and to correlate these with arthrographic, sonographic, clinical, and surgical findings.

Background: A computerized database was searched to retrieve all elbow MR examinations performed from September 2003 to September 2004 at our institution. Images from MR examinations of the elbow of 43 patients were retrospectively evaluated and characterized. MR imaging findings were compared to arthrographic and sonographic findings where available. Clinical data and operative reports were also reviewed.

Procedure Details: 43 patients were identified (35 male, 8 female; mean age 35 years) with injuries sustained during sporting events, recreational activities, motor vehicle accidents, falls, and occupational over use. Injuries include ulnar collateral ligament tears/sprains, lateral and medial epicondylitis, ulnar neuropathy/edema, common flexor and extensor tears/tendinosis, loose bodies, osteochondral defects, biceps and triceps tears/tendinosis, and ganglion cysts. These injuries will be demonstrated with MR, as well as with MR arthrography and sonography where available. The utility of dynamic sonography in the diagnosis of ulnar collateral ligament pathology will be demonstrated. Pearls and pitfalls, and differential diagnoses will be discussed.

Conclusion: MR imaging can accurately identify the extent and location of elbow abnormalities following traumatic injury. MR arthrography and sonography also play an important role in post-traumatic imaging. Dynamic sonography can aid in the diagnosis of ulnar collateral ligament pathology, while arthrography can provide added sensitivity and specificity in detecting ulnar collateral ligament tears.

C-0682

MR arthrography of the shoulder joint: A pictorial review of technique, anatomy and expected range of pathology

R. Bhat, T.B. Oliver; Dundee/UK

Learning Objectives: To illustrate the technique of MR shoulder arthrography, demonstrating normal anatomy, common pathologies, normal variants and pitfalls.

Background: MR arthrography is the most accurate method of assessing internal derangement of the shoulder. It is minimally invasive. Although most commonly performed in patients with uni or multidirectional instability, it also has a role in evaluating the superior labrum (SLAP tears), intra-articular loose bodies and the rotator cuff. Good technique, knowledge of normal shoulder anatomy and its variations and an understanding of the various capsular, tendinous and labro-ligamentous abnormalities which are often subtle to the untrained eye allow accurate diagnosis and guidance of treatment in patients who are often young, active and have high therapeutic expectations.

Procedure Details: In our institution we perform direct MR arthrography for assessment of a range of shoulder disorders. Up to 20 ml of a gadolinium, iodinated contrast and saline mixture is injected into the shoulder under fluoroscopic guidance; the volume injected depending on the laxity of the capsule. T1 fat saturated sequences in three orthogonal planes are obtained using a 1.5 T MR system. A STIR sequence is performed to evaluate bone marrow oedema and a further T1 fat saturated sequence in abduction and internal rotation (ABER) may be added to evaluate subtle anterior labral tears.

Conclusion: MR arthrography is a very useful technique. A detailed knowledge of the anatomy and familiarity with the common abnormalities is essential for interpretation.

C-0683

MR features of ankle impingement syndromes

H. Aniq, S.A. Babar; Liverpool/UK

Learning Objectives: To illustrate MR features of various impingement syndromes around the ankle joint which can be a cause of chronic ankle pain.

Background: Soft-tissue and osseous impingement of the ankle is increasingly recognized as the cause of chronic ankle pain especially in a younger population. These conditions arise from initial ankle injuries leading to development of abnormal osseous and soft-tissue thickening within the ankle joint. Impingement syndromes have been well described in the anterolateral, anterior, and posterior ankle but recently anteromedial and posteromedial entities have also been described.

Procedure Details: We describe the MR appearances of all the impingement syndromes around the ankle. A brief anatomy of the ankle joint and its various compartments and ligaments is presented initially followed by key points in diagnosis; diagnostic difficulties and various differential possibilities are discussed. Conventional radiography is usually the first imaging technique performed and allows assessment of any potential bone abnormality, particularly in anterior and posterior impingement. CT scanning and isotope bone scanning has been superseded by magnetic resonance imaging (MR). MR can not only identify the relative contribution of both soft tissue and bony abnormalities but it is also quite accurate in assessing the capsular injuries.

Conclusion: Knowledge of the typical MR imaging appearances of various impingement syndromes is useful in determining the cause of chronic ankle pain.

Scientific and Educational Exhibits

C-0684

Acute knee trauma: Sonographic emergency?

B. Diris, O. Bonnefoy, O. Hauger, M. Moinard, F. Diard; *Bordeaux/FR*

Purpose: The purpose of this study was to determine the diagnostic accuracy of high spatial resolution ultrasonography (US) in the detection of lipohemarthrosis of the knee and to evaluate this sign as a criterion of intra-articular fracture.

Materials and Methods: Forty-five patients were prospectively examined for a possible knee fracture with clinical examination, conventional radiography, US and computer tomography (CT) imaging within 96 hours of trauma. Changes in the US appearance of the supra-patellar collection were evaluated without knowledge of the CT results and an intra-articular fracture was suspected if lipohemarthrosis with two or three layers was present.

Results: At CT, 65% of the patients with acute trauma have intra-articular fractures with visualization of a lipohemarthrosis in 96% of cases. At US, 93% of those patients with proven intra-articular fractures have positive results (lipohemarthrosis) with false-positive results in one case and false-negative results in two cases. The sensitivity, specificity, positive predictive value, negative predictive value of US in the diagnosis of lipohemarthrosis was respectively 96%, 100%, 100%, 94% compared with 55%, 100%, 100%, 55% obtained for conventional radiographs. Using lipohemarthrosis as a criterion of fracture, the sensitivity, specificity, positive predictive value and negative predictive value of US for early detection of intra-articular knee fractures were respectively 93%, 93%, 96% and 87%, compared with 85%, 87%, 92%, 76% obtained for conventional radiographs

Conclusion: High resolution US is a reliable and accurate method to evaluate intra-articular fractures of the knee. Lipohemarthrosis is the diagnostic key.

C-0685

Prognostic value of reactive interface in femoral head osteonecrosis on magnetic resonance imaging

I. Sedonja¹, V. Jevtic², M. Milcinski²; ¹Murska Sobota/SI, ²Ljubljana/SI

Purpose: The aim of our study was to assess prognostic value of reactive interface (RI) in femoral head osteonecrosis (FHO) on magnetic resonance imaging (MRI) in early stages of disease.

Patients and Methods: In 46 hips in 40 patients (29 M, 11 F, 20-64 y, mean 41 y) with radiographic stage 1 and 2 of FHO T1-weighted, STIR and fat-suppression T1-weighted images enhanced with gadolinium-DTPA in coronal plane were performed. Width of hypointensive line on T1 W MRI, hyperintensive part of RI on STIR and enhanced part of RI on Gd-enhanced images were measured on mid-coronal slice and expressed in % of femoral head diameter (%fhd). RI were classified into narrow RI - less than mean value of RI in all hips on same sequence and wide RI - mean value or more. 39 conservatively treated hips were evaluated for eventual FH collapse.

Results: In 12/46 hips (26.1%) border line was not seen on mid-coronal slice. Width of RI was different (SE T1 W MRI: 2.3 to 12.5%fhd, mean 4.6, SD 2.05; STIR: 2.2 to 12.5%fhd, mean 4.2, SD 1.75; Gd-enhanced MRI: 2.3 to 4.4%fhd, mean 3.2, SD 0.51). Heads with wide RI on MRI collapsed more frequently and earlier (SE T1 W MRI: no visible RI - 0/10; narrow RI - 2/17 (11.8%) in mean 8.3 months; wide RI - 8/12 (66.7%) in mean 3.4 months; chi square, p < 0.01).

Conclusion: Wide RI on MRI in early phase of FHO is bad prognostic factor for head collapse.

C-0686

Imaging features of tarsal coalition

Y. Roca Vanaclocha¹, J. Narvaez², E. De Lama², L. Mones¹, C. Pozuelo¹, C. Medrano¹, D. Mulattieri¹, A. Sanchez²; ¹Badalona/ES, ²Barcelona/ES

Learning Objectives: The aim of this exhibit is to illustrate the distinguishing features of tarsal coalition and emphasize the importance of the different imaging techniques. We will also discuss the adequate protocols.

Background: Congenital tarsal coalition represents the failure of normal segmentation between two tarsal bones. Coalitions may be osseous, cartilaginous, or fibrous. The usual symptoms, which appear when the abnormal union begins to limit inter-tarsal motion, are foot rigidity and pain, relieved by rest. Clinical diagnosis is sometimes difficult, especially in non-osseous types, which are difficult to detect on radiographs. We performed a retrospective study from records between 1994-2003, and 35 cases were found. Talo-calcaneal coalitions were mostly encountered. Images (radiographs, CT and/or MRI) were interpreted by consensus of two radiologists.

Imaging Findings: Conventional radiographs are essential for screening. They may be normal or show secondary indirect signs such us talar beaking, absent middle facet and C sign. Cross-sectional imaging with CT or MR imaging is indi-

cated to confirm the presence and extent of the coalition. CT clearly demonstrates any osseous coalition and fibrous coalition is characteristically shown as joint space narrowing with irregular cortical margins. MR imaging depicts non-osseous fibrous and cartilaginous coalitions. Bone marrow edema and associated joint and tendon abnormalities can be also visualized.

Conclusion: Congenital tarsal coalition is a frequent cause of foot pain and ankle sprains among young patients. Being a generally overlooked diagnosis, it is important to be familiar with the features on the different techniques, so that early adequate treatment can be considered.

C-0687

Long-term follow-up of total knee replacement: Role of high resolution ultrasound

E. Gallardo¹, R. García-Barredo², J.R. Prieto¹, J. García¹; ¹Santander/ES, ²Liencres/ES

Purpose: To describe the normal sonographic findings in long-term total knee replacement (TKR) and to emphasise the abnormalities that can be depicted in cases of painful prostheses.

Materials and Methods: We reviewed 75 TPK performed before 1993. Time since the surgical procedure ranged from 10 to 15 years (average time = 11.5 years). They were 55 patients, 43 women and 12 men (average age = 76.5 years). The radiological study included anteroposterior and lateral radiographs and a Merchant's view. The sonographic study was performed using a 7-10 MHz linear transducer in the supine position, evaluating: polyethylene thickness, bone-to-metal interface, extensor mechanism, joint effusion and synovial thickening.

Results: Thinning of the polyethylene liner was present in 80% of the cases, more severe in the medial compartment. In 30% of the knees we demonstrated an abnormal increase in the metal-to-bone interface. Synovial thickening was shown in 66% of the cases with characteristic findings of metallosis in 3 of them. Post-surgical patellar tendinitis was detected in all patients and heterotopic ossification in 30% of them.

Conclusion: Sonography is a useful method to evaluate peripheral polyethylene liner, metal-to-bone interface, extensor mechanism and synovial thickening. It is also a valuable technique in detection of late complications of TKR such as: polyethylene wear, aseptic loosening, synovitis and extensor mechanism dysfunction. Sonography can be recommended, especially in pre-operative planning of painful prostheses.

C-0688

Intra-articular fat tissue tumors of the suprapatellar recess: Magnetic resonance imaging with pathological correlation

E. Gallardo¹, J. Figols¹, E. Sanchez¹, R. García-Barredo², R. Landeras¹, M. Fernández¹; ¹Santander/ES, ²Liencres/ES

Learning Objectives: To describe the MR characteristic findings of fat tissue tumors affecting the suprapatellar recess of the knee. To emphasise the clues in the differential diagnosis between true tumors and fatty synovial proliferation.

Background: Lipoma is the most common soft-tissue tumor, accounting for up to one half of all subcutaneous tumors. However, intra-articular lipoma is exceedingly rare with a few reports in the literature. On the other hand, lipoma arborescens is currently recognised as a reactive process secondary to degenerative joint disease and not truly a neoplasm, consisting in the proliferation of fatty tissue in the subsynovial connective tissue of joints, most commonly found in the knee.

Procedure Details: 5 patients with lipoma arborescens affecting the suprapatellar recess of the knee were reported in our unit over a period of 2 years (3 female and 2 male). During the same period, we diagnosed 3 true fatty tumors in a suprapatellar location, 1 lipoma and 2 liposarcomas, all of them pathologically proven. All MR studies were performed in a high field scanner, 1.5 T (Signa GE), using T1- and T2-weighted sequences in three planes, and fat suppression images after gadolinium administration.

Conclusion: MR is an excellent method for the diagnosis of lipoma arborescens and true fatty tumors of the suprapatellar recess with an excellent correlation with the pathological findings. This distinction becomes clinically important because the treatment and surgical approach differs between the two entities.

Scientific and Educational Exhibits

C-0689

Clinical and radiological characteristics of spontaneous osteonecrosis of the knee

E. Pérez, A. Sanchez, J. Narváez, D. Martínez de la Haza, E. Merino, X. Mallol; Barcelona/ES

Purpose: To review the Spontaneous Osteonecrosis of the Knee (SONK) in terms of clinical and radiological characteristics and its MR imaging patterns.

Materials and Methods: A retrospective review was performed on all the patients diagnosed with SONK by MR imaging at our institution between June 1994 and June 2004. Clinical charts, plain radiographs (when available) and MR imaging were evaluated. In MR imaging location, morphology and signal pattern of the necrotic lesion and associated findings (bone marrow oedema, cartilage, articular affection, meniscus rupture or degeneration, synovitis, existence of stress fractures and arthropathy) were analysed.

Results: 84 patients underwent our study (48 women and 36 men), aged 50-86. The clinical diagnosis was of internal meniscopathy in more than 75% of cases and radiographs did not show osteonecrosis in more than 50%. Location was unilateral in all cases except from one, involving the internal femoral condyle in 91% and internal tibial plateau in 9%. In 55 patients (65%) oedema was observed, and in 73% of cases a subcondral well defined lesion, hypointense in all sequences. Evidence of meniscal degeneration or rupture was present in 73% of cases, arthropathy in 80% and stress fractures in 5 cases (6%). Differential diagnosis with other pathologies of the knee, including secondary osteonecrosis is discussed at this point.

Conclusion: SONK is a difficult clinical diagnosis that must be suspected in aging patients with acute knee pain. MR imaging provides a precise diagnosis, when radiographs are normal or not conclusive with a characteristic pattern, which was observed in the majority of our patients.

C-0690

MR imaging in assessing the changes of rheumatoid arthritis of hand

O.V. Mazurenko, Y.S. Babiy, E.A. Garmish; Kiev/UA

Purpose: To investigate diagnostics of rheumatoid arthritis (RA) in hand using MR imaging and to study the role of MR imaging for evaluating of treatment effectiveness by defining disease activity.

Methods: 24 patients who fulfilled 1987 American Rheumatologic Association (ARA) criteria for RA, with disease duration 6-37 months, mainly II degree of disease activity, (age: 19-62 yrs) were examined in this investigation. All patients (1st group) were observed by MR imaging and conventional radiography (CR) underwent clinical and laboratory measurements, 9 patients of them (2nd group) were examined by all methods before and 12 months after administering anti-rheumatic treatment. T1-SE, T1-GE axial and coronal images were obtained before and after contrast enhancement (Omniscan®, Nycomed Imaging AS, Norway). Each hand was divided into 11 regions of interest. The quantification assessment of erosions and subchondral cysts, synovial membrane hypertrophy, joint effusion and tenosynovitis were examined. A total number of 273 regions of interest were investigated.

Results: In the 1st group, 285 MR imaging-erosions and subchondral cysts, 106 CR-erosions, joint effusions in 16 patients, tenosynovitis in 19 patients, synovial membrane hypertrophy of different degrees in all patients were found. In the 2nd group, in the first investigation, 170 MR imaging-erosions, 50 CR-erosions were detected; in the second investigation, MR imaging visualized 175 erosions, 67 erosions were found by CR.

Conclusion: These data demonstrate that all components of synovitis complex in RA of hand can be determined by MR imaging, it is important for diagnosing RA and monitoring the effectiveness of treatment, particularly in early stages.

C-0691

SLAP lesions of the glenoid labrum: An imaging study with anatomical correlation

L. Meziti, J.-L. Drapé, A. Mirat, E. Pessis, C. Duffaut-André, H. Guerini, S. Malan, A. Chevrot; Paris/FR

Purpose: Superior labrum anterior-posterior lesions (SLAP lesions) are well described but their characterisation remains difficult given the presence of numerous anatomical variants of the glenoid labrum. Our purpose is to show the different SLAP lesion types and patterns at CT arthrography and MR-arthrography.

Materials and Methods: Retrospective study on 20 patients aged 20-40 years, including sports players (n = 15). All patients had either a multidetector CT-arthrography (n = 15) or an MR-arthrography (n = 5) for a superior labral lesion. All patients had an arthroscopic surgery with anatomical correlation.

Results: Based on the international arthroscopic classification from Snyder, we identified the following SLAP lesions: Type I (n = 4/20), Type II (n = 12/20), Type III (n = 2/20) and Type IV (n = 2/20). We submit a pictorial checklist, which should help to recognize the different lesion types, differentiate anatomical variants (sublabral recesses) from type II lesions and identify the differential diagnoses such as impingement, sublabral hole or Buford complex.

Conclusion: Unstable types II and IV lesions that need arthroscopic surgery and treatment (fixation) must be recognised at CT or MR-arthrography. CT-arthrography remains our preferred imaging modality.

C-0692

Rehabilitation and radiographic imaging of the joints in the post-electrical injury course

M.D. Mylona, M.T. Karamessini, P. Salonikidis, E. Mentzelopoulou, P.A. Dimopoulos; Patras/GR

Learning Objectives: To illustrate the radiographic findings of the joints in electrically injured patients admitted to our rehabilitation center, days to months after the original injury.

Background: Patients with electrical injuries have problems which are unique and they are subjected to two types of trauma: the insult caused by the acute event and complications which occur mostly because of poor positioning, bulky dressings, intramuscular injections and neurotoxic medications. In this exhibit we will describe and illustrate the radiographic findings of the joints in these patients.

Imaging Findings: The most common radiographic finding was bridging extra-articular heterotopic ossification (HO) with preservation of the underlying joint, developed in the elbow, shoulder, knee, hip, distal femur and fibula. It occurred most frequently about the elbow and it was not related to "entrance and exit" wounds; some patients eventually developed bilateral elbow disease. In some cases of HO spontaneous resolution occurred. In few patients with joint pain and normal X-rays, CT scans and ultrasound were performed and revealed soft tissue structures like blood vessels and nerves near the joint, findings which were attributed to HO of early stage. Another radiographic finding was intra-articular fusion and joint destruction due to associated fractures or necrotic tissues and osteoarticular changes, in joints close to "entrance and exit" wounds. Periarticular osteoporosis was also revealed in many cases.

Conclusion: In most cases, X-rays allow noninvasive diagnosis and follow-up of joint abnormalities in the rehabilitation course of electrically injured patients.

C-0693

Extracorporeal shock waves therapy (ESWT) of calcific tendinitis of the shoulder: Clinical and radiologic evaluation

F. Cravero, D. Rozzati, A. Meni, G. Sessa, A. Stecco, A. Carrieri; Novara/IT

Purpose: We present our experience in the evaluation of the effectiveness of extracorporeal shock waves therapy (ESWT) in patients with symptomatic calcifying tendinitis of the shoulder.

Materials and Methods: Between March 2003 and September 2003, 50 patients (21 men and 29 women) with an average age of 53 years, with painful shoulder calcifying tendinitis, were treated with shock waves using Reflectron (High Medical Technology, Kreuzlinger, Switzerland). All patients received four treatments of 600 shock waves per treatment in two weeks. Two criteria were used in the follow-up examination: subjective pain evaluation and X-ray analysis of calcareous deposits. Clinical follow-up of subjective pain was evaluated six and twelve weeks after the last treatment by comparing with the pre-treatment status. All patients had a radiological follow-up two months after ESWT.

Results: In the evaluation of subjective pain after 6 weeks the results showed that: 19 patients (38%) were pain free, 26 (52%) had improved symptoms and 5 (10%) experienced no change. After 12 weeks 20 patients (40%) were pain free, 26 (52%) had improved symptoms and 4 (8%) experienced no change. Radiological follow-up showed that: 12 patients (24%) were completely free of calcareous deposits, 26 (52%) had notable disintegration and 12 (24%) were unchanged.

Conclusions: ESWT can be considered an additional treatment for patients with calcifying tendinitis of the shoulder.

C-0694

Shoulder MR arthrography: Intra-individual comparison of two dimensional vs. three-dimensional with virtual arthroscopy pulse sequences

S. Nicolazzini, A. Puppi, M. Lovisolo, A. Stecco, P. Fornara, A. Carrieri; Novara/IT

Purpose: Aim of the present work is the demonstration of accuracy and sensitivity of 3D compared to multiplanar 2D multiple acquisition in MR arthrography (MR-art).

Scientific and Educational Exhibits

Methods and Materials: We evaluated 16 patients; after MR-art examination they underwent arthroscopic or surgical treatment (gold standard). MR-art has been conducted with percutaneous anterior palpation-guided access; all patients were evaluated with 3D standard MR-arthrographic sequences (SE T1, GRE T1 FATSAT), and supplemental 3DSpoiledGradientEcho T1 slab positioned in the coronal plane.

Results: The access was successful in 16/16 cases. No complications were recorded. Total scan time of 2D was 19 minutes, while 3D sequences required additional 9 minutes. 3DSPGR allowed up to 1 mm slice thickness, while 2D pulses thickness reduced only to 4 mm, to optimize S/N ratio and acquisition time. 31% patients showed Bankart or SLAP lesion at 2D MR, while 3D revealed 2 more (43.7%) patients with SLAP lesion, all confirmed arthroscopically. 56.2% revealed supraspinatus tendon tear at 2D MR evidenced one more case (62.5%), with small partial tendon tear; in one case we evidenced a medium gleno-humeral ligament (MGHL) was thickened. Affidability and sensitivity of 3D in detecting glenoid labrum tears were 87.5% and 93.7%, while 2D pulse had 81.2% and 62.5%; for tendon tear were 100%-100% vs. 93.7%-90%. Virtual Arthroscopy (VA) was performed in all cases, with 30 min mean workstation time for each patient, resulting able to depict correctly the labial tears, the MGHL and tendon ruptures in all cases.

Conclusion: VA images resulted helping in surgical planning but time-consuming.

C-0695

MR imaging vs. arthroscopy in the evaluation of tibio-talar joint impingement

E. Stavroulis, L. Zugaro, N. Limbucci, A. Barile, V. Calvisi, C. Masciocchi; L'Aquila/IT

Purpose: To assess MR imaging diagnostic accuracy in detecting pathological conditions leading to tibio-talar joint (TTJ) impingement, having arthroscopy as a gold standard.

Methods and Materials: 42 patients (aging 19-37 years) clinically complaining of ankle unsteadiness and swelling entered this study; 30 of 42 patients (71.4%) referred a history of ankle sprain. MR imaging examination was performed with both a 1.5 T whole-body (TSE-T2w and SE-T1w sequences) and a 0.2 T dedicated system (SE-T1w and T2w sequences). In 12 cases i.v. contrast agent was administered followed by SE-T1w sequences with fat saturation pulse. All patients underwent arthroscopy.

Results: MR imaging examination revealed the presence of TTJ synovial impingement in 15 patients (35.7%) and in only 5 of them, the presence of contrast enhancement revealed an acute inflammatory stage; arthroscopy always detected a thickened synovial lining. In 7 patients (16.6%) MR imaging showed the presence of tibio-peroneal tendon injury associated with synovial hypertrophy ("meniscoid syndrome"); in 1 of these cases contrast enhancement was evident. In 17 patients (40.7%) MR imaging documented the presence of a bony impingement due to talus and tibial osteophyte, and it was always possible to define if the osteophyte was intra- or extracapsular; in these cases arthroscopy confirmed MR imaging diagnosis. 3 patients (7.1%) had a negative MR imaging examination, one of them showing a 'meniscoid syndrome' on arthroscopy.

Conclusion: As a result of a good correspondence with arthroscopic findings, we consider MR imaging very accurate in the differential diagnosis of pathological conditions causing TTJ impingement. MR imaging is also able to detect extra-capsular causes of impingement.

C-0696

Emergency MR imaging of knee trauma with normal radiographic findings

M. Galluzzo, V. Buffa, A. Cortese, G. Regine, F. Pallotta, V. Miele, L. Adami; Rome/IT

Purpose: To evaluate the clinical impact and medico-legal significance of MR imaging, in acute knee sprain in patients with normal standard radiographs.

Materials and Methods: 128 patients (78 M, 32 F; age: 15- 59), from January 2003 to August 2004 with clinically suspected injuries were reviewed. All patients underwent plain radiographs (AP and LL views) which were negative, and within 5 days had MR imaging. Sagittal SE T1, STIR T2, coronal GE T2 and axial SE T2 weighted images were obtained, using a low field dedicated MR imaging (Arto-scan, Esaote, Italy)

Results: MR identified 48 bone bruises (36 lateral, 12 medial compartment); 12 MCL tears, 3 LCL tears; 5 ACL and 1 PCL isolated lesions; 2 internal derangements; 10 combined (MCL, ACL, internal meniscal) tears; 4 lateral patellar dislocations; 2 posterolateral corner lesions, 8 muscular lesions and 33 normal findings.

Conclusion: Actually, following acute knee trauma MR imaging is limited by availability, cost and time resources. Many lesions are subtle, and can lead to joint instability and early degenerative disease. Accurate diagnosis with MR imaging

allows appropriate treatment and classification of the lesions. Results are significant, and encourage more frequent use of MR imaging in acute orthopedics trauma. MR imaging is going to have a dramatic impact in assessing acute skeletal trauma.

C-0697

Rheumatoid arthritis (RA): The ABC's of hand-bone erosions imaging and management of disease

F. Priolo, A.P. Mancini, F.M. Martina, G. Savino, A. Magistrelli; Rome/IT

Learning Objectives: The aim of our study is to evaluate the role of MR imaging of the hand in detecting early erosions in patients with RA.

Background: The gold standard for joint damage in rheumatoid arthritis is currently the presence of radiological erosions. There is often a delay of 6 to 12 month before erosions can be confirmed by radiography. This fact is important if we consider that anti-rheumatic drugs are most effective in retarding progression of RA in the early stages of disease.

Procedure Details: 37 Patients affected by RA and with no radiological signs of hand/wrist involvement were studied with MR imaging. Signal intensity of pre-erosive lesions, sharply marginated areas of trabecular loss without a visible cortical break and bone defects with sharp margins with a cortical break were analysed. MR imaging ability to detect synovial hypertrophy and pannus formation before the onset of bony erosions has become more valuable with the advent of anti-rheumatic drugs.

Conclusion: MR imaging can reveal precocious erosions as well as synovitis and tendonitis in RA, giving a detailed picture of joint inflammation and damage. In fact, MR imaging of the wrist (carpal bones, distal radius, distal ulna, metacarpal bases) and of metacarpo-phalangeal joints (metacarpal head and phalangeal base) detects early erosions in RA and sharply marginated areas of trabecular loss without a visible cortical break (bone defect) and bone defects with sharp margins (erosion).

C-0698

Knee joint cartilage lesions treated with stem cells grafting

W. Dzienis, P. Jancewicz, E. Tarasow, J. Skowronski, J. Walecki, B. Kubas, J. Janica; Bialystok/PL

Purpose: The authors present clinical and radiological results of cartilage repair using stem cells grafting technique.

Materials and Methods: The studied group consisted of 30 patients suffering from clinically diagnosed and MR imaging confirmed osteochondritis dissecans or Grade IV degree of chondromalatias according to ICRS (International Cartilage Repair Society) score. The autologic marrow stem cell grafts, previously stimulated with growth factor, were applied under the periosteous interponat. Cancellous bone grafts were used simultaneously in case of large subchondral layer deficiency. An MR imaging examination was performed on 1.5 T Marconi Medical System using T1-w, T2-w, PD-w, T2*-w sequences and fat saturation sequences in sagital, coronal and axial plane, before and after operation.

Results: The clinic and radiological outcomes were estimated after 3 months. According to IKDC (International Knee Documentation Committee) score, 85% good and very good results were present, 15% of results were assessed as satisfactory. Poor results were not detected. Supervisory MR imaging demonstrated a solid coverage of the injured region with chondral tissue and good integration with booth surrounding cartilage and subchondral base layer. In 97% of cases the radiological evaluation provides an active remodeling process of subchondral bone.

Conclusion: In light of the presented results stem cells grafting is found to be an effective method of chondral defect repairs and MR imaging study is the method of choice in the evaluation of the clinical and radiological outcomes.

C-0699

Image findings of ruptured Baker's cyst

M. Park, S. Kwon, J. Ohm, B. Shin, Y. Kim; Daejeon/KR

Purpose: To evaluate the image findings of ruptured Baker's cysts.

Materials and Methods: We retrospectively evaluated the image findings of 16 patients with a ruptured Baker's cyst, nine patients with knee MR imaging, and 7 US. Surgical excision in 10 patients and aspiration in eight was done, respectively. We analyzed the direction of rupture, location of fluid collection, continuity between fluid collection and Baker's cyst, and margin of rupture site.

Results: Baker's cyst ruptured superiorly in 10 cases (63%), inferiorly in three, and posteriorly in three. Fluid was located in subfascial area in seven cases, between semimembranous and medial gastrocnemius tendon in six, subcutane-

Scientific and Educational Exhibits

ous in one, gastrocnemius muscle in one. One case showed fluid collection in both subfascial and subsoleus area. In four of 16 cases, fluid collection was far extended to mid-calf. The margin of rupture site was irregular and acute angle in 14 cases (88%). Septations in the cyst were noted in eight cases (50%). The ruptured fluid collection was continuous with main cyst except in three cases.

Conclusion: Most rupture of Baker's cyst occurred downward. The margin of ruptured Baker's cyst was irregular and septated, and showed acute angle.

C-0700

Comparing diagnostic efficacy of sonography and scintigraphy in the diagnosis of rheumatoid arthritis

V.D. Zavadovskaja, M.A. Zorkaltsev, O.Y. Kilina, N.L. Klimentenko, T.B. Perova, A.V. Khodashinskaja, O. Tjuleneva; Tomsk/RU

Purpose: To compare efficacy of scintigraphy with 99mTc-nanocis-labeled leukocytes (LC) and ultrasonography in rheumatoid arthritis (RA) diagnosis.

Material and Methods: We studied 21 RA patients (11 males and 10 females aged 42 ± 9 years). Clinical signs of knee joint injury were seen in 14 patients. LC ("Searle Scintiscan", 370 MBq) was performed 1 hour after indicator administration. Ultrasonography was performed using "Aloka 1700", "Siemens -450", transducers of 7.5-10 MHz.

Results: Local accumulation of a radiopharmaceutical was revealed in 32 knee joints (high accumulation - in 5, mean in 17 and low in 10 joints). Ultrasonography revealed synovitis signs in 15 joints. Accumulation of a radiopharmaceutical in the joints together with synovitis signs on ultrasound were seen in 14 joints (in 4 with high radiopharmaceutical accumulation, in 8 with mean and in 2 with low accumulation). Accumulation of a radiopharmaceutical in the joints without synovitis signs on ultrasound were seen in 18 joints: high accumulation was in 1 joint, mean one in 9 joints and low one in 4 joints. Both scintigraphic and ultrasound inflammation signs were absent in 9 joints. Synovitis ultrasound image did not show accumulation of a radiopharmaceutical in one joint. Radionuclide study showed 32 true-positive results, 9 true-negative ones and 1 false-negative result. Sonography showed 15 true-positive, 9 true-negative and 18 false-negative results.

Conclusion: Sensitivity of LC to reveal synovitis is higher (97%) than of sonography sensitivity (45%). High accumulation of a radiopharmaceutical is associated with presence of fluid and proliferation in 60% of knee joints.

C-0701

Radiological presentation of avulsion injuries of the shoulder, knee, ankle and foot

B. Dobriserevic, D.M. Masulovic, D. Saranovic, A. Ivanovic, A. Djuric; Belgrade/YU

Learning Objectives/Background: Avulsion injuries are common in sportsmen, especially in adolescents exerting the increased physical effort. Different radiological manifestations of both acute and chronic avulsion injuries of the shoulder, knee, ankle and foot enable their differentiation and differential diagnostics in relation to more serious and prognostically more severe diseases, such as neoplasm and infections.

Imaging Findings: Radiographically, the acute injuries, commonly resulting from the extreme, unbalanced, frequently eccentric muscle contractions, may be associated with the avulsion of bone fragments. Subacute injuries have more aggressive characteristics with the areas of mixed lysis and sclerosis. Chronic injuries, which are the result of repeated microtraumas or repeated over-exercise, as well as old inactive injuries, may be manifested as bulges and various growths on bones, and accordingly, may represent a great diagnostic dilemma being confused with neoplastic and infectious process. CT imaging is very beneficial in cases of dubious radiographical findings and injuries that were not radiologically treated in the acute phase. MR imaging is most valuable for the evaluation of muscle, tendon and ligament injuries.

Conclusion: Recognition of characteristics of imaging demonstration and specific pathologic manifestation as well as knowledge of osteomuscular anatomy is very helpful in frequently vague pathological bone conditions. In this study, involving 28 treated patients, the authors have made an attempt to clearly specify radiological criteria for differentiation of mechanical avulsion injuries of the shoulder, knee, ankle and foot from those lesions with similar radiological manifestation, but of more malignant nature.

C-0702

Diagnostic value of ultrasonography in ruptures of the posterior cruciate ligament of the knee

B. Dobriserevic, D.M. Masulovic, D. Saranovic, A. Ivanovic, A. Djuric; Belgrade/YU

Purpose: Based on our practical experience, we have made an attempt, by presenting ultrasonographic findings of the acute ruptures compared with the findings of the same region within physiological limits, to define the place and estimate the value of ultrasound diagnostics in the injuries of the posterior cruciate ligament (PCL) of the knee.

Material and Methods: Ultrasound examination was performed in 10 asymptomatic patients, who were the controls, and 27 patients clinically suspected of acute injury of the PCL of the knee. 21 of 27 patients were verified by MR imaging or MR imaging and clinical examination. Out of these 21 subjects, 8 had normal MR imaging and clinical results, while 13 demonstrated rupture of the PCL verified by MR imaging or surgery, or MR imaging and clinical examination.

Results: Normal ultrasound of the PCL was homogenous and hypoechoogenic, with a well-defined posterior margin. Rupture of the PCL of the knee was manifested as heterogeneous and hypoechoogenic in 10 of 15 patients, with indistinct posterior margin in 9. Ruptured PCLs of the knee were considerably thickened (12 to 20 mm) in relation to normal findings, when compared with the controls (3.7 - 6.2 mm).

Conclusion: The acute rupture of the PCL of the knee, over 10 mm thick, is manifested by the loss of sharpness of the posterior margin and its ultrasonogram is heterogeneous and hypoechoogenic. Ultrasonography may be valuable in patients suspected of the injury of the PCL of the knee.

C-0703

MR imaging of hip pain: Prevalence and mimickers of radiographically occult hip fractures

Y.Y. Ho; Singapore/SG

Learning Objectives: To evaluate the prevalence of radiographically occult hip fractures. To illustrate the MR imaging appearance of some of their mimickers.

Background: A 'hip fracture' is defined as fracture of the femoral neck region. 55 MR imaging studies were performed in 54 consecutive patients with hip pain and a negative radiograph. There was either a history of recent trauma or the study was requested because the patient's medical history suggested the possibility of an unexpected hip fracture.

Imaging Findings: 25% (14/55) studies showed an acute fracture. Of these, 8 had a hip fracture and 6 had fractures in the ischium, pubis and/or sacrum. 16% (9/55) studies had muscle strain or grade 1 muscle tear without a fracture. 15% (8/55) had other bone disease. 15% (8/55) had unrelated soft tissue disease. 31% (17/55) studies showed no cause for hip pain. In our series, the following mimickers were encountered: 5 avascular necrosis, 1 acute myeloid leukaemia, 1 lymphoma, 1 osteoarthritis, 1 trochanteric bursitis, 1 pyomyositis, 3 paralabral cyst, 1 transient osteoporosis of the hip, 1 injection site edema in the gluteal muscles, 1 non-specific hip effusion.

Conclusion: Not everyone with hip pain has a hip fracture. Apart from diagnosing subtle fractures, MR imaging is also useful to demonstrate other bone or soft tissue conditions which cause hip pain. Because of the locations of this wide range of mimickers, an imaging protocol, which extends from the pubic symphysis to the sacrum, is recommended.

C-0704

Evaluation of acromioclavicular joint with MR imaging

P. Calvillo Batllés, M. Graells Ferrer, M. Vega Martínez, F. Delgado Cordón, J. Ballestín Vicente, L. Martí-Bonmatí; Valencia/ES

Learning Objectives: To illustrate the anatomy, morphological variants, and pathology of the acromioclavicular (AC) joint. To quantify the prevalence of these entities in a large number of MR imaging studies of the shoulder.

Background: The AC joint disorders are a common finding on the MR imagings of the shoulder. We reviewed retrospectively the radiological reports of the MR imagings of the shoulder performed at our institution from April 2001 to September 2003 (n = 730). We selected the images with non-degenerative pathology in the AC joint and we assessed the following imaging aspects: 1) morphology and signal intensity of bone marrow 2) joint margins, joint space, capsular distension and fluid joint 3) ligaments and subacromial bursa. The images were obtained using a 1.5 T MR system, in oblique coronal, oblique sagittal and axial planes.

Imaging Findings: From the 730 MR imagings we excluded 15 patients with a history of AC surgery. We found osteoarthritis in 514 shoulders (72%). The other

Scientific and Educational Exhibits

cases (n = 28) were grouped, according to clinical criteria and imaging findings, in the following entities: 4 os acromiale, 5 AC dislocations, 4 posttraumatic or stress-induced distal clavicle osteolysis, 2 resorption of distal clavicle by hyperparathyroidism, 4 non-specific changes of bone marrow, 7 isolated subacromial bursitis and 2 septic arthritis. In 178 shoulders (25%) the acromion morphology corresponded to II and III types.

Conclusion: The radiologist must be conscious of the high prevalence of degenerative changes keeping in mind the other imaging patterns of AC pathology.

C-0705

The ultrasound and MR imaging appearances of the hand and wrist from a busy rheumatology practice: A pictorial review

J. Berry¹, Svasti-salee², K. Satchithananda¹, J.C. Wilkins¹, J. Totman¹, L. Pollard¹, E. Choy¹, D.A. Elias¹; ¹Camberwell/UK, ²London/UK

Learning Objectives: To illustrate the use of grey scale, colour Doppler with spectral trace analysis and the use of microbubble contrast agents to optimally image all the early and late changes of RA and also to show the pitfalls of the technique. To demonstrate how MR imaging and dynamic enhanced MR imaging can be used to both image and objectively monitor disease.

Background: Rheumatoid arthritis (RA) is a common autoimmune disease. It involves a sequence of antibody-mediated events leading from hyperaemia to synovitis and finally cartilage and bone destruction. Imaging is vital in diagnosing the changes early in the disease but also in monitoring response to treatment options available.

Procedure Details: The superficial anatomy of the hand and wrist makes ultrasound of this region ideal. Ultrasound imaging: grey scale images, colour Doppler imaging with spectral wave analysis and microbubble contrast enhanced ultrasound imaging allows all stages of RA including joint effusion, synovitis, tenosynovitis, tendon rupture, cortical abnormalities and erosions to be visualised. MR imaging allows excellent multiplanar imaging of the soft tissue changes (tendons, ligaments and synovium) in the small joints of the hand and wrist. MR imaging with dynamic contrast enhancement also helps to objectively assess hyperaemia and synovitis. MR imaging has the added advantage of imaging not only the osteochondral surface but also the important underlying bone marrow changes.

Conclusion: This exhibit will show all the changes that are seen in the hand and wrist in RA using all the newer ultrasound and MR imaging techniques available today.

C-0706

Clinically significant cases of wrist pathology: MR appearance. Correlation with surgical findings

M. Tzalonikou, A. Foteinos, Z. Athanasopoulou, C. Iliadis, G. Mpouchlis, K. Stringaris; Athens/GR

Purpose: The wrist joint is of complex anatomy. Imaging studies, MR imaging especially, are a necessary supplement in cases of suspected wrist pathology. The aim of this presentation is to review the clinically most significant pathologic entities that involve the wrist.

Materials and Methods: During the past four years 114 patients had MR imaging examinations of the wrist, 68 of whom had pathologic findings that required surgery. All MR imaging examinations were performed on a 1.5 T MR imaging Unit. Dedicated coils were used for imaging; micro-coils (43 mm in diam.) were additionally used in selected pathology. IV Gd was also administered in selected cases. The examinations were retrospectively reviewed by two board certified radiologists to reach a consensus reading. In the cases of surgery, correlation with the surgical findings was made.

Results: The MR imaging findings in cases of pathology of the triangular fibrocartilage and the scapholunate ligament, osteonecrosis of the scaphoid or the lunate bone (Kienbock's disease), instability syndromes, carpal tunnel syndrome, tendon abnormalities, arthritides of different etiologies and bone or soft-tissue tumors in the wrist are described. A case of osteomyelitis of the distal radius and of adjacent soft tissues is also presented. Surgical findings, in cases where surgery was done, are presented and compared to the imaging ones.

Conclusion: MR imaging proves to be a particularly useful means of non-invasive imaging of the wrist that provides important information regarding clinically significant pathology of the wrist.

C-0707

Shoulder MR arthrography: Evaluation of anterior access by palpatory guide

M. Barini, A. Stecco, P. Oronzo, T. Meloni, P. Fornara, A. Carrieri; Novara/IT

Purpose: To evaluate the efficacy and technical aspects of anterior palpatory access in shoulder MR arthrography.

Methods and Materials: 605 shoulders were examined in 11 months; in 242 cases we used intra-articular injection of Gadolinium because of instability, to detect partial lesions of the rotator cuff or to follow-up after surgical repair. Gadolinium injection was performed directly in the MR scan room, identifying an anterior "soft point" access, that corresponded to the anatomical space between external coracoid and medial aspect of the humeral head.

Results: Gadolinium injection was correctly performed in 219 patients (90.5%), while in 23 patients (9.5%) was extracapsular and in 1 patient (0.004%) we had a haematoma in the injection site. Average time to execution is about 3 minutes. All patients, except one, had pain resolution after 20 minutes from injection. We found 66 cases of glenoid labrum tears (30.1%), 89 partial lesions of the rotator cuff (40.6%) and 64 cases were normal (29.2).

Conclusions: We think that MR arthrography by palpatory guide is perfectly feasible and can be rapidly executed, with few periprocedural complications.

C-0708

Ossicle of the knee menisci: MR findings

S. Ortori¹, V. Zampa¹, F. Odoguardi¹, E. Batini¹, E. Ceretti², C. Bartolozzi¹; ¹Pisa/IT, ²Forte dei Marmi/IT

Learning Objectives: To report imaging findings of meniscal ossicle (MO).

Background: MO is an ossification area located inside the menisci usually found in young men. It represents a rare cause of knee pain and its origin is controversial. Commonly it is solitary, small (about 7-10 mm) and located in the posterior horn of the medial meniscus, although it can be placed in the anterior and posterior horn of both menisci. MO is defined as cortical bone containing fatty bone marrow surrounded by hyaline cartilage. Surgical excision is suggested in symptomatic patients.

Imaging Findings: Radiographically MO is an oblong or triangular formation with a rim of cortex and internal trabeculation projecting within the joint space. Spiral CT may be useful especially when two-dimensional reconstructions are performed and it appears as a trabecular bone fragment surrounded by a rim of cortex inside the menisci. MR images show the MO as an intra-meniscal lesion; it is a well-margined structure with a low signal intensity rim in all sequences. The internal part of the ossicle demonstrates the signal intensity of normal fatty bone marrow, high signal intensity on T1 WI that decreases on T2 WI associated with low signal on T2 WI with fat saturation.

Conclusions: MR imaging demonstrates the intra-meniscal location of the MO and allows one to differentiate it from intra-articular loose bodies, ossified osteochondral lesion, bone avulsion and chondrocalcinosis localised on the contrary outside the menisci, to permit an appropriate therapy.

C-0709

Juxta-articular bone marrow edema: Pattern approach on MR imaging

S. Takao, M. Uetani, T. Yamaguchi, Y. Kawahara; Nagasaki/JP

Learning Objectives: To describe various patterns of juxta-articular bone marrow edema on MR imaging. To discuss the differential diagnosis and its clinical significance based on these patterns.

Background: Bone marrow edema (BME) is demonstrated as an ill-defined area of hyperintensity on STIR and hypointensity on T1-weighted images without bone destruction. The lesion usually shows an enhancement effect after administration of Gd-DTPA. We present illustrative cases and discuss the differential diagnosis and clinical significance of juxta-articular BME on MR imaging.

Imaging Findings: The distribution patterns of juxta-articular BME were classified into following three types; type I - subchondral BME in only one side of the joint (e.g. osteochondral fracture, osteochondritis dissecans, subchondral insufficiency fracture, transient osteoporosis), type II - subchondral BME in both sides of the joint (e.g. various inflammatory or degenerative arthritis, bone bruise), type III - non-subchondral BME (e.g. avascular necrosis with collapse, stress fracture, juxta-articular bone tumors).

Conclusion: Juxta-articular BME can be associated with various bone and joint disorders and its distribution patterns could be a useful tool for differential diagnoses.

Scientific and Educational Exhibits

C-0710

Ultrasonography of ankle joint and foot in early diagnosis of rheumatoid arthritis

I. German, I. Dolgova, H. Andriyanicheva, A. Gordeev, A.V. Zubarev; Moscow/RU

Purpose: To compare the diagnostic utility of ultrasound in the diagnosis of early stages of rheumatoid arthritis (RA) of the ankle and foot with MR imaging.

Materials and Methods: 45 patients ages 20 to 55 years (20 men, 25 women) with suspected diagnosis of RA were investigated. All diagnosis were established on the basis of the clinical and laboratory data. All patients underwent US examination with Power Doppler. The structure and thickness of the tendons and ligaments of the ankle and foot joints were studied. US diagnoses were compared with MR imaging.

Results: In 80%, the presence of tenosynovitis of fibularis muscles and flexor muscles was revealed. Narrowing of the development of regional bone erosions were revealed in 60%. In 40% were marked early erosion changes of articulate surface in proximalis interphalanges, calcaneo-phalangeal joints. Sensitivity of the US method in comparison with MR imaging -97%, specificity -88% in detection of RA of ankle joint and foot. Vascularisation degree of the periarticular region correlated in 100% of cases with the laboratory data of the activity of RA.

Conclusion: US allows one to diagnose rheumatoid arthritis of an ankle joint and foot at early stages of the diseases. US may be useful as an additional modality for evaluation of the activity of rheumatoid arthritis.

Quantitative assessment of diffusion in myxoid and non-myxoid soft tissue tumors by line scan diffusion-weighted imaging

M. Maeda, K. Takeda; Tsu/JP

Purpose: Diffusion-weighted imaging (DWI) may be potentially useful to characterize soft tissue tumors. Myxoid matrix is widely observed in various soft tissue tumors either in benign or malignant tumors. We hypothesize that myxoid matrix increases diffusion of soft tissue tumors. Our purpose was to evaluate apparent diffusion coefficient (ADC) of soft tissue tumors and compare ADC between myxoid and non-myxoid type tumors by using line scan DWI (LSDWI).

Methods and Materials: We prospectively studied 43 patients with pathologically proven various soft tissue tumors. The tumors were divided into two groups according to the presence or absence of myxoid. The one group consisted of myxoid-type soft tissue tumors (e.g. myxoid MFH) ($n = 23$), and the other group consisted of non-myxoid type soft tissue tumors (e.g. lymphoma) ($n = 21$). Forty-three patients were histologically divided into 26 with malignant soft tissue tumors and 18 with benign soft tissue tumors. The LSDWI was performed using b-factors of 5 and 1000 s/mm^2 . The ADC was measured for the solid appearing portions of tumors. ADC values were compared between myxoid and non-myxoid, and between benign and malignant tumors.

Results: The ADC (mean \pm S.D.) was $1.92 \pm 0.41 \times 10^{-3} \text{ mm}^2/\text{s}$ in myxoid type and $0.97 \pm 0.33 \times 10^{-3} \text{ mm}^2/\text{s}$ in non-myxoid type ($p < 0.001$). The ADC was $1.45 \pm 0.59 \times 10^{-3} \text{ mm}^2/\text{s}$ in malignant tumors and $1.50 \pm 0.64 \times 10^{-3} \text{ mm}^2/\text{s}$ in benign tumors (no significant difference).

Conclusion: Myxoid matrix significantly increases ADC of soft tissue tumors regardless of benign or malignant tumors.

C-0713

High-resolution US to evaluate post-surgical peripheral nerve lesions

M. Aguilar, V. Gomez-Dermit, R. Landeras, P. Ruiz-Hernandez, P. Zubieta, M.A. Fernandez-Echevarria; Santander/ES

Purpose: To assess the usefulness of HRUS to evaluate and localize post-operative lesions in peripheral nerves.

Materials and Methods: US were performed using a broadband linear transducer of 5.5-12 MHz. We examined 22 patients with post-operative peripheral nerve lesions confirmed by clinical examinations and electro-diagnostic tests (11 lesions after direct nerve surgery and 11 after orthopaedic surgery, usually fracture repair or focal lesions excision). Sonographic findings were correlated with electromyography examinations and surgical results.

Results: US visualized the injured nerve in 17 patients and failed to direct detection in 3 patients: 2 cases of accessory nerve lesions (in these patients atrophy of the trapezius muscle was present) and 1 patient with axillary nerve lesion (detecting deltoid atrophy). US depicted 4 cases of stump neuroma, 9 entrapment nerve cases caused by hypertrophied scar, 4 cases of nerve oedema with thickened nerve and abnormal fascicular pattern and 2 cases of nerve compression due to oedema or haematoma in the surrounding tissues.

Conclusion: HRUS can determine localization, extent and post-operative nerve damage; evaluate the continuity of the nerve in most patients, depicts a loss of the fascicular nerve structure and allows the evaluation of surrounding structures. US is a complementary tool to electro-diagnosis and the clinical findings and may be helpful to decide if surgical treatment is needed. In advanced cases atrophy is shown in denervated muscles. Finally sonography can be useful to follow-up the lesion when conservative treatment is the choice.

C-0714

Imaging of musculoskeletal fibromatosis

M. Bernathova, H. Gruber, G. Bodner, M. Schocke; Innsbruck/AT

Learning Objectives: To define the characteristic appearance of musculoskeletal fibromatosis and to propose a proper diagnostic work-up for this condition.

Background: Fibromatosis of the musculoskeletal system is a broad group of diseases of benign fibrous tissue proliferation with semi-malignant behaviour and potential for local recurrence after surgical resection. The group is divided into the subgroups of superficial fascial fibromatosis and deep musculo-aponeurotic fibromatosis. Whereas deep fibromatosis behaves locally aggressive, superficial fibromatosis typically remains small and less likely to recur despite essentially identical morphology. MR imaging is usually the modality of choice for evaluation

Scientific and Educational Exhibits

of these soft-tissue lesions. However, the specific diagnosis can be made with high resolution sonography as well.

Procedure Details: We retrospectively evaluated MR imaging and sonography images of 57 patients (35 patients with Morbus Ledderhose, 14 patients with Morbus Dupuytren, 1 patient with Morbus Peyronie and 7 patients with abdominal and extra-abdominal fibromatosis) from both subgroups. The definitive diagnosis was made by biopsy, in some patients by long term follow-up.

Conclusion: We could find some new characteristic sonographic features, which allow one to make a specific diagnosis.

C-0715

Radiographic features of heterotopic ossification: A pictorial essay

M.T. Karamessini, M.D. Mylona, P. Salonikidis, I. Vlahomitros, P.A. Dimopoulos; Patras/GR

Learning Objectives: We present a comprehensive review of the radiographic features of Heterotopic Ossification (HO) of patients in our rehabilitation center. **Background:** Heterotopic ossification is the abnormal formation of true bone within extraskeletal soft tissues and represents one of the most common conditions seen in long-term immobilized patients. Forty-five patients with HO were retrospectively studied during a 1-year period. The final diagnoses following admission were: Closed head injuries, spinal cord injury, stroke, orthopaedic injuries, brain tumors, electrocution, bacteraemia, subarachnoid haemorrhage, encephalitis and tuberculous arthritis. Plain radiography was the first imaging modality performed at request and imaging findings are illustrated and discussed.

Imaging Findings: A peripheral zone of early mineralization became apparent 7-10 days after the onset of symptoms and was followed by a mature mass of ossification. The hip was one of the most common sites of HO in patients with traumatic brain injury or spinal cord injury. The next most common sites of involvement in patients with traumatic brain injury were the shoulders and elbows, with the knees rarely affected. In contrast, knees were frequently involved in patients with spinal cord pathology. Other sites of HO occurrence are illustrated. Further investigation using other imaging modalities was not necessary for the diagnosis in the majority of the patients while, where resection of HO was needed computed tomography was performed. Differential diagnosis included the presence of haematoma, joint sepsis, osteomyelitis, local trauma, osteoblastic neoplasms and cellulitis.

Conclusion: HO seen in long-term immobilized patients can be diagnosed and followed-up using plain radiography.

C-0717

MR imaging of overuse tendon conditions

I. Kalaitzoglou, P. Papadopoulou, A.S. Dimitriadis; Thessaloniki/GR

Learning Objectives: To illustrate the MR imaging features, which help in the differential diagnosis of overuse tendon conditions.

Background: The classification and nomenclature of tendinopathies is an area of confusion in the literature. The most recent pathologic classification divides them into four categories: tendinosis, partial rupture or tendinitis, paratenonitis and paratenonitis with tendinosis. Over 3000 joint examinations were performed in two MR units from January to July 2004. Evidence of tendinopathy was present in approximately 250 cases. We selected and present some of the most characteristic ones.

Procedure Details: MR units used ranged from 1.0 to 1.5 Tesla and the examination protocols included T1 W and T2 W fat sat or STIR images in three orthogonal planes, while contrast enhancement was reserved for selected cases only. Dedicated extremity coils, which allow one to utilize a small FOV and thin slices, were used. We illustrate and discuss the imaging findings leading to diagnosis of various tendinopathies. We also present some of the commonest artifacts, which can lead to diagnostic pitfalls.

Conclusion: MR imaging is a very powerful tool in evaluating tendinopathy. Tendon abnormalities are rather easily identified but the distinction between various pathologies can be more challenging since some of them may often co-exist.

C-0718

MR imaging, ultrasonography and color Doppler in the assessment of palpable nodularities of the abdominal wall with post-partum onset

F. Prefumo¹, L. Derchi¹, N. Gandofo², L. Dogliotti², A. Maritano², M. Bazzocchi², L. Bacicalupo¹, G. Serafini²; ¹Genoa/IT, ²Pietra Ligure/IT

Purpose: To define the role of ultrasonography (USG) and magnetic resonance imaging (MRI) in the assessment of palpable nodularities with post-partum onset.

Materials and Methods: A series of 17 palpable lesion of the anterior abdominal wall with onset during the 12 months after delivery (12 vaginal, 5 caesarean) were excised. The pathological diagnoses were desmoid tumour in 7 cases, endometriosis in 7, suture granuloma in 2 and Merkel carcinoma in one. Before surgery, all cases were investigated by USG and 12 also underwent MRI.

Results: In the 7 desmoid tumours, USG showed solid nodules, less echogenic than adjacent fibromuscular structures, with margins clearly identified on a transverse plane, but irregular along the longitudinal plane, highly vascular at color Doppler. MRI documented homogeneous hypointense signals in all sequences due to the presence of fibrous tissue. In the 7 cases of endometriosis, USG revealed a dyshomogeneous structure with fluid areas and variable vascularity; MRI demonstrated the presence of haemoglobin degradation products. The 2 granulomas presented as dyshomogeneous and poorly vascularized hypoechoic nodules, showing small hyperechogenic spots internally. In the single case of Merkel carcinoma, USG showed its subcutaneous localisation, excluding any relationship with the muscles.

Conclusion: During the post-partum period, the USG finding of a solid homogeneous vascular lesion in the context of the muscle fibres of the abdominal wall, is suggestive of a desmoid tumour. Dyshomogeneous lesions with fluid areas and variably hypo- or hyper-vascular can suggest endometriosis on USG. MRI allows the identification of haemoglobin degradation products within these lesions.

C-0719

High resolution ultrasound of the leg

R. Podesta¹, F. Zuccarino¹, A. Picotti², G. Succio¹, S. Bianchi³, C. Martinoli¹; ¹Genoa/IT, ²Siena/IT, ³Geneva/CH

Learning Objectives: To provide an overview of the US aspects of diseases of the leg. To correlate them with clinical, radiographic and MR imaging findings. To emphasize the role of US in the management of these lesions to further delineate the nature and extent of the process.

Background: A wide spectrum of diseases in the soft-tissues of the leg are amenable to US examination.

Imaging Findings: This computer presentation will use schematic drawings, static US images and real-time video clips to illustrate the US appearance of normal leg anatomy and the spectrum of pathologic conditions for which US examination is indicated. Correlation of US findings with the results from other imaging modalities and open surgery will be provided in selected cases. US is able to diagnose several abnormalities affecting muscles (tennis leg, muscle hernias, compartment syndromes), fascial planes (shin splints), nerves (superficial peroneal neuropathy, sural neuropathy) and vessels (gemellary vein thrombosis, phlebitis of calf veins) of the leg. Dynamic US study is ideal to distinguish between partial and complete muscle disinsertions and to assess muscle hernias. In leg neuropathies, US provides useful information on level of compression, nature of constricting findings and continuity of the nerve.

Conclusion: US is able to identify and characterize a variety of diseases in the soft-tissues of the leg. Key advantages of this technique include cost-effectiveness, availability and ability to perform a dynamic examination.

C-0720

Abnormal US features of skeletal muscles of extremities: Correlation with MR images

S. Koh; Anyang/KR

Learning Objectives: To list various causes of abnormalities of skeletal muscles. To become familiar with US features of normal and abnormal skeletal muscles. To know advantages and limitations of US in the evaluation of skeletal muscles of the extremities

Background: In musculoskeletal US, confrontations with skeletal muscles are inevitable. US has many advantages as a first line modality in evaluation of skeletal muscles of extremities. The purpose of this exhibit is to become familiar with abnormal US features of skeletal muscles and to know the advantages and limitations of US in evaluation of skeletal muscles that lead to correct diagnosis, prompt and proper management, and the appropriate next step for further evaluation. We illustrate various US features abnormalities of skeletal muscles with MR correlation.

Scientific and Educational Exhibits

Imaging Findings: Complete and partial muscle tears, intramuscular hematoma, intramuscular pseudoaneurysm, pyomyositis, intramuscular abscess, myositis ossificans before and after ossification, rhabdomyolysis, polymyositis, disuse atrophy and tumors were all well demonstrated on US. US provided images of abnormalities of skeletal muscle of extremities with higher resolution than MR, but MR demonstrated adjacent bone lesions better.

Conclusion: In evaluation of skeletal muscle, US could be a useful imaging tool as a first line modality.

C-0721

Injury of the distal tibiofibular syndesmosis: Assessment with contrast-enhanced 3D-FSPGR MR imaging

Y.-M. Huh, S. Kim, J.-S. Suh, H.-T. Song, J.-W. Lee; Seoul/KR

Purpose: To determine the effectiveness of contrast enhanced (CE), fat suppressed, 3D-FSPGR MR imaging in the diagnosis of the tibiofibular ligament injury of the ankle, comparing to routine ankle MR imaging.

Materials and Methods: CE 3D-FSPGR and routine MR images were reviewed in 18 ankles with arthroscopically proven tibiofibular ligament injury and in 20 control subjects with diagnoses other than the tibiofibular ligament injury. Two sets of images were reviewed in random order: 1) CE 3D-FSPGR MR images (the CE set), 2) the routine MR images (the routine set). When the CE set revealed nodular synovial enhancement on the tibiofibular ligament and the routine set showed either ligament discontinuity or a wavy ligament or non-visualization of the ligament, the injury was regarded as a ligament disruption, respectively. Additionally 3 cadaveric dissections and histology, and 3 cadaveric transections were performed and correlated with MR image to ascertain the histology and anatomy of enhancing structure of syndesmosis.

Results: The CE set had an accuracy of 82% (31/38), sensitivity of 100% (18/18), and specificity of 65% (13/20) for the assessment of the tibiofibular ligament injury; whereas the routine set had an accuracy of 84% (32/38), sensitivity of 83% (15/18), and specificity of 85% (17/20). The CE set finding was well correlated with arthroscopic finding and cadaveric histology study suggesting syndesmotic synovial impingement.

Conclusion: CE 3D-FSPGR MR imaging of the ankle is more sensitive and objective, but less specific in assessing the distal tibiofibular syndesmosis injury of the ankle, comparing to routine MR imaging.

C-0722

Bright soft tissue masses of the extremities on MR imaging: The spectrum of diseases

J. Koo, S. Hong, J.-Y. Choi, I. Lee, J. Lee, Y. Koh, J.-A. Choi, H. Kang; Seoul/KR

Learning Objectives: To familiarize radiologists with bright soft tissue masses of the extremities on MR imaging. To provide distinguishing clues to differentiate amongst the bright masses.

Background: Since the MR imaging features of most soft tissue masses are non-specific; prediction of a specific histological diagnosis remains a challenge for the radiologists. However, there are certain specific lesions showing bright signal intensity on T2-weighted MR images.

Imaging Findings: We exhibit various bright soft tissue masses of the extremities on T2-weighted MR images. Illustrative cases include ganglion, bursitis, epidermal cyst, hemangioma, lymphangioma, intramuscular myxoma, neurogenic tumor, myxoid liposarcoma, and extraskeletal chondrosarcoma. Additional T1-weighted images and gadolinium-enhanced images provide helpful information to differentiate among them.

Conclusion: It is a prerequisite to be familiar with various spectrums of bright soft tissue masses for accurate interpretation of MR imaging and shortening the list of differential diagnoses.

C-0723

MR image findings of acute rhabdomyolysis

S. Kwon¹, K. Jung¹, I. Yang², Y. Kim³, Y. Choi², J. Cha⁴; ¹Daejeon/KR,

²Seoul/KR, ³Gwang-Ju/KR, ⁴Bucheon/KR

Purpose: To evaluate the MR image findings of acute rhabdomyolysis and correlate with clinico-pathological findings.

Materials and Methods: MR images in nine patients (7 men, 2 women; age range 15-45 years) with acute rhabdomyolysis were analyzed. Diagnosis of acute rhabdomyolysis was done by biopsy in two cases, clinical findings & follow-up imaging in 7 cases. The involved muscle, signal intensity and enhancement pattern of the lesion including in follow-up images, were assessed. Four cases with follow-up imaging were also analyzed with the same.

Results: Involved muscles were five cases in gluteal muscle, cervical and lumbar back muscle two, and leg (tibialis and gastrocnemius) & vastus muscle one, respectively. The T2 weighted images show heterogeneous high signal intensity in involved muscles, and central and peripheral rim enhancement pattern on gadolinium enhanced images in all cases. A decrease in initial high signal intensity and degree of enhancement of the involved area paralleled the clinical course in four follow-up cases.

Conclusion: The degree and pattern of signal intensity and contrast enhancement in involved muscle on MR images may contribute to the diagnosis of acute rhabdomyolysis and may parallel the clinical course.

C-0725

Radiological features of histologically proven post-traumatic fat necrosis

G. Raghuathan, S. McKie, G. Bourke, P. Robinson; Leeds/UK

Learning Objectives: 1. Pictorial illustration of fat necrosis by Ultrasound and Magnetic Resonance Imaging (MRI). 2. Correlation of imaging findings with proven histopathology.

Background: Fat necrosis most commonly occurs after trauma, and is well described in the breast. It is however less well documented in other anatomical sites. It can be seen in association with medical conditions such as pancreatitis, obstetric trauma, myeloproliferative and connective tissue disorders. Trauma is thought to cause vascular compromise resulting in necrosis that is propagated by both inflammatory and hormonal influences. The precipitating insult is however only recalled in one third of patients. It is a benign lesion that may be mistaken for malignancy and radiological differentiation is therefore important.

Procedure: The imaging features of fat necrosis are variable but Ultrasound is the primary investigation of choice with MRI used in indeterminate cases. This poster will illustrate the radiological features of 3 cases of fat necrosis with correlation of Ultrasound, MRI and histopathology (obtained with Ultrasound guided biopsy). All cases were referred with a high clinical suspicion for malignancy to the regional sarcoma centre.

Conclusion: The features of fat necrosis by MRI and Ultrasound are illustrated pictorially. A history of trauma is frequently not available and so the clinician relies on the imaging findings to aid diagnosis. Histological confirmation by Ultrasound guided biopsy may be required if clinical suspicion is high. However interpretation of the pathological features must be made in conjunction with the imaging features.

C-0726

The contribution of conventional and color Doppler ultrasonography in the estimation of musculoskeletal infections

C. Kontopoulos, A. Balanika, N. Economopoulos, G.A. Michailidis, N.L. Kelekis; Athens/GR

Purpose: The purpose of this study is to evaluate the role of conventional and color Doppler Ultrasonography in the detection of musculoskeletal infections.

Materials and Methods: Thirty patients (19 men/11 women), age 32-70 years were studied with Ultrasonography over a period of six months. Sonograms were obtained using a high resolution (7-12 MHz) linear transducer. The infection sites were: tibia (9), femur (7), hip joint (6), rib (2), clavicle (2), abdominal wall (2), elbow, (1) knee (1). They were results of contamination after surgical procedures, bone implants and abdominal wall mesh or spread of infections of contiguous site.

Results: The extension, the depth, the echomorphology and the vascularization of the infected tissues were studied. The osseous involvement was estimated by periosteal thickening or lifting, subperiosteal fluid collection, subperiosteal vascularization and presence of bone sequestrum. In seven patients there was suspicion of osteomyelitis, confirmed by MR imaging. In nine patients with abscess formation, aspiration and cytologic examination was performed. The cultured bacteria were *Staphylococcus* (2 MRSAs), *Pseudomonas* and *Proteus*.

Conclusion: Conventional and color Doppler Ultrasonography may contribute in the diagnosis of musculoskeletal infections, their extension and complications. It may also be used for the diagnostic aspiration and the following up of these patients.

Scientific and Educational Exhibits

C-0727

Real-time spatial compound sonography versus conventional US of the Achilles tendon in patients with heterozygous familial hypercholesterolemia
T.V. Bartolotta, M. Galia, G. Mamone, G. Runza, F. Sorrentino, M. Midiri; Palermo/IT

Purpose: To compare Real-Time Spatial Compound Sonography (CS) and conventional US in the evaluation of Achilles tendons in patients with heterozygous familial hypercholesterolemia (HFH).

Materials and Methods: Both Achilles tendons of 40 patients (19 men and 21 women; age range: 11-78 years; mean: 50.5 years) with HFH were studied with conventional US and CS by using a 7.5-10 MHz multifrequency linear-array transducer. Patients with previous history and/or clinical findings of tears and tendonitis were excluded from the study. Two experienced radiologists evaluated in consensus: a) tendon thickness, b) tendon echotexture, including the presence of calcifications and/or hypoechoic lesions (xanthoma). Structural changes were classified as follows: 1) no lesions; 2) unifocal or multifocal hypoechoic lesions, 3) diffuse abnormalities. Readers were also asked to evaluate the conspicuity of the lesions on a five-point scale: 1) definitely present, 2) probably present, 3) not assessable, 4) probably absent, 5) definitely absent.

Results: 7/80 tendons in 5/40 patients showed thickening (AP diameter > 7.1 mm) and abnormal echotexture. Ten xanthomas sized from 2.3 mm to 8.7 mm were identified in 5/80 tendons of four patients. In one patient bilateral, heterogeneous, hypoechoic tendon enlargement and calcifications were detected at US. No difference in the number of xanthomas detected at conventional US or CS was observed. The number of xanthomas classified as definitely present was statistically significant higher with CS than conventional US ($p < 0.05$).

Conclusion: CS is an effective tool in the assessment of Achilles tendons in patients with HFH, by improving xanthoma conspicuity.

C-0728

Myositis ossificans: What is the real diagnostic value of magnetic resonance?

S. Ortori, V. Zampa, F. Odoguardi, L. Marchetti, C. Cappelli, C. Bartolozzi; Pisa/IT

Learning Objectives: To describe the real diagnostic role of MR in the myositis ossificans.

Background: Myositis is an aberrant reparative process that causes benign heterotopic ossification in soft tissue. It is commonly associated with trauma, although in almost one-third of the cases there is no history of injury; usually the clinical presentation is a painful soft-tissue swelling that occurs within skeletal muscle of the extremities.

Imaging Findings: The radiologic diagnostic findings are dependent of the phase of the disease. Three different appearances of myositis ossificans are noted on MR: in the early phase before the appearance of calcification, MR shows a mass isointense to muscle on T1WI and hyperintense on T2WI with marked amount of adjacent edema. When the mineralization appears this is seen as a mineralized core, hypointense on T1 with hypointense rim both T1 and T2WI due to the surrounding rim of calcifications; in the mature phase, the lesion develops as well-defined calcified mass with a rim of decreased signal intensity both T1 and T2W representing the peripheral ossification. Highly diagnostic on radiographs and CT is the presence of calcification that develops between 4 and 6 weeks after the initial trauma.

Conclusion: Plain radiography and CT are superior to MR in demonstrating calcification and ossification, but MR is the best method for early detection and for differential diagnosis (that includes malignant process), and following the progression of changes.

C-0729

MR findings and pathologic correlation of subcutaneous soft-tissue lesions of dermatosis: A pictorial review

S. Otake; Toki, Gifu/JP

Learning Objectives: MR imaging and pathological correlation was performed in 55 subcutaneous soft-tissue lesions of dermatosis. This review includes epidermal cyst (epidermoid cyst, infundibular cyst), eccrine spiradenoma, trichilemmal cyst, porokeratosis, panniculitis, angiolioma, angioleiomyoma, verruca vulgaris, ossifying fibroma, calcifying granulation, neurofibroma, and angiosarcoma.

Background: Pre-operative MR study is useful in localization of soft-tissue lesions and the evaluation of their relationship with the surrounding tissues. However, MR findings of subcutaneous soft-tissue lesions of dermatosis have not been well documented.

Procedure Details: 1.5-T MR equipment and a surface coil were used. Conventional T1- and T2-weighted imaging and fat-suppressed imaging were performed in all the cases. A Gd-enhanced contrast study was performed in selected cases. Surgical resection was performed in all the cases. MR images and pathological findings were retrospectively reviewed. Location, shape, homogeneity, presence of the septa, signal intensity pattern, and degree of contrast enhancement of the lesions were analysed. Signal intensity patterns of the contents were correlated with pathological findings.

Conclusion: MR is useful in demonstrating subcutaneous lesions of dermatosis. Signal intensity patterns represent internal components and provide useful information in differential diagnoses.

C-0730

Soft-tissue vascular malformations: MR and MR angiographic imaging with pathologic correlation

J.C. Vilanova, J. Barceló, M. Villalón, J. Miró; Girona/ES

Learning Objectives: To review, be familiar with and differentiate the typical MR and MRA features of soft tissue vascular malformations with pathologic correlation.

Background: Soft tissue vascular malformations are relatively common. Different classifications separate vascular lesions of soft tissues into hemangiomas and vascular malformations on the basis of their natural history, location, cellular turnover, and histology.

Imaging Findings: These lesions can be categorized on MR imaging because of its typical appearance as multiple lobules with fat overgrowth and serpentine channels depending on the vascular flow. The combination of conventional MR and MR angiography (MRA) enable the differentiation between low flow and high flow vascular malformations and allows a non-invasive diagnostic strategy. Conventional MR sequences (T1, T2 WI and fat suppression techniques) and MR angiography (MRA) technique (3D FGRE-contrast enhanced) on a dynamic acquisition have been used to illustrate and characterize vascular malformations with pathologic correlation.

Conclusion: MR and MRA characteristics of vascular malformations allows one to perform more specific diagnosis and evaluation, to determine the extent of the anomaly and to classify appropriately. It provides a better overall assessment of vascular tumors.

C-0731

Usefulness of high-resolution sonography in the evaluation of soft tissue masses of the foot

V. Gomez-Dermit, R. Landeras, P. Merino, E. Sanchez-Salmon, M. Aguilar, M.A. Fernandez-Echevarria; Santander/ES

Purpose: Soft-tissue masses of the foot are an important clinical problem because of their high frequency and the severe functional importance that in most cases they imply. Our objective is to demonstrate the usefulness of ultrasound in the pre-surgical diagnostic approximation of these lesions.

Materials and Methods: We reviewed the sonographies of 55 patients (39 men, 16 women; with an age range of 17 to 80 years) remitted for the evaluation of tumours located in the foot. Examinations were carried out with two devices, Logiq500 (GE) and Aspen (Acuson), which had multifrequency linear arrays of 7.5-11 MHz and 5-11 MHz, respectively. The analysis of the tumours was focused on the following characteristics: location, size and shape, contours, echostructure and echogenicity, vascularization and relationships with adjacent structures. Excision or biopsy of the masses was practised in all cases with consequent pathological examination.

Results: The histological results contributed 4 lipomas, 12 neuromas, 4 angioleiomyomas, 1 chondroma, 1 synovial chondroma, 1 synovial sarcoma, 2 cases of bursitis, 6 plantar and 1 nodular fibromatosis, 15 cystic synovial lesions, 1 inclusion cyst, 1 giant cells tumour, 1 plantar papilloma and 5 abscesses. The ultrasound study of the tumours give us important details for orientation the possible nature of the lesions, i.e. if they were solid or liquid, pattern of vascularization, pattern of growth and their relationships with other structures.

Conclusion: High-resolution sonography is a technique that allows the radiologist to characterize soft-tissue masses, in most of the cases with an appropriate correlation with the pathological examination.

C-0732

Ultrasound investigation in differential diagnostics and treatment planning of soft tissues pathologies

T. Golovko, V. Medvedev; Kiev/UA

Purpose: We report our experience in ultrasound diagnostics and treatment planning of soft tissue tumors.

Scientific and Educational Exhibits

Methods and Materials: 710 patients with pathological formations of soft tissues were investigated: 240 - with sarcomas, 118 - with malignant disease of lymphoid tissues, 174 - with benign tumors, 92 - with non-neoplastic processes and 86 - with osteogenic sarcomas. Ultrasoundography (including color and energetic Doppler) was applied in all patients; traditional X-ray - in 569, CT - in 476, MR imaging - in 68 patients. 496 patients were surgically treated, 238 of them had neo-adjuvant chemotherapy. Results were compared with those of surgery and morphological investigation (volume part of vitality tumors tissues).

Results: US imaging characteristics of soft tissues pathological formations as well as typical neovascularity of tumors were elaborated. B-mode ultrasound can document the size and extension of tumor including lesion location, surrounding anatomical structure and US imaging characteristics of tumors. Power Doppler detected adjacent vessels, their correlation with tumor. Sensitivity, specificity and accuracy of ultrasound diagnostics were respectively 98%, 96% and 97%. The objectivity of complex ultrasound investigations for the evaluation of sarcomas neo-adjuvant therapy efficacy was proved.

Conclusion: The neoplasm localization is of decisive importance at soft tissues radiation investigation methods choice. The application of complex of methods ensures the most accurate results. Complex ultrasonography can be used for differentiation between potentially good and poor respondents for neo-adjuvant therapy and may be recommended for preoperative therapy effectiveness monitoring.

C-0733

Necrotising fasciitis: A pictorial essay with radiological correlation

A. Halka¹, R.R. Misra², M.C. Uthappa³, S. Kaniyur⁴, M.G. Berry¹,

¹Manchester/UK, ²High Wycombe/UK, ³Aylesbury/UK, ⁴Stevenage/UK

Learning Objectives: We present a pictorial review of several case of Necrotizing Fasciitis (NF) outlining the radiological changes seen with this aggressive condition.

Background: Necrotizing Fasciitis is an insidiously advancing soft tissue infection characterized by widespread fascial necrosis. It is a devastating condition with high mortality. NF may be thought of in three forms; type I, or polymicrobial; type II, or group A streptococcal (GAS); and type III gas gangrene, or clostridial myonecrosis. Type I is generally associated with immune compromise such as diabetes, malignancy, HIV, intravenous drug abuse and hepato-renal impairment. Type II tends to affect healthy patients who may be susceptible if they do not possess antibodies against GAS virulence factors. NF is frequently polymicrobial in children without pre-existing conditions.

Imaging Findings: The main role of imaging is to direct the extent of surgical debridement. CT is sensitive in detecting the changes associated with necrotizing fasciitis but lacks specificity. Several examples will be presented.

Conclusion: Necrotizing fasciitis is optimally managed in a multidisciplinary setting. Prompt imaging, radical debridement and reconstruction are required in order to reduce both the morbidity and mortality that result from this shocking condition.

C-0734

Soft tissues liposarcomas: Relationship between histopathologic features and CT/MR imaging findings

L. Zugaro¹, A. Catalucci¹, A. Barile², M. Monina¹, C. Masciocchi²; ¹Teramo/IT,

²L'Aquila/IT

Purpose: To evaluate MR imaging findings of liposarcomas subtypes and to correlate the histopathologic features with the MR imaging findings.

Material and Methods: Twenty-three patients examined in the last 9 years all underwent ultrasound and MR imaging; CTs were performed in twelve patients. All patients were submitted to biopsy and surgical resection.

Results: The study group had 9 well-differentiated, 10 myxoid, 3 pleomorphic and 1 round cell liposarcomas. Well-differentiated liposarcomas had a largely lipomatous appearance typically with septa and areas which were hyperintense on T2W SE MR images. Myxoid liposarcoma were mildly heterogeneous with high signal intensity on T2W images with lacy or linear septa of fatty tissue in six cases. Pleomorphic and round cell subtypes demonstrated marked heterogeneity indistinguishable from other high-grade sarcomas.

Conclusions: Well-differentiated liposarcomas may be differentiated from other types of the tumor by their largely lipomatous appearance. Myxoid subtypes may be distinguished on the basis of their homogeneous or mildly heterogeneous structure. On the basis of our experience and of literature, we believe that diagnostic criteria exist to distinguish the different liposarcomas subtypes, so allowing the correct differential diagnosis.

C-0735

Routine ultrasound diagnostic of the most frequently injured muscles of professional football players from the transfer list

W. Wawrzynek¹, B. Koczy¹, J. Widuchowski¹, S. Kasprowska¹,
A. Siemianowicz¹, R. Majer¹, J. Baron², A. Krol¹; ¹Piekary Slaskie/PL,
²Katowice/PL

Purpose: The purpose of this work was the confirmation of full fitness and prognosis as to physical efficiency of particular muscular groups for professional football players from the transfer list.

Materials and Method: 32 professional Polish I league football players and 9 foreign players from the transfer list were studied. A Siemens Antares machine with linear matrix head of 9-13 MHz was used. Based upon the experience of over 200 previous examinations, only the muscular groups that are most frequently injured: quadriceps and biceps of thigh and adductors, were examined.

Results: For 8 of 41 players there were fibrous and cicatricial changes in the examined muscles diagnosed. These changes could have an influence on the seasonal efficiency but despite that the transfers have been signed. For 3 foreign players the examination revealed massive cicatricial changes not reported by the players. For two cases the long head of quadriceps of thigh was not cured after sub-total rupture, for one case massive myositis ossificans calcification of long adductor and additionally right gono-arthrosis were diagnosed. For these three cases the transfer was not signed.

Conclusion: Ultrasound diagnostic of muscles of players being transferred in commercial sport disciplines is very important for estimation of the player's fitness and his future efficiency.

C-0736

Usefulness of sonography in diagnosis and postoperative evaluation of carpal tunnel syndrome

J. Cha, J. Park, S. Paik, J. Joh, H. Hong, H. Lee; Bucheon-Si/KR

Purpose: To evaluate the usefulness of the dimpling index on sonography of proximal carpal tunnel in the diagnosis of carpal tunnel syndrome (CTS) and post-operative evaluation.

Materials and Methods: Twenty patients suspected of CTS and control groups of 9 asymptomatic subjects underwent high-resolution sonography of the carpal tunnel. In addition, a comparison between pre and postoperative sonographic findings in six patients was made. Cross sectional area and dimpling index of proximal carpal tunnel, flattening ratio and swelling ratio of median nerve in proximal and distal carpal tunnel were measured between control groups and patients including 6 post-operative patients. We defined the depth of dimpling of median nerve on longitudinal view of sonography in proximal carpal tunnel as the dimpling index. We evaluated electrophysiologically the median nerve function of the affected wrists of all patients.

Results: Analysis revealed that a significant difference in the cross-sectional area of the median nerve and dimpling index on proximal carpal tunnel was found between patients' group and control group with a larger area than 0.09 cm² and a higher value of dimpling index than 0.07 being highly predictive of carpal tunnel syndrome. We also found a significant difference in swelling ratio and dimpling index between pre and postoperative patients.

Conclusion: In this study, we suggest that dimpling index and cross sectional area of median nerve on proximal carpal tunnel are effective value of confirming compression of median nerve and dimpling index and swelling ratio may be useful in the quantitative assessment of post-operative patients.

Imaging of diabetic foot

P. Rajiah, R. Whitehouse; Manchester/UK

Learning Objectives: To learn the role and limitations of imaging in diabetic foot. To illustrate the imaging spectrum of the different lesions in different imaging modalities. To learn the imaging protocol to be followed in different clinical scenarios.

Background: Diabetic foot is a major cause of morbidity in diabetic patients. It is seen in 25% of diabetics and is the common cause of prolonged hospitalisation, eventually ending in amputation in more than 10%. The pathological processes are a combination of neurological and vascular etiologies and include cellulitis, abscesses, sinuses, osteomyelitis, neuropathic joints, traumatic & stress fractures, peripheral vascular disease and gangrene.

Procedure Details: Good quality plain X-rays were obtained in all patients which identifies gross osteomyelitis, ulcerations, foreign bodies, antibiotic pellets, gas, neuropathic joints and fractures. Bone scan, white cell scan and gallium scan were useful in osteomyelitis, cellulitis and neuropathic joints. MR imaging was done for assessing the extent of lesion prior to surgery. MR imaging was performed in sagittal, coronal and axial planes. Gadolinium was administered in subtle lesions or small sinuses. Angiography or MR angiography was done in vascular disease.

Conclusion: Plain X-rays are the initial modality used in diagnosis of diabetic foot complications. Bone scan, white cell scan, gallium scans are helpful in differentiating osteomyelitis, cellulitis and neuropathic joints. CT scan identifies sequestra, periosteal reaction and cortical destruction. MR imaging with its superior soft tissue contrast is very helpful in assessing the exact extent of the disease, which is vital in management of osteomyelitis.

C-0738

Spectrum of cyst-like conditions found in and around the knee

M. Hjelt, A. Buzzi, M. Canedo, S. Gomez Zanetta, A. Mancini; Buenos Aires/AR

Learning Objectives: To recognize the different types of fluid filled structures (normal and abnormal) frequently found in the knee and in the surrounding soft tissues.

Background: There is a broad spectrum of cyst-like or water containing structures adjacent or within the knee. The purpose of this exhibit is to classify and describe these different fluid-filled structures.

Imaging Findings: Three types of fluid-filled structures can be found. Bursae, recesses and cysts. Bursae are synovial lined sacs found between structures that move against each other, whose main purpose is to reduce friction between these structures: the suprapatellar bursae, the subcutaneous pre-patellar bursae, the superficial and deep infra-patellar bursae, the pens anserine bursae, the gastrocnemius bursae and the medial collateral ligament bursae. Recesses are considered direct extensions of the articular cavity. They include Baker's cyst and distended hiatus popliteus. Cysts are liquid masses, including meniscal cysts and ganglion cysts (anterior and posterior cruciate ligament ganglions, intraosseous ganglion and proximal tibia fibular ganglion).

Conclusion: MR imaging is an excellent method to evaluate the different types of water containing structures that are frequently found in and around the knee.

C-0739

Ultrasonography of the musculoskeletal system: Principles of US physics and technology, examination technique, echoanatomy and sonographic features of musculoskeletal disease (a DVD-based teaching file)

C. Chatzimihail, P.S. Zoumpoulis, S. Kyriazi, A. Mihailidis, S. Faitaki, K. Pahou, I. Bechrakis, G. Adamakis, G. Delibasis, H. Tragea; Athens/GR

Learning Objectives: To outline basic US physics, technology and examination technique of the musculoskeletal system. To illustrate the main indications and limitations of the modality. To present normal echoanatomy and correlate abnormal sonographic findings with specific musculoskeletal disease.

Background: Modern high-resolution sonography is increasingly employed in the diagnosis of musculoskeletal injury and disease. The present DVD-Rom is based on a series of lectures focused on facilitating training and incorporates technical aspects of correct US examination with features of normal and diseased echostructure of the joints. Emphasis has been placed on delineating the

significance of appropriate transducer manipulation and selection of machine settings so as to optimize diagnostic results. "Real-time" video files are used to demonstrate correct technique through the simultaneous screen display of transducer positioning and obtained US images. Furthermore, these "hands-on" sessions elucidate the merits of dynamic scanning. A bilingual approach has been carried out by complementing the main Greek text with English subtitles.

Procedure Details: Individual topics include the fundamentals of US physics and technology, study of the shoulder (with particular focus on rotator cuff pathology), elbow, wrist and carpal tunnel syndrome, knee, as well as examination of the paediatric patient and US applications in non-traumatic musculoskeletal disease. Normal sonographic appearances are identified and juxtaposed to abnormal features associated with specific joint pathology. Relevant Doppler findings, aberrations during dynamic scanning and common artefacts are also discussed.

Conclusion: Sonography is a valuable modality for musculoskeletal imaging provided it is implemented meticulously and with consideration of its potentials and limitations.

C-0740

Animal signs in radiology

C.G. Cronin, D.G. Lohan, C.P. Meehan, C.J. Roche; Galway/IE

Learning Objective: To provide an educational and pictorial review of radiological signs, linked by the fact that they are named after and/or having a similar appearance to animals. Each radiological sign will be accompanied by a description of the sign/disease process involved.

Background: Radiologists have unique skills of observation and description. Descriptive signs in Radiology, as in all specialties are extremely useful. Signs aid characterization and classification of disease processes. They can allow confident radiological diagnosis on imaging grounds or help narrow a differential diagnosis.

Imaging Findings/Procedure Details: We will outline each particular sign, its etiology, where possible and provide a pictorial example from our department. These signs include Fish Vertebrae, Butterfly Vertebrae, Butterfly Fragment, Scottie Dog, Elephant Ears, Moth Eaten Bone, Seagull Configuration, Open Fish Mouth Sign of the skeletal system; Caterpillar Sign, Bulls Eye, Bird Beaking, Rat's Tail Sign of the gastrointestinal system; Bat Winging, Mickey Mouse Ears of CNS to name but a few.

Conclusion: This has provided an interesting and informative review of both common and uncommon radiological signs.

C-0741

Rheumatoid foot: Spectrum of imaging findings

E. de Lama, J.A. Narvaez, J. Narvaez, X. Mallol, J. Pellicer, V. Fabregas, C. Canas; Barcelona/ES

Learning Objectives: To review the main imaging features of the rheumatoid foot as seen at radiographs, US, CT and MR imaging. To correlate these imaging features with clinical symptoms, evaluating their usefulness in the clinical management of RA patients. To review the role of tibial posterior tendon dysfunction in the development (only or associated with other entities) of rheumatoid pes planovalgus.

Background: Foot and ankle involvement is common in rheumatoid arthritis (RA), leading to pain, functional impairment, and disability. Radiologic manifestations are predominantly the result of the synovial proliferation and inflammation that characterize the disease. MR imaging and US are valuable imaging methods for early evaluation. MR imaging is the preferred method for detecting early changes in RA. US is a valuable tool for evaluation of synovial arthritis and by facilitating the differentiation of tenosynovitis from articular inflammation and characterizing joint effusions.

Procedure Details: In this exhibit we review the main imaging findings in RA of the foot and ankle (joints, bursal, and tendon injuries as well as rheumatoid nodules) using multiple imaging modalities (radiographs, US, CT and MRI), and we will evaluate their usefulness in the everyday clinical management of these patients.

Conclusion: Knowledge of these imaging findings is important because feet are often affected earlier than hands, and may give a good overall impression of the joint damage, helping to plan the most adequate therapeutic strategy. Special emphasis is placed on imaging assessment of the role of the posterior tibial tendon and other structures in the development of rheumatoid pes planovalgus.

Scientific and Educational Exhibits

C-0742

A practical synopsis of knee cysts imaging

S. Bianchi¹, C. Martinoli², C. Gaingot¹; ¹Chene-Bougeries/CH,
²Largo Rosanna Benzi/IT

Learning Objectives: Musculoskeletal radiologists must be aware of the imaging appearance of cysts of the knee (KC) for their early detection and accurate assessment. Imaging has two crucial roles in the diagnostic work-up of KC. First, it must confirm the clinical suspicion of a KC and evaluate its size, borders, internal composition and relations with the adjacent structures. Second, it must investigate the internal knee structures to detect potentially associated disorders.

Background: KC are common clinical findings and are mainly related to synovial cysts and ganglia. The former are synovium lined, contain synovial fluid and when communicating with the joint cavity, result from a one-way valve mechanism that allows fluid only to pass from the joint space into the cyst. Ganglia are cysts with a fibrous wall and a thick, viscous content that result from a mucoid degeneration of connective tissue. They may or may not communicate with the joint cavity. Typical examples of knee ganglia are meniscal cysts, intramuscular and atypical popliteal ganglia and cruciate ligaments cysts.

Imaging Findings: The goals of this practical synopsis are to describe briefly the patho-mechanism and clinical findings of KC and to illustrate their imaging appearances on standard radiographs, arthrography, ultrasound, MR imaging, CT, CT and MR imaging arthrography. From our teaching file paradigmatic images of different types of KC will be presented. Schematic drawings will be used to clarify the imaging appearance. Special emphasis will be made on correlation among the different imaging modalities.

C-0743

Musculoskeletal manifestations of sickle cell disease. A pictorial review

M. Mashayekhi¹, R.R. Misra², A.L. Hine³; ¹Enfield/UK, ²High Wycombe/UK,
³London/UK

Learning Objectives: We would like to present a pictorial review of the varied musculoskeletal presentations of sickle cell anaemia.

Background: Haemoglobinopathies result from the presence of abnormal haemoglobin chains within haemoglobin (Hb). Sickle cell disease is characterised by the presence of haemoglobin S (Hb-S), which may result in sickle cell anaemia (Hb-SS), sickle cell trait (Hb-SA), or a hybrid Hb. Sickle cell disease is usually prevalent in those of African origin. About 7 percent of Blacks Americans and 40 percent of some African tribes carry Hb-S. Only 0.2 percent of Black Americans manifest Hb-SS. Clinical findings in Hb-SS are explained by the physical properties of the abnormal Hb. Sickle cells are fragile and cause vaso-occlusive crises, which are a striking feature of the disease. The incidence of Hb-SS is decreasing due to antenatal screening, but the disease still causes significant morbidity.

Imaging Findings: Conditions presented include marrow hyperplasia and reconversion, marrow ischaemia, osteomyelitis, muscle and soft tissue abnormalities, extra-medullary haematopoiesis, bone sclerosis, AVN, growth disturbances and changes to the axial skeleton.

Conclusion: We have the second largest population of sickle cell disease in the U.K. and regularly encounter the skeletal manifestations of Hb-SS. We hope that this poster will familiarise general radiologists with their varied appearances.

C-0744

Ilio-psoas compartment: A radiological approach

A. Buzzi, C. Garcia Pellegrino, C. Brizuela, M. Hjelt, M. Buzzi, A. Mancini;
Buenos Aires/AR

Learning Objectives: To show the important role of imaging in the diagnostic approach of ilio-psoas compartment disorders. To review the radiological techniques used in this type of patient. To illustrate the various imaging finding in ilio-psoas compartment diseases.

Background: Iliopsoas compartment disorders include infections, hemorrhage and neoplasms, and their symptoms are often subtle and non-specific. This results in delayed diagnosis and treatment. Anatomical knowledge is essential to understand the radiological findings and to correlate with clinical evidence. CT and MR provide a non-invasive highly precise evaluation of this area, and have led to early detection of pathology.

Imaging Finding: We show the complex anatomy of the region, and findings in pathologic conditions. Imaging can identify different primary disorders and spread of disease to this space.

Conclusion: Imaging plays a pivotal role in the diagnostic approach to ilio-psoas compartment pathologies. This compartment is an important pathway for spread of disease to remote areas.

C-0745

CT and MR imaging of spinal infections

A. Buzzi, V. Alarcon, F. Arredondo, M. Hjelt, M. Buzzi, A. Mancini;
Buenos Aires/AR

Learning Objectives: To review pyogenic and non-pyogenic infections of the spine. To understand the different imaging findings of spinal infections in several imaging modalities and to develop an approach to diagnosis based on these features.

Background: Infections of the spine involve primarily the disc space in children and the vertebral body in adults. Adults in the 6th to 7th decade of life are most frequently afflicted. The lumbar region is mostly involved. Pyogenic infections organisms included: Staphylococcus Aureus (60%), Enterobacter series 30% (Escherichia coli). Non-pyogenic infections organisms included: Coccidioides immitis and Mycobacterium tuberculosis.

Imaging Findings: CT and MR imaging permit both accurate detection and greater specificity in the diagnosis of infectious disease of the spine. The findings are irregularity and erosion of contiguous end plates with associated narrowing of the disc space, and diminished attenuation of the vertebral body. The posterior elements are rarely involved. The presence of marginal sclerosis permitted distinction between pyogenic and non-pyogenic infection.

Conclusion: An understanding of the mechanisms of contamination and the imaging features of spine infections usually lead to accurate diagnosis. MR imaging is the most sensitive technique for detection of osteomyelitis and discitis and is the technique of choice in the evaluation of patients suspicious for spinal infection. Even when all of the characteristic imaging features are not present, an awareness of the varied patterns with which infection may present allows early and accurate diagnosis.

C-0746

Tuberculosis of the spine: CT and MR imaging features

T. Van der Zijden¹, A.I. De Backer¹, F.M. Vanhoenacker², P.M. Parizel³;
¹Antwerp/BE, ²Duffel/BE, ³Edegem/BE

Learning Objectives: To present a comprehensive overview of the imaging features in vertebral tuberculosis (TB) illustrated with multiple cases.

Background: Vertebral TB is the most common site of musculoskeletal TB. Hematogenous spread of the tubercle bacillus is the cornerstone in the pathogenesis of tuberculosis of the musculoskeletal system, resulting in a typical anterior corner involvement of the vertebral body. Two distinct patterns of vertebral TB may be seen: The classic finding of spondylodiscitis, characterized by destruction of two or more contiguous vertebrae and opposed end plates, disk infection and commonly a paraspinal mass or collection. The second pattern is an atypical form of spondylitis without disk involvement. Early diagnosis and therapy is important in preventing severe spinal deformity.

Procedure Details: Plain radiographs are extremely insensitive for early detection of TB spondylitis. They do not detect vertebral involvement until at least 50% of a vertebra is destroyed. MR imaging is generally accepted as the imaging modality of choice for diagnosis and demonstration of both bony and soft tissue extent. Moreover, it may be very helpful in the differential diagnosis with pyogenic spondylodiscitis. Features in favour of TB spondylitis are anterior corner destruction, a relative preservation of the intervertebral disk, multi-level involvement with or without skip lesions and a large soft tissue abscess. CT is still superior in the demonstration of calcifications.

Conclusion: MR imaging is the imaging modality of choice for diagnosis, evaluation of disease extent and follow-up of spinal TB. Final diagnosis is based upon microbiological and/or histological examination.

C-0747

Lumbar foraminal injections: Two techniques under fluoroscopic control

C. Duffaut-Andreux, H. Guerini, A. Feydy, F. Bach, E. Pessis, A. Minoui,
L. Meziti, J.-L. Drapé, A. Chevrot; Paris/FR

Purpose: To report our experience in 54 lumbar foraminal injections performed in our institution over a 9-month period. To describe the two techniques we use for lumbar foraminal injections under fluoroscopic control. To report the indications of steroid injections

Materials and Methods: We retrospectively reviewed 54 lumbar foraminal injections performed in our institution over a 9-month period. Two approaches were used under fluoroscopic control: a strict posterior approach with a patient in procumbitus and a postero-lateral approach with a patient in an oblique ventral position. The good needle position was confirmed on 2 orthogonal views and after injection of 2 ml of contrast material, yielding a periradicular epidural opacification. Delayed-action-corticosteroids were then injected.

Scientific and Educational Exhibits

Results: Disk herniation with nerve root impingement was the most frequent indication for injection, which was performed most commonly at L4-L5 and L5-S1 levels. The injection reproduced the usual radicular pain. No immediate complications were reported.

Conclusion: We conclude that lumbar foraminal injection under fluoroscopic control is a mini-invasive procedure, which may be done on an outpatient basis.

C-0748

Stress MR imaging of the lumbo-sacral spine with an axial loading device. A pictorial essay

B. Jankharia, P. Krishnan, M. Ursekar; Mumbai/IN

Learning Objectives: To illustrate the usefulness and indications of stress MR imaging of the lumbar spine with an axial loading device.

Background: Many symptomatic patients with degenerative disease of the lumbo-sacral spine have normal or minimally abnormal findings on standard supine MR imaging studies. It is known from dynamic myelography that thecal sac and nerve compression is often unmasked only in the erect position. An axial loading device (Dynawell, Sweden) was used in 85 consecutive patients with suspected degenerative disease of the lumbar spine. All patients with obvious disc herniations that explained the patients' symptoms were excluded. All studies were performed on a 1.5 T scanner (Siemens, Erlangen) with pre- and post-stress T2W sagittal, axial and sagittal and coronal MR imaging myelogram sequences. This axial loading device applies a compressive force that is equal to half the body weight of the patient, distributed equally on both sides. This has been shown to simulate the effect of gravity.

Imaging Findings: Stress MR imaging showed significant findings mainly in patients with degenerative soft tissue canal stenosis, especially those with single level stenosis, often reproducing the symptoms as well. It was also helpful in post-operative patients and in patients with synovial cysts. It was rarely helpful in patients with predominantly disc herniations. MR imaging myelogram images were extremely useful in depicting the changes in thecal sac and nerve compression.

Conclusion: Stress MR imaging of the lumbo-sacral spine with an axial loading device is useful in degenerative diseases of the lumbo-sacral spine, mainly in single-level degenerative soft tissue canal stenosis.

C-0749

The spectrum of the failed back surgery syndrome: Radiological comprehension with emphasis on MR imaging

J. Ryu, M. Shin, S. Kim, S. Lee, C. Kang; Seoul/KR

Learning Objectives: 1.To assimilate the complex and various imaging findings of the failed back surgery syndrome, with accurate understanding of the surgical procedure, the post-operative anatomy, and the biomechanical nature of post-operative period. 2.To show the important role of MR imaging after lumbar surgery with or without instrumentation in failed back surgery syndrome.

Background: MR imaging is best suitable for demonstrating the anatomical details of the post-operative spine. With a thorough understanding about the post-operative spine, MR imaging can not only demonstrate the anatomical details of the lumbar disc and vertebra but also give information regarding the other causes of pain that is usually not seen on the other modalities.

Procedure Details: We tried to show the complex and various imaging findings of the failed back surgery syndrome, and the usefulness of MR imaging. Various conditions including usual post-operative findings, post-operative recurrence, infection, instrumentation failure, the changes of facet and disco-vertebral joint and adjacent segment instability, with explanation for the biomechanical nature of the post-operative spine will be included. The advantages and pitfalls of MR imaging in the evaluation of the post-operative lumbar spine will also be discussed.

Conclusion: MR imaging is suitable and useful method for demonstration of failed back surgery syndrome.

C-0750

Diagnosis of skeletal invasion by Hodgkin's disease: Bone versus bone marrow survey

S. Novikov, S. Kanaev, M. Gershovich; E. Shelkoplias, St. Petersburg/RU

Purpose: To compare the diagnostic accuracy of bone & bone marrow survey in patients with Hodgkin's disease.

Material and Method: Whole body bone marrow (BMS) & bone scanning (BS) were performed in 155 pts with Hodgkin's disease. Focal and diffuse changes of tracer uptake were considered as the signs of BM metastatic invasion. Forty-two "high risk" patients had unilateral bone marrow biopsy, which was obtained from the posterior iliac crest. Discordant results of examinations were settled on the

basis of additional survey (MR imaging, X-ray, CT) at presentation and during follow-up.

Results: Fifty-five patients had scintigraphic signs of bone marrow invasion: Focal changes were revealed in 61, multifocal and diffuse - in 25 cases. Positive results of BS were mentioned in 41 cases. Nine patients had BM invasion according to histological examinations of BM. False positive results were revealed in 5 patients - for BMS, 3 patients - BS. Biopsy was always considered correct. False-negative results were mentioned in 6 pts - for BMS, 29 patients - BS and 12 patients - BM biopsy. Sensitivity, specificity and accuracy were as follow: 91.4%, 94.8%, 92.9% - for BM scanning; 49.1%, 97%, 80.6% - for bone scanning, 36%, 100%, 70.7% - for BM biopsy.

Conclusion: In the evaluated patients with HD BM scanning was the most accurate and sensitive method of skeletal survey.

C-0751

Intravertebral vacuum cleft sign: Can we consider it a sign of benign vertebral collapse?

L. Herranz, A. Bermejo, M.A. Martin, R. Carrera, P. Manjon, J. Manrique; Madrid/ES

Learning Objectives: We present a pictorial review of the intravertebral vacuum cleft (IVC) sign and discuss the clinical and radiological features and the mechanism of formation of this cleft gas collection.

Background: The IVC sign appears on radiographs as a transverse, linear or semilunar radiolucent shadow that is located centrally within or adjacent to the endplate of a collapsed vertebral body and is exclusively seen in conjunction with vertebral fracture and collapse. The radiolucent or semilunar shadow represents gas (principally nitrogen) in the fracture line. The observation of IVC in a collapsed vertebral body on plain radiograph was considered virtually pathognomonic for osteonecrosis. Classically it was thought that the mechanism of formation of these gas collections in the vertebral bodies required that neither fluid nor tumor should occupy the cleft. So, almost every author had assured one that the intravertebral vacuum cleft sign militates against the diagnosis of infection and malignancy.

Imaging Findings: We illustrate this phenomenon with some examples including frontal and lateral lumbar column radiographs, CT scans and MR images of osteonecrosis and Kümmell disease (delayed posttraumatic collapse). We also report a case of intravertebral vacuum cleft in vertebral collapse from a metastatic renal cell carcinoma, being to our knowledge the first case described.

Conclusion: Almost all reported cases of intravertebral vacuum phenomena correspond to vertebral collapse of a non-neoplastic and non-infectious origin. However, IVC has been reported in a few cases of vertebral malignancy; therefore it can not be considered a pathognomonic sign of ischemic bone necrosis.

C-0752

Ultrasound-guided intervention in the musculoskeletal system

J.L. del Cura, R. Zabala, A. Legórburu, O. Gorriño, D. Grande; Bilbao/ES

Learning Objectives: To illustrate the different US-guided interventional procedures performed in the musculoskeletal system (MSS). To describe their technique, including the use of drugs when appropriate. To describe their complications and how to prevent and treat them. To discuss their indications and to describe the results.

Background: US allows exploring most of the MSS, including lytic bone lesions. Its flexibility, availability, and low cost makes it the best tool to guide interventional procedures in any MSS lesion visible on US. These techniques include percutaneous biopsy, drainages (abscesses, hematomas, muscular breaks, ganglions, Baker's cysts and bursitis), arthrocentesis and aspiration of calcific tendinitis.

Procedure Details: Percutaneous biopsy is performed using spring-loaded automatic guns that allow obtaining specimens available for histological exam from soft tissues and lytic bone lesions. The technique is highly accurate to distinguish between benign and malignant lesions. Drains can be performed using catheters or needles and avoid a more aggressive approach most of the time. Intracavitary urokinase helps when the aim is to drain clotted hematomas or fibrinous collections. Injection of corticoids is useful in the treatment of ganglions, Baker's cysts and in non-infected arthritis. Calcific tendinitis of the shoulder can be effectively treated using percutaneous "washing" with lidocaine. Calcifications usually disappear and symptoms improve in near 90% of the cases within a year. Most of these techniques are low cost and require only a moderate skill.

Conclusion: US-guided procedures are useful tools to diagnose and treat MSS diseases and should be routine in any imaging department.

Scientific and Educational Exhibits

C-0753

Spinal tuberculosis: Typical and atypical findings at MR imaging

F. Matute Teresa, A. Saiz Ayala, N. Santamaría; Madrid/ES

Purpose: To describe MR imaging findings of typical and atypical tuberculous spondylitis and compare the diagnostic yield of MR versus other radiological modalities.

Materials and Methods: Between January of 1998 and July of 2004, we studied and compare the radiological findings (MR, CT and plain films) of 29 patients (13 men and 16 women, aged 20 to 76 years) that had a final diagnosis of tuberculous spondylitis.

Results: Thoracic spine was the region most commonly affected, partial involvement was detected in the majority of the vertebral lesions. MR imaging evidence of disc space involvement is very infrequent. High signal intensity on T1-weighted images of previously affected vertebrae suggested healing. More typical findings of spinal tuberculosis include destruction of two adjacent vertebral bodies and opposing end plates, destruction of intervening disk space, collapse, and/or occurrence of paravertebral abscesses or extension into the epidural space. Depending on the stage of the disease, three different patterns of infection were revealed: osteitis, osteitis with an abscess and osteitis with or without an abscess plus discitis.

Conclusion: The ability of MR to detect tuberculous spondylitis earlier than other radiological techniques could reduce bone destruction and deformity and diminish the need for surgical intervention. Instability and deformity of the spine can result, mandating prompt diagnosis and treatment to prevent permanent neurological damage. Biopsy is recommended to confirm the diagnosis.

C-0754

Coronal ultra-thick CT reconstructions of the pelvis in the multiple trauma patient: An alternative for the initial conventional radiograph

S. Leschka¹, H. Alkadhi¹, T. Boehm², B. Marincek¹, S. Wildermuth¹; ¹Zürich/CH, ²Chur/CH

Purpose: Uncertainties of the initial conventional pelvic radiographs have questioned its usefulness in multiple trauma patients who will undergo abdomino-pelvic CT scan. Post-processing of axial CT datasets allows for generating coronal ultra-thick multiplanar reconstructions, which resemble conventional AP radiographs. This study was performed to evaluate the image quality and diagnostic accuracy of this reconstruction for pelvic fractures.

Methods and Materials: 33 multiple trauma patients with initial conventional pelvic radiographs and CT imaging were retrospectively reviewed by two radiologists regarding image quality, visualization of anatomical landmarks and diagnostic concordance. Statistics were performed using kappa statistics for inter-observer agreement, Wilcoxon signed-rank test for modality comparison and chi square test of contingency for diagnostic certainty.

Results: Ultra-thick multiplanar reconstructions were superior in terms of image adjustment ($p < 0.02$), absence of overlaying structures ($p < 0.05$), and overall image quality ($p < 0.01$). The ilio-sacral joint ($p < 0.05$) and the anterior and posterior acetabular line ($p < 0.01$ and $p < 0.02$, respectively) were more accurately depicted on reconstructions. Consequently, sensitivity for detection of fractures in the acetabular rear column and ilio-sacral joint were significantly improved. The visualization of all other anatomical landmarks and pathological findings did not differ significantly between both modalities.

Conclusion: If conventional pelvic radiography is omitted while abdomino-pelvic CT scan is performed, the reconstruction of thick anterior-posterior images of the pelvis may be a sufficient alternative to gain conventional radiography-like images.

C-0755

Clinical application of 16-slice multidetector row CT (MDCT) with 2D and 3D image processing in musculoskeletal trauma

J.Y. Hwang, S.W. Lee, H.Y. Choi; Seoul/KR

Learning Objectives: To illustrate the various images of 16-slice multidetector row CT (MDCT) with 3D volume rendering (VR) and multiplanar reformation (MPR) in musculoskeletal trauma of 105 patients. To describe the advantages and limits of MDCT with 3D image-processing and its clinical applications.

Background: With the revolution of MDCT, image quality of MPR and VR from 3D image processing approaches that of axial images from the raw data. The stair-step artifacts were reduced as compared with conventional helical CT owing to higher Z-axis resolution. This study included 105 patients with musculoskeletal trauma who underwent 16-slice MDCT from May 2004 to July 2004. MPR images and 3D volume rendering images were reformatted using a PC-based 3D reconstruction program. In this exhibits, we compared the diagnostic value of

MPR and 3D volume rendering images with axial CT images only.

Imaging Findings: MDCT with 3D VR was particularly helpful in evaluating fractures in the scapula including bony glenoid, elbow, wrist, acetabulum, and in evaluating fixation positioning after operation. Additional MPR CT images were useful in visualizing the spine in patients with kyphosis, scoliosis and severe compression, evaluating fractures in the talus, calcaneus, carpal bone, sacrum, pelvic bone, determining bony union of fractures after fixation, and evaluating post-traumatic complications on follow-up examinations.

Conclusion: MDCT with 3D volume rendering or MPR images clarify the areas of complex bony anatomy in patients with musculoskeletal trauma. It is valuable in operation planning as well as in postoperative follow-up imaging for fixation positioning, healing, and traumatic sequelae.

C-0756

Pelvic ring fractures: Advantages and pitfalls of MDCT

A. Lesavre, A. Miquel, C. Phan, Y. Menu; Le Kremlin-Bicêtre/FR

Learning Objectives: To review the MDCT imaging findings of the pelvic ring fractures. To determine whether they are stable or not with the help of the Tile's classification.

Background: Pelvic ring fractures occur as the result of high-energy blunt trauma, as in motor vehicle collisions. Patients with an unstable pelvic ring fracture require pelvic stabilisation. The approach to classifying pelvic fractures has evolved over the past several decades. Tile's classification into stable and rotational or multiplanar instability is most useful.

Imaging Findings: Conventional X-rays were the gold standard method. Due to the importance of trauma patients, pelvic ring images may be obtained with high quality reconstruction within short acquisitions. Axial slices, as well as coronal, sagittal and oblique reformatted images help the surgeon. 3D imaging may be a simple way to image major fractures in a radiographic manner, although reconstruction algorithm tend to alter fracture detection.

Conclusion: Helical CT should be the first-line imaging method in detection and evaluation of pelvic ring fractures, providing a good communication with the surgeon.

C-0757

MSCT in the postoperative follow-up of vertebral osteosynthetic procedures: Comparison with conventional radiography

M. Lorenzen, U. Wedegärtner, C. Weber, G. Adam, J. Lorenzen; Hamburg/DE

Purpose: Comparison of MSCT and conventional radiography in the evaluation of surgically treated vertebral spines.

Material and Methods: Our retrospective study included 30 patients with surgically treated spines (metastases 5, fractures 20, spondylolisthesis 3, scoliosis 2) who underwent both conventional radiography and MSCT during hospitalisation. MSCT of the operated spine was performed using the following parameters: 140 kV, 200 mAs, collimation 4x1 mm, pitch 0.75. We evaluated the in-situ position of the implanted osteosynthetic devices (OD) as well as the integrity and alignment of the vertebral column. Images were analysed in a consensus reading by two blinded radiologists.

Results: In 9/30 cases, MSCT detected an extraosseous screw tip compared to 5/30 patients by radiography. A displacement of OD into the spinal canal was diagnosed in 8/30 by MSCT and 4/30 by radiography. Bone fragments within the spinal cord were detected by MSCT alone (2/30) and missed on plain films. Based on MSCT findings, corrective surgery was necessary because of malpositioned OD in 1 patient. Fractured OD were detected in 3 cases with both methods equally.

Conclusion: MSCT proved to be superior to conventional radiography in the postoperative assessment of the vertebral column providing clear and relevant information for further therapeutic decisions.

C-0758

Early evaluation of the therapeutic effects of radiotherapy and/or hyperthermia in VX2 rabbit carcinoma using FDG-microPET

K. Ishii, M. Hosono, Y. Wada, S. Kondo, Y. Takada, T. Tada, M. Maeda, Y. Watanabe, Y. Inoue; Osaka/JP

Purpose: The aim of this study was to evaluate the early effect of local irradiation and/or hyperthermia on tumor bearing rabbits using FDG-microPET.

Methods and Materials: Twenty-eight VX2 xenografts in the thigh were divided into five groups; radiotherapy at dose of 10-30 Gy, hyperthermia (43 degrees C, 1 hour) and combination of radiotherapy and hyperthermia (10 Gy+43 degrees C, 1 hour). Primary effect was determined by a comparison of the tumor volume. Finally, all of the xenografts were divided into PR+NC group and PD group. For

Scientific and Educational Exhibits

the quantitative evaluation of FDG, tumor/muscle (T/M) ratios and time activity curve (TAC) were measured using microPET P4 system, at pre-treatment, 24 hours and 7 days after treatments.

Results: In PR+NC group, T/M ratios were 5.0 ± 1.3 , and 6.8 ± 1.9 at 24 hours and 7 days after treatments respectively. In PD group, T/M ratios were 8.0 ± 3.0 , and 8.8 ± 2.5 at each point. Compared to T/M ratios at pre-treatment (9.1 ± 1.9), T/M ratios in PR+NC group were remarkably decreased at 24 hours after treatments ($p < 0.05$). The patterns of TAC were also comparable to the quantitative evaluation of T/M ratios.

Conclusion: Our results suggest that early evaluation of FDG-PET, especially 24 hours after treatments, is useful to predict the primary effects of the treatments.

C-0759

Imaging of extraskeletal osteosarcoma

H. Yoshikawa, T. Ueda, A. Miyaji, N. Tamai, N. Araki, I. Kudawara; *Osaka/JP*

Purpose: Extraskeletal osteosarcoma is a unique and extremely rare neoplasm. In this study, we have analyzed radiologic findings of this tumor, especially focused on pattern of ossification by plain films, computed tomography (CT) and MR imaging.

Methods and Materials: 10 patients with extraskeletal osteosarcoma (7 male and 3 female), aged 49-74 years (mean 61), were reviewed radiologically. The tumors were located in the thigh in 3 patients, the upper arm in 3 patients, in the calf in 2 patients, and in other sites. All cases have been confirmed histologically, and studied radiologically with plain films, CT, and MR imaging.

Results: Plain films and CT revealed calcified or ossified materials in 8 out of 10 cases, but not in the remaining 2 cases. In 3 of the 8 cases with calcification/ossification, spicula formation, so-called 'sunburst appearance', was partly detected within the soft-tissue mass, and in the remaining 5 cases, only amorphous calcification/ossification was detected. All the tumors were heterogenous on MR imaging and demonstrated lower or iso-intensity to muscle on T1-weighted imaging and high signal intensity on T2-weighted imaging. The areas of calcification/ossification showed low signal intensity on both T1 and T2-weighted images.

Conclusion: The "sunburst" appearance, a distinctive periosteal reaction of conventional osteosarcoma, could be a characteristic finding, even in some extraskeletal osteosarcomas. The MR imaging findings are non-specific, but in elderly patients the differential diagnosis of a soft-tissue mass should include extraskeletal osteosarcoma, even in the absence of radiologically discernible calcification/ossification.

C-0760

The influence of oral glucose ingestion during a dynamic FDG-microPET study using a rabbit VX2 tumor model

K. Koyama, T. Okamura, Y. Hamazawa, T. Okuma, Y. Wada, K. Ishii, S. Kondo, Y. Watanabe, Y. Inoue; *Osaka/JP*

Purpose: Delayed images are reported to be useful for differentiating malignant from benign masses, but patients are required to fast for additional hours, which can be stressful. We investigated the influence of oral glucose ingestion during a study on tumor FDG accumulations in an animal tumor model using a small animal PET imaging system with a high spatial resolution (1.85 mm).

Materials and Methods: Japanese white rabbits, with eight transplanted VX2 tumors in their thighs, were employed. As a no-glucose-loading FDG-microPET study, after four hours fasting, dynamic emission data acquisition was performed until 2 hours after intravenous FDG injection. For glucose-loading FDG-microPET study, oral ingestion of 10 ml of 50% glucose solution at one hour after intravenous FDG injection was added to no-glucose-loading study using the same rabbits. Images, reconstructed every ten minutes using a filtered-back projection method, were analyzed visually. Time activity curves (TACs) and tumor-to-muscle ratios (T/M ratios) were also calculated after regions of interest were set in tumors and muscles.

Results: Blood glucose levels after two hours were significantly higher than those before oral ingestion. In visual analysis, tumor FDG accumulations increased with time in both studies. T/M ratios also increased with time and TACs showed increasing curves in both studies. Concerning the ratios of T/M ratios obtained at one hour to those obtained at 2 hours; there was no significant difference between both studies.

Conclusion: Tumor FDG accumulations in dynamic FDG-microPET are not influenced by oral glucose ingestion at one hour after intravenous FDG injection.

C-0761

Comparison of dynamic FDG-microPET study in a rabbit VX2 tumor model and that in a turpentine-induced rabbit inflammatory model

Y. Hamazawa, K. Koyama, T. Okamura, Y. Wada, T. Wakasa, T. Okuma, Y. Inoue; *Osaka/JP*

Purpose: We evaluated the differentiation of tumor from inflammation using FDG-microPET dynamic scans obtained by MicroPET P4 scanner in an animal tumor model and animal inflammation model.

Materials and Methods: Five Japanese white rabbits with 10 tumors, which were transplanted VX2 tumors and 3 Japanese white rabbits with 6 inflammations, which were induced by turpentine oil injection. Helical CT scans were done before the PET studies. In the PET study, after four hours fasting, and following transmission scans, dynamic emission data acquisitions were performed until two hours after intravenous FDG injection. Images, reconstructed every ten minutes using a filtered-back projection method, were analyzed visually. Time activity curve (TAC) and tumor-to-muscle ratio (T/M ratio) or inflammation-to-muscle ratio (I/M ratio) were calculated after regions of interest were set in tumors, inflammatory regions and muscles referring to CT images.

Results: The T/M ratio and the I/M ratio increased with time. Between after 1 hour and after 2 hours, TAC of tumor showed a linear rise, whereas TAC of inflammation showed a convex curve. The T/M ratio was significantly higher than I/M ratio at after 2 hours, although at after 1 hour there was no significant difference between them.

Conclusion: The differentiation of tumors from inflammations not possible using FDG-PET images obtained after 1 hour; on the other hand, it was easy and capable using FDG PET images obtained after 2 hours because of the differing rates of increase. The delayed images were thought to be useful for differentiation between those.

C-0762

High-resolution ultrasonography findings of peripheral nerve abnormalities

Y. Koh, J.H. Cha, D. Han; *Seoul/KR*

Learning Objectives: The object of the poster is to illustrate ultrasonographic findings of various peripheral nerve abnormalities.

Background: MR imaging is the most popular imaging modality in evaluation of peripheral nerve abnormalities. However, modern ultrasonography using high-resolution linear probes offers excellent images of superficial lesions. Therefore, peripheral nerves, except those in the brachial or sacral plexus are potential targets of ultrasonography. The author's experience shows that ultrasonography is a powerful imaging tool in evaluating many peripheral nerve abnormalities.

Procedure Details: All ultrasound examination was done using with ATL HDI 3000 system (Bortheil, WA, USA) with 5-12 MHz linear transducer and Accuson Secquoia (Mountain View, California, USA) with 8-15 MHz transducer. Ultrasonographic findings are correlated with MR imaging findings. This poster presents cases of carpal tunnel syndrome (cubital tunnel syndrome, tarsal tunnel syndrome, common peroneal nerve entrapment syndrome) and traumatic nerve injury (nerve traction injury after base ball pitching, median nerve laceration after elbow joint dislocation, superficial peroneal nerve lateral branch compression neuritis by boot, ulnar nerve neuritis after recurrent ulnar nerve dislocation at cubital tunnel, traumatic neuroma after neuropathy, axonal degeneration of radial nerve by compression by internal fixation after humerus fracture) nerve origin mass lesion (neurilemmoma, neurofibroma, nerve origin lymphoma).

Conclusion: High resolution ultrasonography is a promising tool in the evaluation of peripheral nerve abnormalities. Ultrasound is complementary to MR imaging; it is both faster and cheaper than MR imaging, and it sometimes demonstrates lesions not visualized at MR imaging. In conclusion, ultrasonography should be a major radiologic evaluation tool for evaluating peripheral nerve abnormalities.

C-0763

Intraneuronal ganglion cyst of the common peroneal nerve: MR imaging findings

S. Ruiz, A. Sánchez, J. Narváez, E. Andia; *Barcelona/ES*

Learning Objectives: To describe the MR imaging findings in intraneuronal ganglion cyst of the common peroneal nerve (CPN).

Background: Intraneuronal ganglion cyst is a rare disorder characterized by an accumulation of mucoid substance in one nerve, leading to pseudocyst formation. The CPN is the peripheral nerve most frequently affected. We retrospectively reviewed 5 examinations performed in 5 patients with progressive foot drop. Diagnosis was pathologically confirmed in 4 cases. MR imaging examinations were performed using a surface-coil. Spin Echo T1W and T2W, fat suppression

Scientific and Educational Exhibits

and STIR sequences were obtained. Contrast enhanced MR imaging images were obtained in 2 patients. Location, shape, size and signal intensity of the lesion and muscular oedema-like pattern were analysed.

Imaging Findings: All patients had difficulty in dorsiflexion of the foot and paraesthesia along the nerve's distribution. Palpable mass was present in 1 case and Tinel's sign in 2. MR imaging images showed in all cases, a well-defined round or tubular lesion with homogeneous signal intensity, low on T1-weighted images and bright on T2-weighted images, STIR and fat suppression sequences along the course of the CPN. Slightly peripheral enhancement was seen after gadolinium administration. Oedema-like pattern was observed in anterior or lateral muscular compartments. Intra-neuronal ganglion cyst was pathologically confirmed in 4 patients.

Conclusions: Although intra-neuronal ganglion cyst of CPN is a rare disorder, it should be considered in the differential diagnosis of progressive foot drop due to potential recovery after surgery. MR imaging demonstrated the cystic nature of the lesion, extension and anatomic relationship.

C-0764

High-resolution ultrasonography to evaluate the radial nerve

T. Piedra, V. Gomez-Dermit, R. Landeras, M. Aguilar, P. Zubietta, M.A. Fernandez-Echevarria; Santander/ES

Purpose: Our purpose is to describe the findings on high-frequency sonography of normal and pathologic radial nerve and determine whether sonography can help in the detection and characterization of the disease in these patients.

Materials and Methods: US studies were performed with a 5.5-12 MHz high-resolution linear array transducer. The utilization of Color-Doppler imaging allows the visualization of the artery adjacent to the radial nerve and the detection of hyperperfused areas especially in inflammatory, infectious and tumoral diseases. Patients were in a supine position and the elbow was flexed at 90° to access to the lateral part of the humerus.

Results: We describe the normal anatomy of the radial nerve through the middle and distal thirds of the upper extremity and of its sensory and motor branches. We illustrate different pathologic conditions like affection of the nerve secondary to humeral shaft fractures (5 cases), compression of posterior interosseous nerve (4 cases: 1 lipoma, 1 liposarcoma, 1 synovial cyst, 1 myositis) and superficial branch of the radial nerve (1 schwannoma).

Conclusion: US is an available, innocuous technique that allows identification of the radial nerve in normal and pathologic conditions, contributes to the decision on whether or not nerve exploration should be performed, provides important information about nerve damage especially when surgery is needed and can be used to monitor nerve regeneration in cases conservatively treated.

C-0765

Assessment of entheses by power Doppler technique in ankylosing spondylitis: A pilot study

A. Kiris, A. Kaya, S. Ozgocmen, E. Kocakoc; Elazig/TR

Purpose: Ankylosing spondylitis (AS), a chronic disease leads to progressive spinal ankylosis and deformity. Enthesitis is one of its' most prominent features. The aim of this pilot study is to validate a rationale for the value of power Doppler ultrasonography (PDU) in evaluation of entheses.

Method and Materials: Eleven patients (7M, 4F, mean age 34.3, disease duration 8.6 years) were included in the study. Patients were scrutinized for disease activity parameters, pain on entheses. B-mode and PDU was performed using 7-14 MHz multifrequency broadband linear array transducer. On B-mode examination changes on entheses were noted and power Doppler signals on entheses were graded (0-3). Ten entheses were examined in each patient.

Results: B-mode ultrasonography revealed pathological findings in 51/220 entheses (23%) examined. All patients had pathological changes in B-mode in at least two entheses. PDU revealed detectable flow in 31/220 entheses (14%) examined. Five patients had both flow signals and B-mode changes on entheses, whereas six had no flow signal on PDU although they had pathologic findings in B-mode. Pressure pain threshold was significantly lower in 31 entheses that had PD signals than entheses without PD signals (4.3 vs. 4.9, p = 0.006).

Conclusions: Consequently, B-mode ultrasonography is a valuable tool to examine entheses and a reliable method. Concomitant use of PDU with B-mode may enhance ultrasonographic features and may predict inflammation of enthesitis by means of hypervascularisation. In this regard, there may be a link between inflammation, hypervascularisation and pain on entheses. These results promote a rationale for further studies.

C-0766

MR imaging in spinal injury in patients with ankylosing spondylitis

G. Mantzikopoulos, K. Pikoulas, I. Staikidou, G. Giannikouris, K. Ioannidis, K. Dagiada; Athens/GR

Purpose: To present the imaging findings and the role of MR imaging in the investigation of spinal injuries in patients with ankylosing spondylitis.

Materials and Methods: We retrospectively reviewed the MR imaging studies of 9 patients (7 men & 2 women, 44-75 years of age) with ankylosing spondylitis who had sustained spinal injury and were admitted to our hospital during the last 4 years.

Results: 6 patients had Chance-type flexion-distraction injuries and 2 patients had compression fractures. 1 patient had vertical atlanto-axial subluxation. Involvement of cervical spine was seen in 3 cases and of thoracic spine in 6 cases. Contiguous vertebral injury was present in 4 cases and non-contiguous injury in 2 cases. 3 cases had displaced fractures with significant stenosis of the spinal canal. 1 patient had a fibrous union at the fracture site in a follow-up examination. Bone and soft tissue edema were clearly depicted and the fracture line was evident in all cases. Posterior ligamentous disruption was present in all Chance-type injuries. A horizontal fracture of the posterior neural arches producing a "sandwich sign" was seen in 2 cases.

Conclusion: MR imaging of spinal injuries in patients with ankylosing spondylitis allows a timely and confident diagnosis of the various types of bone and soft tissue injuries present as well as their possible neurological complications.

C-0767

MR imaging evaluation of tibialis posterior tendon: Assessment of its disorders and its role in determining coxa pedis syndrome

C. Bultrini, N. Limbucci, A. Barile, R. Manetta, G. Bonanni, C. Masciocchi; L'Aquila/IT

Purpose: To assess the role of MR imaging in the evaluation of the tibialis posterior tendon (TPT) and its influence in determining coxa pedis syndrome.

Methods and Materials: We retrospectively analysed 45 patients undergoing MR imaging because of the clinical diagnosis of coxa pedis syndrome. MR imaging examinations were performed with 1.5 T whole body and 0.2 T dedicated MR units. The sequences employed were SE-T1W, GE-T2W and SE-T2W with fat-saturation on sagittal and oblique-axial scan planes; the slice thickness was 3-4 mm. All patients were previously submitted to plain film. Five safe volunteers were previously submitted to MR imaging examination to optimize sequences, scan planes and anatomy.

Results: In all cases MR imaging allowed identification of TPT. In 36 of 45 patients (80%) MR imaging showed signal abnormalities suggestive of TPT degeneration with or without tenosynovitis; an associated condition of os tibiale was discovered in 14 of these 36 patients (38.9%). 10 of 36 patients (27.8%) had MR imaging signs of partial TPT tear, and in 4 cases (11.1%) we found complete TPT tear. In 6 of 36 cases (16.7%) we found talo-navicular chondropathy associated to TPT disease and in 2 cases (5.5%) spring ligament pathology.

Conclusion: MR imaging is very accurate in the evaluation of TPT and the other structures of the coxa pedis complex, allowing the diagnosis of TPT disease and the detection of possible associated abnormalities. According to our results, TPT disease is the main factor determining coxa pedis syndrome, this confirms that TPT is the main active stabilization structure of the coxa pedis complex.

C-0768

Bryan cervical disc prosthesis: A radiological study

G. Iannucci¹, R. Fossaceca¹, P. Cervellini², F. Causin², M.D. Marchi², V. Pinna¹, A. Carrieri¹; ¹Novara/IT, ²Vicenza/IT

Purpose: The Bryan Cervical Disc Prosthesis provides an innovative method of restoring mobility in patients with cervical disc degenerative disease. This study radiologically evaluated their stability and normal range of motion as well as the clinical evolution of patients 2 years from surgical implantation.

Methods and Materials: This prospective study included 15 patients. 13 patients with symptomatic cervical radiculopathy and 2 patients with myelopathy. We measured maximal flexion-extension (Cobb method) on plain films of the cervical spine in all cases with 1 and 2 years follow-up. We performed CT of the prosthesis at the same time. Effectiveness of the device was also characterized by evaluating each patient's pain, neurological signs and symptoms.

Results: There were no significant differences between the first and the second control in the follow-up period. The average range of motion of devices in flexion-extension at 1 year (mean flexion 31.1°, SD 9.8; mean extension 30.6°, SD 11.9) was demonstrated to be equal or decreased by ~ 2 degrees when compared to 2

Scientific and Educational Exhibits

years control (mean flexion 29.7°, SD 13.3; mean extension 32.8°, SD 12.4). CT scans of the prosthesis never showed fusion of adjacent vertebral bodies but in 2 cases marginal osteophytes were observed. We demonstrated clinical improvement in 14 patients; 1 patient showed no clinical change. None of the patients deteriorated from the baseline pre-operative assessment.

Conclusion: The two-year follow-up study based on neurological signs and symptoms showed a good assessment of the prosthesis function with relief of pain and improvement of cervical motion function.

C-0769

Advanced chordomas treated with imatinib mesilate: MR imaging tumor response assessment after 18 months follow-up

A. Messina, P. Casali, D. Vergnaghi, A. Gronchi, S. Stacchiotti, R. Musumeci;
Milan/IT

Purpose: To evaluate MR imaging patterns of tumor response to imatinib mesylate in advanced chordomas.

Materials and Methods: Following detection of PDGF-R expression in tumor samples, 12 pts with advanced disease (10 with sacral, one with clivus and one with vertebral chordomas) were treated with imatinib mesylate. Before medical treatment 9 patients underwent debulking surgery for a sacral chordoma. All patients were evaluated with MR imaging at baseline, and then every 1-3 months until 18 months from treatment start. MR imaging was performed with a 1.5 T system using morphologic GRE T1w, TSE T2w and contrast enhanced-GRE T1w sequences.

Results: 8 patients (66%) were judged to be responsive to therapy after 18 months. Pts responsive to therapy showed these hints of tumor response: A) minor and slow decrease in size in the pts with the longest follow-up (18 months), following a transient initial increase in size, which was seen in all pts; B) hypointensity of lesions on T1w and hyperintensity on T2w MR images; C) hypovascularity of lesions on CE-T1w MR images in comparison to baseline assessment. These signs supposed a tumor liquefaction, at least in a substantial portion of the tumor volume.

Conclusion: MR imaging may be useful to assess tumor response in patients affected by advanced chordomas treated with imatinib mesylate. Signs of response may be subtle, likely depending on changes in tumor tissue rather than (or before) decrease in size.

different from those who do, that usually have an acute or subacute course. Several bones affected by bone marrow edema, mottled-pattern edema or diffuse-confluent pattern of edema are findings of less chronic disease. Reticular pattern of signal changes, soft tissue atrophy, and even changes in trabecular configuration correlate better with a long-standing course

Conclusion: MR imaging shows findings that make the diagnosis of RSD possible, in certain kinds of patients with chronic pain around a joint or in a limb, not proportional to initial cause of events. Correlation between this set of imaging findings with clinical evolution is good in patients with a previous diagnosis of RSD, and in those without such a diagnosis but a clinical suspicion. In acute and subacute cases, often there are no conventional imaging findings (X-ray).

C-0770

Magnetic resonance findings in macromelia and macrodactyly

X. Merino-Casabiel, R. Dominguez-Oronoz, E. Castella-Fierro, V. Pineda,
F. Ramirez-Urbano; Barcelona/ES

Learning Objectives: To describe the etiologic spectrum and MR findings in macromelia and macrodactyly.

Background: Localized soft tissue and bone overgrowth may be the result of many different causes and will vary in severity, from involvement of a single digit to one half of the body. There are a variety of causes, including chronic lymphedema; lymphangiomatous malformations; neurofibromatosis; vascular malformations including the Klippel-Trenaunay-Weber syndrome; macrodystrophy lipomatosa; multiple enchondromatosis and Maffucci's syndrome.

Imaging Procedures: We reviewed MR images of all patients referred for clinical macromelia and macrodactyly over the last 10 years.

Conclusion: This review illustrates the importance of MR imaging in not only establishing an accurate diagnosis but also in defining the extent of the underlying abnormality.

C-0771

MR imaging findings in patients with a clinical diagnosis or clinical suspicion of reflex sympathetic dystrophy (RSD)

A. Ferreiro, A. Delgado, P. Muyor, A. Martinez de Aragon, R. Stefanova,
A. Ramirez; Madrid/ES

Materials and Methods: We collect imaging findings of 40 patients with a diagnosis of RSD previously reached by clinician, or patients coming with chronic pain around some joint with or without previous injury, not related with initial degree of harm. Most of the cases are related to knee or ankle, but also wrist and hip. All the studies are performed with a 0.65 T open MR imaging machine (FO-NAR corp.). We use Chi square statistics to set a correlation between clinical and imaging criteria.

Results: We compare chronicity of symptoms with imaging findings, and describe findings in patients without a definite diagnosis but with chronic pain in the joint or limb affected. In most of the patients that don't localize pain, findings are

C-0772

Epileptic mothers and their progeny in fMRI imaging assessment of developmental dyslexia

A. Salagierska-Barwinska, B. Goraj, J. Wendorff, B. Wisniewska; Lodz/PL

Purpose: Although much has been said about the occurrence of developmental dyslexia in families, this problem has not been studied in the group of epileptic parents and their progeny. In 40% of children of epileptic mothers there are specific difficulties in learning to write and read; this constitutes a significantly higher percentage than in the general population. This project assesses two of the important etiological factors of dyslexia, that is family history of disorders and abnormalities in the range of neuropsychological function.

Materials and Methods: fMRI imaging was carried out in 20 participants: 10 epileptic mothers and 10 of their healthy children. Our previous control study was performed in 30 dyslexic participants and 30 healthy participants. All subjects had normal mental development. MR examination with a 1.5 T Siemens Vision scanner equipped with echo-planar imaging software was performed. 21 contiguous brain slices were acquired. Data recording was performed alternating at rest and in task execution. Two different language problems were performed. Functional images were generated using statistical methods - SPM'99 software.

Results: Anatomical location of cortical activation in all participants was unusual comparing with our preceding research in control dyslexic and normal participants. During the tasks in children of epileptic mothers no significant activation in Broca's center (44.45 BA) in the left lobe was observed.

Conclusion: This research indicates the role of two of the most significant etiological factors in developmental dyslexia (family history and CNS functional changes). Our studies have shown deficit in the neural mechanisms underlying phonological processing in children of epileptic mothers.

C-0773

Correlation of diffusion tensor MR imaging with MR spectroscopy in multiple sclerosis

R. Irwan, P. Sijens, M. Oudkerk; Groningen/NL

Purpose: To compare the results of magnetic resonance spectroscopy (MRS) and diffusion tensor imaging (DTI) in multiple sclerosis (MS) patients.

Methods and Materials: Sixteen patients with MS were examined by MRS and DTI using a 1.5 Tesla MR system (Sonata, Siemens Medical Systems, Erlangen, Germany). Point resolved spectroscopy (PRESS, TE/TR = 135/1500) was used for chemical shift imaging applied on a supraventricular transverse volume of interest of 8x8x2 cm³. For the inner 6x6 = 36 voxels the peak areas of choline (Cho), creatine (Cr) and N-acetylaspartate (NAA) were determined by curve fitting. In DTI a segmental spin-echo sequence (TE/TR = 91/5500) was used with the following acquisition parameters: field of view 23 cm; matrix 128 x 128 with interpolated readout to 256 steps; 12 directions and two b-values ($b = 0$ and $b = 1000 \text{ sec/mm}^2$). Five slices of 4 mm each (non-overlapping) were stacked in order to reproduce the 20 mm slab used in MRS. Mean fractional anisotropy (FA) and apparent diffusion coefficient (ADC) were subsequently determined for the 36 voxels defined in MRS.

Results: Significant correlations between the spatial distributions of metabolites and DTI parameters in normal appearing white matter of MS patients were found, most notably that of NAA/Cr ratio and FA ($r = 0.65$ and $P < 0.0001$).

Conclusion: It has been known that MS patients have increased Cho levels, reduced NAA levels, reduced FA and increased ADC. This is the first association of neuronal loss indicated by MRS (NAA drop) with loss of structure as indicated by DTI (FA decrease).

C-0774

Multidetector CT angiography: The method of choice to detect cerebral venous thrombosis?

N. De Graaf, H.L.J. Tanghe, T.C. Leertouwer, H.Z. Flach, D.W.J. Dippel, A. Van der Lugt; Rotterdam/NL

Learning Objectives: To describe the multidetector computer tomographic angiography (CTA) scanning protocol for detection of cerebral venous thrombosis. To describe the postprocessing protocol for analysis of CTA data. To show the cerebral venous anatomy on CTA images. To illustrate the role of CTA in detecting cerebral venous thrombosis.

Background: Cerebral venous thrombosis (CVT) is a relatively rare, but potentially severe condition. Magnetic resonance angiography (MRA) is usually con-

sidered the gold standard to detect CVT. In our institution we have gained experience using CTA instead of MRA.

Procedure Details: This exhibit describes our scanning protocol (delay, scan direction, scan range, contrast volume, bolus chaser, pitch). Postprocessing is done by creating coronal, sagittal, and axial maximum intensity projections. In addition, volume rendering of the inner skull is performed to evaluate the cortical veins. The venous anatomy will be shown on CTA images. Examples of thrombosis of the superior sagittal sinus, transverse sinus, sigmoid sinus, and straight sinus are shown. In addition, an example of isolated cortical vein thrombosis is demonstrated. Pitfalls are also discussed: arachnoid granulations versus thrombosis, and aplasia of the transverse sinus versus thrombosis of the transverse sinus.

Conclusion: CTA can be used in the acute phase of patients suspected of having CVT.

C-0775

Pontine bright lesions: MR imaging findings and differential diagnosis

V.K. Katsaros, M. Mitropoulou, P. Lampropoulou, C. Mourtopoulos, D. Kolomodi, A. Nikolaou, C. Drossos; Athens/GR

Purpose: The aim of this study was to evaluate different MR imaging sequences for the diagnosis of neoplastic, vascular, inflammatory and miscellaneous pontine lesions.

Methods and Materials: 336 brain MR examinations with pontine lesions were performed by a 1.5 T MR unit (Magneton, Vision). The routine brain MR imaging protocol used included axial T1, proton density and T2-W and FLAIR (Dark-Fluid) and coronal, sagittal T2-W images. T2*-W in the axial plane was obtained in cases of suspected hemorrhage. If necessary enhanced T1-W images were obtained. Correlation with clinical and laboratory findings followed.

Results: A pontine volume increase or decrease was proved comparing the data of the normal and affected brain stem. The topography of lesions was clearly documented by MR imaging. Subacute hematomas were better outlined than by CT, while acute infarctions, foci of demyelination and pontine encephalitis were proved only by MR imaging. Small calcifications and vessels of arteriovenous malformations, however, caused the same MR signal patterns. Pathological hyperintensity in T2, T2*W and FLAIR (Dark Fluid) sequences and pathological enhancement in contrast-enhanced T1W images were found in the following lesions: 1) contusion: 1 2)hematoma: 8; 3)vascular malformations: 12; 4)ischemic lesions: 197; 5)infections: 4; 6)multiple sclerosis: 64; 7)central pontine myelinolysis: 2; 8)polyarteritis nodosa: 1; 9)Wilson's disease: 2; 10)neoplastic: 43; 11)radiation: 2.

Conclusion: MR imaging is of utmost importance in the diagnostic work-up of patients with pontine lesions and in correlation with clinical and laboratory findings the correct diagnosis is established.

C-0776

Transcranial color-Doppler sonography (TCDS) today: When and how to use it

A. Pedicelli, A. Bellitti, A. Cina, M. Rollo; Rome/IT

Learning Objectives: 1)To learn the technique and describe the state of the art of TCDS: probes, conventional and non-conventional acoustic windows (AW), morphological and flowmetric studies, common pitfalls, use of sonographic contrast agents and technical innovations. 2)To give an overview of clinical conditions where the method can be used for diagnosis, integration imaging a/o follow-up.

Background: Compared to traditional Doppler, TCDS permits direct visualization of the vessels (course and abnormalities) and precise positioning of sample volumes on vascular segments for selective flowmetric analysis. We report our experience from 1993 to 2004, discuss the present role, with technical improvements, and show the use of the method in assessment of: vasospasm after SAH, arterial stenosis/occlusion, cerebral embolism monitoring, diagnosis of brain-death. Moreover we report our results in diagnosis and follow-up of:cerebral aneurysms, AVMs (including DAVM and CCF with integration of non conventional facial AW). Initial studies of cerebral perfusion are also reported.

Imaging Findings: In the poster, vascular anatomy as demonstrated by the technique is reviewed. We describe AW (pterional, sub-occipital, trans-orbital), analyze the value and describe when to use quantitative and semi-quantitative flowmetric parameters (SPV, EDV, PI, RI) and finally describe pitfalls that occur by wrong parametric setting, calcium-related artifacts, etc.

Conclusion: At present TCDS is a non-invasive, cost-effective, rapid and bedside performable technique that is useful and has acquired a major role in diagnosis and follow-up for many clinical conditions. Limits of TCDS are due to poor AW and thecal bone thickness, which are overcome by sonographic contrast agents in 85% of cases, by power-Doppler modality and increased spatial resolution of new systems.

Scientific and Educational Exhibits

C-0777

Embolization of cavernous dural arteriovenous fistulas via superior ophthalmic vein approach

S.-H. Suh, D.-I. Kim, D.-J. Kim; Seoul/KR

Purpose: To present the results of treatment for cavernous dural arteriovenous fistulas (DAVFs) with transvenous or surgical approach through the superior ophthalmic vein (SOV).

Materials and Method: 10 patients (M:F = 2:8, mean age = 52 yrs) with cavernous DAVFs were treated via transvenous or surgical approach of SOV during a 4-year period. All patients had chief complaints of proptosis, chemosis and decreased visual acuity. Angiography showed preferential venous drainage of DAVFs to an enlarged ipsilateral SOV. 3 patients had surgical exposure of the SOV and 7 patients had a retrograde transvenous approach via the facial vein. Embolization with coil or polyvinylalcohol was performed through a microcatheter at the fistula site and into the root of the SOV and cavernous sinus, until there was complete angiographic closure. In the follow-up period, angiography or magnetic resonance angiography was performed 3 or 6 months after embolization.

Results: Catheterization and embolization was successful in all patients, with complete angiographic occlusion of the fistula. After successful occlusion of DAVFs, clinical symptoms and signs were completely resolved and no early or late complications had occurred. At follow-up (mean 37 months), all except one patient's embolized fistula was persistently occluded. No patients had recurrent symptoms and signs.

Conclusion: Coil embolization of cavernous DAVFs with retrograde transvenous or surgical approach through SOV is a safe and effective treatment, which are not acceptable to transarterial or other transvenous approach.

C-0778

Head and neck paragangliomas: Diagnostic and endovascular therapy

M. De Juan Delago, L. San Roman Manzanares, T. Salinas Yeregui, C. Castaño Duque, E. Guardia Mas, J. Ruscalleda Nadal; Barcelona/ES

Learning Objectives: To define and illustrate imaging features in CT, MR imaging and arteriography, utility and presurgical endovascular embolization techniques in the diagnosis and therapy of head and neck paragangliomas

Background: 25 paragangliomas were evaluated and included: jugulotimpanic, carotid and vagal glomus. All were evaluated with CT and MR imaging. A selective catheterization of the external carotid artery and their branches with presurgical embolization with PVA particles and coils was made in 14 patients.

Procedure Details: The most frequent initial symptom was a laterocervical painless growing mass. Other symptoms included instability, pulsatile tinnitus and cranial nerves palsies. CT and MR imaging showed typical characteristics of these tumors: well defined masses with important enhancement with intravenous contrast, vascular structures inside producing salt and pepper appearance in standard spin-echo magnetic resonance imaging. The angiography studies demonstrated the presence of hypervascular masses with the characteristic "blush". Also allowed a correct valoration of the venous return. Presurgical embolization obtained devascularization about 90% in all the cases, reducing the bleeding spectacularly in relation with the cases nonembolized previously.

Conclusion: We presented the location, the imaging characteristics and the endovascular presurgical treatment of 25 head and neck paragangliomas.

C-0779

Imaging of head and neck venous malformations: A pictorial review

C.M. Flis, S.E.J. Connor; London/UK

Learning Objectives: To review the classification of venous malformations in the context of head and neck vascular malformations and tumors. To describe and illustrate the imaging findings using ultrasound, magnetic resonance imaging (MRI), computed tomography (CT), conventional angiography and percutaneous phlebography and explain how to differentiate from other vascular/lymphatic malformations. To outline the specific role of these imaging techniques and image guided sclerotherapy.

Background: Venous vascular malformations are non proliferative low flow vascular lesions that consist of dysplastic venous channels. Ultrasound and MRI are the initial imaging modalities of choice with a supplementary role for CT. Characteristic appearances of venous malformations include the presence of phleboliths and markedly hyperintense lobulated lesions on T2-weighted MRI sequences. Image guided sclerotherapy is the first line treatment option in selected cases.

Imaging Findings: The plain film, ultrasound (including colour and duplex Doppler), CT and MRI as well as conventional angiographic appearances of head and neck venous malformations will be described and illustrated together with

examples of image guided sclerotherapy. A range of head and neck subtypes including orbit, oral cavity, superficial and deep facial space, supraglottic, intraosseous and intramuscular will be illustrated.

Conclusion: An understanding of the imaging characteristics of venous malformations of the head and neck is important to enable the correct diagnosis. The radiologist plays a pivotal role in selecting the most appropriate diagnostic and therapeutic modalities.

C-0780

fMRI imaging evidence of functionality in polymicrogyric cortex

D. Araújo, D.B. de Araújo, O.M. Pontes-Neto, S. Scorsi-Rosset, L. Wicher-Anna, J.P. Leite, A.C. Sakamoto, A.C. Santos; Ribeirão Preto/BR

Purpose: Malformations of cortical development (MCD) are one of the most common pathological findings in refractory extratemporal epilepsy. Magnetic resonance imaging (MRI) can reliably show these alterations and provide information for surgical resection. However, there is increasing evidence that neurons in MCD areas are functional and may show different organization patterns in comparison to normal brains. Our objective was to analyze patterns of plasticity and function in polymicrogyric cortex in epileptic patients by blood oxygenation level dependent functional MR imaging (fMRI).

Methods and Materials: Six adult patients (4 female), with clinical and neurophysiological evidence of extratemporal epilepsy, and a radiological diagnosis of polymicrogyria were scanned in a 1.5 T Siemens magnet with fMRI sequences according to language (word generation), and motor (finger tapping) protocols.

Results: Statistical maps showed significant activation of polymicrogyric cortex in the motor strip in the 5 cases in which it was present in that location. In two cases language tasks did not show any significant activation.

Conclusion: Functionality was shown in polymicrogyric areas. In some cases there was evidence of reorganization to ipsi and contralateral areas. Surgical resection may be performed but there is need for functional planning due to reorganization and functionality of polymicrogyric cortex.

C-0781

Perfusion CT imaging of angiogenesis in VX2 rabbit brain tumors

Y. Zhang, L.Q. Kang; Tianjin/CN

Purpose: To validate perfusion CT for reflection of angiogenesis in VX2 rabbit brain tumors.

Methods and Materials: The VX2 rabbit brain tumor model was established. 20 New Zealand White rabbits with tumor size over 3 mm in diameter were randomly divided into group 1 (≤ 3 weeks) and group 2 (> 3 weeks). Perfusion CT was performed with GE Hispeed CT/i scanner. 50 cine mode images were acquired before, during and after intravenous injection of 1.5 ml/kg Omnipaque (300 mg/ml) at a speed of 0.4 ml/s. CT measurements of BV, BF and PS from tumor, peritumor and contralateral normal tissue were obtained using GE perfusion-2 software. 2% Evans blue (2 ml/kg) was given intravenously one hour prior to sacrifice to detect breakdown of BBB. VEGF and MVD were evaluated in immunohistochemical examination of the specimens.

Results: Tumors had significantly higher BV, BF and PS ($P = 0.000$) than did peritumor and normal tissue. Tumor BV, BF and MVD in group 2 were significantly higher than those in group 1. We found a significant linear correlation between MVD and BV ($r = 0.915$, $P = 0.000$), MVD and BF ($r = 0.915$, $P = 0.000$), and MVD and PS ($r = 0.459$, $P = 0.042$). We also found a rank correlation between PS and blue stain of tumor ($r_s = 0.861$, $P = 0.000$).

Conclusion: Perfusion CT can distinguish tumor from peritumor and normal tissue clearly, reflect tumor angiogenesis accurately, and thus provide useful information for the evaluation of brain tumors.

C-0782

Diffusion tensor based analysis of the uncinate fasciculus in mesial temporal sclerosis

S. Rodrigo¹, C. Oppenheim¹, F. Chassoux¹, Y. Cointepas², F.-X. Roux¹, J.-F. Meder¹; ¹Paris/FR, ²Orsay/FR

Purpose: Diffusion tensor imaging (DTI) is a noninvasive technique that can assess the coherence of white matter bundles. Our aim was to evaluate the integrity of the uncinate fasciculus, one of the major bundles connecting the frontal and temporal lobe in mesial temporal sclerosis (MTS).

Methods and Materials: We compared 6 right handed patients with intractable epilepsy related to right hippocampal sclerosis (MTS) and 6 right handed healthy controls. DTI was acquired on a 1.5 T unit (41 directions, $b = 00$ s/mm², 60 contiguous, 2 mm-axial sections). We compared the right and left DTI measurements

Scientific and Educational Exhibits

(mean fractional anisotropy (FA) and mean diffusivity (MD)) measured along the uncinate fasciculus delineated by fiber tracking ("Brainvisa/Anatomist" software, <http://brainvisa.info>). Right/left asymmetry of DTI values were compared in each subject using a student T-test.

Results: Five patients had significantly ($p < 0.001$) higher MD in the right uncinate fasciculus, ipsilateral to the MTS, while all controls had higher MD in the left side ($p < 0.001$). One patient, with an atypical EEG pattern, showed a higher MD, contralateral to the MTS. Fractional anisotropy asymmetry did not significantly differ between patients and controls.

Conclusion: While right handed controls showed a MD asymmetry of the uncinate fasciculus (left superior to right), this pattern is inverted when a right MTS is present. This confirms the ability of DTI to depict microstructural abnormalities along the temporo-frontal white matter bundles, which may be involved during the ictal spread.

C-0783

Comparison of BOLD signal strength and susceptibility artifacts between 1.5 and 3.0 Tesla at different TE

B. Schmitz, G. Grön, A.J. Aschoff; Ulm/DE

Purpose: Blood oxygen level dependent (BOLD) signal for functional magnetic resonance imaging (fMRI) relies on changes in susceptibility. Susceptibility artefacts become stronger with increasing B_0 as well as with increasing echo time (TE). We compared BOLD signal strength for different TE at 1.5 and 3.0 Tesla (T).

Methods and Materials: 48 slices with 3.3 mm isotropic voxels covering the whole brain within an interscan interval (TR) of 4500 ms were acquired on a 1.5 T Symphony and 3.0 T Allegra (both Siemens) at echo times of 20, 30, 40, 50 and 60 ms. A blocked finger tapping within subject design was used with 54 volumes scanned, a stimulus onset asynchrony of 16 volumes, and an epoch length of 8 volumes. Beta values were computed from scaled EPI-series within the general linear model (SPM 99) as a quantitative measure of BOLD signal strength.

Results: Significant activation in the hand motor area was achieved in all sessions. BOLD signal increased with increasing TE. At every TE signal strength from 3.0 T was higher than from 1.5 T with a peak at 40 ms with a fourfold increase. Susceptibility artefacts at air-bone interfaces increased with increasing TE and B_0 strength.

Conclusion: The BOLD signal increase at higher B_0 allows shorter TE down to 20 ms, which in turn enhances temporal resolution and allows for scanning volumes at a higher frequency. This will augment statistical power for analysis of functional data. Susceptibility artefacts at the skull base from large B_0 can be overcome by using shorter TE.

C-0784

MR imaging patterns of hypoxic-ischemic encephalopathy in premature and term born infants

J. Nikas, C. Hadjigeorgi, A. Anagnostara, M. Theofanopoulou; Athens/GR

Purpose: To describe and attempt to classify the different MR imaging patterns of hypoxic-ischemic injury in preterm and term infants.

Materials and Method: We retrospectively reviewed the MR scans of 49 children with some type of cerebral palsy (21 preterm and 28 term) and history of perinatal injury.

Results: In all premature children MR imaging revealed lesions of periventricular leukomalacia of different severity. In term infants we observed 6 different MR patterns of ischemic lesions; either isolated or in combination: a)profound-selective lesions, b)parasagittal lesions, c)ulegryria, d)multicystic encephalomalacia, e)periventricular leukomalacia and f)arterial infarcts.

Conclusion: Hypoxic-ischemic brain damage in preterm infants is manifested with periventricular leukomalacia, while in term infants a variety of brain lesions can be found. We describe 6 different MR patterns of hypoxic encephalopathy, occurring in isolation or in combination, which are closely related to the perinatal history and the neurological deficits.

C-0785

Differential diagnosis of lesions involving the brain and spinal cord in patients with lymphoma

A. McGrath, C. Farrelly, N. Sheehy, J.F.M. Meaney; Dublin/IE

Learning Objectives: 1.To describe the spectrum of appearances in patients with primary CNS lymphoma. 2.To illustrate the spectrum of abnormalities in patients with disseminated disease. 3.To illustrate the differential diagnosis of lesions involving the brain and spinal cord in patients with known/treated lymphoma. 4.To highlight changes attributable to the effects of radiation and chemotherapy in patients treated for lymphoma.

Background: Lymphoma most commonly affects the brain as a result of disseminated disease in patients in whom the diagnosis has already been established. Primary CNS lymphoma is increasing in incidence, primarily due to an increasing incidence in patients with immunocompromise (most commonly HIV related). Intramedullary spinal lesions are also usually associated with disseminated disease.

Procedural details: Imaging features are non-specific, and biopsy is usually essential for diagnosis. However, findings that suggest a diagnosis of lymphoma include periventricular white/gray matter involvement, peri-vascular spread, tumour crossing the corpus callosum, low attenuation on CT, low signal intensity on T2W MR imaging and less oedema compared to other tumours. Findings in patients with known lymphoma include lymphoma masses, meningeal infiltration, infections, radiation changes and drug-induced leuco-encephalopathy. Lymphoma associated granulomatous vasculitis is a rare cause of multiple brain lesions.

Conclusion: This electronic poster illustrates the wide spectrum of imaging abnormalities in patients with primary and secondary CNS lymphoma. Treatment related complications are also presented.

C-0786

Cocaine and heroin abuse related to acute encephalopathy: Emergency MR imaging findings

V. Pupillo, E. Puglielli, C. Fiumara, R. De Amicis, C. Masciocchi, M. Gallucci; L'Aquila/IT

Purpose: Many studies have dealt with MR imaging patterns in relation to cocaine and heroin abuse but none concern pts studied in the emergency situation.

Methods and Materials: 12 patients (4 females and 8 males, average age 29.7) entered the study. All of them came from a first aid station and were suffering from an acute encephalopathy resultant from cocaine or heroin abuse. All patients underwent standard MR imaging examination, performed with 1.5 T MR scanner.

Results: In 3 patients Delayed Post-Hypoxic Leucoencephalopathy (DPHL) related to cocaine abuse and consequent to protracted cardiac dysrhythmia were found; in 3 patients with heroin abuse bihemispheric leucoencephalopathy involving also fronto-temporal cortex and basal ganglia were found; in 1 case of heroin and benzodiazepine abuse aspects compatible with a bilateral limbic encephalitis were registered; 1 case of anterior spinal artery ischemia was related to cocaine abuse; 2 cases of cerebellar ischemic lesion and 2 cases of supratentorial cerebral ischemia related to cocaine were registered.

Conclusion: Alterations due to cocaine abuse are usually caused by direct alterations that the drug induces on vessel walls while in the case of heroin, to toxic substances that are "cut" with the drug.

C-0787

Malignant lymphomas and carcinomas involving the cavernous sinus: Assessment with apparent diffusion coefficient

M. Maeda, K. Takeda; Tsu/JP

Purpose: Malignant tumors such as lymphoma and carcinoma can spread into the cavernous sinus. The purpose of this study was to evaluate apparent diffusion coefficient (ADC) of tumors involving the cavernous sinus by line scan diffusion-weighted imaging (LSDWI) and to determine the usefulness of it for differentiating between the two tumors.

Methods and Materials: Four patients with malignant lymphoma (mean maximum diameter, 19 mm) and five patients with carcinoma (mean maximum diameter, 25 mm) were studied. The MR study was performed prior to treatment in all patients. LSDWI was performed using b values of 5 and 1000 s/mm², and effective section thickness/gap of 3/0.5 mm. LSDWI images were obtained in the coronal plane focusing on the cavernous sinus. ADC values were calculated and compared between malignant lymphomas and carcinomas. Mann-Whitney U test was applied to detect any significant differences in mean ADC values.

Results: LSDWI could provide images free from susceptibility artifacts and permit measurements of ADC values in all cases. The ADC value (mean \pm SD) was $0.51 \pm 0.06 \times 10^{-3}$ mm²/s in malignant lymphomas and $1.01 \pm 0.06 \times 10^{-3}$ mm²/s in carcinomas. A significant difference in ADC values was found between the two ($p < 0.01$).

Conclusion: LSDWI enabled quantitative assessment of diffusion in malignant tumors involving the cavernous sinus. Malignant lymphoma showed significantly lower ADC value than carcinoma. This method appears to be useful for differentiating between malignant lymphoma and carcinoma involving the cavernous sinus.

C-0788

Cerebral blood flow in subclavian steal syndrome evaluated by arm exercise Tc-99m ECD SPECT

K. Kaneko, K. Yasumori, T. Matsumura, K. Hiraka, K. Furuya, S. Uehara, S. Fujimoto, Y. Okada, T. Muranaka; Fukuoka/JP

Purpose: To evaluate cerebral hemodynamic state in patients with subclavian steal syndrome, we investigated both arm exercise and arm hemostasis using Tc-99m ECD SPECT.

Methods and Materials: The subjects were ten patients with subclavian steal syndrome who had subclavian stenosis and systolic reversed vertebral flow. SPECT images were obtained using an equal-volume-split dual-injection single-day protocol [resting and vascular reserve (RVR) method]. Then we measured regional cerebral blood flow (rCBF), and automated ROI analysis using a three-dimensional stereotaxic ROI template (3DSRT) was performed in the cerebral cortices and cerebellum.

Results: Four patients showed a decrease of rCBF in posterior cerebral artery (PCA) territory (12.9%; mean) and cerebellum (12.4%) than those of arm hemostasis SPECT, and those of middle cerebral artery (MCA) and anterior cerebral artery (ACA) territory were also decreased. One of four patients who complained of vertigo during the examination showed over 20% decrease of rCBF in cerebral cortices and cerebellum. In other patients, rCBF were preserved in arm exercise SPECT.

Conclusion: Arm exercise may cause cerebral and/or cerebellar hypoperfusion in patients with subclavian steal syndrome. Arm exercise Tc-99m ECD SPECT could show these phenomena, and make it possible to evaluate their degree and distribution.

C-0789

Tractography of corticospinal tract stroke by diffusion tensor imaging:

Clinicotopographical correlation

J.-H. Kim, J.-S. Lee, S.-H. Kim; Seongnam-Si/KR

Purpose: Fiber tracking of the white matter using diffusion tensor imaging is a new imaging technique to visualize the integrity of the white matter. We investigated the capability of this technique in localizing lacunar infarctions, specifically with respect to the body parts affected.

Methods and Materials: Twenty-seven patients with acute lacunar infarctions in capsular and percapsular regions underwent diffusion tensor imaging and subsequent fiber tracking of the corticospinal tract (CST). According to lesion topography with regard to the CST, infarctions were categorized into four different types: 1)cranial type involving the anterior part of the CST, 2)central type involving the middle or whole part of the CST, 3)caudal type involving the posterior part of the CST, 4)intact type not involving the CST. Each type was correlated with the presence or absence of motor weakness of the specific body parts.

Results: Cranial type was found in 9 patients, central type in 9 patients, caudal type in 5 patients and intact type in 4 patients. Motor weakness of the face, upper extremity and lower extremity was found in 100%, 67% and 44%, respectively in cranial type, in 89%, 100% and 89%, respectively in central type, at 20%, 80% and 100%, respectively in caudal type. Intact type was not associated with motor weakness.

Conclusion: Fiber tracking of the CST enables specific localization of lacunar infarctions with regard to the body parts affected. Our results support strongly the topographical accuracy of the fiber tracking of the CST.

C-0790

Metronidazole induced encephalopathy: MR findings and clinical presentation

E. Kim¹, S. Kim², E. Kim¹, D. Na¹, J. Ryoo³, S. Lee¹; ¹Seoul/KR, ²Chunchon/KR, ³Inju-Si/KR

Purpose: To describe the clinical features and magnetic resonance findings of metronidazole induced encephalopathy.

Materials and Methods: Six patients with Crohn's disease (n = 2), pseudomembranous colitis (n = 1), brain abscess (n = 1), spontaneous bacterial peritonitis (n = 1), and intraabdominal abscess (n = 1) were enrolled in the study. They had been treated with metronidazole and subsequently presented with neurological signs and symptoms consisting of ataxia, dysarthria, and weakness or tingling sensation of both extremities. They underwent MR imaging with or without diffusion-weighted imaging (DWI) within 7-66 days after symptom onset. Follow-up MR was obtained in 4 patients after discontinuation of metronidazole.

Results: All patients showed high signal intensity in the splenium of the corpus callosum, red nucleus, and/or dentate nuclei on both T2-weighted and FLAIR

images. High signal intensity was also seen at the bilateral subcortical white matter in two patients; the basal ganglia, anterior commissure, and tectum in one patient. No enhancement was seen in the hyperintense lesions. DWI was obtained in four patients, and showed iso- or hyperintensity and variable ADC values on the corresponding areas. All patients rapidly improved clinically after discontinuation of metronidazole. Repeat MR imaging including DWI was obtained in four patients, and showed near complete resolution of the previous abnormalities.

Conclusion: Hyperintense lesions in the splenium of the corpus callosum, red nucleus, and/or dentate nuclei on T2-weighted and FLAIR images were noted in all patients with metronidazole-induced encephalopathy. They were also noted in the subcortical white matter, basal ganglia, anterior commissure, and tectum. Metronidazole-induced encephalopathy was reversible both radiologically and clinically.

C-0791

18 F-FDG PET in anxiety-obsessive disorders (AOD): Metabolic and clinical correlation study

A.A. Stanzhevsky, L.A. Tyutin, A.V. Korzenev, N.A. Kostenikov, V.A. Shustin, T.A. Skoromets, N.G. Neznanov; St. Petersburg/RU

Purpose: To evaluate metabolic involvement of limbicostrital system structures in patients with AOD before and after treatment.

Methods and Materials: 18F-FDG PET was carried out in 10 patients with AOD and 30 age-matched normal controls. In all cases of AOD the examinations were performed before and after the treatment with serotonin reuptake inhibitors and anxiolytic drugs. The 18F-FDG images of patients with AOD were assessed using statistical parametric mapping. Then PET results were compared with clinical state estimated according to standard scales (Y-BOCS and Spilberger Anxiety State Scale-SASS).

Results: The regional cerebral glucose metabolism was increased in the anterior cingulate before treatment in 5 cases of AOD. Hypometabolism in the head of the caudate in 6 cases and thalamus in 5 cases was observed before treatment. A significant improvement in obsessive-compulsive and anxiety symptoms on the Y-BOCS and SASS was observed after treatment in all patients. Follow up 18F-FDG PET examinations revealed a metabolism decrease in anterior cingulate, increase of metabolism in the head of the caudate and thalamus in these patients. Metabolic and clinical data significantly intercorrelated.(anterior cingulate - Spearman R = 0.68 (Y-BOCS), 0.51 (SASS), p < 0.05, caudate heads - Spearman R = -0.58 (Y-BOCS), -0.46 (SASS), p < 0.05, thalamus- Spearman R = -0.67 (Y-BOCS), -0.43 (SASS), p < 0.05).

Conclusion: This data proves participation of the limbicostrital system in the pathogenesis of AOD. Our results demonstrate the possibility of using 18F-FDG PET for estimation of treatment efficacy of AOD.

C-0792

Trigeminal neuralgia: Imaging of normal anatomy and pathological conditions

P. Bermudez Bencerray, A. Carvajal, M. Zauner, A. Rovira, D. Gil, M. Prenafeta, A. Lüttich; Sabadell/ES

Learning Objectives: 1. To explain and illustrate trigeminal nerve anatomy in its spinal root. 2. To describe the imaging findings for different pathologies involving the trigeminal nerve in its spinal root, based on its anatomical topography and its aetiology.

Background: Understanding the different pathologies that can affect the trigeminal nerve requires thorough knowledge of the anatomy of this cranial nerve, from its real origin in the brainstem through its apparent origin and along its pathways through the cisterns and parasellar region. The different intrinsic and extrinsic pathologies that can cause trigeminal neuralgia have particular characteristics depending on their topography and aetiology.

Imaging Findings: We present a pictorial review of the anatomical details of the trigeminal nerve, including the most significant cases of pathologies involving the trigeminal nerve at different points along its pathway (pons, cisternal and parasellar) from a retrospective review of the examinations carried out in our centre.

Conclusion: Knowledge of the anatomy and pathological states of the trigeminal nerve is essential to understand imaging findings in the different pathologies that affect this cranial nerve and enables a correct differential diagnosis among the different pathological entities.

C-0793

CT perfusion: Possible diagnostic applications

E. Sanchez, E. Marco de Lucas, V. Gomez, T. Piedra, P. Merino, M. Aguilar, P. Ruiz, E. Ruiz, A. Gonzalez; *Santander/ES*

Learning Objectives: CT perfusion is a relatively new technique useful in studying cerebral ischemia; we illustrate the usefulness of this method in the study of other brain lesions.

Background: 113 patients were examined in our department during last year, most of them due to an acute ischemic stroke in order to select possible candidates for fibrinolytic treatment. The other pathologies included were transient global amnesia, migraine attacks, inflammatory processes and infections (AIDS), and neoplasms to measure the permeability surface product area (metastasis, lymphoma, meningioma, glioma...). We consider that CT perfusion is very useful in all of these cases because it can be performed quickly and give additional information comparable to MR. Even in cerebral death it could be an ideal technique in the early diagnosis before the donation of organs.

Procedure Details: We analysed the CT perfusion findings and evaluated the correlation between these findings, the clinical evolution and other methods of diagnosis applied. We used protocol CT perfusion² from GE that allows evaluation of cerebral perfusion by generating maps of Cerebral Blood Flow, Cerebral Blood Volume, Mean Transit Time and Surface Permeability.

Conclusion: CT perfusion is an useful, easy and fast technique to study ischemic, neoplastic, degenerative or inflammatory pathology in the brain, with wide future prospects because of its accessibility; although it will be necessary to carry out further studies in the future to demonstrate these benefits.

C-0794

Cervical vessel dissection: Comparison of CT angiography with digital subtraction angiography and radiological findings

J.M. Martos Becerra, J.J. Espejo Herrero, R. Diaz Aguilera, M. Ramos Gómez, F. Bravo Rodriguez, F. Delgado Acosta, C. Landauro Comesña, E. Roldán Romero; *Cordoba/ES*

Purpose: Spontaneous dissection of cervical arteries is an uncommon but important cause of stroke because it usually occurs in young patients. We show the correlation between diagnosis with CT angiography and digital subtraction angiography (DSA), as well as the statistical association between cranial CT findings in the first 24 hours and the clinical outcome.

Methods and Materials: We analyzed prospectively 43 cases of spontaneous dissection of cervical vessels (32 carotid arteries and 11 vertebral arteries). All patients showed findings in angiography that were compatible with dissection of at least one cervical artery. A cranial CT was carried out in 41 patients and 29 were studied with CT angiography. We collected epidemiological data, radiological findings and three-month outcome (using Rankin modified scale). We performed Chi-square test and Cramer's V test to study the association between findings in CT angiography and DSA and between cranial CT findings and clinical outcome.

Results: The most frequent finding in angiography and angi CT was stenosis (25 patients). We found a correlation between findings in angiography (gold standard) and CT angiography (Chi-square: 0.8949 for p < 0.05; Cramer's V: 0.2483) and a bad prognosis in patients with pathological findings in cranial CT (Chi-square: 0.174 for p < 0.05 Cramer's V: 0.4603).

Conclusion: CT angiography gives a valid and minimally invasive choice for the early diagnosis of cervical artery dissection, showing a good correlation with DSA findings (gold standard). Findings in cranial CT in the first 24 hours are associated with the clinical outcome in those patients.

C-0795

CT angiography in cerebral aneurysms and beyond: A pictorial review

P. Rajiah, T. Patankar, A. Herwadker, N. Hoggard, R. Laitt, D. Hughes; *Manchester/UK*

Learning Objectives: 1. To review the indications, role and limitations of CT angiography (CTA) in neuroimaging. 2. To illustrate the spectrum of normal variants and abnormalities involving cerebral vessels with CTA. 3. To outline the technical difficulties, artefacts and diagnostic pitfalls in CTA.

Background: CTA has become a well established technique in the evaluation of subarachnoid haemorrhage. It is used as an effective alternative and frequently replaces cerebral angiography.

Procedure Details: All examinations were performed on a 4 slice CT scanner (GE Lightspeed). Timing scans were performed using 20 mls of iohexol injected at 4 ml/sec and main acquisition obtained during first pass of a 70 ml bolus [Slice thickness 4x1.25 mm, table speed 3.75 mm/sec, pitch ratio 0.75:1, 0° tilt, 0.5 sec

rotation, 5 mm collimation, 0.63 mm reconstruction interval, 25 cm FOV with a bowtie filter]. Multiplanar and 3D reconstructions were reviewed. Retrospective analysis of the role of CTA in a variety of pathological neurovascular conditions such as aneurysms (76), AV malformations (6), dural fistulas (3), & vertebral dissections (4), intracranial tumours (20) and trauma (5) was performed. We also illustrate the arterial and venous variants, artefacts due to venous contamination and coil and pitfalls due to lack of visibility of small arteries, infundibular dilatation, kissing vessel artefact, venous structures that stimulate aneurysms and inability to identify thrombosis/calcification on 3D images.

Conclusion: CT angiography is good technique in assessment of cerebral vasculature. It has almost completely replaced diagnostic catheter angiography in the evaluation of acute SAH. It is extremely useful in showing other conditions such as AV malformations and fistulas, dissections and planning tumour surgery.

Which is the optimal sequence for the detection of hyperacute intracranial hemorrhage on multimodal stroke MR imaging?

C. Oppenheim¹, D. Hernalsteen², E. Touzé¹, A. Peeters², C. Lamy¹, J.-L. Mas¹, J.-F. Meder¹, G. Cosnard²; ¹Paris/FR, ²Brussels/BE

Purpose: MR imaging is increasingly used as the sole examination for imaging acute stroke patients. Although multisquence MR protocols seem to always be target like for the detection of intracerebral hemorrhage (ICH), the contribution of each single sequence to the diagnosis of ICH is still open to question. We evaluated the sensitivity and specificity of 5 MR sequences for depicting acute ICH.

Methods and Materials: MR images from 102 patients (43 ICH, 59 non-ICH), referred with suspicion of acute stroke and imaged within 6 hours from onset, were independently reviewed by two observers, blinded to clinical status. Reviewers searched for signs of acute ICH on T1- and T2-weighted gradient echo (GRE), FLAIR, T2-echo-planar (T2-EPI) and diffusion-weighted (DWI), each sequence being presented anonymously and singly.

Results: A perfect ($\kappa = 1$) inter-observer concordance for the identification of ICH was achieved for four pulse sequences (T2-EPI, DWI, GRE and FLAIR) and reached $\kappa_{T1} = 0.952$ for the T1-weighted sequence. All patients were correctly classified by both observers on T2-EPI, DWI and FLAIR sequences, while sensitivity_{T1} = 97.4-100%, specificity_{T1} = 97.7-100%, and sensitivity_{DWI} = 100% and specificity_{DWI} = 98%.

Conclusion: In the setting of hyperacute stroke, ICH can easily be identified on any combination of two or more of the 5 studied MR sequences, confirming that emergency MR can be used as the prime and sole screening modality for ultra-fast patient triage prior to treatment decision.

Imaging of the cranial nerves

R. Puy¹, C. Boyer¹, B. Leloutre-Françon¹, V. Ben Amor¹, A. Capdevila², A. Geoffray¹; ¹Nice/FR, ²Barcelona/ES

Learning Objectives: Anatomical-radiological illustration of the 12 cranial nerves.

Background: Several imaging techniques have been used to demonstrate the cranial nerves: MR imaging images (GE 1.5 T) with high definition sequences T1-weighted SE with and without injection of gadolinium, T2-weighted SE and 3D T2 EG, CT images (GE 8 multidetector) with inframillimetric slices in bone windows with reconstructions, US cervical images (14 MHz linear probe GE Logiq 9) and conventional radiographs of the 12 cranial nerves at different levels.

Procedure Details: Images of the 12 cranial nerves are shown from their cerebral emergence to their extracranial pathways, including some osseous canals, foramina and main branches.

Conclusion: This poster will help in recognizing the cranial nerves in various imaging techniques.

Assessment of different ischemic compartments using quantitative multi-slice CT perfusion imaging in patients with acute stroke

G. Bohner, H. Stiepani, H.-C. Bauknecht, R. Klingebiel; *Berlin/DE*

Purpose: Evaluation of CT Perfusion (CTP) in the diagnostic assessment of stroke patients to discriminate between different ischemic compartments.

Methods and Materials: Out of a group of 107 consecutive patients with clinically suspected acute cerebral ischemia in whom multislice CTP was performed on admission a subgroup of 17 patients was chosen. Selected patients had infarction confirmed by follow-up imaging and showed no recanalization. Parameter maps of cerebral blood perfusion (CBP), cerebral blood volume (CBV) and mean transit time (MTT) were generated. Perfusion values were calculated within are-
